Results: Between March 2012 to July 2018, 90 patients underwent CT-fluoroscopic guided nerve root injections at the levels of C2-C8. Complete data was obtained from 23 patients. 54% were female and 46% were male. 76% of these patients reported analgesic benefit with the average duration of analgesic effect lasting 18 months. 3 patients underwent further procedures including discectomy and acupuncture therapy. Patient satisfaction was high and 80% of patients would recommend this procedure to family or friends in a similar clinical situation. The only complication reported was pain on needle insertion.

Conclusion: A dorsal indirect approach to nerve root injections is a safe and well tolerated procedure. We report high rates of long term analgesic benefit for the treatment of cervical radicular symptoms.

B-1289 14:33

Morphological changes of disc herniation following CT-guided periarticular infiltration

S. Talarczyk¹, D.F. Uhlenbrock¹, P. Haage², C.A. Stücker³; ¹Dortmund/DE, ²Wuppertal/DE, ³Witten/DE (sarah.talarczyk@rub.de)

Purpose: Aim of this study was to analyse volume reduction of disc herniation in patients with specific low back pain following CT-guided interventional therapy.

Methods and Materials: Between 5/2017 and 6/2018 volumetric MRI examinations of seven patients suffering from low back pain were compared before and after CT-guided periradicular infiltration therapy. Under CT control therapy a glucocorticoid, a local anaesthetic and a contrast agent were injected close to the affected nerve root. For the volumetric measurement, a volumetric 3D dataset was employed. The measurement itself was performed with Siemens SyngoVia either with the manual 3D tool by two experienced physicians or with the automated 3D-segmentation tool. The findings were paralleled to an age- and gender-matched control group with comparable disc herniations without therapy. Both got a control MRI with volumetric assessment 6 to 12 months after their first MRI. T testing was used to assess the significance of volume reduction, and a ROC analysis to compare the two measurement tools.

Results: Under CT-guided therapy, disc volume was significantly reduced compared to the control group (t=0.02). In the intervention group, disc volume was reduced by an average of 18% whereas the disc volume even increased in the control group by an average of 8%. The measured volume differed significantly between the automated segmentation tool and the manual 3D-segmentation (AUC= 0.5). Consequently, the manual 3D-tool was used for our volume analysis.

Conclusion: Periradicular CT-guided infiltration leads to significant volume reduction of herniated discs over time compared to non-treated patients.

B-1290 14:41

Lumbar nerve root blocks using MR: the effectiveness and safety of ultrasound/MRI fusion image guidance

D.J. Wilson, G.M. Allen, S.A. Bullock, J. Denton; Oxford/UK (wilsonrad@gmail.com)

Purpose: We compared the outcome of nerve root blocks using ultrasound/MRI fusion image guidance combined with needle tracking to fluoroscopic-guided blocks.

Methods and Materials: To assess the efficacy and safety for nerve root blocks in 112 patients using fluoroscopic guidance and 57 patients using fusion guidance. We compared the outcome scores at 24 hours and two weeks. We recorded use of analgesia and the patient's perception of the value of the procedure. We recorded complications, adverse events and duration.

Results: Pain diaries were returned by 68% in the fluoroscopy group and 70% in the fusion group. The visual analogue pain score (0 to 10) was reduced at 24 hours by 3.29 (SD 2.35) for the fluoroscopy group and by 3.69 (SD 2.58) in the fusion group, p 0.399. At two weeks the pain reduction was 3.27 (SD 2.57)

for the fluoroscopic group and 4.21 (SD 2.95) for the fusion group p 0.083. There was no significance different in pain response or in the use of analgesics between the two groups. The patient's overall conclusions for fluoroscopy-guided procedures were "very helpful" 20.3%, "a little helpful" 50.6% and "no change" 29.1%. For the fusion-guided injections, they were "very helpful" 47.5%, "a little helpful" 40% and "no change" 12.5%. The fusion-guided procedures took slightly less time to perform. There were no serious complications recorded in either group.

Conclusion: Ultrasound/MRI fusion imaging with needle tracking is a safe and effective alternative technique compared to fluoroscopic image-guided injection.

Recovering from non-specific low back pain despair: ultrasound-guided intervention in iliolumbar syndrome

D.K. Singh, S.B. Grover, N. Kumar, B.K. Nayak, S. Tomar, S. Suman, A. Katyan, H. Rajani, R.N. Misra; *New Delhi/IN (dksinghrad@gmail.com)*

Purpose: Patients with non-specific low back pain (NSLBP) are normally in despair due to discordance between distressing clinical symptoms and paradoxical normal imaging studies (radiograph and MRI). However, patients of iliolumbar syndrome (ILS) are a potentially recoverable group. This study was, therefore, aimed at assessing the therapeutic role of ultrasound-guided intervention in the latter.

Methods and Materials: Forty consenting patients with NSLBP revealing iliolumbar ligament (ILL) thickening >2 mm on ultrasound were included in this Institutional Review Board-approved prospective interventional study. Two-stage ultrasound-guided interventions were performed under standard aseptic precaution. In primary diagnostic intervention, 4ml of 0.25% bupivacaine was infiltrated in the ILL. Clinical pain scoring was assessed both pre- and 72 hours post-procedure using visual analog score (VAS). The respondents to the primary intervention were considered to have a confirmed diagnosis of ILS. The latter group was further managed with therapeutic platelet-rich plasma (PRP) injection, undertaken by the standard protocol. The VAS was assessed 6 weeks after the second procedure.

Results: Out of 40 patients, 31 (77.5%) were diagnosed with ILS on primary intervention. Of these 31 patients who underwent PRP therapy, 29 (93.5%) showed significant improvement on VAS scale.

Conclusion: Ultrasound-guided diagnostic and therapeutic intervention using bupivacaine and PRP, respectively, were found to result in remarkable recovery in ILS group of patients with NSLBP. The potential of further exploiting this management strategy in patients of NSLBP living a life in despair, needs no further emphasis.

B-1292 14:57

Prospective randomised controlled trial comparing a battery-powered and a manual drill in bone biopsy

C. Tsoi, E.K.C. Law, R.K.L. Lee, A.W.H. Ng, J.F. Griffith; *Hong Kong/HK (caritatsoi@gmail.com)*

Purpose: To compare the diagnostic accuracy, pain score, radiation dose, procedure time and complications of a battery-powered drill versus the traditional manual drilling system in CT-guided bone biopsy.

Methods and Materials: This was a single-centre prospective randomised controlled trial approved by the institutional review board with signed informed consent obtained. Consecutive patients referred to our centre for CT-guided bone biopsy were recruited from November 2015 to July 2018. Patients were randomised into two groups, namely biopsy performed either with battery-powered drill or traditional manual drill performed or supervised directly by one of three experienced musculoskeletal radiologists. Primary outcomes included procedure time, pain score (visual analogue scale; 0-10), radiation dose metrics (CTDIvol and DLP), diagnostic yield, specimen adequacy and complications.

Results: 173 patients were recruited and randomised into a battery-powered drill group ($n=93$) or manual drill group ($n=80$). Baseline demographics including age, sex, lesion characteristics and locations were similar between both groups. When compared with traditional manual drill, biopsy with battery powered drill was quicker to perform (12 vs. 19 minutes; $p<0.05$) with reduced radiation dose (DLP 102 mGy-cm vs. 147mGy-cm; $P<0.05$), and was less painful (visual analogue scale 2.6 vs. 5.8; $p<0.05$). Diagnostic yield and specimen adequacy were similar for both methods (battery: 88% vs. manual 83%). No major or minor complication was identified for either group.

Conclusion: Battery-powered drill was superior to manual drill for CT-guided bone biopsy with a shorter procedure time, reduced radiation dose and pain score, while achieving a similar diagnostic yield.

B-1293 15:05

Ultrasound-guided distension hydrotherapy with graded physiotherapy in primary adhesive capsulitis: a pilot study

D.K. Singh, N. Kumar, S. Tomar, B.K. Nayak, S. Suman, A. Katyan, M.K. Mittal, S.B. Grover, R.N. Misra; *New Delhi/IN (drnishithkumar@rediffmail.com)*

Purpose: Current treatment options for adhesive capsulitis of shoulder joint are associated with variable results. Our study was aimed to evaluate clinical efficacy of ultrasound-guided distension hydrotherapy followed by physiotherapy in patients with primary adhesive capsulitis.

Methods and Materials: 20 patients of primary adhesive capsulitis of shoulder joint consented for distension hydrotherapy were included in this prospective study. Under ultrasound-guided posterior approach, an intra-articular needle was placed in the glenohumeral joint and 4 ml of steroid mixed with local anaesthetic agent was instilled, followed by phasic capsular distension with 30 ml of normal saline. All patients received 4 weeks of physiotherapy 48 hours after distension hydrotherapy. Parameters evaluated before and at 4 weeks post-procedure included visual analogue scale (VAS) pain score and goniometer angle measurement of range of external rotation. Data analysis was done using SPSS version 21.0 and paired t test was applied to determine statistical significance.

Results: Mean VAS pain score was significantly reduced following 4 weeks of combined therapy. Pre- versus post-therapy mean (SD) VAS: 8 (0.79) versus 4 (1.16), respectively, p value less than 0.0001. Mean range of external rotation was significantly increased following 4 weeks of combined therapy. Pre- versus post-therapy mean (SD) external rotation angle: 16.05 (7.56) versus 49.20 (11.25) degrees, respectively; p value less than 0.0001.

Conclusion: Combined therapy using ultrasound-guided distension hydrotherapy followed by physiotherapy achieved encouraging short-term clinical improvement in our pilot study. Further trials are needed to substantiate long-term prognosis.

B-1294 15:13

Ultrasound-guided percutaneous release of the carpal tunnel: comparison between senior vs junior operator and learning curves: a cadaveric study

C. Dekimpe; *Nice/FR (dekimpe.chloe@gmail.com)*

Purpose: The purpose was to evaluate, on a cadaveric cohort, the feasibility and the learning curve of ultrasound-guided percutaneous carpal tunnel release.

Methods and Materials: Fourteen carpal tunnel releases were carried out on un-embalmed cadavers by a senior and a junior radiologist. Procedures were realized with an 18MHz linear probe. An ultrasonographic anatomic evaluation was first performed to detect any anatomical variant. After hydrodissection with lidocaine of the carpal tunnel, a 3-mm hook knife was introduced into the security zone to perform a retrograde section of the transverse carpal ligament (TCL) under ultrasonographic guidance. Anatomic dissection was performed for each wrist. The main evaluation criterion was the complete TCL section. The procedure duration (minutes), skin incision size (millimetres), the integrity of the median nerve, thenar motor branch, and palmar vascular arch were also evaluated.

Results: The senior operator was able to perform a complete release after training on 3 specimens and the junior operator after 4 specimens ($p > 0.05$). In most of the cases when complete release was not achieved, it was due to an incomplete section of distal TCL (10 mm missing section on average). Mean duration time of procedure was 14 minutes (11min senior versus 17min junior, $p > 0.05$). No damage of the median nerve nor the vascular structure was observed. Mean size of the skin incision was 3mm.

Conclusion: The ultrasound-guided percutaneous release of the carpal tunnel demonstrates to be a safe and efficient procedure with a rapid learning curve.

B-1295 15:21

Clinical response in hip osteoarthritis: comparison between intra-articular treatment with hybrid hyaluronic acid (HA) and combined therapy with Platelet-Rich Plasma (PRP) and HA

I. Capretti, P. Palumbo, S. Iafate, F. Bruno, F. Arrigoni, S. Mariani, L. Zugaro, A. Barile, C. Masciocchi; *L'Aquila/IT (ilaria_capretti@hotmail.it)*

Purpose: To evaluate the clinical outcome in patients treated with intra-articular injection of hybrid HA or combining HA and PRP.

Methods and Materials: We included 28 patients (aged between 40 and 70) with moderate-severe grade of hip osteoarthritis, diagnosed by magnetic resonance (MR) exam on 3T MR scanner. Patients with recent trauma or rheumatic or systemic diseases were excluded. Patients received different intra-articular injection in a randomized way: group A (14 patients) were treated with US-guided intra-articular injection of a hybrid formulation of HA; group B (14 patients) treated with a combination of HA and PRP. Clinical outcome and functional evaluation were investigated by means of Visual Analog Scale (VAS) and Harris Hip Score (HHS), before treatment and at six and twelve months.

Results: Group A showed a mean VAS value of 8.5 with a reduction of 78.6% at six months and 58.2% after twelve months; mean HHS value was 69 before treatment and 84 and 80 respectively at the follow-up. Group B showed a mean VAS value of 8.7 before treatment and an improvement of 79.3% and 81% at the follow up; mean HHS value of 67 before treatment and 89.1 and 88 at the follow-up. In group B, patients, aged between 40 and 55, had a better result.

Conclusion: All patients had good clinical recovery, but younger patients achieved better clinical benefit with HA-PRP therapy; while the patients, aged over 55 years, had similar results in both groups.

Safety and efficacy of microwave ablation of stage T1 renal cell carcinoma

K. Mahmoud, H. El Khudari, A. Gunn, E. Keasler, E. Bready, A. Salei, J. Winston, P. Patten, A.M.K. [Abdel Aal](#); Birmingham, AL/US (akamel@uabmc.edu)

Purpose: To evaluate clinical and technical factors associated with treatment outcomes of microwave ablation (MWA) for renal cell carcinoma.

Methods and Materials: We retrospectively reviewed medical records of 29 patients with 31 tumours who underwent MWA for stage 1 RCC between 2008 to 2018 in our institution. Patient demographics, tumour characteristics, technical success defined as absence of residual tumour within 3 months of procedure and complications were reported. The recurrence-free, cancer-specific and overall survival rates were analysed. A univariate analysis was performed to identify any potential predictors of complications, local recurrence, or survival.

Results: Mean age of the patients was 64 ±10.6 years and 34.5% of the patients had chronic kidney disease stage 3 at baseline. The median Charlson comorbidity index was 5 (range: 5-12). The median tumour size was 2.7 cm (range: 1.0 - 6.1) with 18 (58.1%) posterior tumours. Stage T1a tumours were seen in 93.5% of patients. Median number of probes was 1 (range:1-3) and biopsy was performed in 22 (72.4%) tumours. Technical success rate was 93.1%. Minor and major complications were seen in 5 (17.2%) and 1 (3.4%) patients, respectively. No local recurrence was reported. The overall survival was 100%, 84.6% and 84.6% at 1, 3 and 5 years. Cancer-specific survival was 100% at 5 years. There were predictors for complications or survival outcomes.

Conclusion: Percutaneous MWA is safe and efficacious thermal ablation modality for treatment of stage 1 RCC with acceptable outcomes.

Percutaneous management of Indiana pouch stones: a single-centre retrospective study

M. [Ozturk](#), J.C. McDermott, P.F. Laeseke, S.Y. Nakada, S.P. Hedican, S. Best, M.G. Kleedeahn; Madison, WI/US (dr.mesutozturk@gmail.com)

Purpose: To present our experience treating reservoir stones in patients with Indiana pouch urinary diversions using a percutaneous approach.

Methods and Materials: Seven patients were treated percutaneously for Indiana pouch reservoir stones between 2008 and 2018. The Indiana pouch was filled with dilute water-soluble contrast and was punctured with an 18-gauge needle by an interventional radiologist under direct ultrasound guidance. A wire was inserted through the needle and a balloon set was used over the wire to dilate the tract. A 30 F sheath was placed over the fully inflated balloon into the pouch. A urologist inserted a nephroscope through the sheath and removed the stones. At the end of the procedure, a Foley catheter was left through the access sheath into the lumen of the pouch and was left open to drainage.

Results: Mean age of the study population was 47.3 ± 14.7 years (range: 29-69). Five patients had multiple stones and the median stone number was 3 (range 1-8). Mean maximum stone diameter was 24.43 ± 4.89 mm (range: 19-33). All patients underwent technically successful puncture and stone removal of the pouch. Median post-operative hospital admission was 1 day (range: 1-5). The Foley catheters were removed after a median value of 18 days (range: 10-19). No major complications were reported. One patient suffered from flank pain and fever 14 days after the procedure, but responded well to antibiotic treatment.

Conclusion: Percutaneous approach for Indiana pouch reservoir stones provides a direct and safe treatment method without significant peri-procedural complications.

B-1298 14:25

Predictors of outcomes of percutaneous cryoablation for renal cell carcinoma

K. Mahmoud, A. Gunn, H. El Khudari, A. Salei, E. Bready, J. Winston, E. Keasler, P. Patten, A.M.K. [Abdel Aal](#); Birmingham, AL/US (akamel@uabmc.edu)

Purpose: To evaluate the clinical and technical factors affecting the outcomes of percutaneous cryoablation (PCA) of renal cell carcinoma (RCC).

Methods and Materials: The medical records of the patients who underwent PCA for RCC between 2004 and 2018 were retrospectively reviewed and 128 patients were included. Patient demographics, tumour characteristics, technical success defined as absence of residual tumour within 3 months of procedure, and complications were reported. Recurrence-free, cancer-specific and overall survival rates were analysed. A univariate analysis was performed to identify predictors of the outcomes.

Results: Mean age of the patients was 65 (SD=11.5) years. Chronic kidney disease at the baseline was seen in 38.3% of patients. The median tumour size was 3.0 (range: 1.2 - 8.7) cm with 73 (57%) posterior tumour location. The study included T1a (69.5%) and T1b (28.9%) tumours. The median number of probes used was 2 (range:1 - 7) and 81 (63.3%) tumours were biopsied. Technical success rate was 90.6%. Minor complications were seen in 26.6% and major in 6.3% of patients. On univariate analysis, tumour biopsy (p=0.019), endophytic/mixed location (p=0.026), nearness to collecting system (p=0.012) and renal sinus involvement (p=0.003) were associated with complications, and the latter two were associated with decreased overall survival (p=0.036 and p=0.051, respectively). None of the variables predict local recurrence. The recurrence-free, cancer-specific and overall survival at 3 years was 66.6%, 100% and 93.4%, respectively.

Conclusion: Tumour biopsy, tumour location, nearness to collecting system and renal sinus involvement were predictors of outcomes of PCA of RCC.

B-1299 14:33

Role of R.E.N.A.L. nephrometry and PADUA scoring systems in percutaneous ablation for renal cell carcinoma

K. Mahmoud, A. Gunn, H. El Khudari, A. Salei, E. Bready, J. Winston, E. Keasler, P. Patten, A.M.K. [Abdel Aal](#); Birmingham, AL/US (akamel@uabmc.edu)

Purpose: The aim of the study is to investigate the ability of R.E.N.A.L. nephrometry and PADUA scoring systems to predict the complications and survival outcomes in patients with renal cell carcinoma (RCC) who underwent image-guided renal tumour ablation.

Methods and Materials: We retrospectively reviewed the medical records of 175 patients who had RCC that was treated with thermal or non-thermal ablation. The data on demographics, modality of ablation and tumour characteristics were reported. The RENAL and PADUA scores were calculated. Technical success and complications were analysed. Kaplan-Meier curves for recurrence-free, cancer-specific and overall survival were obtained.

Results: The study included 175 patients with 177 tumours, 104 (59.4%) males, with a mean age of 64.7 (SD=11.5) years. There were 53 (30.3%) patients with CKD stage 3. Mean tumour size was 3.04 (SD=1.3) cm, with 75 tumours (42.4%) located posteriorly. Technical success was seen in 159 (90.9%) patients. Thirty-day complications was 27.9%. Recurrence-free and overall survival at 1 year was 94.8% and 98.5%, respectively. There was no correlation between the RENAL and PADUA scores with the occurrence of complications, recurrence-free survival or overall survival. The nearness to the collecting system and biopsy before the procedure correlated with the occurrence of complications (p=0.03 and p=0.02, respectively).

Conclusion: RENAL and PADUA scores do not correlate with the occurrence of complications, recurrence-free or overall survival in patients with RCC treated with percutaneous ablation. The nearness to the collecting system and biopsy correlated with the occurrence of complications.

B-1300 14:41

Modified ABLATE-score (mABLATE): a specific nephrometric score to predict complications and relapses in percutaneous cryoablation of renal lesions

M. Papa, A. Losa, N. Suardi, G. Agostini, T. Maga, F. Gaboardi, G. Cardone; Milan/IT (papa.maurizio@hsr.it)

Purpose: RENAL and mRENAL scores have been validated on predicting complications and relapses in percutaneous treatments of renal lesions. However, these scores remain of surgical origin. We aim to build a specific interventional score (mABLATE).

Methods and Materials: Taking inspiration from the paper "AJR2014;202:894-903" with some changes based on our practical experience, a score was built trying to take into account the real difficulties faced in our experience. The mABLATE was retrospectively assessed on 60 cryoablations to evaluate its predictive value for complications and relapses. Logistic regression was used to predict complications; Cox regression for relapses; ROC analysis for accuracy.

Results: Among 60 renal lesions treated with cryoablation we experienced 3 bleedings with anemia (5%). Among 51 malignant lesions (ML) we experienced 7 relapses (13.7%), with a mean FU of 19,3 months. Mean ML RENAL score: 7.2pts. Mean relapsed RENAL score: 7.71pts. Mean ML mRENAL score: 7.26. Mean relapsed mRENAL score: 8pts. Mean ML mABLATE score: 4.98. Mean relapsed mABLATE score: 8.07pts. The Cox regression analysis for Renal (p=0.35) and mRENAL (p=0.29) showed a lack of predictive value for relapses. mABLATE score was found to be an independent predictor of relapses (HR 1,56; p=0,001). The predictive accuracy based on the ROC analysis of the mABLATE showed an AUC of 89.1%(vs 61,5% for mRENAL and 58,8% for RENAL). In the logistic regression analysis none of the scores showed statistic significance in predicting complications(p>0.05) due to small numbers.

Conclusion: mABLATE score showed to be a better predictor of relapses than RENAL and mRENAL.

B-1301 14:49

Safety and outcomes of percutaneous cryoablation for large T1b renal cell carcinoma

A. Gunn, K. Mahmoud, H. El Khudari, A. Salei, E. Keasler, E. Bready, J. Winston, P. Patten, A.M.K. Abdel Aal; Birmingham, AL/US (akamel@uabmc.edu)

Purpose: To describe the safety, technical results, and clinical outcomes of percutaneous cryoablation of stage T1b renal cell carcinoma (RCC).

Methods and Materials: A retrospective review of the medical records of 36 patients with RCC lesions measuring 4.1-7.0 cm who underwent percutaneous cryoablation from 2004-2018. Patient demographics, co-morbidities, tumour characteristics, technical parameters of the procedure, technical outcomes, complications, and local recurrence rates were recorded. Cancer-specific survival rates were estimated using the Kaplan-Meier method. A multivariate analysis was performed to identify any potential predictors of complications, local recurrence or survival.

Results: Mean tumour diameter was 4.9 cm (± 1.2), with a median of 3 probes (range: 1-7) used. The median number of procedures required to achieve local control was one (mean: 1.5, range: 1-4). Minor complications not requiring therapy occurred in 15 patients (41.7%). Two major complications (5.6%) included one abscess and an incidence of acute renal failure, both which were appropriately managed without long-term sequelae. No significant change in glomerular filtration rate was seen after ablation (p=0.95). Seven patients (19.4%) had local recurrence, which occurred at a mean of 26.7 months (range: 4.3-52.2). Cancer-specific survivals were 100%, 100%, 100%, and 84.6% at 1, 2, 3, and 5 years, respectively. On univariate analysis, endophytic/mixed tumours (p=0.0014) and nearness to the collecting system (p=0.006) were independent predictors of complications. None of the evaluated variables were able to predict local recurrence.

Conclusion: Percutaneous cryoablation is a viable therapeutic option for stage T1b RCC with an overall low rate of major complications.

B-1302 14:57

Comparison of cryoablation and microwave ablation in the treatment of small renal tumours (SRT): technical success, complications and midterm clinical outcome

M. Panzeri, M. Colombo, M. Papa, G. Cardone, M. Venturini, U. Capitano, F. Montorsi, A. Del Maschio, F. De Cobelli; Milan/IT (panzeri.marta@hsr.it)

Purpose: To evaluate feasibility, safety, complication rate and mid-term results of MicroWave Ablation (MWA) with a new high-power system based on Thermosphere™ Technology in the treatment of SRT not eligible for surgery, and to compare these data with those of cryoablation (Cryo).

Methods and Materials: From 2014 to 2018, 78 patients with one or more SRT (total 94) underwent percutaneous ablation (Cryo with Galil Medical or MWA with Thermosphere Emprint) under CT/US guidance. CT/MRI follow-up was performed at 1, 6, 12 and 18-24 months. MRENAL, procedural time,

technical success, complications (according to the CIRSE classification) and follow-up data were recorded.

Results: 49 patients (60 nodules) underwent cryoablation, while 29 patients (34 nodules) were treated with MWA. The median mRENAL score was 7.5 in the Cryo group, 9 in MWA group. No significant difference was found between the two groups in tumour or patient's characteristics. There were 22 complications in the Cryo Group (36%): 18/22 (81%) were grade 1, 2/22 (9%) grade 2, 1/22 (5%) was 3 and 1/22 was 4. In the MWA group 6 complications were recorded (18%), all grade 1 (p=0.85). A generalized linear mixed model adjusted for mRENAL score showed a protective effect against complications of MWA (p=0.74). Median procedural time was 106 minutes for Cryo, 41 minutes for MWA (p<0.0001). During follow-up, residual disease was found in 6/60 patients after cryoablation (10%) and in 3/34 nodules after MWA (9%); no significant difference was found between the two groups.

Conclusion: In our series, MWA has proven to be a safe and effective ablative technique and it could be considered not inferior to cryoablation.

B-1303 15:05

Focused ultrasound subthalamotomy in patients with asymmetric Parkinson's disease: a pilot study

E. De Luis Pastor, M. Del Alamo, R. Martinez Fernandez, J. Mañez Miro, C. Gasca, R. Rodriguez Rojas, J. Pineda Pardo, L. Vela, J. Obeso; Mostoles/ES

Purpose: Ablative neurosurgery has been used to treat Parkinson's disease (PD) for decades. MRI-guided focused ultrasound allows focal lesions to be made in deep brain structures without skull incision. We investigated the safety and preliminary efficacy of unilateral subthalamotomy by focused ultrasound in PD.

Methods and Materials: We performed a prospective, open-label pilot study with ten patients with PD with markedly asymmetric parkinsonism. Enrolled patients underwent focused ultrasound unilateral subthalamotomy. The subthalamic nucleus was targeted with brain images acquired with a 3T MR system. The primary outcomes were safety and a change in motor status of the treated hemibody as assessed with part III of the Movement Disorders Society-Unified Parkinson's Disease Rating Scale (MDS-UPDRS III) in both off-medication and on-medication states at 6 months. Adverse events were monitored up to 48 h after treatment and at scheduled clinic visits at 1, 3, and 6 months after treatment.

Results: The most frequent adverse events were transient gait ataxia (related to subthalamotomy) and transient high blood pressure during the procedure. Transient facial asymmetry and moderate impulsivity were also recorded. The mean MDS-UPDRS III score in the treated hemibody improved by 53% from baseline to 6 months in the off-medication state and by 47% in the on-medication state.

Conclusion: MRI-guided focused ultrasound unilateral subthalamotomy was well tolerated and seemed to improve motor features of Parkinson's disease in patients with asymmetric parkinsonism. Large randomised controlled trials are necessary to corroborate these preliminary findings and to assess the potential of such an approach to treat PD.

B-1304 15:13

The effect of histogram parameters derived from quantitative T1-perfusion on predicting the high-intensity focused ultrasound outcome of uterine fibroids

N.M. Duc¹, C. Li², H. Quang Huy¹, J. Yang², B. Keserci³; ¹Ho Chi Minh City/VN, ²Xi'an/CN, ³Kelantan/MY (bsnguyenminhduc@pnt.edu.vn)

Purpose: To investigate the effect of whole-tumor histogram parameters derived from quantitative dynamic contrast-enhanced MRI (DCE-MRI) on predicting magnetic resonance-guided high-intensity focused ultrasound (MRgHIFU) ablation outcome defined as non-perfused volume (NPV) ratio $\geq 80\%$.

Methods and Materials: Institutional review board approved this prospective study. 28 symptomatic uterine fibroid women (43.3 \pm 4.5 years) were evaluated quantitative DCE-MRI prior to MRgHIFU ablation at the Department of Radiology, the First Affiliated Hospital of Xi'an Jiaotong University. The population was divided into 2 groups: group 1 with NPV ratio $\geq 80\%$ (n = 8) and group 2 with NPV ratio < 80% (n = 20). Mann Whitney U test was carried out to compare four histogram parameters: median, mean, skewness and kurtosis between group 1 and group 2. Multiple logistic regression was accessed independent factors in predicting NPV ratio $\geq 80\%$.

Results: Mean NPV ratio was 94.8% \pm 4.8 for group 1 and 54.4% \pm 12.8 for group 2, respectively (p< 0.05). Median histogram parameter derived from quantitative DCE-MRI which represented the asymmetry and shape of histogram regarding to whole tumor vascular perfusion of group 1 was significantly lower than group 2 (p < 0.05). Multiple logistic regression manifested that there was only median parameter had significant effect on NPV ratio $\geq 80\%$ (p < 0.05).

Conclusion: The achievement of NPV ratio $\geq 80\%$ was feasible in MRgHIFU ablation of uterine fibroids. The median histogram parameter could be served as an effective factor in patient selection criteria for NPV ratio $\geq 80\%$.

The role of magnetic resonance imaging parameters in predicting the treatment outcome of high-intensity focused ultrasound ablation of adenomyosis

N.M. Duc¹, B. Keserci², H. Quang Huy¹, L. Van Phuoc¹, L. Trong Khoan³, D. Duc Cuong⁴, B. Van Giang⁴, V. Dang Luu⁴, N. Duy Hue⁴, ¹Ho Chi Minh/VN, ²Kelantan/MY, ³Hue/VN, ⁴Ha Noi/VN (*bsnguyenminhduc@pnt.edu.vn*)

Purpose: To investigate the role of magnetic resonance imaging (MRI) parameters in predicting the treatment outcome of high-intensity focused ultrasound (HIFU) ablation of adenomyosis defined as the immediate non-perfused volume ratio (NPVr).

Methods and Materials: 50 women (40.3 ± 6.0 years) with symptomatic adenomyosis underwent MRI-guided HIFU ablation. Multivariate linear regression analyses were carried out in (i) baseline parameter group, (ii) T2 signal intensity (SI) group and (iii) semiquantitative perfusion group to investigate the potential predictors of each group affected based on the NPVr. Based on all the significant screening MRI parameters acquired from the multivariate analyses, generalized estimating equation (GEE) was used to predict the immediate NPVr.

Results: The results of multivariate analyses revealed that there were four statistically significant predictors ($p < 0.05$): abdominal subcutaneous fat thickness, T2 SI ratio of adenomyosis to myometrium, relative enhancement ratio of adenomyosis to myometrium, time to peak enhancement ratio of adenomyosis to myometrium. GEE analysis generated linear equation for predicting the immediate NPVr (y) with four statistically significant predictors from multivariate analyses: $y = 165.952 + 0.119x1 - 10.514x2 - 56.177x3 - 39.812x4$, where $x1$ = abdominal subcutaneous fat thickness, $x2$ = T2 SI ratio of adenomyosis to myometrium, $x3$ = relative enhancement ratio of adenomyosis to myometrium, $x4$ = time to peak ratio of adenomyosis to myometrium.

Conclusion: The findings in this study suggest that the outcome of MRI-guided HIFU treatment of adenomyosis based on multivariate analyses and prediction model appears to be clinically feasible.

Presence of coronary artery calcifications on CT is associated with PE-related mortality in patients with acute PE

B.H. Heidinger¹, D.C. DaBreo², B.J. Carroll³, S.A. Feldman³, D. Mohebbi³, I. McCormick³, J.D. Matos³, W.J. Manning³, D. Litmanovich³, ¹Vienna/AT, ²Kingston, ON/CA, ³Boston, MA/US (*beneditkt.heidinger@medunivien.ac.at*)

Purpose: To evaluate the association of coronary artery calcification (CAC) visualised on computed tomography pulmonary angiography (CTPA) at time of acute pulmonary embolism (PE) diagnosis with PE-related mortality.

Methods and Materials: We searched for all patients with an ICD-10 code of PE and included those with PE verified on CTPA in this IRB-approved retrospective study. CAC was visually graded by a cardio-thoracic radiologist into four categories: absent, mild, moderate, or severe. PE-related mortality was defined as death related to PE within 30 days of diagnosis. Logistic regression analysis was used to compare the PE-related mortality according to the presence of CAC.

Results: In the 479 patients who met inclusion criteria, mean age was 63 ± 16 years, 53% were female, and 47% had a prior smoking history. 253/479 (53%) patients had CAC (mild: 143/479, 30%; moderate 89/479, 19%; severe 21/479, 4%). Overall, 19/479 (4%) patients died, with a PE-related mortality of 2% in those with absent CAC, 5% in mild CAC, 7% in moderate CAC, and 10% in severe CAC. PE-related mortality was higher in patients with any CAC than in those without CAC (OR 3.5 95%CI 1.1-10.7; $P=0.028$).

Conclusion: Among patients admitted for PE, CAC was associated with higher PE-related mortality. Evaluation of CAC on CTPA at the time of diagnosis may be utilized as an additional prognostic parameter and could be used to assist in early risk stratification in patients with PE.

B-1307 14:08

Coronary artery calcification and prediction of mortality in patients with pulmonary embolism

L. Norton, D. Maguire, K. Mac a' Bháird, G. Cooper, O. Sheerins, M. Adamson, C. Kelly, G. Roditi; Glasgow/UK (*lindsey.norton@nhs.net*)

Purpose: To assess thoracic CT features that predict mortality in patients with acute pulmonary embolism (PE) on CT pulmonary angiography (CTPA).

Methods and Materials: We evaluated standard CTPA scans of 161 consecutive patients diagnosed with acute PE for signs of right heart strain including right ventricular:left ventricular ratio, SVC cross sectional area, PA trunk diameter (mm), PA trunk area (mm²), Azygous vein diameter (mm), IVC reflux grade and bowing of interventricular septum. Clot burden was assessed using Obstruction index Qanadli score. Coronary artery calcification was assessed using Weston score.

Results: Of 161 patients, 34 were deceased within 6 months of presentation. Univariate analysis revealed Age >65 years ($p=0.004$), PESI score >100 (<0.001) and coronary artery calcification ($p<0.001$) were strongly associated with increased patient mortality. Troponin $>5\text{ng/dl}$ approached significance on univariate analysis ($p=0.053$). High obstruction index (Qanadli score ≥ 20) also correlated with increased mortality ($p=0.012$). Traditional CT indicators of right heart strain were not significantly predictive (Transverse and 4-chamber reformat RV:LV ratio, ($p=0.231$ and $p=0.252$ respectively)).

Conclusion: Coronary artery calcification is a novel and powerful independent predictor of mortality in patients with acute PE performing better than obstruction index (clot burden) and CT features of right heart strain in our study. These results may reflect reduced capacity of underperfused myocardium to respond to increased right ventricular afterload. The relationship between coronary artery disease and subsequent mortality in patients with PE risk deserves further investigation.

B-1308 14:16

Accuracy and variability of coronary CT angiography with iterative model reconstruction for plaque burden assessment compared with IVUS: a pulsating cardiac phantom study

Q. Wen, Y. Hou, L. Yang, Y. Ma, X. Lu; Shenyang/CN (*2609579904@qq.com*)

Purpose: To systematically evaluate the accuracy and intra-/inter-reader variability of coronary CTA with iterative model reconstruction (IMR) in coronary plaque burden assessment compared with intravascular ultrasound (IVUS).

Methods and Materials: A dynamic cardiac phantom mounted with total 12 artificial vessels with 4 different inner diameter (2.5, 3.0, 3.5, 4.0 mm) was scanned on 256-slice CT. Three kinds of coronary plaque were arranged evenly in the iodine-enhanced lumen (350 ± 5 HU at 100 kV) to simulate different stenosis severity (75%, 50% and 25%). CT images were reconstructed with IMR (cardiac routine, level 1). Coronary plaques were categorised into 2 groups: calcified group and non-calcified group. The cross-sectional areas of the lumen (CSA_{lumen}) and vessel (CSA_{vessel}) were assessed by two radiologists; the value of plaque area (PA) and plaque burden (PB) were calculated.

Results: A total of 96 slice (32 calcified and 64 non-calcified) of stenosis were analysed, respectively, in CTA and IVUS image. Average PB assessed by CTA was higher than that of IVUS on the whole ($42.49 \pm 16.18\%$ vs $40.77 \pm 16.15\%$, $P<0.014$). There existed a significant correlation between two methods ($r=0.839$; $P<0.001$). In the sub-group, CTA overestimated the calcified plaque burden by $3.6 \pm 2.0\%$ ($P<0.001$) while there was no statistical difference in non-calcified group between two methods. There exist great inter-/intra-reader correlation of CCTA ($r=0.81$, $P<0.001$; $r=0.89$, $P<0.001$), and there was no significant difference between intra-/inter-reader measurement ($P>0.05$).

Conclusion: With IMR, evaluation of plaque burden by CCTA has a low inter-/intra-reader variability and a great correlation with IVUS measurements, while calcified plaque is overestimated by CCTA.

B-1309 14:24

Retrospective evaluation of the accuracy of coronary computed tomography angiography compared to invasive coronary angiography: radiological and therapeutic approach in CAD-RADS 3/V

C. De Cataldo, A. Corridore, S. Torlone, E. Cannizzaro, P. Palumbo, F. De Matteis, M. Di Luzio, E. Di Cesare, C. Masciocchi; L'Aquila/IT (*camilladeca@hotmail.it*)

Purpose: CAD-RADS is an excellent tool finalized to the optimisation of the management of patients affected by coronary artery disease (CAD) undergoing Coronary Computed Tomography Angiography (CCTA). However, it only allows a marginal consideration of plaque characteristics (modifier V). Our study aims to assess the radiological and therapeutic management of CAD patients, classified by CT examination as CAD-RADS 3/V (stenosis of 50-69% with vulnerable plaque).

Methods and Materials: We retrospectively evaluated 71 patients who underwent CCTA and were defined as CAD-RADS 3/V because of the display of two or more morphological features (low attenuation plaque, spotty calcifications, napkin-ring sign, positive remodeling). Clinical and therapeutic follow up was performed.

Results: A first group of 15 patients was sent to ICA (Invasive Coronary Angiography) with IVUS within three months after CCTA; a second group of 56 patients underwent functional evaluation (Cardiac Magnetic Resonance Stress Imaging with Adenosine) and ICA within a year. The first group displayed an excellent conformity between CCTA and ICA stenosis values ($\mu=1.03$, Coefficient of Variation=12%); in the second, we highlighted a significant discrepancy because of stenosis progression or overlaid thrombosis. A strong correlation was noticed between stenosis entity and morphological features, except for positive remodeling. In the first group, 8 patients underwent PTCA, 50 in the second, 17 of which experienced cardiovascular accident in the period of time between CCTA and ICA.

Conclusion: Our experience confirms the importance of a more effective approach to CAD-RADS 3/V patients, for whom a functional evaluation risks to represent a therapeutic delay.

B-1310 14:32

Improving CAD-RADS score with new iterative model reconstruction algorithm in low dose CCTA: inter-observer agreement and comparison with hybrid iterative reconstruction algorithm

C. Talei Franzesi¹, L. Riva¹, D. Ippolito¹, C. Cangiotti¹, A. de Vito¹, C. Maino¹, M. Porta¹, S. Sironi²; ¹Monza/IT, ²Bergamo/IT (ctfdoc@hotmail.com)

Purpose: To evaluate the inter-observer agreement of the CAD-RADS system and to compare image quality, CNR and SNR between new MBIR (IMR) algorithm and hybrid-iterative reconstruction algorithm (iDose⁴) of low dose cardiac-CT angiography(CCTA).

Methods and Materials: Eighty patients were prospectively enrolled in this study. All patients were examined with a 256-slice scanner (iCT-elite, Philips) using low-dose (80-kV, 70mL of CM) CCTA protocol combined with prospective or retrospective ECG-gated technique, reconstructed with iDose⁴ and IMR algorithm. Each study was evaluated by 2 readers using the CAD-RADS lexicon based on the degree of maximum coronary stenosis (vessel >1.5 mm in diameter). Coronary arteries and aorta contrast-enhancement(HU), standard deviation(SD), SNR and CNR were measured in the axial native images. Inter-observer agreement of CAD-RADS system and image quality scores(5-point Likert scale) was determined using weighted k-statistic. Inter-observer agreement of mean attenuation values(HU) of coronary arteries and aorta was assessed with linear regression analysis and Bland-Altman plots. Radiation dose exposure(DLP, mGy*cm) and effective dose(ED) were reported for all the examinations.

Results: For CAD-RADS agreement, the k-value was very good(0.90). Moreover we found a significant higher value of qualitative analysis, SNR and CNR with the IMR algorithm compared to the iDose⁴, due to a lower noise level($p<0.5$). The mean DLP measured was 191.44mGy*cm and the mean ED was 2.68mSv.

Conclusion: Inter-observer agreement of CAD-RADS was excellent confirming the importance, the feasibility and the reproducibility of CAD-RADS system for CCTA. In addition, we showed a lower noise and higher image quality with IMR algorithm compared to iDose⁴.

B-1311 14:40

Reliability of coronary calcium scoring on low-dose chest CT: comparison with ECG-triggered cardiac CT based on third-generation dual-source CT

C. Xia, A. Alsurayhi, M. Vonder, G. Pelgrim, M. Rook, M. Oudkerk, R. Vliegenthart; Groningen/NL (c.xia@umcg.nl)

Purpose: To assess the reliability of low-dose chest CT-based coronary calcium score (CS), compared with dedicated electrocardiographically (ECG)-triggered cardiac scans using third generation dual-source computed tomography (CT).

Methods and Materials: In the Imaging in Lifelines (ImaLife) study, 646 consecutive participants underwent an ECG-triggered cardiac acquisition immediately followed by a low-dose chest acquisition using CT Force (Siemens Healthineers, Germany). Both cardiac and chest scans were acquired with high-pitch spiral mode and reconstructed with dedicated coronary calcium scoring settings for the purpose of this analysis. Thirty cases were excluded due to cardiovascular interventions or technical issues. CS was measured in Agatston method on both scans using dedicated software (CaScoring, syngo.via, Siemens, Germany).

Results: The median age of the participants was 54 years (range 45-63) and 40% were male. A positive CS was observed in 37% of the cardiac acquisitions. Compared with dedicated cardiac scans, the accuracy, sensitivity, and specificity of chest acquisitions in identifying the presence of coronary calcium was 0.97 (95% CI 0.95-0.98), 0.92 (95% CI 0.87-0.95), and 0.99 (95% CI 0.98-1.00), respectively. The reliability of chest scans in CS risk

categorization was very high (weighted kappa 0.95). Although the mean difference of CS between two acquisitions was 6.94, the reliability of chest acquisitions in quantifying CS was high (intraclass correlation coefficient 0.994-0.996). The CS correlation between chest scans and cardiac scans was strong ($\tau_b = 0.933$).

Conclusion: Coronary calcium can be reliably detected on low-dose chest CT scanning based on third-generation dual-source CT with a sensitivity of 92%.

B-1312 14:48

Accuracy of calcium scoring calculated from contrast-enhanced coronary computed tomography angiography using a dual-layer spectral CT

J. Najdiri, G. Kaissis, F. Meurer, K.-L. Laugwitz, A.S. Sträter, D. Pfeiffer, P.B. Noel, E.J. Rummeny, M. Rasper; Munich/DE

Purpose: The objective of the present investigation was to evaluate the accuracy of virtual non-contrast CACS computed from spectral data in comparison to standard non-contrast imaging.

Methods and Materials: We consecutively investigated 20 patients referred to coronary computed Tomography angiography (CCTA) with suspicion of CAD using a dual-layer spectral CT system (IQon; Philips Healthcare, The Netherlands). CACS was calculated from both, real- and virtual non-contrast images by certified software for medical use. Correlation analyses for real- and virtual non-contrast images and agreement evaluation with Bland-Altman-Plots were performed.

Results: Mean patient age was 57.7 ± 14 years ($n=20$). 13 patients (65%) were male. Inter-quartile range of clinical CACS was 0-448, the mean was 334. Correlation of CACS from real- and virtual non-contrast images was very high (0.94); $p < 0.0001$. The slope was 2.3 indicating that values from virtual non-contrast images are approximately half of the results obtained from real non-contrast data. Visual analysis of Bland-Altman plot shows good accordance of both methods when results from virtual non-contrast data are multiplied by the slope of the logistic regression model (2.3). The acquired power of this results is 0.99.

Conclusion: Determination of calcium score from contrast-enhanced CCTA using spectral imaging with a dual-layer detector is feasible and shows good agreement with the conventional technique when a proportionality factor is applied. Our data suggest that radiation exposure can be reduced through omitting additional native scans for patients referred to CCTA when using a dual-layer spectral system without the usual limitations of dual-energy analysis.

B-1313 14:56

Influence of image reconstruction parameters on cardiovascular risk reclassification by computed tomography coronary artery calcium score

C. Mantini¹, E. Maffei², P. Toia³, F. Ricci¹, A.R. Cotroneo¹, F. Cademartini⁴; ¹Chiati/IT, ²Treviso/IT, ³Palermo/IT, ⁴Rotterdam/NL (c.mantini@rad.unich.it)

Purpose: To investigate the influence of different CT reconstruction parameters on coronary artery calcium scoring (CACS) values and reclassification of predicted cardiovascular (CV) risk.

Methods and Materials: CACS was evaluated in 113 patients undergoing ECG-gated 64-slice CT. Reference CACS protocol included standard kernel filter (B35f) with slice thickness/increment of 3/1.5 mm, and field-of-view (FOV) of 150-180 mm. Influence of different image reconstruction algorithms (reconstructed slice thickness/increment 2.0/1.0-1.5/0.8-3.0/2.0-3.0/3.0 mm; slice kernel B30f-B45f; FOV 200-250 mm) on Agatston score was assessed by Bland-Altman plots and concordance correlation coefficient (CCC) analysis. Classification of CV risk was based on the Mayo Clinic classification.

Results: Different CACS reconstruction parameters showed overall good accuracy and precision when compared with reference protocol. Protocols with larger FOV, thinner slices and sharper kernels were associated with significant CV risk reclassification. Use of kernel B45f showed a moderate positive correlation with reference CACS protocol (Agatston CCC = 0.67), and yielded significantly higher CACS values ($p < .05$). Reconstruction parameters using B30f or B45f kernels, 250 mm FOV, or slice thickness/increment of 2.0/1.0 mm or 1.5/0.8 mm, were associated with significant reclassification of CV risk ($p < .05$).

Conclusion: Kernel, FOV, slice thickness and increment are major determinants of accuracy and precision of CACS measurement. Despite high agreement and overall good correlation of different reconstruction protocols, thinner slices thickness and increment, and sharper kernels were associated with significant upward reclassification of CV risk. Larger FOV determined both upward and downward reclassification of CV risk.

B-1314 15:04

Coronary calcium screening with non-gated standard and low-dose chest CT in comparison with ECG-gated calcium scoring CT

K.N. Zhuravlev, V.E. Sinitsyn, A.V. Shpektor; *Moscow/RU (Kir232@mail.ru)*

Purpose: Coronary artery calcification (CAC) is a recognized marker of coronary atherosclerosis. It is frequently detected on chest CT. The purpose of this study was to evaluate the correlation between the coronary calcium scoring values obtained with gated CT and those obtained with non-gated standard and low-dose chest CT.

Methods and Materials: 425 consecutive patients were prospectively studied with non-gated chest CT. The standard CT protocol was used in 214 cases, and low-dose one in 211 cases. ECG-gated cardiac CT for CAC scoring was performed in the same patients. Agatston calcium score values and stratification of patients into five risk categories according to calcium score values were compared with the reference data from the gated cardiac CT group.

Results: Included in the final analysis were 398 patients. The mean calcium scores were 288.3 for the standard CT protocol and 287.7 for the low-dose CT. The correlation between CAC scores obtained with gated and non-gated CT was high ($r=0.977$ for standard CT and 0.988 for low-dose CT). It remained high after exclusion from analysis of CAC score values of 0 ($r=0.975$ and 0.986 , resp.). Categorization of patients into the five risk groups according to the calcium score values was also high for the both chest CT protocols ($\kappa=0.877$ and 0.892 , resp.).

Conclusion: The study shows that analysis of CAC and the risk stratification of the screened patients is feasible with help of non-gated chest CT. These results could be used for combined screening of the lung cancer and coronary atherosclerosis.

B-1315 15:12

Association between coronary artery calcium score and cardiovascular magnetic resonance imaging parameters in patients with end-stage renal disease

Q. Xie, X. Zhou, L. Lin; *Shenzhen/CN (15800011332@163.com)*

Purpose: Whether coronary artery calcium score (CACS) is reliable for risk stratification of cardiovascular disease in patients with end-stage renal disease (ESRD) remains controversial. Our study aimed to investigate the associations between CACS, CMR and clinical parameters in ESRD patients.

Methods and Materials: 33 ESRD patients (18 males; mean age 45 ± 11 years) and 43 healthy volunteers (24 males; mean age 43 ± 10 years) underwent CMR examinations. All the ESRD patients underwent CACS scans. CACS, LV function parameters, global LV strains, LV myocardial native T1 and T2 of the mid-cavity slice of all the subjects were measured and compared. The ESRD group were divided into 3 subgroups according to tertiles of the CACS, and their clinical and CMR parameters were compared. Correlations between CACS and the CMR and clinical parameters in the ESRD group were analysed, respectively.

Results: LV global longitudinal strain (GLS) was statistically impaired in ESRD group ($-14.2 \pm 3.2\%$) compared with healthy group ($-16.5 \pm 2.2\%$, $p < 0.001$). LV GLS were statistically impaired in the upper tertile ($-12.3 \pm 3.6\%$) compared with the lower tertile ($-15.4 \pm 2.5\%$, $p = 0.023$). CACS was correlated with LV GLS ($r = -0.41$, $p = 0.018$). CACS was strongly correlated with years of chronic kidney disease ($r = 0.58$, $p < 0.001$) and years of dialysis ($r = 0.53$, $p = 0.002$). There was no correlation between CACS and native T1, T2, LV GLS, LVMASS, LVEF ($p > 0.05$).

Conclusion: ESRD patients demonstrated impaired LV GLS compared with healthy people. Increased CACS was associated with impaired LV GLS as well as long duration of the chronic kidney disease and dialysis in ESRD patients.

B-1316 15:20

Implications of incidental coronary artery calcification on thoracic computed tomography

V. Tilliridou, J. Murchison, E.J.R. van Beek, D.E. Newby, M.C. Williams; *Edinburgh/UK*

Purpose: Coronary artery calcification (CAC) can be identified on thoracic CT performed for non-cardiac indications. Although CAC is associated with increased mortality, we do not know the implications for management of reporting incidental CAC.

Methods and Materials: This audit assessed the images of all patients undergoing contrast or non-contrast CT of the thorax over a 1-month period. Information on cardiovascular risk factors and current medication were obtained from electronic patient records. Ten-year cardiovascular risk was assessed using the ASSIGN score, a cardiovascular risk tool validated for the Scottish population. The presence of coronary artery calcification was recorded and graded on a 4-point scale in each coronary artery, and summed to give a total CAC score (CACS). The presence of aortic and mitral valve calcification was also assessed.

Results: The images of 326 patients were assessed (66 ± 14 years, 51% male). CAC was identified in 216 patients (66%), and 47 patients (14%) had severe CACS. Patients with CAC had a higher 10-year cardiovascular risk score (27 ± 15 versus 12 ± 10 , $p < 0.0001$); 39 (12%) patients had a 10-year risk of $< 20\%$ and 10 patients (3%) had a risk of $< 10\%$. Age, male gender and smoking were independent predictors of the presence of CACS ($p < 0.001$). Although patients with CAC were more likely to be taking preventative medications ($p < 0.001$), nearly a half (97/216, 45%) were not taking any preventative medication.

Conclusion: CAC is prevalent on thoracic CT performed for non-cardiac indications and can identify patients who may benefit from preventative medication despite low-cardiovascular risk scores.

Evaluation of virtual grid post-processing for paediatric no-grid radiography in an unselected paediatric patient cohort

M. Beeres¹, J.-E. Scholtz¹, D. Leithner¹, A. Barakat², T.J. Vogl¹, T. Gruber-Rouh¹, B. Kaltenbach¹, C. Polkowski¹, A.M. Bucher¹; ¹Frankfurt a. Main/DE, ²Liverpool/UK (beeres@gmx.net)

Purpose: Virtual grid post-processing (VGP) allows for the calculation of anti-scatter grid images from digital radiographs taken without a physical anti-scatter grid. Because a physical scatter grid is frequently avoided in the paediatric setting for radiation protection purpose, application of VGP is especially interesting in this population.

Methods and Materials: 250 pediatric digital projection radiographs were evaluated with VGP and an intra-individual reference without virtual grid post-processing. Radiographs of the hand ($n=100$), extremities ($n=50$) and chest ($n=100$). Indication for hand radiographs was bone age determination, chest and extremities were taken from with a variety of clinical indications. All images were compared by two readers. Delineation of bone structure, soft tissue differentiation and delineation of foreign material were rated by each reader.

Results: Mean age was 7 years. All images were of diagnostic quality. For chest radiographs, a clear benefit was shown for VGP in all three categories in delineation of bone structure ($p < 0.01$), soft tissue differentiation ($p < 0.01$) and delineation of foreign material ($p < 0.01$). Bone delineation for hand and extremities was inferior in RVGP due to loss of trabecular structure ($p = 0.01$). There was no benefit in delineation of osteosynthetic material for VGP in skeletal images ($p > 0.8$). Inter-reader agreement was good ($k = 0.82$).

Conclusion: VGP is beneficial in chest radiographs in the pediatric setting, since delineation of ribs, pulmonary vasculature and semitransparent foreign material can benefit from VGP reconstructions. VGP did not show improvements when compared with no-grid hand or extremity radiographs, or when evaluated on osteosynthetic material.

Impact of detector pixel size on clinical image quality of digital neonatal chest X-ray images

M. Smet¹, L. Breysem, M. Wang, H. Bosmans, N. Marshall, S. Rodríguez Pérez; *Leuven/BE (Marleen.Smet@uzleuven.be)*

Purpose: To compare neonatal chest X-ray clinical image quality (IQ) of digital detectors with different pixel sizes (ps) using visual grading analysis (VGA).

Methods and Materials: Over a period of 14 weeks, routine bedside neonatal chest image acquisitions for a given patient were alternated between two CsI-detectors: the Agfa[®] DX-D 35C (ps=0,125mm) and the novel Agfa[®] DR10s (ps= 0,148mm). A relative VGA study was performed on 50 chest X-ray image pairs (100 images) of 30 neonates. Two experienced paediatric radiologists and one radiology trainee scored the images following the European quality criteria, with additional questions on tube/catheter visibility. The relative VGA scores were analysed using visual grading characteristics (VGC). Noise and diagnostic acceptability were scored on all images individually using absolute VGA.

Results: Area under the VGC curve with associated 95% confidence interval (CI) was 0.54 (0.45-0.62), 0.63 (0.55-0.71) and 0.56 (0.48-0.64) for readers 1, 2 and 3. Only one (experienced) reader scored image quality significantly higher for the small ps detector (i.e. CI excluded 0.5). Using the median score from all readers the AUC= 0.56 (0.48-0.64), i.e. no significant statistical difference existed between the detectors. Intraclass correlation coefficient was 0.64 (95% CI: 0.50-0.76), indicating reasonably good reader agreement. Absolute scores showed similar noise levels for both detectors, with 7 as median value (1-10 scale (10=best)). The three readers classified 98% of images as acceptable for diagnostic use.

Conclusion: Clinical IQ for the larger ps detector was not significantly different from the small ps detector in neonatal chest X-ray imaging applications.

B-1319 14:16

Post-mortem ultrasound-guided biopsy for perinatal death investigation: a pilot study

S.C. [Shelmerdine](#), J.C. Hutchinson, N.J. Sebire, O.J. Arthurs; *London/UK* (susie_c_s@yahoo.co.uk)

Purpose: Minimally invasive autopsy methods are becoming more acceptable as they reduce the need for large disfiguring incisions. Laparoscopic approaches and percutaneous 'blinded' biopsies of organs have been trialled, without imaging guidance, with variable success. This study aims to assess tissue yield of post-mortem ultrasound-guided biopsies in a perinatal cohort.

Methods and Materials: All perinatal deaths consented for minimally invasive autopsy were included in this prospective study over a 1-year period. Ultrasound-guided biopsies of the liver, both kidneys, both lungs, spleen and myocardium were performed using a 14G cutting biopsy needle via either a periumbilical or subcostal route. A pathologist, blinded to the intended target organ, assessed samples for organ type, sufficient tissue volume for analysis and underlying abnormalities.

Results: 12 perinatal cases underwent image-guided organ biopsies, 6 via the periumbilical route and 6 via the subcostal route. Excluding the spleen, the intended target organ was obtained in 80-100% of cases via periumbilical route and 66.7-91.7% via subcostal route. Splenic tissue was obtained in 20% of samples via periumbilical route versus 16.7% subcostal route biopsies. All samples obtained via periumbilical route and 80-100% via subcostal route yielded sufficient tissue for analysis.

Conclusion: Post-mortem ultrasound-guided organ biopsies are a feasible technique for obtaining the majority of tissue samples in perinatal death investigation. A periumbilical route resulted in higher target organ yield than a subcostal route, and will be assessed in a larger study for diagnostic accuracy. Splenic tissue remains difficult to sample using this method.

Pediatric Computer Tomography (CT) Diagnostic Reference Levels (DRLs) by age and size

S. Yu, P. [Chu](#), R. Smith-Bindman; *San Francisco, CA/US* (philip.w.chu@gmail.com)

Purpose: Contribute to the creation of pediatric (<15 years) CT radiation dose benchmarks by age and size. We report the distribution of radiation dose metrics based on CT scans submitted in 2017 from a large international dose registry comprised of 139 institutions from 7 countries. The registry was supported through the US National Institutes of Health (NIH) and Patient Centered Outcomes Research Institute (PCORI).

Methods and Materials: We describe mean pediatric doses for dose length product (DLP) across institutions in Europe and US. Pediatric age is split into four age categories and dose metrics were categorized by quintiles.

Results: We analyzed 3,007 European pediatric CT scans and found the following mean DLP values (in mGy-cm): youngest age group and smallest patient diameter: abdomen (50), chest (36), and head (270); oldest age group and largest patient size: abdomen (278), chest (149), and head (715). We analyzed 57,252 US pediatric CT scans and found the following mean DLP values (in mGy-cm): youngest age group and smallest patient diameter: abdomen (99), chest (42), and head (269); oldest age group and largest patient size: abdomen (514), chest (273), and head (704).

Conclusion: Dose among pediatric patients varies greatly by age and size in the United States and Europe. Within the same patient size category, mean DLP in the head, chest, and abdomen can double in dose comparing the highest age group to the lowest age group. A larger and more representative sample is needed to reliably confirm the result dose in European pediatric scans.

B-1321 14:32

Evaluation of ultra low dose CT examinations of the paediatric chest using spectral shaping and an iterative reconstruction algorithm

M. [Wetzl](#), D. Weinmann, M. Kopp, J. Roth, R. Heiß, W. Wuest, O. Rompel, M. Uder, M.S. May; *Erlangen/DE* (matthias.wetzl@uk-erlangen.de)

Purpose: Aim of this study was to evaluate the minimum diagnostic radiation dose in paediatric CT using a step wise approach with spectral shaping and advanced iterative reconstructions.

Methods and Materials: 62 paediatric patients with the indication for CT of the chest were examined using a third generation dual source scanner, equipped with a 0.6 mm tin filter. The patients were randomized to different imaging protocols (100Sn kVp, 96/64/32 reference mAs) representing 15%, 10% and 5% of the institutional reference protocol. Images were reconstructed using FBP and different levels of an advanced iterative reconstruction algorithm (ADMIRE). Image noise and subjective image quality were assessed. Radiation doses of CTs were compared to 64 chest radiographs.

Results: Mean age was 13.7 years and mean BMI was 18.9 without significant differences in the subgroups. Mean doses were 0.22, 0.15, and 0.07 mSv (p< 0.01) for the CT subgroups and 0.035 mSv for chest radiographs. In all subgroups image noise was reduced up to 53 % (p< 0.01) using ADMIRE level 4, compared to FBP. A sufficiently high subjective image quality was achieved using ADMIRE level 3 in the 96 mAs subgroup and using ADMIRE level 4 in the 64 mAs subgroup. With the 36 mAs protocol, which provided radiation doses comparable to radiographs in two planes, adequate image quality was limited to central lung structures, pleura, and lung nodules using ADMIRE level 4.

Conclusion: The combination of latest technological developments allows for high diagnostic image quality in paediatric CT examinations of the chest while approaching radiation doses from radiographs.

Relative regional air volume change as a biomarker in humidifier disinfectant-associated lung injury in children with normal-looking chest CT

H. [Ko](#)¹, J. [Choi](#)², K. [Chae](#)³, S. [Park](#)¹, J. [Jang](#)³, C. [Lee](#)²; ¹*Seoul/KR*, ²*Iowa City, IA/US*, ³*Jeonju/KR*

Purpose: Many routine chest CT scans of the children exposed to humidifier disinfectants (HDs) were normal and could not provide any evidence of humidifier disinfectant-associated lung injury (HDLI). The purpose of the study was to investigate relative regional air volume change (RRAVC) in HD-exposed children with normal-looking chest CT.

Methods and Materials: 32 children (11.1±3.6 yrs) with normal-looking chest CT were enrolled in this study. Inspiration-expiration CT image matching via image registration was used to compute RRAVC of acinar scale lung regions. Subjects were divided as diffuse homogeneous (V1, n=14), diffuse heterogeneous (V2, n=10) and increased ventilation in the lower lung (V3, n=8). PFTs including DLco and questionnaire data relevant to HD exposure were obtained.

Results: Coefficient of variation (CV) of RRAVC was significantly higher (p<0.05) in V2 (0.830±0.446) than V1 (0.228±0.057) and V3 (0.356±0.093). There was a significantly longer HD exposure in V3 (V1, 15.4±8.6; V2, 14.7±5.7; V3=29.8±11.4 months; p=0.004), who showed relatively increased ventilation in the lower lobes. No significant difference was found between normal subjects and subjects with decreased DLco and/or FEV1 in HD exposure duration and RRAVC distribution category.

Conclusion: Heterogeneity of local ventilation and relatively increased ventilation in the lower lobes can be new characteristics of HDLI-induced pulmonary functional abnormality. RRAVC characteristics may be used as a biomarker to illustrate earlier regional ventilation change for the children who have been exposed to chemical agents by inhalation.

CT chest under general anaesthetic: is the degree of atelectasis improved by prone positioning?

A. Kirby, A.J. Quigley, J. Jones, S. McGurk; *Edinburgh/UK (akirby3@nhs.net)*

Purpose: Anaesthesia-related pulmonary atelectasis is a common problem when performing paediatric CT imaging under general anaesthetic. This can make interpretation of pulmonary parenchyma more challenging and can lead to both false-positive and false-negative results. Anaesthetic techniques have been proposed to limit the degree of atelectasis but the use of a prone position rather than a standard supine position has not been explored. This study investigates prone positioning versus the standard of supine positioning. The primary outcome measure is the severity of pulmonary atelectasis encountered.

Methods and Materials: 109 cases were prospectively and randomly assigned to the comparison (prone n=43) and control (supine n=63) groups. Prone cases were rotated to the standard axial plane and were reviewed independently by two consultant radiologists. Concordance between the two assessors was measured by means of a weighted Cohen's Kappa test. Superiority of comparison versus control group was investigated by means of a Mann-Whitney U test.

Results: Inter-observer concordance was found to be 'very good' with a Kappa of 0.868 (95% CI 0.84-0.90). There was found to be no statistical significance between prone and supine imaging in the severity of atelectasis with a p value of 0.57.

Conclusion: As no significant improvement was demonstrated between prone and supine positioning, the status-quo of standard supine positioning is suggested. This has both practical and anaesthetic benefits over prone imaging. Further investigation into other avenues of anaesthetic technique, positioning and scan technique may yet yield benefits over current best practice.

B-1324 14:56

PET-MRI is non-inferior to PET-CT in paediatric and adolescent Hodgkin's lymphoma for staging and early response assessment

M.V. Verhagen, T.A. Watson, D. Neriman, S. Punwani, S. Taylor, S. Daw, A. Shankar, L. Menezes, P.D. Humphries; *London/UK (mvverhagen@gmail.com)*

Purpose: Treatment regimens for paediatric Hodgkin's lymphoma (HL) depends on accurate staging and treatment response assessment, for which the reference standard is PET/CT. We hypothesised that PET/MRI is non-inferior to PET/CT for both staging and response assessment.

Methods and Materials: 24 patients (mean age 15.4 years, range 8-19.5 years) with histologically proven HL were prospectively recruited in 2015 and 2016. 3 patients did not undergo response assessment PET/MRI, resulting in 24 scans (720 nodal and extranodal sites) at staging, and 21 (630 sites) at response assessment. PET/CT was immediately followed by PET/MRI for both staging and response assessment. Anatomical MRI and PET/MRI were prospectively evaluated by blinded radiologists/nuclear medicine physicians and compared to PET/CT as reference standard. A multidisciplinary panel corrected for perceptual errors to create an enhanced PET/CT reference standard and corrected MRI and PET/MRI data.

Results: Corrected staging anatomical MRI sensitivity was 85.8% (95%CI 77.4%-89.9%), specificity 97.9% (95%CI 96.3%-98.9%). Corrected staging PET/MRI sensitivity was 100% (95%CI 96.7%-100%), specificity 99.5% (95%CI 98.36-99.87). Corrected response assessment anatomical MRI sensitivity was 0% (95%CI 0%-48.32%), specificity 99.7% (95%CI 98.7%-99.9%). Corrected response assessment PET/MRI sensitivity was 83.3% (95%CI 36.5%-99.1%), specificity 100% (95%CI 99.2%-100%). Modified Ann-Arbor staging agreement was moderate (k 0.403) for MRI and excellent (k 1.0) for PET/MRI. MRI response assessment disagreed with PET/CT in 6 out of 21 patients. Deauville grading agreement between PET/MRI and PET-CT was excellent (k 0.835).

Conclusion: PET/MRI is non-inferior to PET/CT for staging and early treatment assessment of HL in adolescents.

B-1326 15:12

Magnetic resonance imaging assessment of iron status in paediatric patients with hematologic disorders

E. Nazarova, D. Kupriyanov, G. Tereshenko, N. Smetanina, G. Novichkova; *Moscow/RU (evelina.nazarova@fcho-moscow.ru)*

Purpose: To introduce MRI T2*-method for iron assessment in parenchymal organs of transfusion-related paediatric patients with hematologic disorders.

Methods and Materials: MRI investigation was performed using a 3T MR scanner in 85 paediatric patients aged from 2 to 18. For iron estimation we have used Radial T2*-mapping with free breath technique. T2* values were evaluated by special relaxation maps tools and for liver were correlated with iron concentration measured by liver biopsy immediately after MRI scan.

Results: For non-invasive assessment of LIC (liver iron concentration) we have received a calibration curve between the biopsy data and the R2* (R2*=1/T2*) values with correlation coefficient 0.95 (R²=0.89; confidence interval of 87% - 97% with CC= 95%). According to the grades of liver siderosis patients were divided into groups and we have obtained reference T2* values in ms for myocardium (M), pancreas (P) and pituitary gland (PG): non-iron overload - M > 15 ms, P > 11 ms, PG > 11 ms; mild - M = 11-20 ms, P = 4-25 ms, PG = 11-40 ms; moderate - M = 15-30 ms, P = 2-15 ms, PG = 9-20 ms; severe - M = 10-18 ms, P = 1-10 ms, PG = 7-30 ms.

Conclusion: Iron assessment by MRI is a good indicator of iron content in the parenchymal organs.

Diffusion kurtosis imaging (DKI) utility in differentiating low- and high-grade gliomas in paediatric patients: further experience

I. Voicu, A. Napolitano, M. Vinci, F. Diomedes-Camassei, C. Carducci, A. Carai, A. Mastronuzzi, P. Toma, G. Colafati; *Rome/IT (paul.voicu@hotmail.it)*

Purpose: To investigate whether diffusion kurtosis imaging (DKI) can differentiate low- and high-grade gliomas (LGG and HGG) in paediatric patients.

Methods and Materials: DKI sequences (30 directions, 3 b values: 0, 1000, 2000) acquired with simultaneous multislice technique (SMS) are part of the diagnostic neuro-oncologic protocol in use in our Institution, performed on a 3T magnet. Fifty consecutive children (median age 8.6 years, 27 males) affected by histologically confirmed gliomas were retrospectively studied. Mean kurtosis (MK), axial kurtosis (AK), radial kurtosis (RK), fractional anisotropy (FA) and apparent diffusion coefficient (ADC) values were calculated and the corresponding maps were obtained. The solid volume of the tumour (VOI) was segmented semiautomatically. Mean and highest 20 percentile (H20%) DKI values in tumour VOIs were calculated for each metric. Based on tumour location, patients were further categorized into brainstem location (bl) or non-brainstem location (nbl). Differences among DKI-derived metrics in VOIs of low and high-grade gliomas (LGG and HGG respectively) in different locations (bl or nbl) were assessed with a MANOVA. Post-hoc analysis was performed with independent sample t tests.

Results: after excluding three patients for motion artefacts, the scans of forty-seven children (32 LGG and 15 HGG) were analysed. MANOVA revealed significant differences between LGG and HGG (Pillai's trace <0.0001). Post-hoc analysis revealed all metrics were significantly different between nblLGG and nblHGG, while AK and H20%AK were significantly lower in blHGG compared to blLGG (p<0.008 and p<0.006, respectively).

Conclusion: DKI metrics can differentiate low and high-grade gliomas in paediatric patients with location-specific patterns.

Determining the best leader nodes in Alzheimer networks

A. Moradi Amani¹, L. Meyer-Baese², A. Tahmassebi³, K. Pinker-Domenig⁴,
¹Melbourne/AU, ²Atlanta, GA/US, ³Tallahassee, FL/US, ⁴Vienna/AT
 (lisameyerbaese@gmail.com)

Purpose: Fusing modern network theory and control strategies yields a novel transformational paradigm in dementia research. One research direction is determining the best driver nodes in Alzheimer networks that can be directly

manipulated via external inputs to influence the overall network trajectory and simulate the disease progression. Identifying the best driver set in these networks is an unsolved problem in brain connectomics.

Methods and Materials: We examine 249 subjects with FDG-PET and T1-weighted MRI images consisting of 68 control, 111 mild cognitive impairment (MCI) and 70 Alzheimer's disease (AD). We consider only 42 out of the 116 from the AAL in the frontal, parietal, occipital and temporal lobes. Different from previous work on controllability of disease networks, we determine the best disease driver nodes based on a centrality measure in the connection graph.

Results: We demonstrate the precision of the proposed centrality for correctly determining driver nodes and compare it with heuristic methods including considering hub nodes with maximum degree, maximum betweenness, and maximum closeness. We show the differences in structural and functional brain networks reflecting the changes from controls over MCI to AD, and their locations in the frontal and temporal lobe.

Conclusion: We have established a new method to determine the best driver nodes that are influencing the dynamics of the dementia networks. Implicitly, we can gain an understanding of dementia evolution and the subsequent development of therapeutic solutions.

B-1329 14:08

Quantitative MR-phase information enables classification of Alzheimer's disease stages

H. Ino¹, T. Yoneda¹, N. Kurehana¹, Y. Tatewaki², T. Mutoh², A. Ishiki², N. Tomita², H. Arai², Y. Taki²; ¹Kumamoto/JP, ²Sendai/JP
(170w0201@st.kumamoto-u.ac.jp)

Purpose: The purpose of this study was to show quantitative MR-phase corresponding to iron in the amyloid plaque (AP) could classify a group of Alzheimer's disease (AD) patients with high Mini-Mental State Examination (MMSE) score from one of lower score, which would connect to noninvasive image diagnosis of AD.

Methods and Materials: AD patients (8 males, 9 females, 79 ± 5 y) with high MMSE score (≥ 25, 10 patients) and low score (≤ 20, 7 patients) were scanned by 3T-MRI with multi-echo GRE sequence (1st TE = 7.3 ms. ΔTE = 8 ms). Phase data was collected from typical cortices (Superior Frontal Gyrus; SFG, Superior Temporal Gyrus, Precuneus, Cuneus) and evaluated by Double Gaussian Analysis already reported (M. Tateishi et al., MRMS, in print) to define a phase corresponding iron in the amyloid plaque. We derived a proportionality coefficient (PC) of the phase with TE as a quantitative metric representing AP accumulation in the cortex we measured. The PC of two groups were statistically evaluated by Welch's t test (p < 0.01, significantly different) in all regions.

Results: Although subtraction of PC (SPC) between SFG and others were only statistically significantly different, that of other regions did not show it.

Conclusion: The SPC may represent difference of iron loading in the AP and relate to clinical evaluation MMSE score. Our study showed the SPC noninvasively and easily derived from MRI data might be a quantitative metric correlated to MMSE score and classify the AD stages.

B-1330 14:16

Altered cortical thickness related to single nucleotide polymorphisms (SNPs) in the major histocompatibility complex (MHC) in antipsychotic-naïve schizophrenia

B. Tao, Y. Xiao, W. Zhang, L. Yao, S. Lui; Chengdu/CN
(1945828646@qq.com)

Purpose: To explore the relationship between changes in cortical thickness and single nucleotide polymorphisms (SNPs) in the major histocompatibility complex (MHC) in a group of antipsychotic-naïve schizophrenia (AN-SCZ) patients.

Methods and Materials: Twenty-five AN-SCZ patients and 51 healthy controls (HCs) participated in the present study. General linear models were used to explore the associations between the average cortical thicknesses of each brain region (N=68) and each of the 11 SNPs in the MHC in the AN-SCZ patients and HCs, respectively. Next, we performed an independent-sample t-tests to investigate whether there were significant decreased cortexes in the AN-SCZ patients compared with HCs in the brain regions that were significantly associated with the SNPs. Finally, we examined the correlation of clinical symptoms with cortical thickness in the above brain areas in the patients group using Pearson correlation tests.

Results: Seven of the 11 SNPs within the MHC regions exhibited significant associations with the cortical thickness in the AN-SCZ patients, including rs1635, rs1736913, rs2021722, rs204999, rs2523722, rs3131296 and rs9272105. And the AN-SCZ patients exhibited significant reductions in cortical thickness in the above brain regions, especially the frontal cortex. Furthermore, the left entorhinal region showed a negative correlation with PANSS activation scores in the AN-SCZs (r=-0.601, P=0.03).

Conclusion: The present study provided evidence for the potential effect of MHC risk variants on cortical thickness deficits in AN-SCZ.

B-1331 14:24

Drug effects on brain structure in acute and chronic schizophrenia

J. Zeng, W. Zhang, Y. Xiao, J. Liu, B. Tang, G. Fu, S. Lui; Chengdu/CN
(jiaxinzengscu@163.com)

Purpose: The study aims to reveal the effects of antipsychotics on brain structure in schizophrenia patients. We intend to find out the brain regions that are vulnerable to antipsychotics throughout the acute and chronic treatment stage in a large cohort of first episode drug-naïve schizophrenia patients.

Methods and Materials: Diagnosis of schizophrenia were determined using the Structured Interview for the DSM-IV (SCID-P). T1 images were acquired from 179 first episode drug-naïve schizophrenia patients (M/F=77/102), 41 six-week follow-ups (M/F=16/25), 71 one-year follow-ups (M/F=26/45) and 36 two-year follow-ups (F/M=14/22). Grey matter volume was obtained using voxel based morphometry. The FreeSurfer software package was performed to acquire the cortical thickness and surface area. General liner modal was carried out through each comparison between first episode drug-naïve schizophrenia patients and six-week, one-year and two-year follow-ups after treatment using age and gender as covariates. After false discovery rate correction, common brain regions which differ in drug-naïve schizophrenia patients and treated patients through the three comparison were extracted.

Results: Grey matter volume showed common altered brain regions in right and left thalamus in first episode drug-naïve schizophrenia patients compared with six-week, one-year and two-year follow-ups, respectively. Besides, grey matter volume decreased in all treated groups compared with drug-naïve schizophrenia patients at baseline in right and left thalamus. There are no overlap brain regions in cortical thickness and surface area between those groups after correction.

Conclusion: Thalamus is vulnerable to antipsychotics in not only acute phase but also chronic phase, which reveals the pharmacology and physiology mechanism of drugs on schizophrenia.

B-1332 14:32

Heterogeneity of brain structure alterations in patients with never-treated first episode schizophrenia

Y. Xiao, J. Zeng, G. Fu, B. Tang, C. Yang, S. Lui; Chengdu/CN

Purpose: Although schizophrenia is a heterogeneous clinical syndrome, one important question that remains largely unanswered is whether the complex and subtle deficits revealed by MRI could be used as objective biomarkers to resolve neurobiological heterogeneity within this disorder.

Methods and Materials: To address this question, 163 drug-naïve first-episode schizophrenia (FES) patients and a confirmation data set of chronic-treated patients (n=133) were recruited. High-resolution anatomic data were acquired and processed via FreeSurfer software to obtain cortical thickness, surface area and cortical volume measurements. Subsequently, a density peak-based clustering algorithm was employed to classify schizophrenia into subtypes with distinct neuroanatomical patterns.

Results: We found three subtypes of neuroanatomic alterations that were also observed in the confirmation sample. Subtype 1 showed mainly increased surface area and cortical volume in left inferior parietal, superior frontal, superior temporal and right fusiform cortex than healthy controls. Subtype 2 showed subtle cortical alteration. Subtype 3 showed mainly decreased surface area and cortical volume in left precentral, inferior temporal, right superior parietal and rostral middle frontal cortex.

Conclusion: Current findings, in a sample of never-treated FES patients, demonstrated three subtypes of patients with distinct patterns of grey matter alteration. Further, the three subtypes' pattern were confirmed by another data set of chronic-treated patients, suggesting the subtyping defined by FES structural MRI are relatively stable after illness onset, which could help to compressively explain the complex and heterogeneous findings of schizophrenia.

B-1333 14:40

An amplitude of low-frequency fluctuation study in first-episode drug-naïve patients with major depressive disorder

X. Hu, X. Hu, H. Li, L. Zhang, L. Lu, X. Bu, S. Tang, Q. Gong, X. Huang; Sichuan/CN (820546310@qq.com)

Purpose: The purpose of the current study is first to investigate the alterations of amplitude of low-frequency fluctuation (ALFF) in first-episode drug-naïve MDD patients with relatively short illness duration and then to explore whether these changes could be reversed by antidepressant treatment.

Methods and Materials: Thirty first-episode, drug-naïve MDD patients (mean illness duration = 14 weeks) and 52 healthy controls (HC) were scanned with resting-state functional magnetic resonance imaging to obtain the ALFF within the whole brain. After MRI examination, antidepressant treatment was applied for all patients. After 6 weeks, 9 follow-up MDD patients were scanned again. Voxel-based analysis of ALFF maps were compared between pre-treatment MDD and HC using two-sample t test. Correlations between ALFF and HAMD score or illness duration were conducted using multiple regression. Paired t

test was used to compare ALFF maps between post-treatment MDD and pre-treatment MDD.

Results: Compared with HC, pre-treatment MDD patients had increased ALFF in the left dorsal anterior cingulate cortex (dACC) and inferior posterior lobe of cerebellum ($p < 0.05$, FWE corrected). The ALFF of right dorsolateral prefrontal cortex (rDLPFC) was negatively correlated with HAMD score in MDD patients ($r = -0.591$). Post-treatment MDD patients had significantly decreased ALFF in the left dACC compared to pre-treatment MDD patients ($p < 0.05$, FWE corrected).

Conclusion: Our study demonstrates that left dACC, cerebellum and rDLPFC play an important role in the early course of MDD without interference of antidepressants and the left dACC may be a potential target for antidepressants.

B-1334 14:48

Role of MR functional connectivity in discriminating cognitive impairment in BD

M.M. [Eid](#), M.H. Othman, S. Abdelal, H.A. Hasan, H.E. Khakifa, S. Sayed; [*AsyutEG \(Mido_eid1985@yahoo.com\)*](mailto:AsyutEG (Mido_eid1985@yahoo.com))

Purpose: Disorders in functional communication have been suggested for the cognitive contribution and emotion deficit observed in bipolar disorder (BD). Technical contact between cortical prefrontal cortex (mPFC) and other brain regions may be particularly abnormal. The aim of this study was to describe the dynamics of time to Default Mode network connection (DMN) status in BD and to study its association with perception.

Methods and Materials: Our study included , euthymic BD ($n = 16$) and sound healthy comparison (HC, $n = 25$) participants performed resting-state functional MRI, we used of high resolution sequences extracted from the human neural network project, and completed neural measures to address operational function. A dynamic functional connectivity approach was used to measure DMN correlations in each participant, with other brain areas of interest as mPFC , posterior cingulate cortex (PCC), and para hippocampal region. To do description of temporal dynamics between these regions and other DMN nodes using subsets of the time series.

Results: We found marked decreased (marked variability) dynamic functional connectivity between mPFC and PCC , in the bipolar group compared to healthy controls . On the other hand we found apparent connectivity between DLPFC ,brainstem and right amygdala in the Bipolar group with more dynamic range in compare to the control group.

Conclusion: The fluctuation in the resting-state functional connectivity may be an index of the interlinkage flexibility that decreases in BD and link to ongoing cognitive disability during periods of euthymia.

B-1335 14:56

Spectrum of autoimmune encephalitis: establishing imaging patterns on FDG PET/CT for specific antibody sub-types

V. Gupta, R. Verma, R. Ranjan, E. [Belho](#), H. Mahajan; [*Delhi/IN \(ethelbelho@gmail.com\)*](mailto:Delhi/IN (ethelbelho@gmail.com))

Purpose: To establish specific imaging patterns on 18 FDG PET/CT in different antibody sub-types of autoimmune encephalitis.

Methods and Materials: A total of 35 serologically proven cases of autoimmune encephalitis that underwent F-18 fluoro-deoxy glucose (FDG) PET/CT scan were included. The patterns of FDG uptake in different antibody subtypes were recorded and comparison with normalised data was attempted. The areas of hypo-/hyper-metabolism that were two standard deviations from the mean were considered as abnormal. The patients were also analysed based on the Z score surface maps of the 3D stereotactic surface projections (SSP) image and regional Z scores were evaluated. Post-treatment follow-up scans were also acquired.

Results: All the patients had an abnormal pattern of 18 FDG uptake, both on visual inspection and semiquantitative analysis. Voltage-gated potassium channel (VGKC) complex receptor antibody encephalitis patients were found to have typical areas of hypermetabolism in bilateral medial temporal regions and bilateral basal ganglia with relative global hypometabolism in rest of the cortical and subcortical structures. The subjects with N-methyl-D-aspartate-receptor antibody (NMDAR-Ab) encephalitis showed variable degrees of focal hypermetabolism in bilateral fronto-temporal regions, basal ganglia, thalamic and cerebellar hemispheres with inhomogeneous parieto-occipital hypometabolism. The post-treatment FDG PET/CT scans showed reversal to normal metabolism in the corresponding areas.

Conclusion: 18 FDG PET/CT scan may serve useful as a non-invasive diagnostic modality in the early diagnosis and management of patients with clinical suspicion of autoimmune encephalitis.

Central nervous system (CNS) imaging findings in granulomatous polyangiitis (GPA), IgG4-related (IgG4-RD) and Erdheim-Chester diseases (ECD): comparison and pictorial essay

S. Gerevini, E. Bozzolo, R. [Cao](#), E. Della Torre, V. Canti, G. Cavalli, M. Lanzillotta, L. Dagna, A. Falini; [*Milan/IT \(robertacao1@gmail.com\)*](mailto:Milan/IT (robertacao1@gmail.com))

Purpose: Background: GPA, IgG4-RD and Erdheim-Chester diseases are immune disorders characterized by systemic inflammatory infiltration. Aim: to investigate and compare radiological differences of CNS involvement in these different forms of disorders and revision of the literature.

Methods and Materials: We retrospectively reviewed neuroradiological studies of patients with a diagnosis of GPA, IgG4-RD or ECD, presenting an involvement of the CNS. Specific involvement of different structures of brain, paranasal sinuses and of dural layers was classified according to location and imaging findings and compared between the three groups.

Results: 29 patients with GPA, 15 with IgG4-RD and 17 with ECD were enrolled. In GPA, paranasal sinus involvement was always observed (29/29) with a maxillary predominance (28/29). A lower rate of sinus infiltration was observed among IgG4-RD (11/15) and ECD (2/17) patients. Orbital involvement was present in all the groups but in ECD patients with an intraconal component (9/9), whereas in GPA and IgG4 with an extraconal predominance (6/6 and 7/8, respectively). In IgG4 patients, dural layers showed a basal involvement (6/6), whereas in ECD distribution involved falx and convexities. In ECD patients, 9 presented with white matter lesions, and 4 with a hypophysary involvement whereas fewer cases of cerebral lesions were observed in the other 2 groups (3 in GPA and 1 in IgG4).

Conclusion: Despite a common definition of CNS location of involvement of these groups of diseases according to the literature a direct evaluation showed some differences that should be considered for a differential diagnosis.

Tissue sodium concentration (TSC) in normal brain: preliminary study

P. [Wawrzyniak](#), B. Bobek-Billewicz, A. Hebda, A. Awramienko, P. Mazgaj; [*Gliwice/PL \(pawel.wawrzyniak@io.gliwice.pl\)*](mailto:Gliwice/PL (pawel.wawrzyniak@io.gliwice.pl))

Purpose: Purpose of this work was to establish database of tissue sodium concentration (TSC) in normal brain of healthy volunteers. TSC can be used as a marker of tissue viability in stroke or radiation therapy monitoring.

Methods and Materials: This study was approved by local bioethics committee. 35 volunteers were scanned with 23 Na protocol in the span of year (10.2017-10.2018), from this pool 29 studies were of acceptable quality. Volunteer mean age was 37 years (min 22 and max 64). Volunteer acquisitions were acquired in one scanner session which lasted approximately 1 hour. Two bottles with 70 and 20 mmol/l Na concentration were placed inside coil for calibration. One scanner session consisted of 23 Na GRE acquisition (radial 3D GRE, TR/TE 100/2.87 ms, FA 90 deg, NeX 23, FoV 300x300 mm, matrix 64x64 which gives 4.7x4.7x4.7 mm voxel) performed twice, MPRAGE (1x1x1 mm), SPACE-FLAIR and Resolve-DTI. Only 23 Na and MPRAGE acquisitions were used. Denoising filtration was done to 23 Na and MPRAGE images. MPRAGE were segmented, and for MPRAGE and 23 Na normalization and coregistration was also done, all in SPM12. Next 23 Na signal intensity from WM, GM and CSF was acquired using masks from MPRAGE segmentation. Than calibration curve was acquired from phantom signal and TSC was calculated from GM, WM and CSF.

Results: In healthy volunteers, mean TSCs were GM 33.21 +/- 4.76 mmol/l, WM 28.41 +/- 4.03 mmol/l and for CSF 41.3 +/- 6.69 mmol/l.

Conclusion: This work is a base for further papers with sodium imaging in brain lesions.

Clinical feasibility assessment of T3 sub-stage in rectal cancer using MRI

P. [Tripathi](#)¹, W. Guo², C. Yang², B. Rai¹, M. Zeng², H. Yu¹; ¹Wuhan/CN, ²Shanghai/CN (pratik9_band@hotmail.com)

Purpose: To investigate the reproducibility of the distance of mesorectal extension by tumour invasion in T3 stage rectal cancer by evaluating sub-stages T3a, T3b T3c and T3d individually versus T3ab and T3cd combined together using MRI.

Methods and Materials: 188 patients with surgically and histologically confirmed T3 rectal cancer who underwent preoperative MRI were enrolled in this study. Two blinded radiologists evaluated the maximum distance of mesorectal extension (mrDME) in T2-weighted image in MRI. The study population was sub-classified into T3a (< 1 mm), T3b (1-5mm), T3c (5-15 mm) and T3d (>15 mm) according to the distance of mesorectal extension by tumour invasion. The inter-/intra-observer data were assessed statistically.

Results: Inter-/intra-observer kappa (k) and intraclass coefficients (ICC) between the two groups were very distinct. In the individual group, the inter-observer and intra-observer k for the mrDME were 0.700 and 0.718, respectively; the inter-observer and intra-observer ICC were 0.772 and 0.786, respectively. In the combined group, the inter-observer and intra-observer k for the mrDME were 0.819 and 0.883, respectively; the inter-observer and intra-observer ICC were 0.829 and 0.796, respectively.

Conclusion: There was a distinct increase in the kappa (K) and ICC value in the combined group compared with the individual group. This high reproducibility result suggested that it is more reliable to measure T3ab and T3cd combined together than individually. This finding can play a crucial role in the management of rectal cancer and clinical decision-making for non-expert radiologists in a non-academic setting.

B-1340 14:08

Preoperative MR restaging of rectal cancer in UKMMC: correlation with surgical and histopathologic findings

C. Lee, S. Osman, L. Mazlan, F. Mohammed; *Kuala Lumpur/My (dr.leechungyuen@gmail.com)*

Purpose: To determine the accuracy of restaging MRI in rectal cancer post-neoadjuvant chemoradiotherapy.

Methods and Materials: Between November 2016 and May 2018, we did a comparative cross-sectional analysis of 26 patients who underwent restaging MRI following neoadjuvant chemoradiotherapy. 3.0T MRI is used and images were evaluated by an experienced radiologist and on-table intraoperative tumour T staging is determined by an experienced colorectal surgeon. Both were blinded to results from the other as well as histological results. Interobserver variability was determined. Accuracy of restaging MRI was assessed through the comparison of tumour characteristics on MRI with histopathologic outcomes.

Results: Restaging MRI correctly predicted tumour T staging in 18 cases, representing an accuracy of 69.2%. Overstaging was more common than understaging. Positive predictive values (PPV) for T0 is 100%. For T1/2, PPVs and NPVs were 66.7% and 94.1%, and for T3/4 they were 93.3% and 90.9%. MRI suggested tumour regression grade did not correspond with histopathologic tumour regression grade. Interobserver agreement is fair to moderate ($\kappa = 0.371-0.579$).

Conclusion: Restaging rectal cancer MRI is inaccurate for prediction of tumour T staging, and the interobserver variability is significant.

B-1341 14:16

Magnetic resonance of rectal cancer response to therapy: comparison between 3.0 and 1.5 Tesla

E. Lucertini¹, M. Zerunian¹, D. Caruso¹, D. De Santis¹, G. Moltoni¹, F. Landolfi¹, T. Biondi¹, E. Iannicelli¹, A. Laghi¹; ¹Rome/IT, ²Belvedere Marittimo/IT (elena.lucertini@gmail.com)

Purpose: To evaluate Signal Intensity(SI) differences between 3.0T and 1.5T on T2 weighted(T2w), Diffusion Weighted Imaging(DWI) and Apparent Diffusion Coefficient(ADC) in rectal cancer pre, during and post-neoadjuvant chemoradiotherapy(CRT).

Methods and Materials: 22 patients with locally advanced rectal cancer were prospectively enrolled. All patients underwent T2w, DWI and ADC pre, during and post-CRT on both 3.0T MRI and 1.5T MRI. A radiologist drawn regions of interest(ROIs) of the tumor and obturator internus on the selected slice to evaluate SI and relative SI(rSI). Additionally, a sub analysis evaluating the SI before and after-CRT(Δ S.I.pre-post) in complete responder patients(CR) was performed on T2w, DWI and ADC.

Results: Significant differences were observed for T2w and DWI on 3.0T MRI compared to 1.5T MRI pre, during and post-CRT(all $P < 0.001$), whereas no significant differences were reported for ADC among all controls(all $P > 0.05$). rSI showed no significant differences in all the examinations for all sequences(all P values > 0.05). Δ SI_{CR} showed significant differences between 3.0T MRI and 1.5T MRI for DWI Δ SI_{CR}(188.39 \pm 166.90 vs 30.45 \pm 21.73 P value 0.0262) and ADC Δ SI_{CR}(-0.58 \pm 0.27 vs -0.21 \pm 0.24 P value 0.0265), while no significant differences were observed for T2w Δ SI_{CR}.

Conclusion: T2wSI and DWISI showed significant differences for 3.0T compared to 1.5T in all 3 controls, while ADCSI showed no significant differences on both field strengths. rSI was comparable for 3.0T and 1.5T MRI, therefore rectal cancer patients can be assessed both at 3.0T MRI and 1.5T MRI. However, a significant DWI Δ SI_{CR} and ADC Δ SI_{CR} on 3.0T might be interpreted as a better visual assessment in discriminating response to therapy compared to 1.5T.

B-1342 14:24

Prognostic value of tumour regression grade on MR in rectal cancer: a large-scale, single-centre experience

H. Yoon, S.H. Kim, J.H. Yoon, B.Y. Hur, J.H. Kim, H.E. Park, H. Oh, J.K. Han; *Seoul/KR (zelkova0712@gmail.com)*

Purpose: To determine the prognostic value of tumour regression grade on MR (mrTRG) in rectal cancer compared to pathology (pTRG) and to assess the effect of diffusion-weighted image (DWI) on inter-observer agreement.

Methods and Materials: We retrospectively enrolled 489 patients (M:F=323:166; mean age, 59.67years) with histopathologically proven rectal cancers who underwent both pre-chemoradiotherapy (CRT) and post-CRT MRI between January 2005 and December 2016. Two radiologists individually determined mrTRG using a 5-point grading system without and with DWI. Two pathologists graded pTRG using a 5-point grading system. For assessment of interobserver variation, intraclass correlation coefficients (ICC) were used. Kaplan-Meier estimation and Cox proportional hazard models were used for survival analysis.

Results: According to mrTRG, 48 patients (7 for mrTRG1 and 41 for mrTRG2) were classified as good responders while 355 (130 for mrTRG3, 214 for mrTRG4 and 11 for mrTRG5) as poor responders. By pTRG, 60 patients (6 for pTRG1 and 54 for pTRG2) were classified as good responders while 298 (191 for pTRG3, 96 for pTRG4 and 11 for pTRG5) as poor responders. For mrTRG, ICC between the two radiologists was 0.273 (fair agreement) on MR without DWI and improved to 0.333 when DWI was added. Overall survival (OS) was significantly different according to the age, pre-CCRT variables (EMD and EMVI), post-CCRT variables (tumour size, T and N stages, EMD, extramesorectal node, EMVI) and mrTRG, but not by pTRG.

Conclusion: mrTRG better predicts OS than pTRG. The addition of DWI on T2W MR improves the interobserver agreement.

B-1343 14:32

Importance of tumour volume reduction rate on T2w and DWI during and after CRT for prediction of treatment response to CRT in locally advanced rectal cancer (LARC)

A. Di Chiara, A. Palmisano, G. Della Vecchia, A. Esposito, P. Passoni, C. Fiorino, A. Del Maschio, F. De Cobelli; *Milan/IT*

Purpose: A complete response to CRT improve patients' prognosis and may address patients to a conservative management. To MR is asked high accuracy in the prediction of response and in the identification of residual cancer. Aim of this study was to investigate volumetric imaging biomarker prior, during and after CRT derived from DWI and T2w images.

Methods and Materials: 43 patients with LARC underwent 1.5T MRI before, during and after CRT. Tumour volume was manually segmented on high resolution T2-weighted sequence (VT2w) and on DWI b₁₀₀₀ image (Vb₁₀₀₀) at each time point, then tumour volume reduction rate (TVRR_{T2w} and TVRR_{b₁₀₀₀}) calculated. After surgery, patients were classified according with Rödel's tumour regression grade (TRG) in: Non Responders (NR:TRG 0,1,2), Partial Responders (PR:TRG3) and Complete Responders (CR:TRG4). Kruskal-Wallis test was used to compare measurements in different classes and multinomial regression analysis for the prediction of classes of response performed.

Results: According to TRG: 10 patients were NR, 22 PR and 10 CR. TVRR_{b₁₀₀₀} resulted significantly different among classes only after CRT (CR: -97%, PR: -78%, NR: -69%, $p = 0.0020$), with higher reduction in CR respect to PR ($p = 0.0021$) and NR ($p = 0.0001$). At multivariate analysis predictor of CR were TVRR_{T2w} ($< -58%$, $p = 0.0028$) at mid-MRI and TVRR_{T2w} and TVRR_{b₁₀₀₀} at postMRI ($< -83%$ $p = 0.0090$ and $< -87%$, $p = 0.0265$), with a sensitivity of 91%, 82% and 91% respectively.

Conclusion: Tumour volume modification on T2w and b₁₀₀₀ images is effective in the prediction of response to CRT; in particular early modification on T2 images seems useful to predict CR during treatment.

B-1344 14:40

Whole-tumour texture analysis of ADC maps in the prediction of pathological response of locally advanced rectal cancer (LARC)

A. Di Chiara, A. Palmisano, A. Esposito, P. Rancoita, P. Passoni, A. Del Maschio, F. De Cobelli; *Milan/IT*

Purpose: Tumour heterogeneity is an imaging biomarker of aggressiveness. Texture analysis allows to extract features of tumour heterogeneity from conventional images. Aim of our study is to evaluate the role of whole-tumour histogram-based texture analysis of ADC maps in the prediction of pathological response of LARC to chemoradiotherapy (CRT).

Methods and Materials: 43 pts with LARC underwent 1.5T MRI before CRT(pre-MRI), during (mid-MRI), and after CRT (post-MRI). Cancer volumes were segmented on ADC maps at each time-point using T2W-images as reference. The following histogram-based parameters were extracted: 25th, 50th, 75th percentile, mean, skewness and kurtosis and their role in the prediction of histopathological response was evaluated with multinomial

Impact of body mass index on set-up variations and treatment margins for patients receiving radiotherapy to the prostate

S. Farrugia, G. van Dijk, S. Mercieca; Msida/MT
(sarah.farrugia.14@um.edu.mt)

Purpose: The aim of the study was to evaluate the impact of body mass index (BMI) on set-up variations and planning target volume (PTV) margins for patients receiving radiotherapy for prostate cancer to ensure accurate treatment delivery.

Methods and Materials: The mean random (RV) and systemic set-up variation (SV) in the lateral, supero-inferior and antero-posterior directions were calculated from daily variations of 49 patients, selected through exhaustive sampling. Spearman rank correlation (r_s) was used to analyse the correlation between BMI and the SV and RV. The van Herk formula was used to calculate the PTV margin required.

Results: The mean SV was 1.4mm, 0.9mm and 1.4mm and the mean RV was of 1.7mm, 1.5mm and 1.8mm in the supero-inferior, lateral and antero-posterior directions, respectively. A significant correlation was calculated between patient BMI and overall set-up variations, with a negative correlation in the supero-inferior (r_s : -0.137, p value: <0.001) and the lateral directions (r_s : -0.158, p value <0.001), and a positive correlation in the antero-posterior direction (r_s : 0.065, p value: 0.020). Correlations between SV or RV and patient BMI were similar in direction, however, weaker and not statistically significant. The PTV margin for the new local protocol was 4.7mm in the supero-inferior direction, 3.4mm in the lateral direction and 4.9mm in the antero-posterior direction.

Conclusion: A uniform PTV margin of 5mm is suitable to treat prostate cancer. A positive correlation was noted in the antero-posterior direction for the BMI indicating that for patients with high BMI, reduction of margins needs to be more carefully evaluated.

B-1351 14:04

An augmented patient-specific approach to administration of contrast agent for CT renal angiography

C. Saade; Beirut/LB (charbel.saade@aub.edu.lb)

Purpose: Retrospective and prospective study performed on 200 consecutive patients undergoing renal CTA, investigates the opacification of renal vasculature, radiation dose, and reader confidence.

Methods and Materials: 100 patients were assigned retrospectively to protocol A and the other 100 were allocated prospectively to protocol B. Both protocols implemented a contrast material and saline flow rate of 4.5 mL/sec. Protocol A utilized a 100mL of low-osmolar nonionic IV contrast material (Ioversol 350 mg I/mL) while protocol B employed a patient-tailored contrast media formula using iso-osmolar non-ionic (Iodixanol 320 mg I/mL).

Results: Arterial opacification in the abdominal aorta and in the bilateral main proximal renal arteries demonstrated no statistical significance ($p > 0.05$). Only the main distal renal artery of the left kidney in protocol B was statistically significant ($p < 0.046$). In the venous circulation, the IVC demonstrated a significant reduction in opacification in protocol B ($59.39 \text{ HU} \pm 19.39$) compared to A ($87.74 \text{ HU} \pm 34.06$) ($p < 0.001$). Mean CNR for protocol A ($22.68 \text{ HU} \pm 13.72$) was significantly higher than that of protocol B ($14.75 \text{ HU} \pm 5.76$) ($p < .0001$). Effective dose was significantly reduced in protocol B ($2.46 \pm 0.74 \text{ mSv}$) compared to A ($3.07 \pm 0.68 \text{ mSv}$) ($p < 0.001$). ROC analysis demonstrated significantly higher area under the ROC curve for protocol B ($p < 0.0001$), with inter-reader agreement increasing from moderate to excellent in renal arterial visualization.

Conclusion: Employing a patient-tailored contrast media injection protocol shows a significant refinement in the visualization of renal vasculature and reader confidence at reduced radiation dose during renal CTA.

regression analysis.

Results: 11 patients resulted to be complete responders (CR), 22 partial responders (PR) and 10 non-responders (NR). Only at pre-MRI, 3D-ADCmean values were significantly different among the groups (median: NR $1.07 \times 10^{-3} \text{ mm}^2/\text{s}$, PR $1.14 \times 10^{-3} \text{ mm}^2/\text{s}$ and CR $1.27 \times 10^{-3} \text{ mm}^2/\text{s}$; $p = 0.0079$), resulting higher in CR than in PR and in NR ($p = 0.0042$ and $p = 0.0029$, respectively). At multinomial regression analysis 75th percentile and 3D-ADCmedian at pre-MRI were positive predictor of response ($p = 0.0247$ and $p = 0.0415$, respectively). A 3D-ADC median cutoff-value of $> 1.198 \times 10^{-3} \text{ mm}^2/\text{s}$ at pre-MRI resulted best predictor of CR with a sensitivity, specificity and accuracy of 82%, 88% and 86%, respectively.

Conclusion: Pretreatment features of ADC distribution values might be an helpful tool in the prediction of tumour response to CRT.

B-1345 14:48

T2-weighted signal intensity (T2SI) textural analysis in an evaluation of neoadjuvant chemoradiotherapy (CRT) response in patients with locally advanced rectal adenocarcinoma

G. Della Vecchia, A. Di Chiara, M. Panzeri, A. Palmisano, A. Esposito, P. Passoni, A. Del Maschio, F. De Cobelli; Milan/IT

Purpose: Tumour response to CRT is often characterized by fibrotic evolution associated, however the sole visual assessment is characterized by low sensitivity. Aim of the study was to assess the value of histogram-based analysis of tumor T2SI in the assessment and prediction of complete pathological response in locally advanced rectal cancer (LARC).

Methods and Materials: 67 patients with LARC underwent 1.5 T MRI before, during and after CRT. High-resolution multiplanar T2w sequences were acquired. Cancer volume was manually segmented and the histogram analysis of T2SI in the entire lesion was performed with the extraction of the following parameters: 25th, 50th, 75th percentile, range, mean, standard deviation, skewness and kurtosis calculated. After surgery, patients were classified according to Rodel tumor regression grade (TRG) in Non-Responder (NR=TRG0-2), Partial Responder (PR:TRG3), Complete Responder (CR:TRG4).

Results: At histopathology 14 patients were NR, 37 PR and 16 CR. Any difference in T2SI texture parameters was found before and during treatment. After CRT, only T2SI mean value was different among classes of response, in particular it was significantly lower in CR compared to other groups (median, IQR: NR 530.7 ± 154.8 , PR 526.9 ± 233.7 , CR 359.8 ± 195.4 ; $p = 0.008$). Based on ROC analysis, at restaging MRI, a T2SI cut-off value of 363.93 was able to predict CR with an AUC of 72, a sensitivity of 78% and a specificity of 63%.

Conclusion: Histogram-based analysis of whole tumour T2SI might provide a new insight in tumour heterogeneity and be a promising tool in the assessment of tumoural complete response after CRT.

B-1346 14:56

Diffusion and perfusion MR parameters to assess preoperative short-course radiotherapy response in locally advanced rectal cancer

R. Fusco, V. Granata, B. Pecori, A. Petrillo; Naples/IT
(r.fusco@istitutotumori.na.it)

Purpose: To assess preoperative short-course radiotherapy (SCR) tumour response in LARC by means of Standardized Index of Shape (SIS) by dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI), apparent diffusion coefficient (ADC), intravoxel incoherent motion (IVIM) and diffusion kurtosis imaging (DKI) parameters derived from diffusion-weighted MRI (DW-MRI).

Methods and Materials: 34 patients who underwent MRI scans before and after SCR followed by delayed surgery were enrolled. SIS, ADC, IVIM parameters (tissue diffusion (Dt), pseudo-diffusion (Dp), perfusion fraction (fp)) and DKI parameters (mean diffusivity (MD), mean of diffusional kurtosis (MK)) were calculated for each patient. IVIM parameters were estimated using two methods, namely conventional bi-exponential fitting (CBFM) and variable projection (VARPRO). After surgery, the pathological TNM and tumour regression grade (TRG) were estimated.

Results: The best results to predict pCR were obtained by VARPRO Fp mean value pre-treatment with AUC of 0.84, a sensitivity of 96.4%, a specificity of 71.4% and an accuracy of 91.2%. The best results to assess after treatment pCR were obtained by SIS with an AUC of 0.89, a sensitivity of 85.7%, a specificity of 92.6% and an accuracy of 91.2%. Moreover, the best results to differentiate after treatment responders vs. non-responders was obtained by SIS with an area under ROC of 0.94, a sensitivity of 93.3%, a specificity of 84.2% and an accuracy of 88.2%.

Conclusion: SIS is a hopeful DCE-MRI angiogenic biomarker to assess preoperative treatment response after SCR with delayed surgery. Furthermore, an important prognostic role was obtained by VARPRO Fp mean value pre-treatment.

B-1352 14:08

Improving technical quality in mammography

V. Risi¹, M. Zanardo², R.M. Trimboli³, C.B. Monti², G. Di Leo³, L.A. Carbonaro³, F. Sardanelli², ¹Lumezzane/IT, ²Milan/IT, ³San Donato Milanese/IT (verarisi1@gmail.com)

Purpose: To improve the technical quality of mammograms through personal information of radiographers.

Methods and Materials: Craniocaudal (CC) and mediolateral oblique (MLO) views of both breasts were evaluated using criteria defined by European guidelines. Presence of the pectoral muscle, nipple in axis and in profile, presence of inframammary angle, and skin folds were evaluated. Each mammography examination was evaluated using a 5-point Likert scale, ranging from 1 (lowest quality) to 5 (highest quality). While the entire group of radiographers was informed about the general performance, each of them received her personal data through a non-public report. Thereafter, the performance of the group was re-evaluated with the same criteria. Data were reported using median and interquartile range (IQR). Mann-Whitney Utest and χ^2 test were used.

Results: A total of 156 mammographic studies were evaluated (78 pre-audit and 78 post-audit). Pre-audit CC views had a median score of 4 [IQR 3-4], with 107 (69%) good (score 4) to excellent (score 5) quality examinations, while post-audit CC views had a median score of 4 [IQR 4-4], with 134 (86%) good to excellent quality examinations ($p < 0.008$). Pre-audit MLO views had a median of 4 [IQR 3-4], with 38 (24%) good to excellent quality examinations, while post-audit MLO views had a median score of 4 [IQR 3-4], with 93 (60%) good to excellent quality examinations ($p < 0.001$).

Conclusion: Technical performance in mammography was significantly improved for both views by a means of personal information of each radiographer about her performance. High-quality MLO views remain a more challenging goal.

B-1353 14:12

Reflective clinical portfolios as a tool to develop competence in radiography students

M. Morris; Limerick/IE (mikealammorris07@gmail.com)

Purpose: Reflective clinical portfolios are used in undergraduate health science degree programmes to prepare students for their professional careers by promoting reflective practice and critical thinking. The current study investigated the impact of reflective clinical portfolios on the development of competence in Radiography students and which elements of reflective clinical portfolios students valued most.

Methods and Materials: An online survey was disseminated to undergraduate radiography students and recent graduates to gather their opinions on the impact of reflective portfolios on competence development. Recent graduates were defined as those who had been working for less than one year. A stratified sampling approach of second, third and fourth year undergraduates and recent graduates from an Irish University was adopted to represent the population.

Results: Tutor feedback and competency assessments were reported to be beneficial in developing competence. Respondents who chose self-reflections as the most beneficial were all in Stage 4 or qualified. Those who ranked this as the least beneficial were in Stage 2 or Stage 3. Modality objective lists were considered unbeneficial by 45% of respondents. The online e-portfolio was chosen as the preferred portfolio format by 62% of respondents. Challenges outlined with portfolio use included lack of guidance and technical problems.

Conclusion: There was a general consensus that the reflective clinical portfolio is a valuable learning tool in developing competence during the Radiography degree programme, despite some respondents' dissatisfaction with specific aspects of these tools. Areas for improvement of clinical portfolios have been identified for consideration by educators.

B-1354 14:16

A comparative analysis of local diagnostic reference levels for adult projection radiography of the chest, abdomen and pelvis in Irish centres

M. Malone, S.J. Foley, L.A. Rainford, R. Toomey; Dublin/IE (mariamalone16@gmail.com)

Purpose: Diagnostic reference levels (DRLs) are important tools for optimisation in identifying atypical doses for standard patients undergoing radiological examinations. This research aimed to determine why local diagnostic reference levels (LDRLs) for adult projection radiography of the chest, abdomen and pelvis vary significantly across Irish centres.

Methods and Materials: Stratified sampling was performed to select one site from each of four hospital categories (tertiary referral, regional, general and private). Dose-area product measurements, exposure factors, source-to-image distances and the use of filtration were retrospectively recorded in each site for chest (postero-anterior), abdomen (antero-posterior) and pelvis (antero-posterior) examinations. Systematic random sampling was employed to sample

30 patients from the total number of examinations performed three months prior to the date of data retrieval. The data were utilised to formulate LDRLs based on the 75th percentile of the distribution of dose data. Kruskal-Wallis tests were performed to comparatively analyse the data.

Results: Significant variations were observed in LDRLs established for radiographic examinations of the chest ($p < 0.001$), abdomen ($p = 0.02$) and pelvis ($p < 0.001$), with differences of up to 86%, 85% and 130%, respectively, between the departments with the highest and lowest LDRL. The national diagnostic reference level (NDRL) for chest imaging was exceeded in the general department while the NDRLs for the abdomen and pelvis were exceeded in the regional site.

Conclusion: Imaging protocols, namely high mAs settings, low kVp settings and lack of additional filtration, can be attributed to the significant variations observed in LDRLs between the sites studied.

B-1355 14:20

Dose optimisation in CT for cocaine body packing: where is the limit of extensive dose reduction?

J. Aissa, L.M. Sawicki, E. Appel, P. Heusch, C. Thomas, G. Antoch, J. Boos; Düsseldorf/DE (joel.aissa@med.uni-duesseldorf.de)

Purpose: To evaluate the detection rate and image-quality in CT-body-packer-screening at different radiation dose levels and to determine a dose threshold that enables a reliable detection of incorporated body packs and incidental findings with a maximum of dose saving.

Methods and Materials: We retrospectively included 27 individuals who underwent an abdominal CT due to suspected body. CT images were reconstructed at different radiation dose levels of 50%, 10%, 5% and 1%. All 135 CT reconstructions were evaluated by three independent readers. Reviewers determined the presence of foreign bodies and evaluated the image quality using a 5-point ranking scale. Additionally, visualization of incidental findings was assessed.

Results: A threshold of 5% (effective dose 0.11 ± 0.07 mSv) was necessary to correctly identify all 27 patients with suspected body packing ($p < 0.008$). Extensive noise insertion to a dose level of 1% (0.02 ± 0.01 mSv) led to false positive solid cocaine findings in three patients. Image quality was comparable between 100% and 50% ($p < 0.024$). The threshold for correct identification of incidental findings was 10% of the initial dose (effective dose 0.21 ± 0.13 mSv).

Conclusion: A dose reduction to 0.11 mSv seems sufficient for detection of incorporated cocaine body packets. However, a minimum effective dose of 0.21 mSv seems to be required to properly identify incidental findings.

B-1356 14:24

Evaluation of radiology request forms

S. Kitalla, J. Sakwa, E. Aswani, L. Kanamu; Nairobi/KE (shellakitalia@gmail.com)

Purpose: Radiology request forms are essential communication tools used by doctors and clinicians referring patients for radiological investigation. Their importance, however, is highly underestimated.

Methods and Materials: Radiology request forms (RRF) formed the study sample. 295 request forms formed the sample size. 37 (12.54%) request forms were excluded because they entailed the use of unconventional papers. During data collection, systemic random sampling method was used and data were collected using observational checklist. The collected data were then analysed using statistical package of social sciences software and presented on pie charts, bar graphs and frequency tables for better understanding.

Results: The study revealed that radiology requesting practice is poor. In the 258 radiology request forms, none was completely filled. The least filled field were patients' address (9.63%), referring department (5.12%) and the hospital number (27.04%). The best-filled field in the study was patients' name at 97.33%. Age of the patient was filled in 67.00% of the forms. Date was blank in 88.93% of the request forms. 14.34% of the RRF had not indicated the examination requested. This study revealed that 59.84% of the RRF did not provide patients' clinical history. Only 1.62% of the forms provided patient's LMP. 62.09% of the RRF provided the referring clinician name. 48.98% of the forms had referring clinician's signature.

Conclusion: Radiological request forms are often omitting relevant patient information. It is important that clinicians be educated on the value of filling radiology request forms to provide relevant information to aid in proper patient diagnosis.

B-1357 14:28

Obstetric ultrasound - knowledge and perception of pregnant women in Portugal

R.A. Santos, R. Fernandes; Coimbra/PT (rutemartinssantos@gmail.com)

Purpose: To evaluate the knowledge and perception of pregnant women on obstetric ultrasound of diagnosis performed during pregnancy.

Methods and Materials: The study will be conducted by means of a questionnaire to pregnant women whose pregnancy surveillance is being

performed in Portugal. It will be carried out at national level in public and private health units.

Results: Pregnant women are expected to have some knowledge about the objective of diagnostic obstetrical ultrasound but a lower level of knowledge regarding the parameters evaluated and safety of the examination and that the influence of the completion of an enlightenment/training session is results of the questionnaire responses.

Conclusion: The perception and knowledge of Portuguese pregnant women about diagnostic obstetric ultrasound is not yet studied and fundamental for the effectiveness of diagnosis and follow-up of pregnancy, as well as it is essential that pregnant women have an active participation in the change of the National Health Plan in Portugal, revision and extension to 2020.

B-1358 14:32

Expectant mothers' perception of prenatal sonography in southeastern population in Nigeria

H.C. [Elugwu](mailto:elugwuemeka@yahoo.com); *Nnewi/NG (elugwuemeka@yahoo.com)*

Purpose: The study was conducted to assess the perception of pregnant women to prenatal sonography and to investigate the factors affecting maternal satisfaction to prenatal sonography in some tertiary institutions in south-eastern Nigeria.

Methods and Materials: The study was a cross-sectional study that involved 150 patients. It was conducted by administering semi-structured questionnaires. The questionnaire contained a total of 17 questions consisting of 16 close-ended questions and 1 open-ended question. The respondents were pregnant women who presented for obstetric sonography in Federal Teaching Hospitals and Federal Medical Centers in south-eastern Nigeria. The data were analyzed descriptively using frequency tables and percentages.

Results: There was a high indication of clinical use of obstetric ultrasound such as the health and well-being of the foetus (35.3%), foetal age determination, and the expected date of delivery (24.7%). Most respondents (84.6%) perceived prenatal sonography as being necessary, and 66.7% of the patients considered the result of obstetric sonography to be reliable. Majority of the respondents (88.7%) considered the services rendered during their sonographic scan to be satisfactory.

Conclusion: Most of the women perceived prenatal sonography as necessary and reliable. The services rendered during sonography were also considered satisfactory by most women; however, most pregnant women did not know about diagnostic ultrasound safety during the prenatal period.

B-1359 14:36

Mobile phones as a potential vehicle of nosocomial pathogens in radiology departments

T.C.P.L. [Guerreiro](mailto:Guerreiro35@gmail.com)¹, L. Ribeiro², A.F. Abrantes², S. Rodrigues², R. Raposo², F. Soares², R.P.P. Almeida²; ¹*Santiago Do Cacém/PT*, ²*Faro/PT (tatianguerreiro35@gmail.com)*

Purpose: Mobile smart phones have become increasingly integrated into the practice of radiographers, and can be colonized by potential bacteria pathogens. For this reason, adherence to hand hygiene by radiographers is crucial to prevent nosocomial infections. The main goal of this study was to assess the Radiographers knowledge about hand hygiene and to investigate the potential level of contamination on their mobile phones.

Methods and Materials: A self-applied questionnaire about knowledge and attitudes regarding hand hygiene and the use of mobile phone during clinical practice was applied to 21 radiographers from a public hospital. Their phones were swabbed using a standardized technique to check the types of microorganisms and the amount of contamination of the mobile phones.

Results: 85% of radiographers received training about nosocomial infection control, 81% considers hand hygiene important to prevent the nosocomial infections, 100% admits to use mobile phone during the shift and 76% don't have special attention to his mobile phone hygiene. Microorganisms like *Staphylococcus* (positive coagulase and oxacillin resistant) and alpha-haemolytic *Streptococcus* were identified. A fungus suggestive of *Candida Albicans* was also found.

Conclusion: This study demonstrates that mobile phones are potentially vehicles for pathogenic bacteria in the radiology departments. Despite the radiographers are aware of the importance of hand hygiene, adequate knowledge and a positive attitude are needed for optimal compliance. Disinfection guidelines utilizing alcohol wipes for regular cleaning of mobile phones should be developed and implemented to reduce the transmission of pathogens.

B-1360 14:40

Diffusion tensor imaging of the growth plate: a preliminary study

O. [Kvist](mailto:kvist@ll.se)¹, S. Diaz Ruiz¹, T. Dorniock¹, J. Sanmartin Berglund², C.-E. Flodmark¹; ¹*Stockholm/SE*, ²*Karlskrona/SE (ola.kvist@ll.se)*

Purpose: To determine the feasibility of diffusion-tensor imaging (DTI) and tractography of the distal femur for the evaluation of the physis maturation related to age and sex.

Methods and Materials: Forty adolescents, 14-17 years old, 5M/5F in each group were examined. Image acquisition using echo-planar DTI was performed on a 3T MRI scanner, 15 directions; b values of 0 and 600 s/mm². Fibre tracks were reconstructed using Philips Fibertrak with ROI in the physis of the distal femur in three separate slices. A minimum fractional anisotropy (FA) of 0.15 and a maximum angle threshold of 30° were used. FA and apparent diffusion coefficient (ADC) of fibre tracts were measured and evaluated against age and sex. The physis was visually graded on the b0 images as open (14, 4F/10M), partly open (13, 4F/9M) and closed (13, 12F/1M) and compared to FA and ADC.

Results: FA increased linearly with age (increase 0.1/year from 0.4 to 0.7). For females, plateau was reached at 16. FA values for males were lower (>0.2 before reaching maximum). ADC decreased non-linearly from 0.8-10-3 mm²/s at age 14 to 0.5-10-3 mm²/s at 17. ADC for males was larger than average at all ages with decreasing gender difference with age. Plotting FA and ADC against the grading type showed a linear increase in FA and a linear decrease in ADC, with a smaller gender-related difference (<0.1).

Conclusion: FA increases and ADC decreases with progressing physis maturation, earlier for females than for males. FA and ADC correlate well with visual grading.

B-1361 14:44

Comparison of extremity cone beam-computed tomography and multidetector-computed tomography in injured children

S. [Tschauer](mailto:Tschauer@klinikum-graz.at), R. Marterer, E. Nagy, G. Apfaltrer, G. Singer, M. Riccabona, E. Sorantin; *Graz/AT (Sebastian.Tschauer@klinikum-graz.at)*

Purpose: To compare extremity cone beam-computed tomography (CBCT) and multidetector-computed tomography (MDCT) in injured children.

Methods and Materials: 61 CBCT examinations were prospectively acquired. 10 MDCT studies were completed in parallel, and 51 were retrospectively matched with MDCTs of the same region, age and sex. 7 study pairs were excluded due to differences in cast or metal implant presence. Optimized exposure protocols were used in both modalities to achieve a realistic comparison. Image quality assessment was performed quantitatively and qualitatively. Moreover, dose records were read out.

Results: Objective image quality measurements were superior in CBCT (noise and contrast-to-noise ratio, p<0.001). Subjective image quality ratings revealed more streak artefacts in CBCT (p<0.001), which degraded the CBCT image impressions with varying degrees. Overall, motion artefacts were infrequent, but only seen in CBCT. CT dose index (CTDIvol) was significantly lower in CBCT (p<0.001).

Conclusion: CBCT was able to achieve better objective image qualities at lower doses than MDCT in paediatric extremity imaging. However, CBCT image impression was commonly degraded by streak artefacts, which made the modality's advantages partly ineffective.

Artificial intelligence in bone age assessment: accuracy and clinical efficiency of a novel fully automated algorithm for bone age assessment in comparison to the Greulich Pyle method

C. [Booz](mailto:boozchristian@gmail.com), I. Yel, L. Lenga, A. Al Kamali, S. Boettger, J.L. Wichmann, T.J. Vogl, M.H. Albrecht, B. Bodelle; *Frankfurt a. Main/DE (boozchristian@gmail.com)*

Purpose: To evaluate the accuracy and clinical efficiency of a novel artificial intelligence (AI) system for bone age (BA) assessment compared with the Greulich Pyle (GP) method.

Methods and Materials: Radiographs of left hand and wrist of 414 patients (mean chronological age 10.3 years, range 3-17 years) were retrospectively analyzed. Total BA was assessed independently by three blinded radiologists using the GP method. In comparison, an AI system automatically calculated total BA. Reference BA was determined by the consensus of two blinded experienced radiologists (28 and 32 years of experience in paediatric imaging) using the GP method. Root mean square deviation (RMSD), mean absolute

difference (MAD), Pearson product-moment correlation and Bland-Altman plot were calculated for statistical analysis.

Results: Reference mean total BA was 9.9 years. AI-derived mean total BA was 10.0 years, mean total BA calculated by the three reviewers was 10.2 years. RSMD and MAD were significantly lower between AI-derived BA and reference BA (RSMD 0.2 years, MAD 0.1 years) than between BA calculated by the three radiologists and the reference standard (RSMD 0.7 years, MAD 0.5 years) (all comparisons, $p < .001$). There was significantly higher correlation between AI-derived BA and reference BA ($r = 0.99$) than between BA assessed by the three radiologists and reference BA ($r = 0.90$) ($p < .001$). Mean evaluation times were reduced by 87% using the AI system compared to reviewer-based BA assessments.

Conclusion: A novel AI system allows for accurate BA assessment and improves clinical efficiency by reducing evaluation times without compromising the accuracy compared with the GP method.

High-resolution MR imaging of the orbit in patients with retinoblastoma: prospective study correlated with histopathological results

Y.S. Habib, A. Youssef, H.A. ElKiki, H.A. ElZomor, M.M. Rezk; *Cairo/EG (yomnahabib85@gmail.com)*

Purpose: To assess diagnostic accuracy of preoperative magnetic resonance (MR) imaging for the detection of tumour extent in patients with retinoblastoma.

Methods and Materials: Fifty-eight eyes in 30 girls and 27 boys with retinoblastoma (mean age at diagnosis was 23 months ± 18.9) were reviewed on unenhanced T1-weighted, spin-echo T2-weighted, and gadolinium-enhanced T1-weighted MR images with and without fat suppression. MR imaging parameters such as anterior chamber hyperintensity, involvement of choroid, ciliary body, optic nerve, sclera, orbital fat, and pineal gland were determined.

Results: The accuracy of MRI in detection of choroidal invasion is 86.2% with sensitivity, 95.3% and specificity, 60%. Regarding detection of prelaminar optic nerve invasion, MRI has 60% sensitivity, 82.9% specificity, and 75.8% accuracy. Postlaminar optic nerve invasion was detected in 23 eyes with MRI accuracy, 86.2%; sensitivity, 85.2%; specificity, 87%. Of nine eyes with histologically proven scleral invasion, MRI has accuracy, 93%; sensitivity, 55.6%; specificity, 100%. Extraocular fat invasion was suspected on MRI in 5/58 eyes with accuracy, 98.3%; sensitivity, 100%; specificity, 98%. Anterior chamber enhancement correlated well with main MRI and histopathology findings. Tumour size (maximum diameter in mm) was statistically associated with postlaminar optic nerve invasion ($p = .002$) and choroidal invasion ($p = .007$).

Conclusion: MR imaging shows promising role for tumour staging and detection of metastatic risk factors.

B-1364 14:56

Should we still look for a correlation between ADC and SUV in lymphoma: a volumetric [18F] FDG-PET/MR study of paediatric Hodgkin's lymphoma

M.G. Riga¹, G. Orsatti¹, A. Varotto¹, F. Crimi¹, M. Weber², R. Stramare¹, P. Zucchetta¹, E. Quaia¹, C. Giraudo¹; ¹Padua/IT, ²Vienna/AT (mariagiovanna.riga@gmail.com)

Purpose: Previous studies showed controversial results about the correlation between metabolic activity and cellular density in lymphomas. Thus, our aim was to investigate the relationship between ADCs and SUVs simultaneously acquired in paediatric patients with Hodgkin's lymphoma (HL) at staging, using a volume-based histogram analysis.

Methods and Materials: Paediatric patients with histologically proven HL were enrolled in this prospective study and underwent a whole body integrated 3T [18F]-FDG-PET/MR, including DWI, for staging. PET images were re-sliced according to the ADC maps and, for each patient, the lesion with the largest volume was selected. A volumetric region of interest (vROI) has been then drawn on the DWI images along the margins of the tumour including the entire lesion. The same ROIs were copied on the corresponding PET dataset. Pixel-based SUVs and ADCs were collected from each entire vROI. The Pearson correlation coefficient was applied to assess the relationship between SUVs' and ADCs' mean, median, skewness, and kurtosis.

Results: Fifteen paediatric patients (eight female; mean age 13.33 \pm 3.53 yrs) have been enrolled. According to Ann Arbor, four patients were stage I, seven stage II and four stage IIIS. The mean (\pm SD) lesion volume was 46.39 \pm 62cm³. No significant correlation between ADCs' and SUVs' mean ($r = 0.003$, $p = 0.990$), median ($r = -0.039$, $p = 0.890$), skewness ($r = -0.116$, $p = 0.682$) or kurtosis ($r = 0.085$, $p = 0.763$) emerged.

Conclusion: Our preliminary results showed that volumetric ADCs and SUVs simultaneously acquired are independent biomarkers in paediatric HL at staging. Future studies after chemotherapy are necessary to further assess this evidence and its clinical implications.

B-1365 15:00

Diagnostic value of C-reactive protein and the influence of visceral fat in patients with obesity and acute appendicitis

A.D. Do Amaral Castro¹, F.A. Sulla Lupinacci¹, S. P. Pribeiro¹, E. Kaiser Ururahy Nunes Fonseca¹, M.R. Peixoto¹, T. Larocca Skare², A.T. Sakuma¹, F. Yamauchi¹, A. Tachibana¹; ¹São Paulo/BR, ²Curitiba/BR (felipesulla@gmail.com)

Purpose: The purpose of this study is to assess sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of CRP in patients with AA and their correlation to body mass index (BMI) and body fat composition.

Methods and Materials: This is a retrospective study based on clinical records and imaging studies of 191 subjects with histopathologically confirmed AA compared to 249 controls who underwent abdominal computed tomography (CT). Clinical and epidemiological data, BMI, and CRP values were extracted from medical records. CT scans were assessed for AA findings and body composition measurements.

Results: CRP values increased according to patients' BMI, with varying sensitivity from 79.78% in subjects with normal or lean BMI, 87.87% in overweight, and 93.5% in individuals with obesity. A similar pattern was observed for NPV: an increase with increasing BMI, 69.3% in individuals with normal or lean BMI, 84.3% in overweight, and 91.3% in individuals with obesity. There was a positive correlation between CRP and visceral fat area in patients with AA.

Conclusion: Variations exist for sensitivity, specificity, PPV, and NPV values of CRP in patients with AA, stratified by BMI. An increase in visceral fat area is associated with elevated CRP across the BMI spectrum.

B-1366 15:04

Impact of added CT venography performed in combination with CT pulmonary angiography on the detection of deep venous thrombosis and relevant occult CT findings

P.I. Douek, D.C. Rotzinger, R. Meuli, V. Dunet, S. Schmidt Kobbe; *Lausanne/CH (pauline.douek@gmail.com)*

Purpose: To assess the additional diagnostic value of CT venography (CTV) simultaneously performed with CT pulmonary angiography (CTPA) in the context of thromboembolic disease for the detection of deep venous thrombosis (DVT) and other relevant CT findings.

Methods and Materials: Patients older than 49 years referred for suspected pulmonary embolism (PE) from January 2015 to December 2016 and undergoing CTPA combined with CTV were included in this monocentric retrospective study. While one radiologist reviewed clinical records of all patients, two other radiologists blinded to all results independently analysed the CTV images in view of DVT of lower extremities and/or other relevant pathological findings visible, which were registered and classified into non-relevant or major with therapeutic consequences (yet unknown pelvic tumours or inflammation). Interobserver agreement for the detection of DVT was evaluated using the Cohen's kappa coefficient.

Results: Among 696 patients, 119 had PE (17.1%) and 54 had DVT (7.8%), of which 16 (2.3%) occurred without concomitant PE. Interobserver agreement kappa between the two readers was substantial ($k = 0.78$). CTV examinations led to the diagnosis of major incidental findings in 40 patients, of which 8 had PE associated or not with DVT, and 4 had only DVT. Additional CTV lead to a change of therapeutic management in 30 patients (4.3%), consisting of 16 DVTs without PE and 14 relevant pelvic findings with therapeutic consequences.

Conclusion: In patients with suspected PE, additional CTV performed with CTPA rarely enables the detection of DVT without concomitant PE or relevant underlying pelvic lesions with therapeutic consequences.

B-1367 15:08

Reliability of on-call radiology residents' interpretations in detecting intracranial aneurysms on 640 slice multidetector computed tomography angiography

M.B.H. Chaudhry, M. Azeemuddin, M.N. Ahmad, F. Mubarak, T.U. Haq; *Karachi/PK (mustafa.b.chaudhry@gmail.com)*

Purpose: To assess interobserver agreement (IOA) between on call resident (OR) and neuroradiologist (NR) in detecting intracranial aneurysms (IA), on 640-MDCTA, in patients referred from emergency department (ED).

Methods and Materials: Prospective study was performed between June 2016 to July 2017. Patients with history of vascular pathology, prior intervention or acute head trauma were excluded. Sample size of 71 was calculated, taking previous Kappa(κ) value of 0.84 between NR, for 320-slice MDCTA. All MDCTA were interpreted by senior OR, year 3 to 5 (PGY3 to PGY5). MDCTA were reinterpreted and finalised by NR, following morning.

Results: 77 patients, 39(52%) males and 38(48%) females were prospectively included. Mean age was 47.7 \pm 15.2 years. 24(31%) cases were read by PGY3, 32(41%) by PGY4 and 21(28%) by PGY5. 31(40%) cases were

Quantitative assessment of liver function before hepatectomy using two-dimensional shear wave elastography correlated with indocyanine green clearance test

R. Fu, T. Qiu, Q. Lu, Y. Luo; Chengdu/CN (448939373@qq.com)

Purpose: To find the possibility of quantitative liver function assessment before hepatectomy using non-invasive two dimensional shear wave elastography (2D-SWE) by analysing the correlation between liver stiffness measured by 2D-SWE examination and the results of indocyanine green (ICG) clearance test, and to determine the cutoff point of liver stiffness value to differentiate normal and abnormal liver function.

Methods and Materials: We retrospectively studied 236 patients who were examined by 2D-SWE and ICG clearance test before liver resection. Liver stiffness of background parenchyma and ICG retention rate at 15 minutes (ICG-R15) were noted.

Results: Liver stiffness values of ICG-R15 < 10% group (median: 10.0 Kpa, IQR: 7.1-13.5Kpa, range: 4.5-31.0Kpa) were significantly smaller than that of ICG-R15 ≥ 10% group (median: 14.2 Kpa, IQR: 11.3-19.0Kpa, range: 5.3-38.2Kpa), with analysis of Mann-Whitney U test ($p < 0.0001$, $Z = -4.292$). Spearman correlation test showed the significant correlation between liver stiffness and ICG-R15 ($r = 0.427$, $p < 0.0001$). Receiver operating characteristic (ROC) curve showed a liver stiffness cutoff point of 11.0 Kpa to determine normal or abnormal liver function, with sensitivity of 84.4%, specificity of 68.0%, and area under the ROC curve (AUC) of 0.742 ($p < 0.05$).

Conclusion: 2D-SWE examination exhibits promising performance for quantitative assessment of liver function reserve before hepatectomy, and has good efficiency to differentiate normal and abnormal liver function.

B-1371 14:08

Liver function evaluation with Gd-EOB-DTPA-enhanced MRI: can visual scoring replace signal measurement?

S. Xie, J. Li, H. Wang, W. Shen; Tianjin/CN (xiess1989_happy@163.com)

Purpose: To assess liver function with Gd-EOB-DTPA-enhanced MRI using visual score of liver parenchyma and portal vein signal difference at hepatobiliary phase in comparison with relative liver enhancement (RLE).

Methods and Materials: This retrospective study included 52 patients (Child-Pugh class A, n=26; B, n=15; and C, n=11). Visual difference in Signal intensity (SI) between liver parenchyma and portal vein at hepatobiliary phase images was evaluated using a 5-point scale (5, liver SI was obviously higher than that of portal vein; 4, liver SI slightly higher than portal vein; 3, liver SI equal to portal vein; 2, liver SI slightly lower than portal vein; 1, liver SI obviously lower than portal vein). Pre- (SI_{pre}) and postcontrast (SI_{20min}) liver SI were measured using ROI placement. RLE calculated as follow: $RLE = SI_{20min} / SI_{pre}$.

Results: Both Visual score and RLE were decreased as the progression of liver function damage. Visual score (Child-Pugh class A, 4.80 ± 0.50 ; B, 3.47 ± 0.99 ; C, 2.45 ± 0.93 ; $P < 0.001$) and RLE (Child-Pugh class A, 2.01 ± 0.31 ; B, 1.50 ± 0.24 ; C, 1.30 ± 0.14 ; $P < 0.001$) had significant differences between different liver function groups. Pairwise comparison showed visual score and RLE had significant difference between Child-Pugh class A and B ($P = < 0.001$, < 0.001), A and C ($P = < 0.001$, < 0.001), no significant difference between B and C ($P = 0.233$, $= 0.447$).

Conclusion: In Gd-EOB-DTPA-enhanced MRI, visual score of liver parenchyma and portal vein signal difference at hepatobiliary phase can be easily used for liver function evaluation, and had similar value to RLE.

finalised by assistant professor, 19(25%) by associate professor and 27(35%) by professor. 42 IA in 29(38%) patients were reported by RR, while NR finalised 35 IA in 25(32.5%) patients on following morning. Discrepancy was noted in 4(14%) cases when OR over called 7(16.7%) IA. No IA was missed by OR on MDCTA. Mean height of IA is 8.3 ± 7.3 mm and mean width is 6.9 ± 6.5 mm. Strong IOA between OR and NR ($\kappa = 0.88$, CI 95%, p -value < 0.001). Stratified κ -value for grade of OR[0.81(PGY3) vs. 1(PGY4) vs. 0.84(PGY5)]. Sensitivity of 640-MDCTA in detecting IA by OR is 1, specificity is 0.92, PPV is 86.2% and NPV is 100%

Conclusion: 640-MDCTA is reliable in diagnosing IA, if read by OR, ruling out the need for DSA in ED.

B-1368 15:12

Forensic relevance and diagnostic impact of a novel 3D-reconstruction technique (cinematic rendering) of severe injuries in postmortem computed tomography

J. Böven, J. Boos, R.S. Lanzman, P. Kröpil, Y. Klosterkemper, C. Thomas, G. Antoch, J. Aissa; Düsseldorf/DE (judith.boeven@med.uni-duesseldorf.de)

Purpose: Performance and forensic relevance of a novel, photorealistic 3D-reconstruction method used for visualisation of traumatic injuries in comparison to conventional postmortem computed tomography (PMCT).

Methods and Materials: In total 38 pathologies from 22 human cadavers undergoing whole-body PMCT after traumatic death were retrospectively analysed. PMCT was performed and all pathologies were reconstructed with 3D-cinematic rendering and CT slices in all 3 dimensions. Images were evaluated according to their expressiveness and judicial relevance by two forensic pathologists using a five-level scale (1: high expressiveness, 5: low expressiveness). In addition, readers decided whether cinematic rendering reconstructions are suitable for judicial reviews. Two radiologists analysed all images due to the detection rate of pathologies in cinematic rendering reconstructions and PMCT.

Results: Forensic estimation: mean expressiveness of cinematic rendering reconstructions: reader 1: 2.4 ± 1.1 (range: 1-5); reader 2: 1.9 ± 1.2 (range: 1-5); total: 2.1 ± 1.2 (range: 1-5). Mean expressiveness of conventional PMCT: reader 1: 4.1 ± 1.1 (range: 2-5); reader 2: 3.7 ± 1.1 (range: 1-5); total: 3.9 ± 1.1 (range: 1-5). Concerning forensic interpretation and demonstration aspects results showed that CR reconstructions were significantly more expressive than conventional PMCT ($p < 0.05$). Regarding the radiologic detection rate of all pathologies the evaluation of both radiologists lead to no significant difference between 3D reconstructions and original CT slices for all pathologies.

Conclusion: There is no significant difference concerning the detection of pathologies by radiologists between PMCT and cinematic rendering reconstructions. For forensic pathologists, CR reconstructions are more helpful than standard PMCT for correlation with autopsy results and judicial reviews.

B-1369 15:16

Neonatal chest X-ray

S. Johansen; Oslo/NO (safora.johansen@oslomet.no)

Purpose: To our knowledge, there is little known about radiation optimization in neonatal chest X-ray imaging. The aim of this study was to consider radiographic techniques, protocols, and radiation dose in four countries to assess possible learning outcomes.

Methods and Materials: The protocols and exposure parameters from one hospital in Norway, Portugal, South Africa and Canada were collected and analysed. Dose area product (DAP) and effective dose (ED) from 200 neonatal chest X-ray examination were calculated.

Results: There were differences in protocols, field of view (FOV) and radiation dose. The highest and lowest median DAP (dose) belonged to Portugal and Norway, 13.7 and 9.0, respectively. The kV and mAs differed between 50 and 73 and 0.5 and 2.2 between the involved hospitals. The used inherent filter was highest in Norway (2.9mm Al) and lowest in Canada (2.5mm Al). Field of view (FOV) varied remarkably between the involved hospitals. The largest FOV was 891 cm^2 in Portugal and the smallest was 90 cm^2 in Norway.

Conclusion: The results show that the high kVp-low mAs protocol, with careful collimation, gives lower radiation dose and is, therefore, preferable in neonatal chest X-ray imaging. There is a strong need of standardization of neonatal chest X-ray protocol to avoid high dose to this patient group.

B-1372 14:16

Assessing liver function: diagnostic efficacy of parenchymal enhancement and a liver volume ratio of Gd-EOB-DTPA enhanced MRI studies

D. Ippolito¹, A. Pecorelli¹, L. Riva², C. Maino¹, A. de Vito¹, I. Salemi¹, M. Porta¹, C. Talei Franzesi¹, S. Sironi³, ¹Monza/IT, ²Missaglia/IT, ³Bergamo/IT (davide.atena@tiscali.it)

Purpose: To assess whether Gd-EOB-DTPA enhanced-MRI study is useful to determine liver function in comparison to Child Pugh (CP), Model for End-stage Liver Disease (MELD) score and biochemical test.

Methods and Materials: We retrospectively reviewed all Gd-EOB-DTPA enhanced-MRI studies performed between May 2010 and September 2016. Patients were divided in study and control group according to the presence or absence of liver cirrhosis. Liver volume was calculated using the software Intellispace Portal(Philips) on hepatobiliary phase. The rate of liver-to-muscle ratio was calculated on T1 sequence in portal(irPOR) and hepatobiliary phase(irHEP) and then normalized for liver volume(irPOR/LV and irHEP/LV).

Results: 303 Gd-EOB-DTPA enhanced-MRI studies were included in the study. Cirrhosis was present in 175 (57.8%) cases. IrHEP was significantly lower in cirrhotic than in non-cirrhotic patients(0.54±0.28 vs 0.66±0.39,p=0.001). When considering only cirrhotic patients, irHEP significantly correlates with both CP and MELD score (R= -0.316,p<0.0001 and R= -0.170,p=0.010 respectively). The irHEP progressively decreased from CP-A to CP-C (0.59±0.29 to 0.25±0.19,p<0.0001) and from MELD≤10 to MELD 19-24 (0.58±0.29 to 0.45±0.41, p=0.030). Same results were observed when irHEP was normalized for liver volume. Among biochemical parameters total bilirubin, GOT and albumin had the strongest correlation both with irHEP and irHEP/LV (R=-0.278 and -0.285,R=-0.277 and -0.291;R= 0.282 and 0.262 respectively). None correlations were found with irPOR.

Conclusion: Gd-EOB-DTPA enhanced-MRI studies significantly correlates with clinical score used to evaluate liver function. In clinical practice this imaging technique could be used to correctly characterize focal liver lesion.

B-1373 14:24

MR relaxometry in chronic hepatitis b and c: the contribution of MollI T1 mapping and T2 mapping in hepatic function evaluation with Gd-EOB-DTPA-enhanced magnetic resonance

D. Kuru Oz, E. Peker, M. Kul, I. Erden, A. Erden; Ankara/TR (digdem_k@hotmail.com)

Purpose: To investigate the contribution of pre-and postcontrast T1 mapping with Gd-EOB-DTPA, obtained with different MOLLi sequences and T2 mapping to the evaluation of hepatic function in patients with chronic hepatitis B/C (CHB/C).

Methods and Materials: A total of 41 patients with CHB/C were included in this study. T1 mapping before (MOLLi5(3)3, 3(3)3(3)5, MOLLi3(2)3(2)5 and MOLLi5(3)3 adjusted for heart rate(ahr)) and 20 min after administration of Gd-EOB-DTPA (MOLLi4(1)3(1)2, MOLLi3(3)3(3)5, MOLLi3(2)3(2), MOLLi4(1)3(1)2(ahr)) and T2mapping were performed. Pre- and postcontrast T1 relaxation times of the liver (T1 liver), changes between pre-and postcontrast T1 liver ($\Delta T1$ liver), adjusted postcontrast T1 liver (postcontrast T1 liver-T1 spleen/T1 spleen) and T2 values were evaluated among Child-Pugh stages. To differentiate Child-Pugh A-B stages ROC analysis was used.

Results: Of the 41 patients 29 were in the Child-Pugh A, 12 in the Child Pugh B group. No significant relationship was found between the Child-Pugh stage and precontrast T1-T2 relaxation times in any sequence (p>0.005). Postcontrast T1 mapping, $\Delta T1$ liver and adjusted postcontrast T1 liver values were significantly different between Child-Pugh A-B groups (p<0.001). For $\Delta T1$ liver the cutoff values, sensitivity, specificity and accuracy were for MOLLi5(3)3-MOLLi4(1)3(1)2; 0.625, 100%,65%,76%, for MOLLi3(3)3(3)5-MOLLi3(3)3(3)5 and MOLLi3(2)3(2)5- MOLLi3(2)3(2)5; 0.643, 100%,65%,76%, for MOLLi5(3)3-MOLLi4(1)3(1)2(ahr); 0.589, 90%,69%,76%, respectively. The cutoff value of adjusted postcontrast T1 liver, sensitivity, specificity and accuracy for MOLLi5(3)3-MOLLi4(1)3(1)2 was -0.558, 90%,88%,89%, respectively. The cutoff values of adjusted postcontrast T1liver were for MOLLi3(3)3(3)5-MOLLi3(3)3(3)5; -0.587, for MOLLi3(2)3(2)5-MOLLi3(2)3(2)5; -0.581, for MOLLi5(3)3-MOLLi4(1)3(1)2(ahr); -0.561, with sensitivity, specificity and accuracy of 88%,88%,88%, respectively.

Conclusion: Postcontrast T1 liver, $\Delta T1$ liver and adjusted postcontrast T1 liver may provide additional information regarding the clinical severity in CHB/C patients.

Predicting liver failure after extended liver resection following portal vein embolisation with gadoteric acid-enhanced MRI

D. Theilig, I. Steffen, T. Denecke, B. Hamm, D. Geisel; Berlin/DE

Purpose: Predicting post-hepatectomy liver failure (PHLF) after major liver resection following portal vein embolisation (PVE) by means of sequential gadoteric acid-enhanced MRI scans.

Methods and Materials: 36 patients who underwent extended liver resection following PVE were evaluated prospectively with gadoteric acid-enhanced MRI scans at set intervals during the course of their treatment, that is, before, 14 days and 28 days after PVE as well as 10 days after extended liver resection. Relative enhancement (RE) and liver volume of the left and right liver were determined. The study population was divided into two groups with respect to signs of PHLF according to the PHLF severity grading system of the International study group of liver surgery. Differences between the two groups were assessed using Mann-Whitney U Test and ROC curve analysis.

Results: RE of the left lobe prior to PVE versus 14 days after PVE was significantly lower in patients with PHLF than in those without PHLF (MWU test p< 0.001) and proved to be the best predictor of PHLF in ROC analysis with a AUC of 0.854 (p<0.001) and a cut-off value of -0.044 with a sensitivity of 75.0% and a specificity of 92.6%.

Conclusion: Gadoteric acid-enhanced MRI as an imaging-based liver function test performed before and after PVE can help to predict PHLF. The risk of PHLF can be predicted as early as 14 days after PVE underscoring the hypothesis that it may be feasible to perform extended liver resection earlier after PVE than the current standard.

Shear wave dispersion slope obtained by shear wave elastography could help detect allograft abnormality after liver transplantation

D. Lee, J. Lee, J. Bae; Seoul/KR (dhlee.rad@gmail.com)

Purpose: To evaluate whether shear wave dispersion slope could help detect allograft abnormality after liver transplantation.

Methods and Materials: From Jan 2018 to Sep 2018, we prospectively enrolled 93 patients who underwent liver transplantation. Before liver biopsy, shear wave elastography evaluation was done, and both stiffness (kilopascal, kPa) and shear wave dispersion slope ([m/s]/kHz) were obtained. Allograft abnormality was diagnosed by histopathologic examination. Mann-Whitney U test and receiver operating characteristic analysis were used to evaluate relationship between allograft abnormality and parameters derived from shear wave elastography evaluation.

Results: Allograft abnormality was detected in 43 patients (43/93, 46.2%): acute cellular rejection, n=27; cholangitis, n=9; reperfusion injury, n=1; reactivation of viral hepatitis, n=2; non-alcoholic steatohepatitis, n=1; alcoholic hepatitis n=1; and chronic rejection, n=2. Mean liver stiffness value with allograft abnormality was 10.4±8.7 kPa, and significantly higher than liver stiffness value without allograft abnormality of 6.4±1.7 kPa (P<0.001). Mean shear wave dispersion slope was 15.7±5.6 [m/s]/kHz in 43 patients with allograft abnormality, and significantly higher than 10.9±2.3 [m/s]/kHz in 50 patients without allograft abnormality. The area under the curve for the prediction of allograft abnormality was 0.853 for shear wave dispersion slope, and significantly higher than 0.744 for stiffness value (P=0.0013). The optimal cut-off value of shear wave dispersion slope to detect allograft abnormality was set at 10.8 [m/s]/kHz with sensitivity of 97.7% (42/43) and specificity of 60% (30/50).

Conclusion: Shear wave dispersion slope obtained from shear wave elastography could be useful to detect allograft abnormality after liver transplantation.

B-1376 14:48

Spleen ARFI: a noninvasive tool for detection of oesophageal varices in cirrhotics

M. Rajasekaran¹, R. Rathinasamy², M. Viyyannan², D. Bala Lakshmoji²; ¹Bangalore/IN, ²Coimbatore/IN (muthusubramanian1989@gmail.com)

Purpose: Current guidelines recommend all cirrhotic patients should undergo upper gastrointestinal endoscopy (UGI scopy) screening for detection of oesophageal varices. This imposes heavy burden on endoscopy units and decreases patient compliance. Thereby, this study was performed to determine the utility of spleen ARFI as non-invasive predictor for the detection of oesophageal varices and to assess the efficacy of spleen ARFI in differentiating low-grade from high-grade oesophageal varices.

Methods and Materials: Consecutive 50 cirrhotic patients with EVs and 50 cirrhotic patients without EVs, who had undergone screening UGI scopy were included. B mode ultrasonography and acoustic force impulse imaging (ARFI) elastography was done with Siemens Acuson S2000™/Acuson S3000™ ultrasound systems. Demographic, clinical, bio-chemical, ultrasonography and elastography parameters were recorded. Independent sample 't' test and Chi-square test were performed to identify predictors of EVs and high-grade EVs. Cut-offs of significant indicators were determined by ROC analysis.

Results: Spleen ARFI cut-off of ≥ 3.16 m/s (AUROC: 0.906) precisely detects EVs with 94% sensitivity and 92% specificity. Diagnostic accuracy of spleen ARFI in detection of EVs is the highest of all the noninvasive parameters analysed in this study. Furthermore, exclusively spleen ARFI cut off of ≥ 3.29 m/s (AUROC: 0.874) can confidentially differentiate low-grade vs high-grade varices with 85% sensitivity and 100% specificity.

Conclusion: Spleen ARFI can be used as a noninvasive tool for the detection of oesophageal varices and differentiating high-grade vs low-grade oesophageal varices, with high degree of diagnostic accuracy in cirrhotic patients.

B-1377 14:56

The extent of portosystemic collaterals depends on portal pressure and hepatic dysfunction rather than on PIGF-driven neoangiogenesis

K. Lampichler, L. Reider, B. Simbrunner, A. Stadlmann, M. Mandorfer, T. Buccis, R. Paternostro, U. Asenbaum, T. Reiberger; Vienna/AT (katharina.lampichler@meduniwien.ac.at)

Purpose: Despite a growing body of evidence from experimental studies, the impact of hepatic dysfunction and neoangiogenesis on portosystemic collaterals/shunts (PSS) has yet to be systematically investigated. Placental growth factor (PIGF) is a pro-angiogenic factor that has been linked to liver fibrosis and portal hypertension in animal studies. We assessed the association of PSS with portal pressure, hepatic dysfunction and PIGF levels in patients with chronic liver disease (CLD).

Methods and Materials: 107 patients with CLD were prospectively enrolled. The severity of portal hypertension (PHT) was assessed by hepatic venous pressure gradient (HVPG). Hepatic dysfunction was evaluated by ALBI and Child-Pugh score (CPS). PSS were semiquantitatively classified as mild, moderate or severe on contrast-enhanced CT and MRI scans.

Results: The extent of PSS was significantly associated with HVPG (mild:12 vs. moderate:19 vs. severe:15 (median; mmHg); $p=0,0095$), portal vein thrombosis (3,9% vs. 26,3% vs. 44%; $p=0,0002$), ascites (25,5% vs. 47,4% vs. 33,3%; $p<0,0001$), hepatic encephalopathy (13,7% vs. 34,2% vs. 11,1%; $p=0,0337$), FIB-4 score (3,9 vs. 5,2 vs. 8,8; $p=0,0001$) and ALBI score (-2,41 vs. -1,96 vs. -1,9; $p=0,0021$). There was no significant difference between PIGF levels and extent of PSS. PIGF levels showed positive correlations with HVPG ($r=0,2348$, $p=0,0149$) and ALBI ($r=0,3144$, $p=0,001$) and increased in parallel to CPS (A:22,09 vs. B:25,12 vs. C:39ng/dl; $p=0,0001$). PIGF levels were higher in patients with PVT (22,38 ng/dl vs. 27,3 ng/dl; $p=0,0163$).

Conclusion: The extent of PSS is mainly determined by portal pressure, hepatic dysfunction and fibrosis/cirrhosis. PIGF-driven neoangiogenesis was not associated with PSS formation.

B-1378 15:04

A comparative study of sound touch elastography measurement on liver's right lobe and left lobe for diagnosis of chronic liver disease using liver biopsy as gold standard

I. Gatos¹, P. Drazinos², S. Yarmenitis³, I. Theotokas¹, A. Kanavaki¹, E. Manesis¹, P. Zoumpoulis²; ¹Athens/GR, ²Kifissia/GR, ³Marousi/GR (p.zoumpoulis@echomed.gr)

Purpose: Chronic Liver Disease (CLD) is currently one of the major causes of death. Sound Touch Elastography (STE) that is available in Resona 7 Ultrasound (US) device and is similar to Shear Wave Elastography (SWE), seems promising for CLD diagnosis but needs to be validated. Standard STE examination protocol involves measurements on the Right Lobe (RL) when feasible. An alternative measurement on Left Lobe (LL) can be performed but has not been yet evaluated. The aim of this study is to compare the performance of STE on liver's RL and LL in CLD diagnosis using Liver Biopsy (LB) as 'gold standard'.

Methods and Materials: 163 subjects, 56 normal (F0) and 107 with CLD (F1-F4), were included in the study. A B-Mode and Elastographic examination was performed on each patient with Resona 7 US device. STE measurements were performed on the RL and LL of each patient. STE measurements on each lobe were compared to LB results (Metavir Stage: F0-F4). Receiver Operating Characteristic analysis was then performed on each set of STE measurements (RL and LL) to obtain best cut-off stiffness values.

Results: ROC analysis for each lobe (RL/LL) showed: Accuracy_{RL} / Accuracy_{LL}=0.9476/0.9524 for F=F4, Accuracy_{RL} / Accuracy_{LL}=0.9476/0.9429 for F>F3, Accuracy_{RL} / Accuracy_{LL}=0.9619/0.9619 for F>F2, and Accuracy_{RL} / Accuracy_{LL}=0.8524/0.8190 for F>F1. Best cut-off stiffness values for each lobe (RL/LL) were: F=F4: 13.7/14.25 kPa, F>F3: 9.5/9.45 kPa, F>F2: 9.15/9.05 kPa, F>F1: 6.15/6.85 kPa respectively.

Conclusion: This study shows that STE LL measurements, when feasible, are reliable for CLD diagnosis and can be used as an RL measurement alternative.

The primary study of low-dose 640-slice volume liver perfusion CT: a whole-organ perfusion in patients with cirrhosis of the liver before and after portosystemic shunting

N. Djuraeva, A. Ikramov, N. Yakhidova, A. Amirhamzaev, K. Shamirzaev, A. Sultanov; Tashkent/UZ (sidikovan@yandex.ru)

Purpose: To study and compare the perfusion parameters of the liver in patients with cirrhosis using volumetric low-dose computed tomographic perfusion of the liver before and after portosystemic shunting.

Methods and Materials: 50 patients with cirrhosis (28M and 22F) aged 43 ± 1.5 years, weighing 65 ± 3.5 kg were included. The control group without liver pathology comprised 10 people. All patients underwent volume low-dose (16-cm detector width) liver perfusion, a contrast medium content of 40 ml, Kv 100/80, MA 200/150, effective radiation dose (E) of 17 mSv ($20 \pm 1, 2$). E was calculated using DLP (mGy*cm) multiplied by e; e is the dose coefficient for the corresponding anatomical region (0.015mSv/mGy*cm).

Results: The parameters of hepatic arterial blood flow (HABF), hepatic portal blood flow (HPBF), hepatic perfusion index (HPI) in the control group were HABF 36 ml/min/100 ml (± 5), HPBF 120 ml/min/100ml (± 15), HPI $39\% \pm 4$. Differences of HABF, HPBF, HPI before and after portosystemic shunting were statistically significant ($P \leq 0.05$). The parameters of HPI after portosystemic shunting increased from 20% (± 7.5) to 27% (± 6), HABF from 34.9 ml/min/100 ml (± 12.5) to 49.5ml/min/100ml (± 15), HPBF decreased from 144.3 ml/min/100ml (± 17.5) to 128.3 ml/min/100ml (± 15). The width of portal vein after portosystemic shunting was reduced by 16-20% (± 3 mm), splenic vein increased by 16-20% (± 3 mm).

Conclusion: Volume low-dose (17mSv) CT perfusion of the liver is a non-invasive method that allows quantitative assessment of statistically significant changes ($P \leq 0,05$) in liver perfusion after portosystemic shunting in patients with cirrhosis of the liver.

B-1380 15:20

Comparison of liver stiffness evaluated by shear wave elastography in morbidly obese patients prior to bariatric surgery with liver biopsy

F. Rajabzadeh, A. Jangjoo, T. Jamialrahmadi, L. Goshayeshi, M. Nemati, K. Ghafarzadegan; Mashhad/IR (farnood@yahoo.com)

Purpose: Non-alcoholic fatty liver disease is a prevalent condition among severely obese patients. It can gradually progress to liver fibrosis. Shear wave elastography has been validated as a noninvasive diagnostic tool for liver stiffness measurement in a wide range of liver disorders associated with fibrosis. However, technical feasibility and accuracy of this method are still under debate in severely obese patients. We aimed to assess the diagnostic accuracy of shear wave elastography (SWE) as a non-invasive tool by comparing it with that of liver biopsy as the standard test in bariatric surgery candidates.

Methods and Materials: A total of 111 severely obese candidates for bariatric surgery were recruited. Liver stiffness was measured using SWE fourteen days before liver biopsy. Liver biopsy was taken on the day of surgery. The area under the receiver operating curve (AUROC) was calculated for the staging of liver fibrosis. Liver biopsy was considered as the gold standard.

Results: As the fibrosis stage progressed, the median liver stiffness measurement (LSM) increased on 2D-SWE. Patients with a higher fibrosis stage exhibited LSMs with markedly higher median values than those of subjects with less severe fibrosis (all p values < 0.05).

Conclusion: Non-invasive LSM with SWE is a viable option in severely obese patients. Using SWE, patients with NASH could be distinguished from those with NAFLD. Finally, SWE may be considered as a diagnostic tool in clinical evaluation before bariatric surgery.

MRI diagnostic accuracy of placental adhesion disorders and diagnostic impact on foetal-maternal outcomes in interventional radiology-assisted delivery

F. Monelli, F. Flocchi, A. Pecchi, F. Casari, E. Bertucci, E. Petrella, P. Torricelli; Modena/IT (mofilippo@hotmail.it)

Purpose: Assess accuracy and reproducibility of MRI and specific findings in the diagnosis of invasive placentation (IP) in high-risk patients and to evaluate the impact of interventional radiology (IR) assistance on delivery outcomes.

Methods and Materials: 21 patients (mean age 36.05) with clinical/echographic risk factors for invasive placentation underwent 1.5T MRI examination. Images were reviewed by two readers. Gold standard was histology or obstetric evaluation at the delivery. Sensitivity and specificity of MRI findings were calculated, and reproducibility was estimated with Cohen's K-test. Impact of eventual IR assistance was evaluated regarding multiple maternal-child factors during and after delivery.

Results: Incidence of IP was 61.90% (of placenta percreta was 14.29%). MRI had sensitivity of 100% (0.7530-1.0000) and specificity of 87.5% (0.4735-0.9968). Gold standard was histology in 10 cases and obstetric evaluation in 11. MRI findings with higher sensitivity were placental heterogeneity, uterine bulging and thinning of the uterine-placental interface. Findings with higher specificity were uterine scarring, placental heterogeneity and myometrial interruption. MRI inter-rater agreement with Cohen's K was 1 (1.0000-1.0000). IR assistance was performed on 11 of the 14 patients diagnosed with IP and it had a positive impact on almost every outcome evaluated with a statistical significance ($p < 0.05$) in terms of blood loss, red cell transfusion, APGAR at 1st and 10th minute and risk of being transfused.

Conclusion: MRI is an accurate, reproducible and useful tool in prenatal diagnosis of IP in particular to plan a safe and appropriate delivery with eventual IR assistance, which positively affects delivery outcomes.

B-1382 14:08

Role of shear wave elastography of placenta in the prediction of preeclampsia in high-risk pregnancies

M. Singh¹, T. Singh², V. Singla², V. Jain²; ¹Kurukshetra/IN, ²Chandigarh/IN (mandeep.virk12@gmail.com)

Purpose: We aimed to compare placental elasticity values between normal pregnancies and preeclamptic pregnancies and evaluate the utility of shear wave elastography of placenta as a predictor for preeclampsia.

Methods and Materials: A prospective analytical study was performed with 90 singleton pregnancies. Patients having any of the 7 risk factors for developing preeclampsia [primigravida, past h/o preeclampsia, family history of preeclampsia, h/o pregestational diabetes, chronic hypertension, advanced maternal age (≥ 40) and BMI ≥ 26] were enrolled in the study. Shear wave elastography was performed in all patients at 20-24wks gestation and at 34-36wks gestation, at two sites - center and edge of placenta. The patients were divided into two groups - normal pregnancies (group A) or developed preeclampsia (group B). Women with posterior placentation, obstetric disorders other than preeclampsia or multiple gestation were excluded from the study.

Results: Shear wave elasticity values at 20-24wks gestation for group B at centre of placenta (21.73 vs 9.72kPa) as well as at edge of placenta (21.6kPa vs 10.15kPa) were significantly higher than those for group A ($P < .05$). Similar results were seen at 34-36wks gestation. The best results were obtained with edge of placenta reading at 34-36wks gestation; using cut-off of 13.1kPa, we attained sensitivity of 95.2%, specificity of 92.8% and diagnostic accuracy of 93.3% for predicting the development of preeclampsia.

Conclusion: Patients with preeclampsia have significantly higher stiffness of the placenta. Shear wave elastography is useful to evaluate placental function. Elastography can be used as a supplementary tool to existing methods for prediction of preeclampsia.

B-1383 14:16

Imaging detection of placenta adhesion disorder in patients with placenta previa: comparison between US and MR findings

A. Volpe, V. Romeo, M.I. Ginocchio, S. Maurea, P.P. Mainenti, M. Petretta, L. Sarno, P. Martinelli, A. Brunetti; Naples/IT (valeria.romeo@unina.it)

Purpose: The diagnostic performance of ultrasound (US) and magnetic resonance (MR) in the detection of placental adhesion disorders (PAD) in patients with placenta previa (PP) is not currently established; the aim of this study was to compare US and MR imaging findings to detect PAD in patients with PP.

Methods and Materials: Fifty-one patients with PP underwent US and MR examinations. The presence of US and MR imaging findings suggestive of PAD was assessed. Penalized maximum likelihood logistic regression was performed in order to identify US and/or MR imaging findings independently associated to PAD, considering histology as standard of reference. Only variables statistically significant ($p < 0.05$) at univariate analysis were considered for multivariate analysis. Receiver operating characteristic curve (ROC) analysis was performed and the area under the curve (AUC) was calculated to determine the predictive value of the significant identified variables on imaging studies.

Results: At univariate analysis, loss of retroplacental clear space, smallest myometrial thickness and placenta lacunar spaces on US as well as intraplacental dark bands, focal interruption of myometrial border and abnormal vascularity on MR were statistically significant ($p < 0.01$); of these, only intraplacental dark bands at MR ($p = 0.002$) was independently associated to PAD at multivariate analysis. ROC curve analysis showed an AUC value 0.942 for MR significantly higher as compared to that (0.798) of US ($p = 0.02$).

Conclusion: MRI demonstrated a significantly higher diagnostic accuracy to detect PAD in patients with PP as compared to US with intraplacental dark bands being the most reliable imaging finding.

B-1384 14:24

MRI criteria and sequence evaluation for the diagnosis of placental adhesive disorder among radiologists with different reporting experience

J.P. Zawaidh¹, J. Smith², A. Bruining³, P.L. Moyle², E. Sala², H.C. Addley², S. Freeman²; ¹Genoa/IT, ²Cambridge/UK, ³Amsterdam/NL (jeriesp89@gmail.com)

Purpose: To determine the most useful MR sequence to accurately diagnose placental adhesion disorders (PAD). To assess inter-reader differences in accuracy, sensitivity, and specificity for specific MRI characteristics, based on experience.

Methods and Materials: Retrospective review of placental MRI of 27 women (17 with PADs) was undertaken by 5 radiologists: 2 junior radiologists: 2- and 5-year MRI-reporting experience; 3 senior radiologists: >8-year experience (although 1 without obstetric-radiological background). All readers evaluated the presence of previously identified MRI features (dark T2W bands, placental heterogeneity, uterine bulging, abnormal vascularity, myometrial thinning, retroplacental dark zone loss, tenting of the bladder and direct invasion of adjacent pelvic structures), scored the overall degree of placental invasion (normal placenta, placenta accreta/increta or percreta) and chose the most useful/diagnostic MRI sequence. For each reader overall accuracy, sensitivity and specificity were calculated.

Results: The senior radiologists' accuracy was significantly higher than that of juniors, 83.3% and 67.9%, respectively. Presence of dark T2W bands was the most sensitive criteria for diagnosing PAD (92.9%), followed by uterine bulging (82.7%). Abnormal vascularity, myometrial thinning and loss of retroplacental dark zone manifested high sensitivity for the senior radiologists but demonstrated low sensitivity for the least experienced reader. All readers considered sagittal T2w SSFSE the most useful sequence. Steady-state sequence and DWI were of limited use in diagnosis.

Conclusion: The preferred MR sequence to assess PAD was sagittal SSFSE. Overall the most reliable imaging feature is the presence of T2W dark bands. However, the diagnostic value significantly depends upon the reader's experience.

B-1385 14:32

Comparison of diagnostic accuracy between clinical risk factors and MRI to predict placental adhesion disorders in patients with placenta previa

S. Maurea, M.I. Ginocchio, F. Verde, V. Romeo, P.P. Mainenti, M. Petretta, L. Sarno, P. Martinelli, A. Brunetti; Naples/IT (valeria.romeo@unina.it)

Purpose: In patients with placenta previa (PP) clinical risk factors have been suggested to predict the occurrence of placental adhesion disorders (PAD). The aim of this study was to assess the diagnostic accuracy of clinical risk factors and magnetic resonance imaging (MRI) to predict PAD in PP.

Methods and Materials: Seventy patients with PP who underwent MRI on the basis of ultrasound suspicion of PAD were evaluated. The presence of clinical risk factors and MRI signs suggestive of PAD was assessed. Univariate analysis was performed to identify clinical risk factors and/or MRI signs

independently associated to PAD considering histology as standard of reference. Only variables statistically significant ($p < 0.05$) were considered for multivariate analysis. Receiver operating characteristic curve (ROC) analysis was performed and the area under the curve (AUC) was then calculated.

Results: At univariate analysis, smoking, previous cesarean section (PCS), intraplacental dark bands (IDB), focal interruption of myometrial border (FIMB) and abnormal vascularity were statistically significant; of these, only IDB ($p < 0.001$) and FIMB ($p < 0.05$) were independently associated to PAD at multivariate analysis. ROC curve analysis showed an AUC value of 0.62 for smoking and PCS and of 0.90 when considering the presence of DB and FIMB at MRI ($p < 0.05$); an AUC value of 0.92 was observed when the combination of MRI signs along with smoking and PCS was considered ($p = ns$).

Conclusion: Clinical risk factors do not improve the diagnostic accuracy of MRI to predict PAD in patients with PP.

Epithelial ovarian cancer: tumour staging and detection of lymph node metastasis using ADC histogram parameters

F. Wang, J. Liu, Y. Wang, Y. Zhou, C. Liu, D. Liang, L. Xie; Beijing/CN (wfang1223@sina.com)

Purpose: The purposes of this study were to investigate the potential of ADC histogram parameters in epithelial ovarian cancer (EOC) for distinguishing different tumour stages and lymph node status, and to correlate ADC values with p53 and Ki-67 expression.

Methods and Materials: 43 patients with pathologically proven EOC underwent preoperative MRI (including DWI). Staging and lymph node status were determined postoperatively. ADC values were calculated using histogram analysis. The following histogram metrics were obtained: mean, median, 10th and 90th percentile. Ki-67 labeling index (LI) was defined as the percentage of positive cells, while p53 expression was categorised as wild-type and mutated p53. ADC parameters were compared among different tumour groups (staging and lymph node status) using one-way ANOVA test and independent sample t test. The latter was also used to compare ADCs between two p53 types, while Pearson correlation analysis was used to correlate Ki-67 LI with ADCs.

Results: ADC parameters differed significantly between stage I and II, I and III, I and IV ($P < 0.05$). ADC parameters were significantly lower in lymph node-positive than in lymph node-negative group ($P < 0.05$). There were significant negative correlations between ADC parameters and Ki-67 LI (r was -0.420 , -0.356 , -0.446 and -0.436 for mean, 10th, 90th and median, respectively, $P < 0.001$). ADCs were all significantly lower in mutated p53 than in wild-type p53 ($P < 0.001$).

Conclusion: ADC histogram analysis can help discriminate stage I EOC from advanced stage EOC and detect lymph node metastasis. ADCs were well correlated with Ki-67 LI and may be indicate p53 expression.

A mathematical-descriptor of tumour mesoscopic structure from CT images annotates prognostic and molecular phenotypes of epithelial ovarian cancer

A.G. Rockall¹, P. Lee¹, H. Lu¹, M.A. Arshad¹, G. Avesani², E. Curry¹, A. Thornton¹, F. Kanavati¹, C. Fotopoulou¹, E.O. Aboagye¹; ¹London/UK, ²Mantova/IT (philippa.lee08@gmail.com)

Purpose: CT images can be quantitatively analysed to describe intuitive features such as shape and texture. The features generated from such analyses (i.e. texture analysis or radiomic data) have been associated with prognosis and cellular pathways in many cancer types. In this study, we aimed to investigate the clinical value of radiomic data as a potential biomarker in serous ovarian cancer (OC).

Methods and Materials: Following ethical approval, we annotated 364 CT scans of women with OC including expert segmentation of disease, clinical and comprehensive molecular information (fresh frozen tissue and blood) with copy number profile, proteomic and molecular subtype of cases. Using TextLab 2.0, 657 quantitative mathematical descriptors were extracted. Using machine learning, we derived a non-invasive summary-statistic of the primary ovarian tumour based on 4 descriptors, which we name 'Radiomic Prognostic Vector' (RPV).

Results: RPV reliably identifies the 5% of patients with median overall survival less than 2 years, significantly improves established prognostic methods, and the finding was validated in two independent, multi-centre cohorts. Genetic, transcriptomic and proteomic analysis from two independent datasets elucidate that stromal phenotype and DNA damage response pathways are activated in RPV-stratified tumours, consistent with a biological correlate for RPV. RPV demonstrates a significant difference in outcome in patients undergoing complete cytoreductive surgery.

Conclusion: RPV and its associated analysis platform could be exploited to guide personalized therapy of OC and may help inform triage of patients for cytoreductive surgery and tailoring of surgical radicality. It is potentially transferable to other cancer types.

B-1388 14:56

Adnexal cystic lymphangioma in patients with massive leiomyomatous uterus: a not so uncommon finding

C. Bourgioti, K. Chatoupis, A. Antoniou, C. Tzavara, E. Panourgias, M. Vergetidou, L. Mouloupoulos; Athens/GR (kostas.chatoupis@bayer.com)

Purpose: To investigate any association between the presence of an adnexal cystic lymphangioma (ACL) and an enlarged leiomyomatous uterus.

Methods and Materials: A retrospective observational study was conducted by two expert radiologists with consensus using a 10-year MRI database (July 2008-June 2018); eighty-five patients (mean age: 45.5 years) were considered eligible due to the presence of a single ($n=31$) or multiple ($n=54$) leiomyomas causing marked uterine enlargement. The association of specific leiomyoma features (maximum diameter, location, number) or uterine volume with the presence of ACL was statistically tested. Chi-square tests and Fisher's exact tests were used for the comparisons of proportions; student's t-tests and Mann-Whitney tests were used for the comparison of continuous variables between subjects with and without ACL.

Results: ACL (unilateral=9, bilateral=8) was recorded in 17/85 (20%) of the cases; it was more frequently observed when the largest leiomyoma was located in the uterine fundus (33.3%). Patients with ACL had significantly more leiomyomas (median:6vs2, $p=0.001$), greater maximum diameter of largest leiomyoma (median:13.3vs7.2cm, $p<0.001$) and larger uterine volumes (median:676.7vs223.1cm³, $p<0.001$) compared to patients without ACL. ROC curve analysis for number of leiomyomas showed that the optimal-cut-off for the prediction of ACL was the presence of 5 leiomyomas with 53.8% sensitivity and 84% specificity [area under the curve (AUC)=0.65, 95%CI:0.51-0.83, $p=0.049$]; for the uterine volume, the optimal-cut-off was 310cm³ with 71% sensitivity and 75% specificity (AUC=0.79, 95%CI:0.66-0.92, $p<0.001$).

Conclusion: The presence of ACL is significantly associated with increased number of leiomyomas and larger uterine volume; follow-up studies are needed to investigate its clinical significance.

B-1389 15:04

MRI correlates of molecular classification of endometrial cancer: a preliminary study

M. Bonatti¹, R. Valletta², F. Lombardo², G. Avesani³, F. Erdini¹, G. Negri¹, G. Zamboni², G. Schifferle¹, G. Bonatti¹; ¹Bolzano/IT, ²Verona/IT, ³Mantova/IT (matteobonatti@hotmail.com)

Purpose: To evaluate the MRI features of the different molecular classes of endometrial carcinoma (EC).

Methods and Materials: IRB-approved retrospective study. We included 22 consecutive patients who underwent preoperative MRI and hysterectomy for EC in our institution between Jan 2017 and Sep 2018. Two readers independently evaluated 15 qualitative MRI parameters of EC including growth pattern (polypoid/infiltrative), tumour margins (sharp/irregular) and peritumoural T2-hyperintensity (yes/no); discrepancies were solved by consensus. A third reader manually segmented EC on para-axial T2-weighted images and ADC maps using commercially available software (LIFEx); neoplasm volume and radiomic features including first and second order textural parameters were calculated. MRI data were compared with the molecular subgroup (1-4) assigned by the pathologist according to p53 and POLE mutations and microsatellites instability.

Results: The pathologist classified 4 EC in group 1, 7 in group 2, 8 in group 3 and 3 in group 4. Interobserver agreement in qualitative parameters evaluation was 0.79 for peritumoural T2-hyperintensity, 0.53 for growth pattern and 0.39 for tumour margins. None of the qualitative parameters showed a statistically significant correlation with the molecular subclass of EC. Group 2 ECs were significantly larger than others (median 30.5cc vs 2.1cc). Grey-level co-occurrence matrix homogeneity and grey-level run length matrix of T2-weighted images were significantly higher in group 2 ECs than in others; none of the other first- and second-order textural parameters reached statistically significant differences.

Conclusion: MRI showed promising results in differentiating molecular subgroups of EC; larger cohort studies must be performed to reach statistical significance.

B-1390 15:12

The potential of IVIM model as a marker of normal placenta microstructural changes during pregnancy: a foetal MR study

A. Antonelli¹, L. Manganaro¹, S. Capuani¹, R. Grimm², B. Kuehn², A. de Rinaldis², C. Catalano¹; ¹Rome/IT, ²Erlangen/DE (amanda.antonelli@hotmail.it)

Purpose: To investigate the potential of intravoxel incoherent motion (IVIM) model in the quantification of placenta micro-perfusion obtaining apparent diffusion coefficient D, perfusion fraction fp and pseudo-diffusion coefficient D*.

Methods and Materials: 35 normal placental MR examination using a clinical 1.5 T scanner (Siemens Healthcare, Erlangen, Germany) were enrolled. The study protocol included a diffusion-weighted spin echo-EPI prototype sequence

using 10 different b values (0, 10, 30, 50, 75, 100, 150, 400, 700, 1000 s/mm²). 'Siemens MR Body Diffusion Toolbox' prototype software was used to obtain D, f and D* maps. For each placenta, six ROIs were manually placed on both foetal and maternal side: central ROI (C-ROI), peripheral ROI (P-ROI) and umbilical ROI (U-ROI). Pearson test with Bonferroni correction was performed to study the correlation between D, D*, f and GA, body mass index (BMI) and basal glycaemia (bG).

Results: The fraction of perfusion fp in foetal umbilical and in foetal peripheral ROIs are significantly higher (U: p <0.000049; P: p<0.048) than in maternal umbilical and maternal peripheral ROIs, reflecting that foetal placenta is richer in villi than mother's side. In the foetal side, there are statistically significant differences between umbilical and central ROIs and between umbilical and peripheral ROIs. D and D* showed significantly different values in foetal umbilical and peripheral ROIs. In the maternal side, umbilical fp is significantly higher than peripheral fp.

Conclusion: Results are in substantial agreement with physiological placenta micro-perfusion phenomena during gestation. IVIM parameters of non-pathological placenta are powerful and helpful tools able to quantify the physiological microperfusion of placental parenchyma, reflecting its physiological maturation during gestation. In clinical practice, those data will be helpful to better assess placental abnormalities.

B-1391 15:20

The role cerebroplacental ratio in prediction of foetal outcome among patients with pre-eclampsia

S.F. [Kenis](#), J.B. Igashi, D. Ibe, A. Saliu, N.B. Adams, I. Aliyu; *Zaria/NG (shedrackkenis@yahoo.com)*

Purpose: To evaluate the value of cerebroplacental ratio as predictors of foetal outcome among patients with pre-eclampsia and to determine the cut-off birth weight below which brain sparing response occurs.

Methods and Materials: Cross-sectional study involving ninety patients with pre-eclampsia. Patients underwent Doppler examination of the umbilical artery and middle cerebral artery. The foetal outcomes were also noted. The sensitivity, specificity, positive predictive value and negative value of the cerebroplacental ratio to predict adverse foetal outcome were computed. The relationship between the cerebroplacental ratio and the birth weight ratio (BWR: birth weight divide by mean birth weight for the same gestational age) was determined.

Results: The sensitivity, specificity, PPV and NPV of MCARI/UARI in predicting perinatal outcome were determined. The point of intersection of the curve of the relationship between MCARI/UARI and the BWR with the line for all normal foetuses >=30 weeks (MCARI/UARI=1.08) corresponds to BWR = 0.78. Above this cut-off, increasing the BWR does not affect the MCARI/UARI, i.e. no variation in cerebroplacental ratio. Below this cut-off, however, the lower the BWR the lower the cerebroplacental ratio (i.e the severer the brain sparing response). The mean MCARI/UARI ratio of foetuses with birth weight ratio <0.78 (0.77±0.32) is significantly lower than the mean MCARI/UARI of foetuses with birth weight ratio of >=0.78 (1.29±0.33).

Conclusion: Cerebroplacental ratio shows good test performance in the prediction of perinatal outcome. It appears that birth weight ratio of less than 0.78 is the critical weight below which brain sparing response appears.

Can artificial intelligence predict prostate cancer local stage on unenhanced MRI? A preliminary report

R. [Cuocolo](#), A. Stanzione, A. Ponsiglione, V. Romeo, S. Cocozza, A. Brunetti, M. Imbriaco; *Naples/IT (renato.cuocolo@gmail.com)*

Purpose: To identify the best treatment option for prostate cancer patients, an accurate local staging is crucial and currently MRI is the recommended imaging modality. Aim of our study was to assess the performance of different machine learning algorithms applied to texture analysis features extracted from unenhanced MRI in the prediction of prostate cancer local stage using radical prostatectomy specimens as reference standard.

Methods and Materials: In all, 39 patients were enrolled in this retrospective study. Manual segmentation of MRI index lesions was performed on both T2-weighted images and ADC maps for texture analysis data collection. Features of first, second and higher order were extracted from both the original images and after filter application (wavelet transform). Combinations of different feature selection methods and machine learning classifiers were tested, and their performance was compared to a baseline accuracy reference (zero rules algorithm).

Results: The classifier showing the best performance was the Bayesian Network, using the dataset obtained by the Subset Evaluator feature selection method. It showed a percentage of correctly classified instances of 82%, an AUC of 0.88, a true-positive rate of 0.82 and a true-negative rate of 0.80. These values were found to be significantly higher compared to the ones obtained by the baseline reference algorithm.

Conclusion: A combined machine learning and texture analysis approach appears as a feasible tool to predict histopathological local stage of prostate cancer on biparametric MR images.

B-1393 16:08

CT based machine learning radiomics for differentiating tumour grade in clear cell renal cell carcinoma

X. [Yi](#), Y. Zhang, L. Liu; *Changsha/CN (yixiaoping@csu.edu.cn)*

Purpose: To develop and validate CT-based machine learning Radiomics method for preoperative prediction of low and high WHO/ISUP grades in clear cell renal cell carcinoma (ccRCC).

Methods and Materials: A single-center retrospective review was conducted on 264 ccRCC patients [training cohort: 199; validation cohort: 65], which were sub-classified into two groups: low-grade (Grade I and II) and high-grade (Grade III and IV). Machine learning Radiomics based on the least absolute shrinkage and selection operator (LASSO) method, Random forest (RF) method, and Support vector machine (SVM) method, was used. The area under the curve (AUC) of operating characteristics (ROC) was used to evaluate their performance.

Results: Based on texture features, the SVM classifier (Score 3) yielded an AUC value of 0.8170 (95% CI: 0.7353-0.8987) in the training cohort and 0.8017 (95% CI: 0.6878-0.9157) in the validation cohort. Based on traditional radiological features, a new SVM classifier (Score 6) achieved an AUC of 0.9175 (95% CI: 0.8765-0.9585) in the training cohort and 0.8088 (95% CI: 0.7064-0.9113) in the validation cohort. The SVM 3 method (Score 7), constructed on the basis of Scores 3 and 6, provided an AUC of 0.9235 (95% CI: 0.8646-0.9824) in the training cohort and a AUC of 0.9099 (95% CI: 0.8324-0.9873) in the validation cohort.

Conclusion: A machine learning Radiomics method of CT demonstrated improved performance in predicting low or high WHO/ISUP grade for ccRCC preoperatively, which may potentially affect treatment strategies.

B-1394 16:16

Differentiation of clear cell and non-clear cell renal cell carcinomas by all-relevant radiomics features from multiphase CT

G. [Liu](#), G. Wu; *Shanghai/CN (sdzclgq@126.com)*

Purpose: To develop a radiomics model with all-relevant imaging features from multiphase computed tomography (CT) for differentiating clear cell renal cell carcinoma (ccRCC) from non-ccRCC, and to investigate the underlying molecular basis of the all-relevant imaging features by assessing their possible radiogenomics link with a key ccRCC driver gene, the VHL gene mutation.

Methods and Materials: In this retrospective two-center study, 255 patients (188 ccRCC and 67 non-ccRCC) were included. 156 radiomics features were extracted from standardized triphasic CT. Two radiomics models were built using random forest from a training cohort (170 patients), where one model was built with all-relevant features selected by Boruta algorithm and the other with features selected by minimum-redundancy maximum-relevance ensemble (mRMRe) algorithm. The potential radiogenomics association that linked the selected imaging features with the VHL mutation were investigated. All models were tested on an independent validation cohort (85 patients).

Results: Correlation with gold standard volume measure was greatest for the automated algorithm (95 % confidence interval for R2 is 0.962 to 0.988), followed by measures of seeding (0.773 to 0.923), ellipse (0.755 to 0.916), area (0.645 to 0.872), diameter (0.491 to 0.803), and perimeter (0.491 to 0.803). Phantom studies on partial volume regions showed the accuracy of the partial volume measurement was 5% (c.f. 13% for repeated area measurements).

Conclusion: All-relevant radiomics features in corticomedullary phase CT can be used to differentiate ccRCC from non-ccRCC with high accuracy. These subtype-discriminative imaging features were found to be significantly associated with the VHL gene mutation.

B-1395 16:24

Influence of segmentation margin on machine learning-based high-dimensional quantitative CT texture analysis: an experimental radiomics study on renal clear cell carcinomas

B. Kocak, E.S. Memis Durmaz, E. Ates, M. Baykara Uluhan, O. Kilickesmez; Istanbul/TR (drburakkocak@gmail.com)

Purpose: To determine the influence of slight differences in segmentation margin on reproducibility of each step of the machine learning (ML)-based high-dimensional quantitative computed tomography (CT) texture analysis (qCT-TA).

Methods and Materials: For this retrospective study, 47 patients with renal clear cell carcinomas (RcCCs) were included from a public database. Two segmentations were obtained by two radiologists for each tumour: (i) contour focused and (ii) margin shrinkage of 2mm. Using PyRadiomics, 828 texture features were extracted from filtered and non-filtered CT images. Interobserver reproducibility was assessed by intraclass correlation coefficient (ICC). Attribute selection was done using correlation-based feature selection. ML classifier was *k*-nearest neighbors. Classifications were performed with and without using synthetic minority oversampling technique (SMOTE). Main performance metric was the area under the curve. Reference standard was nuclear grade.

Results: The segmentation with margin shrinkage of 2mm (772 of 828) yielded more texture features with excellent reproducibility (ICC≥0.9) than contour-focused segmentation (714 of 828). The attribute selection algorithms resulted in different subset of texture features for two segmentation data with only one common feature. Either with or without SMOTE, all ML-based models based on contour-focused segmentation (AUC range 0.865-0.984) performed better than those with shrinkage of 2mm (AUC range 0.745-0.887), *p*<0.05.

Conclusion: Each step of a ML-based high-dimensional qCT-TA was susceptible to the slight change of 2mm in segmentation margin. Despite yielding less features with excellent reproducibility, use of the contour-focused segmentation provides better classification performance in qCT-TA of RcCCs for distinguishing nuclear grade.

B-1396 16:32

To categorise ovarian epithelial cancers and predict clinical outcome using multiparametric radiomics

H. Zhang, X. Liu, P. Zhang, G. Zhang; Shanghai/CN (dr.zhanghe@yahoo.com)

Purpose: To evaluate the ability of multiparametric MRI radiomics in categorising ovarian epithelial cancer and determine whether MRI radiomics are associated with survival in ovarian cancer patients.

Methods and Materials: The total 280 patients with pathologically proven OEC were retrospectively included in this study. Axial T1WI, sagittal fat-suppressed T2WI, coronal T2 WI and apparent diffusion coefficient map were chosen as the premium picture for the lesion segmentation. We calculate the diagnostic performance of the signatures derived from MRI radiomics in differentiating both between ovarian benign and malignancies and Type 1 and Type II ovarian epithelial cancers. Least absolute shrinkage and selection operator (Lasso) method is used for feature selection for determining the associations between MRI radiomics and survival data.

Results: For the classification between benign and malignancy, MRI radiomics model achieves an area under the receiver operating characteristic curve of 0.97 and accuracy of 0.90 in leave-one-out cross-validation. The result of independent validation cohort is 0.95 of AUC and 0.87 of accuracy. For the classification between Type 1 and Type II subtypes, our method achieves an AUC of 0.86, an accuracy of 0.93 in leave-one-out (LOO) cross-validation and an AUC of 0.85 and an accuracy of 0.84 in independent validation cohort. Patients with higher risk scores are more likely to have poor prognosis (HR = 3.891, *p* < 0.000).

Conclusion: Radiomic features extracted from MRI are highly correlated with ovarian cancer classification and prognosis of patients. Multiparametric MRI radiomics can provide ovarian cancer diagnosis and prognosis estimation with high accuracy.

B-1397 16:40

Automated multiregional prostate segmentation in magnetic resonance using deeply supervised convolutional neural networks

R.L. González¹, V. Venugopal², A. Jimenez-Pastor¹, L. Marti-Bonmati¹, A. Alberich-Bayarrí¹, M. Barnwal², V. Mahajan²; ¹Valencia/ES, ²New Delhi/IN (rafaellopez@quibim.com)

Purpose: A CNN-based automatic prostate segmentation method is proposed, aiming to identify and differentiate central-transitional and peripheral prostate glands as well as seminal vesicles.

Methods and Materials: A total of 131 axial T2-weighted MR prostate examinations were acquired in different 3T machines and with different acquisition protocols. The central and peripheral glands and the seminal vesicles were manually labelled in all the acquired T2-weighted series by an expert to train the models. A deeply supervised U-Net-based architecture was

used to train this network with the Dice score coefficient as cost function and Adam as optimization algorithm. To maximize the performance of the CNN, a cyclic learning rate was used during the training stage. Also, image processing algorithms were used to further refine the predicted segmentation masks during inference.

Results: The clinical validation was performed on a different set of 25 T2-weighted cases from an external centre which was not part of the training set. The segmentation results from the network were compared and corrected by an expert radiologist to match best truth. Finally, the Dice score coefficient between the model's predictions and the expert corrected masks was calculated. The scores for the central-transitional gland, peripheral gland, seminal vesicles and background were 0.92±0.03, 0.90±0.05, 0.91±0.05, and 0.99±0.00, respectively.

Conclusion: Fully automated multiregional segmentation of the prostate gland and seminal vesicles can be addressed by deeply supervised CNN. This step will help localizing prostatic lesions and characterizing the pattern of prostatic enlargement.

Deep learning with a convolutional neural network for predicting Fuhrman grade of clear cell renal cell carcinoma at MSCT

X. Li¹, W. Li²; ¹Nanjing/CN, ²Shanghai/CN (lixiao19901020@yeah.net)

Purpose: To investigate diagnostic performance by using a deep learning method with a convolutional neural network for the prediction of histologic grade in clear cell RCC at dynamic contrast agent-enhanced computed tomography.

Methods and Materials: Approved clinical retrospective study from January 2013 to July 2017, patients with clear cell RCC were identified from the pathology database. 69 low grade ccRCC patients and 28 high grade ccRCC patients. All patients were examined with a 320-slice dynamic volume CT by using same four phase renal protocol (unenhanced phase, corticomedullary phase, nephrographic phase and excretory phase). The CNN was composed of four convolutional layers, four maximum pooling layers, a flatten layer and three fully connected layers. The process used in building models was consistent with section one. The diagnostic performance of CNN models in differentiating grade of ccRCC were evaluate.

Results: The mean AUC for distinguishing low-grade ccRCC and high-grade ccRCC in model unenhanced, model corticomedullary, model nephrographic, model excretory, model enhanced and model quadruple with the test data cohorts was 0.55 (95% CI: 0.49,0.61), 0.77 (95% CI: 0.74,0.79), 0.76 (95% CI: 0.74,0.79), 0.69 (95% CI: 0.66,0.72), 0.78 (95% CI: 0.76, 0.79), 0.75 (95% CI: 0.74, 0.77).

Conclusion: Our results show that maybe the CNN models except model unenhanced could be used to differentiate the Fuhrman grade of ccRCC at dynamic CT. This technique requires further validation on a larger scale prior to implementation into clinical practice.

Feature rejection for radiomic analyses based on variations of tumour segmentation masks

B. Schachtner, M. Ingris, E. Gresser, M.J. Schneider, A. Schreier, O. Solyanik, G. Magistro, D. Nönerberg; Munich/DE (Balthasar.Schachtner@med.lmu.de)

Purpose: Radiomics tools as e.g. pyradiomics can easily produce more than 1000 features, some of which depend strongly on small variations to the boundary line of the segmentation of the region of interest. The approach presented rejects those without the need to specify the target class of the classification problem or using a test-re-test procedure.

Methods and Materials: A dataset of 86 patients with prostate carcinoma was used in a radiomic analysis. Segmentations of tumours were performed by expert radiologists and 1482 features were extracted with the pyradiomics package. Variations of these features were calculated using masks dilated and eroded by one pixel in the plane of high resolution. The impact of these variations on the features with respect to the distribution of the features was evaluated using the intraclass correlation coefficient (ICC). The impact on classification performance was tested using a simple machine learning setup with minimum-redundancy maximum-relevancy (mRMR) feature selection and a random forest in cross-validation.

Results: In a simple machine learning setup the auROC could be raised by 10 percentage points from not using the feature rejection to using a cut on ICC of 0.83.

Conclusion: Feature rejection based on variations of the segmented masks provides a target-class agnostic way to reject unstable features and may help to improve the performance of classification algorithms.

CT quantification of spatial heterogeneity of boundary between fibrotic and non-fibrotic areas in idiopathic pulmonary fibrosis

J. Park, J. Jung, S.H. Yoon, H. Hong, J.-H. Yoon, H. Kim, J.M. Goo; *Seoul/KR (et_2004@naver.com)*

Purpose: This study aimed to quantify the spatial heterogeneity of boundary between fibrotic and non-fibrotic areas on chest CT in patients with idiopathic pulmonary fibrosis (IPF) for evaluating IPF severity and survival prediction.

Methods and Materials: We retrospectively included 93 consecutive IPF patients who underwent baseline thin-section standard-dose chest CT from 2006 through 2016. The non-fibrotic areas were segmented below a threshold value of -500 HU, followed by the extraction of boundary between fibrotic and non-fibrotic areas using an in-house software. Gaussian curvature analysis was performed for calculating histogram features including entropy and uniformity. We analysed the correlation between those CT features and gender, age, and physiology (GAP) score, or CT fibrosis score and evaluated the prognostic value of the features in patients' survival.

Results: The boundary curvature between fibrotic and non-fibrotic areas was more heterogeneous in patients with higher GAP score (Spearman ρ for entropy=.320, $p=.002$; ρ for uniformity=-.337, $p=.001$). The heterogeneity of boundary curvature was also positively correlated with CT fibrosis score (entropy, $\rho=.250$, $p=.016$; uniformity, $\rho=-.269$, $p=.009$). In the univariate Cox-regression analysis, the higher entropy ($p=.017$), the lower uniformity ($p=.009$), right-sided skewness ($p=.038$), and kurtosis ($p=.047$) were significantly associated with worse survival.

Conclusion: The spatial heterogeneity of boundary curvature between fibrotic and non-fibrotic areas was correlated with the GAP score as well as the degree of CT fibrosis, along with predicting survival in patients with IPF.

B-1404 16:08

Fibrotic lung disease in MPO-ANCA positive patients

B. Del Rio Carrero, P. Luburich Hernaiz, S. Bolivar Cuevas, E. Carreño García, V. Vicens Zygmunt, M. Molina Molina; *Barcelona/ES (belendrio@gmail.com)*

Purpose: Association between fibrotic interstitial lung disease (ILD) and anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides has been well established. However, while findings shown in eosinophilic granulomatosis with polyangiitis (EGPA) and granulomatosis with polyangiitis (GPA) have been extensively described, those presenting in patients with microscopic polyangiitis (MPA) and in MPO-ANCA positive patients without vasculitis diagnosis are still poorly understood. Our purpose is to describe lung CT findings in patients with MPA and in those with MPO-ANCA positive titres not fulfilling criteria for vasculitis.

Methods and Materials: In this retrospective descriptive study we reviewed every patient with a positive MPO-ANCA quantification in our hospital in the last 3 years and selected those with at least one chest CT with acceptable technical quality. From this 69 patients, we excluded 11 diagnosed with GPA and EGPA. Chest CTs of the remaining 58 patients were reviewed by 2 radiologists establishing findings by consensus. Patients with fibrotic ILD were subdivided according to radiologic patterns of UIP, possible UIP, NSIP and cystic disease not fulfilling all the criteria for UIP.

Results: Fibrotic ILD was found in 22 (37.9%) out of 58 patients; 8 (13.8%) presented UIP pattern, 1 (1.7%) presented possible UIP pattern, 3 (5.2%) presented NSIP pattern and 10 (17.2%) presented cystic disease not fulfilling criteria for UIP pattern.

Conclusion: Patients with MPO-ANCA positive titres with or without MPA diagnosis frequently present with fibrotic ILD. The most frequent pattern presented was the cystic disease not fulfilling all the criteria for UIP, followed by UIP and NSIP.

B-1401 17:12

Deep convolutional neural network for histopathological classification of pancreatic neuroendocrine neoplasms

Y. Luo; *Guangzhou/CN (luoyanji163@163.com)*

Purpose: To evaluate the efficacy of deep convolutional neural network (DCNN) for the pathological classification of pancreatic neuroendocrine neoplasms (P-NENs) on contrast agent-enhanced computed tomography.

Methods and Materials: 103 patients (poor differentiated [G3], $n=19$; well differentiated [G1+G2], $n=84$) preoperatively investigated with multispiral computed tomography (MSCT) and subsequently with histopathologically proven P-NENs were enrolled. The 103 datasets were normalised and augmented by multiple preprocessing techniques (rotated, contrast-enhanced and noise-added images), and were split into training (81.6%), validation (5.8%), and test set (12.6%) with 8-fold cross validation. The DCNN with the residual learning framework (ResNet) was used to classify the images as having manifestations of poor- or well-differentiated P-NENs. The DCNN was composed of 50 convolutional, one maxpooling, one global average pooling and two fully connected layers. Training and testing were performed eight times. Accuracy, sensitivity, and specificity for categorising poor- and well-differentiated P-NENs with DCNN model and the area under the receiver operating characteristic curve for poor- versus well-differentiated P-NENs were calculated.

Results: The accuracy, sensitivity, and specificity of classifying poor- and well-differentiated P-NENs were 80.6%, 79%, and 81%, respectively. The area under the receiver operating characteristic curve for differentiating histopathological grading of P-NENs was 0.79.

Conclusion: Deep learning with DCNN showed high diagnostic performance in differentiating histopathological classification of P-NENs at dynamic CT images.

B-1402 17:20

Comparison of automated quantitative ultrasound image analysis vs expert scoring systems for prediction of malignancy in thyroid nodules

A. Galimzianova, T.S. Desser, S. Siebert, S. Syed, A. Kamaya, D. Rubin; *Stanford, CA/US (tsdesser@stanford.edu)*

Purpose: To develop a computational framework to predict malignancy in thyroid nodules seen on ultrasound (US) images, and compare it to existing expert scoring systems.

Methods and Materials: We collected retrospectively a dataset of US images of 92 biopsy-confirmed nodules. The nodules were manually delineated and two expert radiologists annotated them using the standardized TIRADS lexicon of American College of Radiology. As reference estimators, we implemented five expert scoring systems: ATA, ACR TIRADS, BTA, K-TIRADS and EU-TIRADS. Our automated quantitative method combined computer-extracted features for echogenicity, texture, edge sharpness and margin curvature of thyroid nodules in a regularized logistic regression model. A leave-one-out cross-validation was performed using area under the receiver operating characteristic curve (AUC), sensitivity and specificity metrics.

Results: The AUC of our automated method was 0.83 (0.70, 0.95), a performance result similar to the expert scoring systems, with AUC values from 0.68 to 0.83 ($p=0.99$, DeLong's test). However, our method was superior in that it could spare the need for biopsy in 20 out of 46 benign nodules when following a curative strategy to triage (at sensitivity of 1.00, statistically significantly higher than three other expert systems), or identified 10 out of 46 malignancies when following a conservative strategy (at specificity of 1.00, statistically significantly higher than five other systems).

Conclusion: Our automated method predicted thyroid nodule malignancy at the level of five expert systems. It could thus be an objective tool for thyroid nodule triage and may reduce unnecessary thyroid nodule biopsies.

To assess clinical and radiological disease severity in a population of IPF patients which differ for the presence of diffuse pulmonary ossification (DPO) on HRCT

M. Palermo, G. Sambataro, F. Tiralongo, C. Desiderio, D. Falsaperla, S. Torrisi, A. Basile, C. Vancheri, S. Palmucci; Catania/IT (monica.palermo91@gmail.com)

Purpose: To assess clinical and radiological disease severity in a population of IPF patients which differ for the presence of Diffuse Pulmonary Ossification (DPO) on HRCT.

Methods and Materials: This retrospective study was carried out on a 47 IPF patients - 25 with DPO on baseline HRCT (group A, average age 68.5) and 22 (group B, average age 66.3) with no calcifications detected on baseline HRCT. The quantification of lung fibrosis was obtained using a semiquantitative method, based on HRCT fibrosis score. Therefore, the overall extent (percentages) of normal attenuation, reticulations, honeycombing and traction bronchiectasis was quantified on three HRCT slices - selected at different levels (apex, mid-lung and base). Pulmonary Function Tests (PFTs) - acquired nearest to the baseline HRCT - were compared between the two groups, using a t-test; HRCT fibrosis scores were compared using a U-test of Mann-Whitney.

Results: PFTs values were not different among the two groups $p = 0.22$ for FVC and 0.59 for DLCO. Considering HRCT fibrosis scores, the Mann-Whitney U-test revealed no statistical difference (p value of 0.48) between group A and B with a median value of 216.5 for DPO patients and a median value of 241.5 for non-DPO patients.

Conclusion: Although literature shows that DPO is an important marker of fibrosis, in our preliminary study disease severity seems to be similar in IPF patients with and without DPO. A longitudinal analyse should be invoked to better investigate prognostic value of DPO.

B-1406 16:24

Combined pulmonary fibrosis and emphysema (CPFE): epidemiological and clinical features, visual scoring and quantitative CT assessment in 72 patients

A. Carnevale, A. Cossu, E. Cotti, M. Graziano, S. Chiarello, M. Giganti; Ferrara/IT (moni.graziano@gmail.com)

Purpose: To retrospectively evaluate epidemiological, clinical and radiological data of 72 patients exhibiting chest CT features consistent with combined pulmonary fibrosis and emphysema (CPFE); to compare two different quantification methods of lung fibrosis (LF) in these patients: a reader-based visual scoring system and a computer-aided one.

Methods and Materials: We retrospectively identified 72 consecutive adult patients (64m/8f) who exhibited CPFE features at chest CT. All patients' data, including smoking habits, professional exposure, autoimmune conditions, were collected. For each study, LF percentage extent was determined, using Horos open-source DICOM viewer, by comparing quantitative assessment (QCT) of LF volume and total lung volume. An experienced chest radiologist, blinded to QCT results, evaluated CT images for the extent of fibrosis, and emphysema separately, by visually estimating the percentage of parenchymal involvement as the mean of five anatomical sections' results. LF and emphysema patterns were also assessed. Statistical analysis was performed through dedicated software (MedCalc).

Results: CPFE patients were more frequently males, smokers or former smokers ($n=64/66$). Female patients were more frequently affected by a rheumatologic condition ($p < 0.0001$). A strong correlation between QCT-based and reader-based assessment of LF extent was found ($r=0.80$; $p < 0.0001$).

Conclusion: This work confirmed the relevant role of cigarette smoking in the pathophysiology of CPFE, and highlighted the importance of autoimmunity in female subjects. We demonstrated a strong correlation between a LF reader-based scoring system and a computer-based analysis, thus providing the hypothesis that the latter method may be a feasible tool for LF quantification even in CPFE patients.

B-1407 16:32

Can we reduce the radiation dose with wide-volume scan mode in a 320 detector-rows CT for interstitial lung disease?

A. Abdo, E. Karam, S. Leygnac, T. Henry, K. Haioun, A. Khalil, M.-P. Debray; Paris/FR (alainabdo7@gmail.com)

Purpose: Wide-Volume (W-V) mode is an alternative to helical mode to explore large anatomic zones with wide-area detector rows CT. Despite its ability to reduce the radiation dose, it is infrequently used for lung diseases. The purpose of this study is to compare image quality and radiation dose of W-V chest CT to those of standard helical CT in the setting of interstitial lung diseases (ILD).

Methods and Materials: We evaluated 53 patients referred for follow-up or screening of ILD, requiring prone scan in addition to the routine unenhanced supine scan. Each examination included both helical and W-V mode acquisitions (320x0.5mm or 240x0.5mm collimation, according to the height of the thorax). Comparative analysis was performed by two radiologists blindly to the acquisition mode, including analysis of normal anatomical structures and elementary signs, overall image quality and artifacts.

Results: Median CTDI and DLP with W-V (3.1 mGy and 93.2 mGy.cm) were significantly reduced ($p < 0.0001$, Wilcoxon rank test) as compared to helical mode (3.7 mGy and 124.4 mGy.cm), leading to a mean 16% [95% CI 11-20%] and 27% [95% CI 22-30%] reduction of CTDI and DLP, respectively. Image noise and quality were not significantly different between the two modes. Shifting artifact at the junction of two volumes was inconstantly seen in the W-V scans and, when present, did not impair diagnostic quality in 87% of cases.

Conclusion: W-V mode allows significant radiation dose reduction as compared to the standard helical mode and could be routinely used for diagnosis and follow-up of ILD.

Applying the low-dose protocol in high resolution computed tomography examination in patients with rheumatoid arthritis

B. Zwierko, M. Dura, P. Zuchowski, S. Jeka; Bydgoszcz/PL (p.zuchowski81@gmail.com)

Purpose: In the course of rheumatoid arthritis (RA), some of the most common complications are lung diseases. Presently, the gold standard in lung diagnostics is the high resolution computed tomography (HRCT). The aim of this study is to evaluate the utility of the low dose protocol in HRCT examination of the lungs in patients with RA.

Methods and Materials: 35 (28F/7M) patients with RA were enrolled. Average disease duration was 8,8 years. The study lasted 12 months. Only patients with previously diagnosed lung changes via HRCT were enlisted. All patients had already undergone standard HRCT lung examination at baseline and "low dose" protocol examination at 12 months. All exams were evaluated by two radiologists. A single tomograph was used in the study - GE Lightspeed Pro 32.

Results: Both radiologists noted a loss in image quality in every exam using the "low dose" protocol. It is the radiologists' opinion that it had no negative impact on the diagnostic quality of the examination. The average value of the Dose-Length Product (DLP) index with the standard HRCT examination was 146 mGy*cm, while with the "low dose" protocol - 53 mGy*cm (significant difference, $p < 0,05$).

Conclusion: The use of the "low dose" protocol in HRCT examination allowed for a moderate reduction of DLP by 64% in comparison with the standard examination protocol. The "low dose" protocol adheres perfectly with the basic principle of patient radiation protection - ALARA.

B-1409 16:48

Feasibility of low-dose CT with spectral shaping and third-generation iterative reconstruction in evaluating interstitial lung diseases associated with connective tissue disease

X. Xu, X. Sui, L. Song, Y. Huang, Z. Jin, W. Song; Beijing/CN (xxlpositive@163.com)

Purpose: To investigate the feasibility of low-dose CT (LDCT) with tin-filtration and third-generation iterative reconstruction (IR) in evaluating interstitial lung diseases associated with connective tissue disease (CTD-ILD).

Methods and Materials: 53 consecutive adult patients with CTD-ILD underwent regular-dose chest CT (RDCT) at 110 kVp followed by LDCT with tin-filtered 100 kVp. RDCT was reconstructed with filtered back projection (FBP) and advanced modelled iterative reconstruction (ADMIRE), and LDCT with ADMIRE. Image noise, streak artefact, image quality and visualisation of normal and abnormal CT features were evaluated and compared among RDCT ADMIRE, RDCT FBP and LDCT ADMIRE groups.

Results: The mean radiation dose of LDCT was reduced to 20% of RDCT. Objective image noise of RDCT ADMIRE (38.08 ± 6.37 HU), LDCT ADMIRE (51.68 ± 9.06 HU) and RDCT FBP (62.09 ± 10.95 HU) increased progressively ($p < 0.001$ in any two pairs). RDCT ADMIRE significantly improved subjective image noise, streak artefact and overall image quality compared with RDCT FBP and LDCT ADMIRE ($ps < 0.001$), while no significant difference was noted between the latter two groups. All abnormal lung structures were better scored in RDCT ADMIRE compared with RDCT FBP ($ps < 0.001$). LDCT ADMIRE was inferior to RDCT FBP in visualising peripheral bronchi and vessels as well as reticulation ($ps < 0.001$); other normal and abnormal structures were similar between the two groups.

Conclusion: LDCT with tin-filtration and third-generation IR was applicable in evaluating CTD-ILD. Image quality was significantly improved after applying ADMIRE algorithm to CT protocols.

HRCT does not offer added discriminatory value for eosinophilic lung diseases in patients presenting to a severe asthma clinic
E. Robinson, M. Mak, D. Jackson, B. Kent, G. Santis, A. Nair; *London/UK* (szemun.mak@gstt.nhs.uk)

Purpose: To assess the frequency and discriminatory ability of HRCT features and diagnostic sensitivity of radiologists for distinguishing allergic bronchopulmonary aspergillosis (ABPA), eosinophilic granulomatosis with polyangiitis (EGPA) and severe asthma only (SevA).

Methods and Materials: 64 patients' (21 ABPA, 21 EGPA, and 22 SevA) HRCTs were analysed. Two blinded radiologists scored 30 features per lobe and specified a diagnosis (ABPA/EGPA/SevA). The frequency of variables was calculated. One-way analysis of variance and Chi-squared test were used to assess continuous and categorical variables, respectively. Logistic regression models for diagnosing ABPA and EGPA using potentially statistically significant HRCT variables (LR-CT), including clinically useful variables (LR-All), were assessed with area under the curve (AUC) analysis. Sensitivity and inter-observer agreement for diagnosis were calculated.

Results: Bronchial wall thickening was the most frequent finding. Bronchiectasis (Bxt) (upper or proximal) and consolidation distribution did not discriminate between the diagnoses. Serum IgE, Bxt extent and severity, HDP, volume loss, centrilobular nodules, distal mucus plugging, and FEV1/FVC were greater ($p < 0.05$) in ABPA compared to EGPA and SevA. With LR-CT, only greater Bxt severity and HDP predicted ABPA ($p < 0.001$, AUC=0.89, CI 0.78-0.96), only a lower Bxt extent ($p = 0.03$, AUC=0.67, CI 0.53-0.78) predicted EGPA. With LR-All, no variable predicted ABPA, and only a lower serum IgE ($p = 0.005$, AUC=0.76, CI 0.62-0.86) predicted EGPA. Overall diagnostic sensitivity was low (53.1%) with only fair inter-observer agreement ($k = 0.29$).

Conclusion: Traditional HRCT distributions of abnormality are not helpful in predicting ABPA or EGPA. No single HRCT variable is discriminatory when clinical variables are accounted for.

B-1411 17:04

Relevance of high-resolution computed tomography in diagnosis of infectious disease versus rejection reaction in patients after lung transplantation with acute respiratory symptoms

S. Maier¹, A. Ernst², U. Sommerwerck³, G. Weinreich¹, F. Nensa¹, L. Umutlu¹, H. Kuehl⁴; ¹Essen/DE, ²Neustadt Holstein/DE, ³Wuppertal/DE, ⁴Kamp-Lintfort/DE

Purpose: Complications after lung transplantation (LTX) are still common. The diagnostic value of chest CT in LTX patients with respiratory symptoms and the possible differentiation between rejection reaction and infection were examined.

Methods and Materials: The included patients showed dyspnea, signs of bronchopulmonary infection, worsening of the general condition or decrease of the forced expiratory pressure in 1 second (FEV1). Selected clinical parameters were compared with morphological changes in the HRCT.

Results: 60% (198) of patients showed a decrease of FEV1, 30% (94) showed no losses in FEV1. In 10% of patients no spirometry data were available. Comparing the FEV1 with pathologic changes in lung morphology the HRCT showed a sensitivity of 80% at a specificity of 95%, a LR+ of 14.96 and a LR- of 0.22 which indicates a high diagnostic evidence. In 50% (158) of patients a histological examination was performed. In 20% (63) pathological changes were found. In comparison to the histological results the morphologic changes in the HRCT showed a sensitivity of 86% at a specificity of 83%, a LR+ of 5.09 and a LR- von 0.17.

Conclusion: Morphologic changes in CT-scans showed in 16 of 20 examined clinical features at least high diagnostic evidence (LR+ 2-5, LR- 0.2-0.5), giving HRCT-exams a high diagnostic value in diagnosis of acute dyspnea in patients after lung transplantation. A specific differentiation between an infectious cause and an immune reaction against the graft associated with acute dyspnea based only on the HRCT findings is not possible.

B-1412 17:12

Clusters of micronodules in active pulmonary tuberculosis: prevalence, patient characteristics, and natural history
J. Hong, S. Yoon, J. Goo, J.-J. Yim, J.-G. Im; *Seoul/KR* (keke4@naver.com)

Purpose: To evaluate the prevalence, patient characteristics, and natural history of clusters of micronodules (CM) in active pulmonary tuberculosis (TB).

Methods and Materials: From January 2013 through July 2018, we enrolled a total of 881 consecutive patients with bacteriologically or PCR-proven active pulmonary TB who had a diagnostic chest CT. Patients were categorized into three groups based on whether they have a typical radiologic bronchogenic spread of TB, CM, or both. Among the patients solely having CM, we analysed radiologic findings of incidental pre-diagnostic CT if available, along with those of diagnostic CT.

Results: CM was the sole radiologic finding in 23 patients (2.6%) and was in accompany with radiologic bronchogenic spread in 48 patients (5.4%). Compared with patients without CM (830 patients, 91.9%), patients with CM only were less smear or PCR-positive (29.9% vs 5.0%, $p < 0.01$) and higher proportion of male (60.1% vs 82.6%, $p < 0.01$). Mean diameter of CM at pre-diagnostic CT was 4.8 ± 2.7 cm. CM only had paucity-segmental (median 2.0, IQR 1.0-3.0) involvement at diagnostic CT. During the progression, median time to change was 17.0 months (IQR, 8.1-39.4) and bronchial wall thickening (58.7 vs 83.3%), bronchiectasis (58.3% vs 100%), and lobular consolidation (33% vs 83.3%) were additionally found along with the increased extent of CM (median involved segment, 1.0 vs 2.0).

Conclusion: TB solely manifesting as CM was found in 2.6% of patients with active pulmonary TB and prevalent in male with less smear or PCR-positivity. During the progression, CM had a unique indolent nature and accompanied by bronchocentric changes.

B-1413 17:20

Correlation of USG diaphragm thickness measurements with pulmonary function and inspiratory strength tests in myotonic dystrophy type 1
S. Kose, F. Koç, I. Hanta; *Adana/TR* (sevgulkarakose@gmail.com)

Purpose: Myotonic dystrophy type 1 (DM-1) is the most common neuromuscular disease in adults and its prevalence is 1/8000. The aim of this study is to evaluate the correlation between diaphragm thickness measured by B mode ultrasound with pulmonary functions tests in DM-1 patients.

Methods and Materials: Total number of 31 patients diagnosed with DM-1 followed by the Çukurova University Hospital, Department of the Neurology were included in this study. All patients had full laboratory and genetically confirmed diagnosis. The study designed as a prospective matched case control study. There were 18 healthy patients in control group. Diaphragm thickness was measured in B mode ultrasound with a high frequency linear transducer. Pulmonary function tests and inspiratory strength tests were measured supine and sitting position.

Results: Mean diaphragm thickness in millimeters at end of the inspiration and expiration for DM-1 disease and control group were 2.16, 1.85, 3.47, and 2.72 consecutively. Diaphragm thickness at end of inspiration and expiration of DM-1 patient group was significantly thinner than control group with p values of < 0.01 and < 0.01 , respectively. There was a positive correlation between diaphragm thickness and pulmonary function tests. Statistical analysis showed also a positive correlation between diaphragm thickness and inspiratory strength tests.

Conclusion: Diaphragm ultrasound is an easy, cheap method which strongly and significantly correlates with pulmonary function and inspiratory strength tests in DM-1 patients. Therefore, diaphragm ultrasound may be effectively used in the surveillance of respiratory function.

Correlation of cerebrovascular reserve assessed by acetazolamide-stress SPECT with collaterals on arterial spin-labeling MRI in patients with carotid occlusive disease

H. Kang, Y. Kim; *Seoul/KR* (gknroo@gmail.com)

Purpose: We evaluated the correlation between cerebrovascular reserve (CVR) on acetazolamide-stress single photon emission computed tomography (SPECT) brain scans and intracranial collaterals on arterial spin-labeling (ASL) magnetic resonance imaging (MRI) in internal carotid artery (ICA) stenosis.

Methods and Materials: 86 patients with ICA stenosis ($> 70\%$) underwent cerebral blood flow (CBF) examinations by pulsed ASL brain MRI and SPECT imagings with Tc-99m HMPAO in the resting and after acetazolamide challenge. We observed the presence of intracranial collaterals, which are manifested by arterial transit artefact, on ASL brain perfusion scan. CVR based on rest-SPECT and acetazolamide-stress SPECT was calculated. With acetazolamide stress SPECT, the 82 patients were grouped as either showing or not showing evidence of decreased CVR. We assessed the relationship between reduced CVR and intracranial collaterals shown as ATA on ASL brain perfusion.

Results: In 61/86 (70%) of the ICA stenosis patients, ASL showed ATA in ipsilateral to the stenosis. With acetazolamide stress SPECT, the 27/82 (32%) patients showed evidence of decreased CVR. In 45/55 (81%) of the normal

CVR group and 16/27 (59%) of the reduced CVR from the SPECT results, pulsed ASL showed ATA in ipsilateral to the stenosis. Significant relationship was observed between normal CVR group and ATA showing group in ICA stenosis patients on ASL brain perfusion ($p=0.035$, chi-square test).

Conclusion: Our results suggest that ATA with pulsed ASL imaging represents intracranial collaterals and good CVR in the setting of chronic stenosis or occlusion of the ICA.

B-1415 16:04

Long-term neurodegeneration of substantia nigra secondary to ipsilateral infarct is quantified with iron-sensitive imaging and impacts motor outcome

P.-A. Linck¹, G. Kuchcinski², F. Munsch³, R. Griffier¹, G. Okubo⁴, P. Renou¹, V. Dousset¹, I. Sibon¹, T. Tourdias¹; ¹Bordeaux/FR, ²Lille/FR, ³Boston, MA/US, ⁴Kyoto/JP (pierre.linck@hotmail.fr)

Purpose: To demonstrate that long-term neurodegeneration of substantia nigra (SN) secondary to disconnection by a supra-tentorial infarct can be quantified with iron-sensitive imaging and contributes independently to clinical outcome.

Methods and Materials: 181 stroke patients (75 striatum infarcts, 106 other locations) were prospectively evaluated at 24-to-72h (baseline) and at one year (follow-up) clinically and with MRI to quantify iron through R2*. SN was segmented to measure an asymmetry index (SN-AI) of R2*. We focused on the 95th percentile as a metric of high iron content. SN-AI₉₅ was compared according to infarct location with unpaired *t* test and also regressed with variables expected to influence iron accumulation. Voxel-based analysis was conducted on average R2* maps. We also identified individual voxels whose infarction was significantly associated with high SN-AI₉₅ through voxel-based lesion-symptom mapping (VLSM). Multiple regression models were used to test the independent association between SN-AI₉₅ and clinical scores.

Results: Visual inspection, SN-AI₉₅ and average maps consistently showed a delayed increase of R2* within SN that was significantly higher if ipsilateral striatum was involved than if not ($p<0.0001$). VLSM confirmed that striatum but also insula, internal and external capsules were associated with increased SN-AI₉₅. This association was independent of infarct volume, baseline SN-AI₉₅ and other confounders ($\beta=4.99$ [2.94; 7.04], $p<0.0001$). Such increase of SN-AI₉₅ was an independent contributor of poor motor outcome (Box-and-Block, $p=0.01$) but not of cognitive or emotional outcome.

Conclusion: Long-term neurodegeneration of SN remotely from an ipsilateral infarct can be quantified with R2* and independently impacts motor outcome at follow-up.

B-1416 16:08

Detection and prevalence of cerebral microbleeds in middle and old age groups: a clinical-based approach

S.E.E.E. Elbadawi; Mansoura/EG (Free_s10@hotmail.com)

Purpose: Cerebral microbleeds are increasingly recognized neuroimaging finding. Aim was to examine clinical determinants in middle and old age population (50 years and older).

Methods and Materials: 471 individuals underwent brain MRI at 1.5T, including susceptibility weighted imaging (SWI). 36 persons were excluded due to the presence of neoplasms. Associations between hypertension, diabetes mellitus, cognitive impairment and history of ischaemic heart disease or prior cerebrovascular accidents with the presence of CMBs were assessed by logistic regression model.

Results: Two groups were enrolled according to the presence or absence of microbleeds; microbleeds group ($n=177$, 40.7%) (age, 67.5 ± 8.8) and control group ($n=258$, 59.3%) (age, 66.8 ± 8.4). No significant difference in age categories between the two groups was detected. However, for those aged 80 years or more, a higher proportion fell into microbleeds group (13.6% versus 3.5%). There was a statistically significant higher proportions of male gender ($P=0.005$), hypertensives ($P=0.003$) and history of CVA ($P=0.016$) in the microbleeds group while there was no significant difference regarding history of DM ($P=0.629$), IHD ($P=0.445$) or cognitive impairment ($P=0.147$). Binomial logistic regression was performed. HTN had 2.9 times and patients with history of CVA had 2.5 times higher odds to exhibit microbleeds. The most frequent site of CMBs was lobar.

Conclusion: CMBs' prevalence rises with ageing. Confounders including male gender, hypertension and history of CVA strongly correlated with CMBs.

B-1417 16:12

Carotid artery plaque detected on ultrasound is associated with impaired cognitive state in the elderly: a population-based study in Wakiso district, Uganda

M. Kenneth¹, F. Ameda², R.K. Byanyima², N. Nakasujja²; ¹Mbarara/UG, ²Kampala/UG (mworozikenneth@gmail.com)

Purpose: Carotid artery disease which includes carotid artery stenosis, plaques, clots and increased intima media thickness has been reported by

several studies to be associated with dementia. Dementia is an end stage of usually asymptomatic cognitive impairment. This study set out to determine the prevalence of abnormal carotid ultrasound findings and their association with cognitive function among the adults ≥ 60 years in Wakiso district, Uganda, in 2018.

Methods and Materials: This was a cross-sectional study which included 210 participants. Carotid artery stenosis, presence of plaque, stenosis and intima media thickness were assessed by Doppler ultrasound. Cognitive status was assessed using a Mini Mental State Exam (MMSE) test.

Results: The prevalence of plaque was 21.4%. Plaque was associated with an abnormal cognitive function at both univariate and multivariate analyses, respectively, with OR=3.8 (95% CI=1.90-7.54, p value=0.0001) and OR=3.4 (95% CI=1.38-8.15, p value=0.007). The cognitive function was 43.8%, 19%, 34.3% and 2.9% for normal, mild, moderate, and severe status, respectively.

Conclusion: The prevalence of carotid artery plaque was high in this elderly population. Carotid artery plaque was associated with abnormal cognitive function.

B-1418 16:16

Are aneurysmal subarachnoid haemorrhage scales applicable to non-aneurysmal subarachnoid haemorrhage?

D. Páez Granda, M.J. Martínez Cutillas, J. Díaz Pérez, G. Parrilla Reverter, J. Berná-Serna, M. Espinosa de Rueda Ruiz, B. García-Villalba, J. Zamorro Parra, J. Felices Farias; Murcia/ES (drdiegopaez@hotmail.com)

Purpose: Aneurysmal subarachnoid haemorrhage (aSAH) and non-aneurysmal subarachnoid haemorrhage (naSAH) have a different clinical evolution. The objective of this work is to analyse if a clinical scale used in the evaluation of patients with aSAH (Hunt and Hess (HH)), and a radiologic scale that estimates the risk of vasospasm in cases of aSAH (modified Fisher Scale (mFS)), could be applied in naSAH.

Methods and Materials: We reviewed the radiology database and medical records of all patients who presented to our hospital during an 8-year period. The inclusion criteria were patients with spontaneous SAH, negative angio-CT (aCT), and at least one digital subtraction angiography (DSA) of cerebral vessels without disclosed neurovascular pathology. We divided cases in perimesencephalic (pmSAH) and aneurysmal type (atSAH) haemorrhages.

Results: One patient of the pmSAH group and 14 with atSAH reached a score >2 in HH scale on admission. The commonest complication was hydrocephalus, observed in 1 patient of the pmSAH group (mFs of III), and 14 of the atSAH group, all of them mFs IV. Delayed cerebral ischaemia (DCI) was the second most frequent complication, detected in 1 case of pmSAH (mFs of III) and 4 from the atSAH group, all of them mFs IV.

Conclusion: The rate and type of neurological complications in our cohort of naSAH is different than the reported incidence in aSAH. The categorization of these bleedings in pmSAH and atSAH is a more helpful tool than mFs to predict neurological complications. Worst HH scores are related to the development of these complications.

Lactate-weighted imaging of brain tumours using chemical exchange saturation transfer (CEST) MRI at 7 Tesla

D. Paech, J.-E. Meissner, M. Wennmann, A. Radbruch, M. Bendszus, W. Wick, A. Unterberg, M. Ladd, H.-P. Schlemmer; Heidelberg/DE (d.paech@dkfz.de)

Purpose: Cancer cells exhibit up-regulated lactate dehydrogenase (LDH) resulting in increased levels of lactate production in tumours (Warburg effect). The purpose of this study was to investigate lactate levels in tumours of patients with newly diagnosed glioma using Lactate-weighted Chemical Exchange Saturation Transfer (Lactate-CEST) at 7 Tesla (7T).

Methods and Materials: Ten patients (5 female, 5 male) with newly diagnosed and histologically proven glioma (8 patients with glioblastoma WHO grade IV and 2 patients with glioma WHO grade II) were enrolled in this prospective IRB-approved study. Lactate-CEST MRI was performed at a 7T whole-body scanner (Magnetom 7T; Siemens Healthcare, Germany) employing a centric-reordered 2D-GRE-CEST sequence (resolution of $1.71 \times 1.72 \times 5 \text{ mm}^3$) and a 24-channel head coil. Pre-saturation consisted of 10 Gaussian-shaped pulses (pulse length: $t_p = 90 \text{ ms}$, duty cycle: $DC = 80\%$, and saturation power $B_1 = 1.1 \mu\text{T}$). Magnetization transfer asymmetry, defined as $MTR_{\text{asym}} = Z(\Delta\omega = -0.6 \text{ ppm}) - Z(\Delta\omega = +0.6 \text{ ppm})$, yields the lactate-weighted MRI contrast. Lactate-w. signals were investigated in three regions of interest (solid tumour, necrosis, contralateral white matter = CLWM) and compared using the Wilcoxon rank-sum test.

Results: Lactate values were significantly increased both in solid (3.94 ± 1.22) and necrotic (4.06 ± 1.29) tumour regions compared to CLWM (3.45 ± 1.21) overall patients ($p<0.05$). There were no statistically significant differences between the solid tumour and necrosis ($p>0.05$).

Conclusion: Lactate-CEST MRI could serve as an additional imaging biomarker providing complementary information about the heterogeneity of tumours, with implications for biopsy targeting, patient therapy and response monitoring.

B-1420 16:24

Analysing the impact of sarcopenia on brain: using correlation between paraspinal muscle and brain volume

H. Lee, H.S. Seo, Y.H. Lee; *Ansan/KR (kkkmucu@naver.com)*

Purpose: Muscle density is one of the important values in assessing sarcopenia, and closely related to skeletal muscle lipid content. We compared paraspinal muscle size and density to volume of variable compartments of brain in elderly, to find a correlation between sarcopenia and brain functions.

Methods and Materials: Total 1293 participants (M:F = 620:673, mean age = 63.52±7.16, range 53-82 yrs) were enrolled in the study, and went through visceral fat CT and brain MRI. Size and density of paraspinal muscle were measured at umbilical level cut of visceral fat CT. Each volume of brain compartments was processed by BRAINS Auto-Workup tool. Pearson's correlation and partial correlation were used to reveal the relationship between size and density of paraspinal muscle, and volume of the brain, while control, the covariates including age, sex, BMI, smoking, alcohol consumption, hypertension and diabetes.

Results: Pearson's correlation showed positive correlation between paraspinal muscle size, density and virtually all of the volume of brain compartments. On partial correlation, positive correlations were found between paraspinal muscle size and supplementary motor cortex, inferior lat. Ventricle. Besides, positive correlations were found between paraspinal muscle density and grey matter, white matter, cerebrum, cerebellum, frontal lobe and parietal lobe.

Conclusion: There was positive correlation on both paraspinal muscle size and muscle density to brain volume, and muscle density is significantly more correlated. Several compartments of brain such as frontal and parietal lobes, which have the main role in executive and cognitive functions, and motor and sensory functions showed relationship with paraspinal muscle density.

B-1421 16:28

Glymphatic pathway of gadolinium-based contrast agents through the brain: overlooked and misinterpreted

K. Deike-Hofmann¹, J. Reuter¹, D. Paech¹, S. Bickelhaupt¹, R. Gnirs¹, M. Forsting², C. Heussel¹, H.-P. Schlemmer¹, A. Radbruch¹; ¹Heidelberg/DE, ²Essen/DE (k.deike@dkfz-heidelberg.de)

Purpose: The "glymphatic system" (GS), a brain-wide network of cerebrospinal fluid microcirculation, supplies a pathway through and out of the central nervous system (CNS); malfunction of the system is implicated in a variety of neurological disorders. In this exploratory study, we analysed the potential of a new imaging approach that we designed, delayed T2-weighted gadolinium-enhanced imaging, to visualize the GS in vivo.

Methods and Materials: Heavily T2-weighted fluid-attenuated inversion recovery MRI (hT2w-FLAIR) was obtained before, 3h and 24h after intravenous gadolinium-based contrast agent (GBCA) application in 33 neurologically healthy patients. Signal intensity (SI) was determined in various cerebral fluid spaces and white matter hyperintensities (WMHs) were quantified by applying the Fazekas scoring system (FS).

Results: Delayed hT2w-FLAIR showed GBCA entry into the CNS via the choroid plexus and the ciliary body, with GBCA drainage along perineural sheaths of cranial nerves, and along perivascular spaces of penetrating cortical arteries. In all sites, a significant SI increase was found 3h and 24h p.i. compared to baseline ($p < .01$). Furthermore, SI increase and FS were positively correlated in the perivascular spaces 3h p.i. ($p < .05$).

Conclusion: Delayed T2-weighted gadolinium-enhanced imaging can visualize the GBCA pathway into and through the GS. Presence of GBCAs within the GS might be regarded as part of the natural excretion process and should not be mixed up with gadolinium deposition. Rather, the found correlation between WMH, an imaging sign of vascular dementia, and GS functioning demonstrated feasibility to exploit the pathway of GBCAs through the GS for diagnostic purposes.

B-1422 16:32

Arterial spin labelling for the evaluation of immediate postoperative residual lesion in adult brain tumours

C. Cohen¹, B. Law-Ye², D. Dormont², M. Sanson², D. Galanaud², N. Pyatigorskaya²; ¹Tours/FR, ²Paris/FR (clara.cohen.cc@gmail.com)

Purpose: In brain tumours, evaluation of surgical resection on postoperative MRI can be challenging. Our goal was to evaluate the contribution of pseudo-continuous arterial-spin-labelling (pCASL) in the postoperative residual lesion research.

Methods and Materials: Sixty-four patients were prospectively included. On the basis of the results of preoperative DSC-PWI assessment, some lesions, such as high-grade gliomas (31), certain metastases (11), and meningiomas (4), were classified as hyper-perfused (HP+ group, n=49); other lesions, such as low-grade gliomas (10) and certain metastases (2), were classified as non-hyper-perfused (HP- group, n=15). To confirm the absence/presence of a residual lesion or disease progression, postoperative MRI including pCASL sequence, and follow-up MRI, were performed within 48 hours and 1-6 months

after the resection, respectively. All the images were qualitatively and quantitatively evaluated by two raters. The ASL cerebral blood flow (CBF) was calculated and normalised to the contralateral tissue. The pCASL-CBF maps and contrast enhancement were visually assessed.

Results: In HP+ group, the mean normalised CBF was 2.21 ± 1.03 or 0.99 ± 0.31 ($p < 0.001$, AUC=0.965, cut-off=1.16) for patients with or without residual tumours, respectively. The mean normalised CBF was not discriminative for assessing residual tumours in HP- group ($p=0.639$). Visual CBF evaluation allowed classifying correctly 94.10% patients belonging to HP+ group (sensitivity 94.12%, specificity 86.67%, $p < 0.001$). Visual evaluation correlated with contrast-enhancement evaluation and with the mean normalised CBF values ($r = 0.5458$ and 0.5469 , respectively).

Conclusion: Qualitative and quantitative ASL evaluation has high diagnostic performance in postoperative assessment of hyper-perfused tumours. In this case, postoperative pCASL may be useful, especially if contrast injection cannot be performed or when contrast enhancement is doubtful.

B-1423 16:36

Arterial spin-labeling and magnetic resonance spectroscopy as imaging biomarkers for the detection of epileptogenic zone in non-lesional focal impaired awareness epilepsy

R.E. Mohamed, R.M. Dawoud, A.A. Aboelsafa; *Tanta/EG (rany1997@yahoo.com)*

Purpose: To recognise the epileptogenic zone in patients with non-lesional focal impaired awareness epilepsy (FIAE) by evaluating the interictal changes in rCBF and cerebral metabolic alterations using PASL-MRI and MV 1H-MRS, respectively.

Methods and Materials: 26 patients with non-lesional FIAE (14 females and 12 males) were subjected to PASL-MRI for estimating rCBF and MV 1H-MRS for measuring NAA/Cho, NAA/Cr, NAA/(Cho+Cr), MI/NAA, Glx/NAA and Glx/Cr ratios, in addition to ASL asymmetry index percent (ASLAI%) and percent asymmetry factor (%AF).

Results: For the identification of the epileptogenic zone; increased ASLAI% assessed by PASL-MRI (at cut-off value $\geq 5.96\%$ and AUC of 0.968) showed 96.01 sensitivity, 91.70% specificity and 95.78% accuracy, and increased %AF (at a cut-off value $\geq 9.98\%$ with AUC of 0.983) showed 100% sensitivity, 97.65% specificity and 98.14% accuracy, while decreased NAA/(Cho+Cr) ratio estimated by MV 1H-MRS (at a cut-off value ≥ 0.59 with AUC of 0.977) showed 100% sensitivity, 96.90% specificity and 97.74% accuracy. Moreover, the combined use of PASL-MRI and MV 1H-MRS yielded 100% sensitivity, 98.45% specificity and 98.86% accuracy.

Conclusion: The combined use of PASL-MRI and MV 1H-MRS can be considered as in vivo biomarkers for the proper identification of epileptogenic zone in patients with non-lesional FIAE.

B-1424 16:40

Fully automated segmentation of meningiomas using deep learning on multiparametric MRI: automated segmentation yields accuracies as good as manual interreader variabilities

K.R. Laukamp, F. Thiele, L. Pennig, R.P. Reimer, G. Shakirin, D. Zopfs, M. Timmer, M. Perkuhn, J. Borggrefe; *Cologne/DE (kai.laukamp@uk-koeln.de)*

Purpose: Volumetric assessment of meningiomas is highly valuable for primary assessment and therapy/surgery planning. Further, it is more sensitive for detection of tumor growth than conventional diameter methods and thereby serves as an effective tool in meningioma monitoring. We used a state-of-the-art deep-learning-model (DLM) on routine multiparametric MR-data to investigate performance in automated detection and segmentation.

Methods and Materials: 56 MR-datasets (T1-/T2-weighted, T1-weighted contrast-enhanced [T1CE], FLAIR; n=19 from local scanners and n=37 from referring institutions) of n=38 grade I and n=18 grade II meningiomas were included. The DLM was trained on two independent datasets of 249 gliomas and 60 meningiomas. It segments four different tumor classes as defined in BRATS-benchmark. Preprocessing included registration, skull stripping, resampling, and normalization. DeepMedic-architecture (Kamnitsas, 2016) was used as basis. 3D-convolutional-neural-network for segmentation and a 3D-post-processing-step to remove false positives were applied. Detection and segmentation results were compared to manual segmentations from two experienced radiologists in consensus in FLAIR and T1CE tumor volume.

Results: 55 of 56 meningiomas were detected correctly by the DLM. Fully automated segmentation correlated very well with manual segmentations: average dice-coefficients were 0.87 ± 0.15 for contrast enhancing tumor volume in T1CE and 0.82 ± 0.12 for total tumor volume (union of tumor volume in FLAIR and T1CE).

Conclusion: Deep learning based automated segmentation yielded excellent segmentation accuracies, comparable to manual interreader variabilities, and thereby might improve and facilitate clinical management of this highly frequent tumor entity.

Imaging the seizure onset zone and fast electrical circuit activity in epilepsy with electrical impedance tomography

A. [Witkowska-Wrobel](#), K. Aristovich, M. Faulkner, J. Avery, D. Holder; London/UK (anna.wrobel@ucl.ac.uk)

Purpose: Electrical impedance tomography (EIT) is a new method for imaging internal impedance changes within a subject using EEG electrodes. It could advance the management of epilepsy by imaging changes occurring over milliseconds due to ion channel opening or seconds due to cell swelling and so image seizure onset and propagation in epileptic patients. It requires the use of intracranial electrodes, already used in presurgical evaluation for epilepsy. The feasibility of its use in epilepsy has been evaluated in a modelling study based on intracranial patients.

Methods and Materials: The accuracy of seizure onset zone localisation was evaluated using 10M element patient-specific Finite Element Models (FEMs) created from frontal/mesial temporal lobe epilepsy patients with 8-12 depth electrodes inserted. 30 seizures were simulated as resistance changes 1cm in diameter, for either ion channel opening or cell swelling (1/10% change respectively). EIT images were compared to EEG inverse source modelling (EISM) and visual spike recognition (SEEG).

Results: Seizure onset localisation was significantly improved with EIT compared to EISM/SEEG. EIT could detect seizures more accurately, independently of orientation, and with broader coverage whereas EISM/SEEG were blind to tangential and distant sources (15/15 vs. 8/15 detection EIT vs. SEEG respectively). The reconstructed localisation error was 46.2 ± 25.8 mm (EISM) and 5.2 ± 1.8 mm (EIT, $n=30$, $p < 0.01$).

Conclusion: Results suggest EIT could provide a radically improved method for localising seizure onset by providing functional real-time information. Work is in progress to evaluate its accuracy in anesthetized pigs and in human epilepsy subjects.

Meta-analytic investigations of grey matter alterations in patients with Tourette syndrome

S. [Zhang](#), W. Wang, X. Su, H. Sun, Q. Yue, Q. Gong; Chengdu/CN (835408876@qq.com)

Purpose: Tourette syndrome (TS) is a neurodevelopmental disorder characterized by chronic motor and phonic tics. The neuroimaging studies revealed grey matter volume alterations in TS, but the previous findings have not found a common theme with respect to functionally important regions that could drive TS behaviour. The aim of this paper was to find consistent grey matter alterations in TS patients.

Methods and Materials: We searched Pubmed, Embase and Web of Science for articles published from inception to October 2018, with the search terms "Tourette syndrom" or "TS" plus "VBM" or "voxel-based morphometry". After excluding ineligible publications, we identified 10 relevant studies that investigated grey matter alterations in TS, then we performed a meta-analysis using the effect size signed differential mapping method to quantitatively estimate regional grey matter abnormalities in patients with TS.

Results: We included 10 studies comprising 342 TS patients and 356 healthy controls in our meta-analysis. The meta-analyses showed robust GMV reductions in the bilateral inferior frontal gyrus (IFG) and increased GMV in the midbrain area in patients with TS.

Conclusion: Our findings suggested that the consistent GMV alterations in TS patients were decreased in IFG and increased in midbrain area. The IFG is involved in decision-making through its function in the representation of value and reward. Volume reduction in IFG could explain deficits in the flexible control of behaviour in TS patients. Besides, the midbrain GMV alternations may play a role in triggering specific vocal responses on the basis of the environmental and motivational information.

B-1427 16:52

Grey matter network changes with ageing in a large group of never-treated patients with schizophrenia

B. [Yang](#), W. Zhang, B. Tao, J. Liu, S. Lui; Chengdu/CN (1045561481@qq.com)

Purpose: Abnormal structural brain networks are believed to be an important neuropathology of serious mental illness. The knowing of brain network changes with ageing could advance our understanding of these network disturbances and potential pathophysiology of schizophrenia. In the present study, we enrolled a large group of never-treated schizophrenia patients to investigate the pattern of network changes with ageing.

Methods and Materials: We stratified 152 never-treated schizophrenia patients into 4 subgroups A1-A4 by age (16-24, 25-34, 35-44,>45), and matched controls for each subgroup were selected from 210 healthy subjects. High resolution T1 images of brain were obtained with a 3.0 T MR scanner (GE), and preprocessed by FreeSurfer. The gray matter network matrices were constructed by correlating the cortical thickness of every pair of regions within AAL brain segmentations across individuals. The network properties including nodal centrality and efficiency were then calculated.

Results: Compared to healthy controls, all patient subgroups showed some common network property changes while some distinct changes. The common changes along ageing were nodal centrality loss at regions mainly within default mode network (DMN), control network (CN). More importantly, the network deteriorates with ageing and more nodal centrality decreases at isthmus cingulate, right caudal anterior cingulate were showed at subgroups A2-4, and more abnormality of left precuneus showed at A3-4.

Conclusion: The alternations of topological properties within DMN and CN may represent trait-related structural network changes in schizophrenia, while the changes at later ageing may represent illness progression with more-wide spread brain abnormalities.

B-1428 16:56

Role of whole brain diffusion kurtosis neuroimaging in disentangling bipolar depression from unipolar depression

V. Gupta, M. [Maralakunte](#), S. Grover, C.K. Ahuja; Chandigarh/IN (muniraju987@gmail.com)

Purpose: Depression is the most common morbidity affecting people worldwide. Fact to be noted is that *not all depressions* are same. Bipolar depression (BD) is frequently misdiagnosed as unipolar depression (UD), leading to inefficient treatment and worst clinical outcome. Purpose of the study is to identify novel neuroimaging markers in differentiating bipolar depression from unipolar depression in the context of depressive episode.

Methods and Materials: Depressed subjects with BD ($n=21$), UD ($n=18$) and healthy control (HC) ($n=20$) were subjected for diffusion kurtosis imaging (DKI) evaluation. The diffusivity and kurtosis metrics, such as mean diffusivity (MD), axial diffusivity (AD), radial diffusivity (RD) and fractional anisotropy (FA) measured at b1000, and mean kurtosis (MK), axial kurtosis (AK), radial kurtosis (RK) and kurtosis fractional anisotropy (KF) measured at b2000 value, employing whole brain atlas-based analysis.

Results: Bipolar depression subjects exhibited significant diffusivity and kurtosis metric abnormalities involving right external capsule, left amygdala and right hemiserebellum, as compared to UD and HC.

Conclusion: Present study is a unique study which explored whole brain DK MR technique to evaluate microstructural changes in BD, UD and HC. It has provided additional insights into the brain areas which might play central role in etio-pathogenesis of depression. Present study is able to find specific imaging markers which potentially differentiate BD from UD.

B-1429 17:00

Brain MRI characteristics in neuromyelitis optica spectrum disorders: a multi-center study in China

G. [Cao](#), Y. Duan, W. Zhu, Y. Liu; Beijing/CN (caoguanm@163.com)

Purpose: To investigate the brain MRI features in neuromyelitis optica spectrum disorders (NMOSD) and its clinical relevance in China in a multi-center setting.

Methods and Materials: 238 NMOSD patients (202 females, age mean \pm SD: 41.5 ± 13.7 years) were recruited from six centers in China, who satisfied the 2015 diagnostic criteria. The brain MR manifestations were classified into 4 types: (1) normal; (2) NMOSD-specific lesions (high AQP-4 regions); (3) multiple sclerosis lesions (satisfying 2015 McDonald criteria); (4) nonspecific white matter change. The lesion probability map was calculated with SPM12 after drawing the ROI. Demographic and cognitive features were analyzed.

Results: Eighty-three (86/238, 36%) patients had normal MR imaging findings, and the others (152/238, 64%) had abnormal MRI findings: forty-two patients (18%) with NMOSD-specific lesions distribution in dorsal brainstem, corticospinal tract corpus, callosum and periependymal lesions surrounding the ventricular system; fourteen patients with MS-like abnormalities (6%); and ninety-six patients with nonspecific lesions (40%). Lesion probability map showed the distributions. The average age of patients with specific lesions was smaller than those with nonspecific lesions (36.8 years and 44 years respectively, $P=0.005$). Patients with abnormal MRI findings (type 2-4) performed worse cognitive performance [Montreal Cognitive Assessment (MoCA) test] than those without brain lesions ($P=0.049$).

Conclusion: In this relatively large NMOSD cohort, nonspecific lesions were the most common findings in NMOSD, and NMOSD-specific lesions were observed in 18% patients. Patients with lesions presented worse cognitive performance than patients with normal MRI.

B-1430 17:04

Less regulated, more segregated ventral visual network in patients with major depressive disorder

H. Chen, J. Yan, K. Liu, Y. Deng, X. Huang, R. Su, Z. Xiaojun; *Guangzhou/CN*

Purpose: Previous studies indicate that major depressive disorder (MDD) can profoundly modify the visual cortices as well as the visuo-attentional systems of brain. However, little is known on the specific pattern of the network-level abnormalities of brain visual system in MDD. In this study, based on a series of previous evidences of visual cortical hyperactivity, we hypothesize that the ventral/dorsal visual network in MDD is possibly characterized as a status of increased autonomy (i.e., a hyperinteractive intra-network configuration, while receiving less outside modulation from attention network).

Methods and Materials: RS-fMRI scans were collected from 148 participants, including 78 medication-free MDD patients and 70 matched healthy controls. The dorsal/ventral visual networks were defined based on our previously published brain coordinates from activation likelihood estimation analyses. The static and dynamic network properties were, respectively, calculated and compared between MDD and control groups. Moreover, the inter-network connectivity quantified using the multivariate distance correlation between the dorsal attention network (DAN) and visual/dorsal network was also assessed between two groups.

Results: Results indicated that both dorsal ($p=0.019$) and ventral visual ($p=0.002$) networks in MDD were found with significantly increased clustering coefficient. A higher mean variability of dynamic functional connectivity was found in both the networks ($p=0.002$, 0.003 , respectively). Moreover, ventral visual network in MDD group showed a decreased inter-network connectivity to DAN compared with control group ($p=0.018$).

Conclusion: These evidences may reveal a hyperinteractive, while less regulated, network characteristic of the ventral visual system, thus reflecting an autonomous status under the pathological effect of depression.

Extended memory network degeneration in Parkinson's disease patients with lean muscle loss

Y.-N. Wu, W.-C. Lin, C.-H. Lu; *Kaohsiung/TW (echo7221@gmail.com)*

Purpose: Parkinson's disease (PD) is a common neurodegenerative disease associated with gray matter atrophy. Development of frailty and decrease muscle mass were observed and might relate to increase morbidity in life span. This study aimed to evaluate the relationship of decrease lean muscle mass to gray matter volume (GMV) and other risk factors PD patients.

Methods and Materials: Thirty patients with PD (all Hoehn & Yahr ≤ 2) and fifteen healthy volunteers underwent brain and bilateral thigh MRI. For thigh MRI, IDEAL sequence was employed, and the ROI of fat percentage was measured at level of 50% femur length. Voxel-base morphometry (VBM) was used to access regional GMV difference between groups. Further correlation analysis was performed to evaluate the changes between GMV and fatty percentage of bilateral thigh after adjusting for age and gender. Multiple linear regression analysis was used to identify risk factors of decrease lean muscle mass of the thigh in PD.

Results: Compared with controls, patients with PD had significantly higher thigh fat percentage and smaller GMV in several brain locations of the extended memory network, including left superior temporal gyrus, right uncus and left inferior temporal gyrus. Further multiple linear regression study suggested that higher fat percentage of thigh can be predicted by female gender, increase disease duration and smaller GMV in left superior temporal gyrus in patient with PD.

Conclusion: Patients with PD experience muscle mass loss in thighs, and these alternations are associated with extended memory network degeneration, longer disease duration and female gender.

B-1432 17:12

Dendritic growth and branching of the cortical neurons can be altered by ultrasound exposition

Z. Ferenczi, T. Papp, B. Szilagyi, P. Szucs, E. Berenyi, Z. Meszar; *Debrecen/HU (fzsuzsanna.90@gmail.com)*

Purpose: Ontogeny of the cerebral cortex requires complex spatial and temporal orchestration of postmitotic neurons for populating this highly organized laminated structure of the brain. After migration and lamination, appropriate dendritic growth and branching are essential for proper circuit formation and correct function of neurons. Coordinated dendritic growth is largely determined not only by intrinsic factors but also by environmental effects. Ultrasound (US) examination is one of the most important and commercial examinations during pregnancy worldwide. US stimuli can modify the number of proliferation of neurons in vivo, but we do not know exactly how this stimuli effects on dendritic differentiation. Thus, we investigated the effect of US stimuli on dendritic development in the frontal cortex and the hippocampus of prenatal mice.

Methods and Materials: We labelled cortical plate neurons at E14.5 with GFP by in utero-electroporation which was followed by ultrasound exposition for 10 minutes (frequency: 3.0 MHz, mechanical index 0.9, thermal index: 0.9) at E18 and then at P3 the newborn mice were sacrificed and their brains were processed for histology. Analysis of hippocampal and cortical pyramidal cells was performed with Imaris and Neurolucida software.

Results: During the examination of pyramidal cells, there seemed to be a higher branching frequency and there was an increase in spine density as well compared to the neurons of the nontreated animals.

Conclusion: Our data suggest that ultrasound has prolonged effects on the morphology of differentiating cortical neurons.

B-1433 17:16

The relationship between cognitive function and magnetic resonance spectroscopy findings in Parkinson disease patients

M. Sanei Taheri, M. ArabAhmadi, H. Haghighatkah, M. Ranjbar, M. Amiri; *Tehran/IR (mehrnan_arabahmadi@yahoo.com)*

Purpose: Cognitive impairment (CI) is one of the most notable disabilities of Parkinson's disease that is associated with lower quality of life. Early detection of CI is, therefore, very important for these patients. The purpose of this study was to examine the relationship between cognitive function and the metabolic data from magnetic resonance spectroscopy (MRS) of the patient suffering from Parkinson's disease.

Methods and Materials: We recruited 45 patients with Parkinson's disease and subjects were divided into three groups based on scales for outcome from Parkinson cognition (SCOPA-COG) test. Patients were classified as non-cognitive impairment (NCI; n=15), mild cognitive impairment (MCI; n=15) and dementia (PDD; n=15). All subjects underwent MRI and 1H-MRS techniques and metabolic changes such as NAA/Cr and NAA/Cho ratios, which were measured in the left hippocampal area of the brain.

Results: The mean and standard deviation of the NAA/Cr ratio in the three cognitive groups (NCI, MCI, PDD) were (2.51 ± 0.037) , (2.50 ± 0.033) and (2.47 ± 0.025) , respectively. ANOVA test showed a significant difference in the three groups. Furthermore, the Scheffé test showed a significant difference between patients in the MCI and PDD groups ($p=0.01$). There was no significant difference between the non-cognitive impairment and mild cognitive impairment groups ($p=0.54$). No significant difference was found in NAA/Cho ratio ($p=0.91$).

Conclusion: A decreasing NAA/Cr ratio has an influence on cognitive function and the development of severe cognitive dysfunction in Parkinson-suffering patients. Furthermore, H-MRS determinant can be useful to evaluate cognition in Parkinson patients.

Percutaneous stereotactic CT-based microwave ablation for neuroendocrine liver metastasis

M.H. [Maurer](#), A. Lachenmayer, G. Beldi, D. Candinas, J.T. Heverhagen, C. Kim-Fuchs; *Berne/CH* (martin.maurer@insel.ch)

Purpose: To analyse the success of CT-based percutaneous stereotactic microwave ablation (MWA) for liver metastases from neuroendocrine tumours (NET) in terms of local recurrences or reduction of symptoms in a palliative setting.

Methods and Materials: Between 01/2015 and 06/2018, 380 different hepatic tumours were ablated percutaneously in 203 patients. Of these, 18 (4.7%) ablations were done in seven patients with NET liver metastases. Median age was 69 years (54-75 years). Three primary tumours were in the pancreas, four in the small bowel and one of unknown primary. Ablations were either done in a curative setting or as a means of reducing tumour load to treat symptomatic patients.

Results: There were no peri-, and postinterventional complications. The first follow up with an MRI was done three months after the intervention, with an overall median follow up of 18.9 months (4.2-33.1). There was no local recurrence in patients treated with curative intent. One out of six patients developed new metastases in the liver and received two further sessions (five lesions) and is now tumour free. The patient with palliative ablation had a significant reduction of symptoms in the follow up.

Conclusion: Percutaneous CT-guided MWA for patients with NET liver metastasis is a safe treatment option. Ablations can be used to treat metastasis in a curative setting or to reduce tumour load and symptoms in patients not amenable to definitive surgery. Especially patients with difficult to reach intrahepatic lesions profit from stereotactic guidance.

Minocycline hydrochloride as a soft sclerosing agent for symptomatic simple renal and hepatic cysts: our experience

A. [Paladini](#)¹, D. Beomonte Zobel², M. Falcione², A. Borzelli³, C. Di Stasi², A. Cina², G.E. Vallati², G. Pizzi², E.M. Amodeo²; ¹Novara/IT, ²Rome/IT, ³Naples/IT (andreapaladini1988@gmail.com)

Purpose: The aim of this paper is to retrospectively evaluate our ten years' experience on the sclerosing procedure of simple hepatic and renal cysts. We used minocycline hydrochloride, an antibiotic drug from the tetracycline family, as sclerosing agent. Through ultrasound-guided percutaneous access, it was injected in the cysts. In conclusion we evaluated efficacy and safety of the procedure.

Methods and Materials: We analysed 75 patients (54 patients with 60 renal cysts and 21 patients with 24 liver cysts) with symptomatic cysts. Patients were treated with ultrasound percutaneous drainage of cystic formation and subsequent injection of minocycline hydrochloride into the cyst itself. In larger cystic formulations, the treatment was repeated twice. We performed follow-up with ultrasound 6 and 12 months after procedure.

Results: The success rate of this treatment is 100% - in case of liver cysts - and 86% for renal cysts. Among minor complications, 5 patients reported fever (<38 °) in the 24 h following treatment, treated with paracetamol.

Conclusion: In conclusion, sclerosing treatment with minocycline hydrochloride is effective and safe, with a low level of complications. Symptoms disappeared in all patients with liver cysts (100% success rate) and 93% of patients with renal cysts.

Reduced periablational inflammation for microwave ablation (MWA) compared to radiofrequency (RF) and irreversible electroporation (IRE)

M. [Kak](#), N. Goldberg; *Jerusalem/IL* (drkkradiologist@gmail.com)

Purpose: To determine the extent of variable post-ablative inflammatory response in the periablational tissue when using microwave (MWA), radiofrequency thermal ablation (RF), and irreversible electroporation (IRE).

Methods and Materials: Wild-type C57b 9-10-month old mice (n= 27 for MWA) (total n=192) were anaesthetized and subject to laparotomy to enable direct liver ablation. For MWA (n= 27), 10 W were applied for 12 seconds [AMICA MWA system]; data for RF and IRE collected from other researchers in

our unit (Bulvik et al.). Mice were sacrificed at days 1, 3, 7, 14, and 21 to permit analysis of the dynamic inflammatory changes in the border zone. Activated inflammatory cell populations in the border zone were assessed to detect the inflammatory changes in MWA, RF and IRE, respectively. Additionally, cells entering G1 phase (CDC47) were measured, counted and compared among the three methods of ablation in both the periablational and distant regions of the liver.

Results: Overall, the border zone was less extensive in MWA (37 µm) (stdev=10.4) than RF (82 µm) (stdev=8.6), and IRE (108 µm) (stdev=10.3) (p<0.01). There were fewer macrophages in the border zone and fewer percentage of hepatocytes cells entering G1 phase (CDC47) in MWA (35%) in the distant liver compared to either RF (44%) or IRE (60%).

Conclusion: MWA produces less of an inflammatory response than RF or IRE. Reduced recruitment and activation of these potentially tumorigenic cell populations potentially may lead to reduced systemic effects including development of distant liver tumours after MWA.

B-1437 08:54

Safety and efficacy of IRE after major liver surgery

A. [Barabasch](#)¹, P. Heil², M. Distelmaier¹, C.K. Kuhl¹, P. Bruners¹; ¹Aachen/DE, ²Essen/DE (abarabasch@ukaachen.de)

Purpose: In patients with tumor recurrence in the liver remnant after liver-surgery, local ablation often is the procedure of choice. IRE is a non-thermal ablation-technique that has shown to avoid damage of vessels and bile ducts, crucial for patients left with a single draining vein, single portal-vein-branch or bile-duct that must remain patent to preserve liver-function. Additionally, these patients exhibit innumerable surgical-clips which might interfere with IRE. We report on our experience with IRE in this situation with regards to efficacy, safety, and liver-function.

Methods and Materials: 16 patients were treated with CT-guided-IRE for recurrent primary or secondary liver-malignancies. 13/16 had undergone trisectorectomy, 3/16 had non-anatomic major liver-resection. Distances from the active-tip of the IRE-probe to the nearest surgical-clip were measured on CT-images acquired during IRE. Liver function was assessed by the MELD-score immediately before, 1 and 6 weeks after IRE. Wilcoxon-signed-rank-test was used to investigate changes in MELD-Score.

Results: All patients had titanium-surgical-clips in an average distance of 24±21mm (range 0-65mm) from the active tip of the probe. In 8/16 patients, surgical clips were located closer than 20mm. Based on post-interventional-CT and follow-up-MRI, complete ablation was achieved in all cases. Presence of clips did not modulate the ablation zone. No patient exhibited vessel thrombosis. Average MELD-score before IRE was 4.4±4.9, 1 week after IRE 3.9±3.7 and 6 weeks after IRE 4.9±3.8 (p>0.05).

Conclusion: IRE is a safe local ablative method for patients after major liver surgery. Surgical clips close to the IRE probes do not interfere with the ablation.

B-1438 09:02

Stereotactic image-guided microwave ablation of hepatocellular carcinoma

M.H. [Maurer](#), V. Banz-Wüthrich, G. Beldi, C. Kim-Fuchs, D. Candinas, P. Tinguely, J.T. Heverhagen, A. Lachenmayer; *Berne/CH* (martin.maurer@insel.ch)

Purpose: To assess the therapeutic success of CT-based percutaneous stereotactic microwave ablation in patients with hepatocellular carcinoma (HCC).

Methods and Materials: We retrospectively analyzed a cohort of patients treated with percutaneous stereotactic image-guided microwave ablation for HCC at our institution between 01/2015 and 12/2017. All interventions were performed using CT-guidance with needle trajectory planning by landmark-based registration and an aiming device for precise needle placement.

Results: In total 163 interventions were performed in 92 patients (mean age 66 (50-84) years, 81 (83.5%) men). Patients presented on average with one tumor (1-6), a maximum of four tumors were ablated per session. Forty-three patients (44.3%) had one or more previous HCC treatments, 14 (14.4%) were transplanted afterwards. Mean tumor size was 16 mm (5-43 mm), mean ablation time per lesion was 5 (1-24) minutes. Within 30 days, no major or liver-specific complications occurred, six (4.6%) patients had minor (grade 1-2) complications after a total of 131 interventions. Of the 77 patients with a minimum 6-month follow-up after intervention, mean overall survival was 13.9 months after ablation and 23.7 months after initial diagnosis. Local recurrence occurred in 20/131 (15.2%) lesions, but could successfully be re-ablated in 14 cases (12.2%). Tumor size ≥ 3 cm was significantly correlated to local tumor recurrence (p=0.005).

Conclusion: Percutaneous stereotactic image-guided microwave ablation is safe and efficient for the treatment of HCC. It might offer a curative treatment approach especially for inoperable and conventionally unablable lesions by an accurate and precise needle positioning in a minimally-invasive setting.

B-1439 09:10

Comparison between percutaneous and laparoscopic microwave ablation of hepatocellular carcinoma

A. Della Corte, P. Marra, F. Ratti, F. Giombi, S. Gusmini, M. Salvioni, M. Venturini, L. Aldrighetti, F. De Cobelli; Milan/IT (dellacorte.angelo@hsr.it)

Purpose: Based on patient and nodule characteristics, some authors favor laparoscopic over percutaneous HCC microwave ablation (MWA), however data are controversial. We compared the two approaches in terms of technical success, complications and local tumor control rates.

Methods and Materials: From October 2014 to September 2018, 60 consecutive patients underwent percutaneous or laparoscopic MWA of 68 HCC nodules with a 2450MHz/100W Microwave generator (Emprint, Medtronic). Complete ablation (technical success) and LTP at follow-up were assessed by contrast-enhanced CT/MRI. Forty-five patients (51 HCC nodules) satisfied inclusion criteria (adequate follow-up, complete ablation), of which 27 (29 nodules) underwent percutaneous MWA and 18 (22 nodules) underwent laparoscopic MWA.

Results: Technical success and complication rates did not significantly differ between the two groups ($p=0.27$ and $p=0.15$, respectively). 6/45 patients (13.3%) suffered procedure-related complications (CIRSE classification grade-3): 2 cases (abscess, haematoma) in the percutaneous group (7.4%) and 4 (pneumothorax, respiratory failure, fever, portal thrombosis) in the laparoscopic group (22.2%). 5/51 (9.8%) HCC nodules showed local progression with 1- and 2-year LTPFS rates of 93% and 83.6%, respectively. Four LTPs occurred in the percutaneous group (13.7%), while 1 LTP in the laparoscopic one (4.5%) ($p=0.27$). At logrank analysis, operative approach was not a statistically significant predictor of LTPFS ($p=0.47$). Subgroup analysis showed that subcapsular nodules had worse LTPFS after percutaneous procedures (1-year LTPFS 100% laparoscopic vs 50% percutaneous, $p=0.04$).

Conclusion: No significant difference in complication rate was found between the two approaches. Laparoscopic MWA should be preferred over percutaneous MWA for treatment of subcapsular HCC.

B-1440 09:18

Value of ultrasound fusion imaging for the thermal ablation of medium-sized hepatocellular carcinoma

E. Xu, L. Luo, K. Li, Q. Zeng, L. Tan, Y. Long, Q. Huang, R. Zheng; Guangzhou/CN (xuerjiao@126.com)

Purpose: To investigate the effectiveness and safety of thermal ablation of patients with medium-size hepatocellular carcinoma (HCC) under the assistance of ultrasound fusion imaging.

Methods and Materials: From Dec. 2010 to Dec. 2017, 76 patients with 78 medium-size (3-5 cm) lesions of HCC who underwent radiofrequency ablation (RFA) or microwave ablation (MWA) in our institute were included. Ultrasound fusion imaging was used to assist the ablation procedures and assess the technical success immediately, then guide supplementary ablation. Contrast-enhanced CT/MR was performed one month later to assess the technique efficacy. The complication, local tumour progression (LTP) and intrahepatic distant recurrence (IDR) were followed up. The overall survival (OS) was analysed.

Results: With the assistance of ultrasound fusion imaging, single electrode or antenna was used in 68.4% (52/76) of patients. According to the ultrasound fusion imaging evaluation, 30.8% (24/78) of lesions received supplementary ablation immediately during the ablation procedure. 71 of 78 liver tumours achieved 5 mm ablative margin. There were no ablation-related deaths, and the major complication rate was 6.6%(5/76). The technique efficacy rate was 100%(78/78) according to the contrast-enhanced CT/MR one month later. Patients were followed up from 6 to 79 months with a median time of 22 months. LTP rate was 5.1% (4/78) and IDR rate was 28.9% (22/76). The 1-, 3-, 5-year OS rates were 95.7%, 89.4%, 80.6%, respectively.

Conclusion: With the assistance of ultrasound fusion imaging, thermal ablation of medium-sized HCC is effective and safe which could achieve a higher technique efficacy rate and a lower LTP rate.

B-1441 09:26

Radiofrequency ablation of liver cancers adjacent to the gallbladder without additional invasive measures under contrast-enhanced ultrasound monitoring: a preliminary study

E. Xu, Y. Long, R. Yan, K. Li, L. Luo, Q. Zeng, L. Tan, M. Zhang, R. Zheng; Guangzhou/CN (xuerjiao@126.com)

Purpose: The purpose of this study was to investigate the feasibility, safety and efficacy of intra-procedural contrast-enhanced ultrasound (CEUS) monitoring of the radiofrequency ablation (RFA) of liver cancers adjacent to gallbladder (GB) without invasive measures.

Methods and Materials: From July 2016 to April 2017, patients with liver cancers adjacent to GB (≤ 10 mm) who intended to undergo ultrasound-guided RFA without invasive auxiliary means in our hospital were prospectively enrolled. During the RFA procedures, CEUS was employed to evaluate the

therapeutic response and the perfusion integrity of the GB wall. The outcomes of GB and liver cancers were followed up and recorded.

Results: 23 patients (18 male, 5 female) with 23 liver cancers (mean 18 mm, range 8-34mm) adjacent to GB were enrolled. There were 12 tumours that abutted the GB while 11 tumours located within 10 mm of the GB. After the RFA procedures, intra-procedural CEUS evaluation demonstrated the perfusion of the GB wall was integrated in all 23 patients and technical success rate of RFA was 100% (23/23). According to the contrast-enhanced CT/MR one month after RFA, the technical efficacy rate was 100% (23/23). During the follow-up period (range: 12-23 months, median: 17 months), no local tumour progression occurred in any lesion and no major complications arose in any patient. Overall survival at 1-year was 100%. Thickening of GB wall was detected in 12 patients. Five of them were restored.

Conclusion: CEUS-monitored RFA of liver cancers adjacent to GB without invasive auxiliary means was feasible, safe and effective.

B-1442 09:34

Stereotactic image-guided microwave ablation for malignant liver tumours: can computer-assistance broaden treatment eligibility?

M.H. Maurer, A. Lachenmayer, V. Banz-Wüthrich, S. Weber, D. Candinas, J.T. Heverhagen, P. Tinguely; Berne/CH (martin.maurer@insel.ch)

Purpose: Treatment success of microwave ablation for liver lesions depends on tumor reachability and accurate ablation probe positioning. We investigated factors influencing targeting accuracy, procedural efficiency and technical success of percutaneous Stereotactic Image-guided MicroWave Ablation (SIMWA) for malignant liver lesions.

Methods and Materials: Data from all patients treated with SIMWA from 2015 to 2017 were analyzed retrospectively. A computed tomography (CT)-based navigation system was used for needle trajectory planning, stereotactic needle positioning, validation of needle positions and validation of ablation zones and technical success. Factors potentially influencing target positioning errors (TPE) of positioned ablation needles were analyzed using univariable and multivariable linear generalized estimating equations (GEE).

Results: Overall 301 lesions (174 HCC, 87 CRLM, 17 NET, 23 other) were treated in 153 patients. In 25 (8%) lesions multiple parallel needles were placed to create larger ablation zones. Correction of needle position was necessary in 4 (1%) lesions. Median TPE per ablation needle was 2.9mm (0.2-14.1mm) ($n=384$). Factors significantly influencing TPE were underlying cirrhosis (Mean diff. 0.686, CI 0.212-1.161), trajectory length (0.202, 0.127-0.277) and trajectory angle (-0.085, 0.170-0.000). Subcapsular or superior dorsal lesion location (segments VII/VIII) did not influence TPE. Median time per intervention was 67min (20-253min), and technical success rate was 96% (290/301 lesions).

Conclusion: Due to precise trajectory planning and stereotactic needle positioning, SIMWA allows highly accurate and successful targeting of intrahepatic lesions, even for otherwise difficult-to-target tumors. This might allow broadening of treatment eligibility for patients with malignant liver tumors not reachable with conventional image-guidance.

B-1443 09:42

Percutaneous cryoablation in early-stage hepatocellular carcinoma: analysis of local tumour progression factors

D.K. Kim, K. Han; Seoul/KR (kdk7118@yuhs.ac)

Purpose: To assess the efficacy and safety of percutaneous cryoablation for early- or very early stage hepatocellular carcinoma and evaluate risk factors for local tumour progression after percutaneous cryoablation.

Methods and Materials: In this retrospective study, 34 consecutive treatment-naïve patients were treated with percutaneous cryoablation for three or fewer nodules smaller than 3 cm in size. The safety of percutaneous cryoablation was evaluated by assessing percutaneous cryoablation-related complications and comparing hepatic function before and after percutaneous cryoablation. The efficacy was evaluated by calculating technical success, local tumour progression rates, and disease progression rates. Furthermore, prognostic factors of percutaneous cryoablation for local tumour progression were analysed.

Results: The technical success rate was 100%, and complete response was achieved in all patients (100%) by 1 month after percutaneous cryoablation. During a mean 24.5 ± 12.0 -month follow-up interval, the incidences of local tumour and disease progression were 11.8% and 38.2%, respectively. The respective cumulative local tumour progression-free and disease-free survival rates were 93.1% and 83.6% at 1 year and 84.0% and 60.7% at 2 years. Hepatic function was normalized within 3 months after percutaneous cryoablation. No major complications occurred other than one case of small haematoma. On multivariate analysis, a minimal ablative margin < 5 mm was a significant risk factor associated with local tumour progression.

Conclusion: Percutaneous cryoablation is an effective and safe therapy for patients with early- or very early stage hepatocellular carcinoma. A minimal ablative margin < 5 mm was a significant prognostic factor for local tumour progression.

B-1444 09:50

TRANS-FUSIMO: preliminary in-vivo animal results of MR-guided focused ultrasound of liver under respiratory motion

C. [Gagliardo](#)¹, P. Toia¹, M. Schwenke², J. Strehlow², L. Cicero¹, G. Cassata¹, A. Melzer², T. Preusser², M. Midiri¹, ¹Palermo/IT, ²Bremen/DE, ³Dundee/UK (cesare.gagliardo@unipa.it)

Purpose: Treating liver tumors using Focused Ultrasound (FUS) is a great challenge. Prior to human applications, an in-vivo animal trial using the TRANS-FUSIMO treatment system (TTS) is ongoing in order to evaluate the safety and the technical efficacy and efficiency of generating predefined necrotic lesions.

Methods and Materials: The trial includes a crossbred porcine model of thirty large white swine (all females; 55-85Kg) that will be treated using the TTS under general anaesthesia with intubation. All treatments have been performed under ventilator-controlled breathing and using an improved non-clinical prototype FUS transducer integrated with a 1.5T MRI unit; a set of interventional flexible coils were used. Before the treatment, a 3D LAVA sequence was scanned; 3D FIESTA sequences were then used for planning. During each sonication, real-time multi reference thermal monitoring was achieved using a 3mm isotropic EPI-GRE slice (8Hz). At the end of the treatment session we injected 2ml/Kg of gadobenate dimeglumine and a 3D LAVA sequence was then scanned to identify any necrotic lesion.

Results: The results from the first successfully treated animals will be presented. Liver lesioning was possible during both breath-hold and ventilator-controlled breathing due to the TTS motion compensation algorithm which allows the HIFU electronic steering to be controlled according to the MRI images. During all pre-clinical sessions, the TTS was used, including real-time multi reference thermal monitoring.

Conclusion: Although the TRANS-FUSIMO animal trial is still ongoing and subject to further optimizations the TRANS-FUSIMO treatment system is capable of perform liver lesions compensating respiratory motion.

Comparison of single shot echo planar imaging and turbo spin echo diffusion weighted imaging of the orbit in patients with uveal melanoma

E. [Gumeler](#), S. Parlak, G. Yazici, E. Karabulut, H. Kiratli, H.K. Karli Oguz; Ankara/TR (ekimgumeler@gmail.com)

Purpose: Although orbital diffusion weighted imaging (DWI) has become an essential part of orbital magnetic resonance imaging, susceptibility to magnetic inhomogeneities of echoplanar imaging (EPI) DWI has inherent obstacles. This study was conducted to compare single shot (SSh) turbo spin echo (TSE) DWI with SShEPI-DWI in patients with uveal melanoma.

Methods and Materials: Both T1, T2 WI and DWI of 32 patients with uveal melanoma were assessed qualitatively including geometric distortion, lesion discrimination and overall quality by two radiologists based on a 4-point scale. Distortion ratio (DR), signal-to-noise (SNR) and contrast-to-noise ratios (CNR) and apparent diffusion coefficient (ADC) measurements for each DWI were noted. General linear model for repeated measurements and Friedman test was applied for comparison. Pearson correlation test was performed to reveal the relationship between T1, T2 and DWI signal intensities.

Results: Geometric distortion was higher in EPI-DWI, overall quality was better in TSE-DWI for both reviewers. One reviewer scored EPI-DWI slightly better for lesion discrimination, the other found no significant difference. DR was higher in EPI-DWI; SNR and CNR were better in TSE-DWI (p<0.05). Pearson correlation demonstrated negative correlation between T1 and both T2, EPI-DWI and TSE-DWI signal intensities (p<0.05 for all). ADC values were also higher in TSE-DWI.

Conclusion: TSE-DWI, less sensitive to magnetic field inhomogeneities and susceptibility artefacts, may be a good alternative to EPI-DWI for orbital imaging. Negative correlation between T1 versus both T2 and DWI signal intensities is a confounding factor, suggesting that the amount of intrinsic melanin may affect the DWI signal.

B-1446 08:38

MRI in the assessment of orbital invasion: diagnostic accuracy and impact on surgical planning

G. [Nocivelli](#), M. Ravanelli, M. Ferrari, A. Deganello, R. Maroldi, D. Farina; Brescia/IT (gnoci89@gmail.com)

Purpose: To assess MRI performance in detecting infiltration of periorbit, extrinsic muscles, apex, nasolacrimal duct (NLD) in patients with nasoethmoidal or maxillary sinus malignancies.

Methods and Materials: Retrospective analysis of 103 MRI (SET2, SET1, VIBE, high resolution matrix, slice thickness ≤3mm) in patients with maxillary (71/103) or nasoethmoidal (32/103) cancer. Periorbital invasion was considered when the tumour was abutting the medial/inferior orbital wall using periorbital focal interruption or irregular tumour-to-extraconal fat interface as criteria. Extrinsic muscle invasion was assessed only in tumours infiltrating intra/extraconal fat, using focal replacement/enhancement of muscular fibers as criteria. Criteria for apex invasion were invasion of optic canal or superior orbital fissure. Criteria for NLD were interruption of bony wall or mucosal layer. Imaging findings were compared to retrospectively revised surgical specimens (exenteratio orbitae 50/103, sparing surgy 53/103).

Results: In the assessment of periorbital invasion MRI obtained sensitivity 57%, specificity 71%, PPV 74%; pathological evidence of neoplastic necrosis is related to significant increase of MRI accuracy. For extrinsic muscles infiltration MRI obtained specificity 86% and NPV 78%, with sensitivity 58% and PPV 70%. Overall accuracy was 76%, significantly higher in the absence of perineural spread. On apex MRI obtained 100% specificity and PPV, sensitivity 56% and NPV 78%. For NLD sensitivity was 89% and NPV 88%, specificity (41%) and PPV (44%) were lower.

Conclusion: Diagnostic performance on periorbital infiltration is limited by microscopic breaches undetectable with MRI, that however generally are treated conservatively. Muscular and apex invasion (decision boundaries for enucleation) is more accurately identified.

B-1447 08:46

The intrinsic iodine content of the thyroid is correlated to the HU value of the thyroid on true non-contrast scans

A.M.J.L. [van Kroonenburgh](#), S.M.J. van Kuijk, A.A. Jacobi-Postma; Maastricht/NL (anna.van.kroonenburgh@mumc.nl)

Purpose: Virtual non-contrast (VNC) scans from Dual energy CT are thought to reflect True non-contrast (TNC) images and could therefore be used as a substitute to lower radiation dose. The difference in thyroid imaging however exceeds the normally accepted 15 HU, this is thought to be due to the intrinsic iodine content of the thyroid. We investigated the correlation between Thyroid Stimulating Hormone (TSH) and the density measurements on TNC and VNC.

Methods and Materials: In the period from November 2016 until June 2018 we included forty-seven patients who underwent a DECT scan of the head neck region. The correlation of TSH values and density measurements on TNC and VNC, as well as the ΔHU between VNC and TNC were calculated.

Results: TSH of patients: mean 2.3, range (0.14-7.1). 35 Patients were euthyroid, 1 hypo- and 4 hyperthyroid. 7 Patients did not have a TSH test prior to the CT scan. Density thyroid VNC: mean 52.2, range (27.8-77.5); Density thyroid TNC: mean 104.0, range (48.0-151.4); deltaHU mean 51.8, range (6.7-110.5). The correlation between TSH and the HU value on TNC scan is 0.32 (p=0.050) and for VNC reconstructions -0.08 (p=0.64).

Conclusion: No correlation between TSH and VNC is found as expected, because the intrinsic iodine is subtracted from the images. The increased organification of iodine due to higher TSH levels is reflected in the density measurements of the TNC. Therefore Δ HU measurements reflect the intrinsic iodine content of the thyroid.

Additional diagnostic value of dynamic MRI sequences in patients with temporomandibular joint dysfunction compared to static imaging

J.-E. [Scholtz](#), D. Günther, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To evaluate the added value of a dynamic magnetic resonance imaging (MRI) sequence for the assessment of the temporomandibular joint (TMJ) compared to standard static MRI sequences in patients with TMJ dysfunction (TMD).

Methods and Materials: In this retrospective study 71 patients with TMD underwent MRI exam. We acquired 5 static T1- and T2-weighted sequences in parasagittal and paracoronal views and one dynamic sequence (trueFISP) in parasagittal view for each TMJ. We evaluated morphology and function of intra-articular structures and rated dynamic images as (1) "more informative", "equal informative", and (3) "less informative" compared to static images.

Results: Mean age was 35±14.7 years and 50/71 (70.4%) were female. 127/142 (89.4%) TMJs were diagnostic. 42 (33.1%) TMJs had no disc displacement (DD), 56 (44.1%) had DD with reduction (DDwR), and 29 (22.8%) had DD without reduction (DDwoR). In 38/127 (29.9%) TMJs, dynamic images were rated "more informative", in 84/127 (66.2%) "equally informative", and in 5/127 (3.9%) "less informative" compared to solely static images for intra-articular structures. Therefore, 27/71 (38.0%) patients benefited from dynamic sequences while dynamic and static sequences were "equally informative" in 44/71 (62.0%) patients. Dynamic images were "more informative" in 23/56 (41.1%) TMJs with DDwR ($p<0.001$) and in 13/29 (44.8%) TMJs with DDwoR ($p=0.007$).

Conclusion: Dynamic MRI sequences are beneficial for evaluation of morphology and function of the TMJ in patients with disc displacement compared to static sequences.

Pilot study of three-dimensional MRI in the evaluation of eye shape of high myopia and classification of posterior staphyloma

L. Zheng, L. Zhang, G. Zhang; *Shanghai/CN (zhenglinfeng04@aliyun.com)*

Purpose: To study the feasibility of quantitative measurement of shape of high-myopia eyes and classification of posterior staphyloma using 3D MRI.

Methods and Materials: 246 eyes with high myopia (Diopter \geq 600 and axial length \geq 26.0 mm) in 129 patients and 50 emmetropia (Diopters -100 to 100, emmetropic eye group) were included in our hospital. Then using 3D-FIESTA sequence and MR scanner, we acquired 3D image data covering entire orbit and reconstructed with volume rendering by workstation. Next, we evaluated eye morphology, shape and extent of posterior staphyloma and relationship of posterior staphyloma with the optic nerve. In addition, length of anterior to posterior (AP), left to right (RL), and superior to inferior (SI) for every eye were measured and the ratios of RL/AP and SI/AP were calculated. Finally, we classified the posterior staphyloma as broad and narrow type according to shape and extent of staphyloma.

Results: Of the 246 high-myopia eyes, 100 eyes showed only axial elongation (axial elongation group), and 146 showed posterior staphyloma (posterior staphyloma group). There was a statistically significant difference in AP line length, ratio of RL/AP and SI/AP (reflected eye ball deformation) among the emmetropic eye group, the posterior staphyloma group and the axial elongation group ($P<0.001$). The age differences between these three different groups were statistically significant ($P<0.001$). Of the 146 posterior staphyloma, 111 were wide-type staphylomas and 35 were narrow-type staphylomas.

Conclusion: 3D MRI is a useful tool to measure quantitatively the morphology of high-myopia eyes, diagnose and classify the posterior staphyloma.

B-1450 09:10

Mineralisation patterns of laryngeal cartilages: normal variations and their clinical impact

R.H. Kshirsagar, N. Sable, A. Mahajan, M. Thakur; *Mumbai/IN (rupalikhshirsagar90@gmail.com)*

Purpose: The aim of our study was to determine the variations in location, distribution, and sex predilection of laryngeal cartilage mineralization, particularly of sclerosis in a population of persons without laryngeal cancer as an aid to understanding the significance of this entity when seen in patients with laryngeal cancer.

Methods and Materials: This is a retrospective study of record-based cross-sectional type. A total of 185 subjects were included in the study after application of the inclusion and exclusion criteria. Two independent observers evaluated the CT images. In case of discrepancy, third radiologist evaluated these scans. The cartilages assessed were thyroid, cricoid and arytenoids. Mineralization was categorized as calcification, sclerosis, and ossification. When the cartilage demonstrated soft-tissue attenuation, it was considered as non-mineralized. The frequencies of total, symmetric and asymmetric mineralization of these cartilages were calculated.

Results: Asymmetric mineralization of the thyroid, cricoid and arytenoid cartilages was seen in 45.4%, 15.7% and 21.1% of our study population, respectively. Asymmetric thyroid, cricoid and arytenoid sclerosis were seen in 4.3%, 1.6% and 7.6% of study population, respectively. Asymmetric thyroid and cricoid sclerosis was more commonly seen in women than in men while asymmetric arytenoid sclerosis was more commonly seen in men than in women, but the differences were not statistically significant. Unilateral arytenoid sclerosis was seen more frequently on the left side compared with the right.

Conclusion: Normal variations in mineralization patterns should be taken into consideration when evaluating CT scans of patients with laryngeal cancer for cartilage invasion to avoid false-positive reads.

Orbital adnexal lymphoma: diagnosis and follow-up with combined [18F]FDG-PET-CT

U.G. Mueller-Lisse, A. Klingenstein, A. Garip-Kuebler, C. Hintschich; *Munich/DE (ullrich.mueller-lisse@med.uni-muenchen.de)*

Purpose: Combined whole-body 18F-fluoro-2-deoxyglucose positron-emission tomography with computed tomography ([18F]FDG-PET-CT) demonstrates location, morphology and metabolism of FDG-avid tumours, such as, e.g., lymphomas. We tested for associations between the maximum of the standardized uptake value (SUVmax for [18F]FDG) and therapy status, lymphoma stage, and histological grading in orbital adnexal lymphoma (OAL).

Methods and Materials: With ethics-committee-approval, pre- and post-therapeutic whole-body-[18F]FDG-PET-CT-scans of 21 patients with OAL diagnosed by means of incisional biopsy between July, 2002, and November, 2016, were identified and re-evaluated for SUVmax in respective OAL tumours in a single-armed retrospective single-centre study. Two-tailed Fisher-exact-tests were statistically significant for $p<0.05$ in contingency tables with SUVmax as the dependent variable and status prior to/after systemic therapy, pre-therapy Ann-Arbor-classification-based lymphoma stage, and histological grading as the respective independent variables.

Results: [18F]FDG-PET-CT showed all OAL lesions. Histology identified 18 malignant B-cell-non-Hodgkin lymphomas, two malignant T-cell-lymphomas, and one systemic lymphoma with associated chronic polypoid sinusitis. SUVmax levels of OALs decreased significantly after systemic therapy ($p<0.001$). Higher-stage OALs showed significantly higher SUVmax levels ($p=0.014$). There were no statistically significant associations between histological tumour grade and SUVmax level.

Conclusion: Whole-body-[18F]FDG-PET-CT in patients with OAL showed significant associations of SUVmax levels in orbital tumours with both tumour stage prior to therapy and therapy status, but not with histological tumour grade. Findings imply that [18F]FDG-PET-CT can be reasonably applied for whole-body staging and follow-up in patients with OAL.

Validation of exophthalmos MRI measurements in patients with Graves orbitopathy, compared to ophthalmometry results

E. Wnuk, E. Maj, A. Jabłońska-Pawlak, O. Rowinski; *Warsaw/PL*

Purpose: Although evaluation of the orbital structures using magnetic resonance imaging (MRI) is well described in literature, there is no consensus on which measurement method is the most useful in exophthalmos assessment. The aim of the study is to correlate two MRI methods of exophthalmos measurement with exophthalmometry results and to determine a proper technique of exophthalmos measurement.

Methods and Materials: Fifty-four patients (108 orbits) with exophthalmos in the course of Graves orbitopathy were enrolled in the study. Two measurements on axial T2W orbital MRI images were performed by two independent radiologists: the distance from the interzygomatic line to the corneal apex (anterior distance) and to the sclera (posterior distance). Within four weeks an exophthalmometry was performed by ophthalmologist using Hertel exophthalmometer. The interobserver variation was assessed by the Pearson correlation coefficient. Values were analysed using mean and standard deviation and t-student test.

Results: On MRI images the mean anterior distance measured by the first observer was 2.06±0.3 cm and by the second observer was 2.06±0.29 cm. The mean posterior distance values were 0.29±0.28 and 0.34±0.28 cm respectively. The mean exophthalmometry result was 2.1±0.33 cm. There was a very high agreement between observers for the anterior ($r=0.98$, $p=0.01$) and high for the posterior ($r=0.95$, $p=0.01$) distance measurement. Exophthalmometry results strongly correlated with MRI anterior distance measurements ($r=0.9$, $p=0.01$).

Conclusion: The distance measurement between the corneal apex and interzygomatic line possesses better reproducibility and is directly correlated with Hertel exophthalmometry. This method is sufficient enough in routine practice.

Evaluation of quantitative shear wave sonoelastography of major salivary glands in Sjögren's syndrome

E. Temel, E. Cindil, S. Ozhan Oktar, N.B. Demir, H.N. Sendur, S. Haznedaroğlu, H. Satis, R. Bilici Salman; *Ankara/TR*

Purpose: To investigate the diagnostic performance of the quantitative elasticity values derived from shear wave elastography (SWE) of the involvement of major salivary glands in patients with Sjögren's syndrome (SS).

Methods and Materials: A total of 134 patients with SS and 30 healthy volunteers were involved in this study. The same ultrasonography device (Logiq E9, GE Healthcare, Milwaukee, WI, USA) with a linear transducer (9 MHz) was used for the SWE imaging of bilateral submandibular and parotid

Comparison of ⁶⁸Ga-DOTATOC PET-MRI and MRI-DWI for whole body staging of patients with neuroendocrine tumours

A. Salem¹, J. Grueneisen¹, B.M. Schaarschmidt², M. Chodyla¹, O. Martin², C. Rischpler³, M. Forsting¹, K. Herrmann¹, L. Umutlu¹; ¹Essen/DE, ²Düsseldorf/DE, ³Munich/DE (ahmed.salem@uk-essen.de)

Purpose: To compare the diagnostic potential of integrated ⁶⁸Ga-DOTATOC Positron emission tomography-magnetic resonance imaging (PET-MRI) and diffusion weighted imaging-MRI (DWI-MRI) for whole-body staging of patients with neuroendocrine tumours (NET).

Methods and Materials: A total of 43 patients with a histopathologically proven NET (50% G1, 30% G2 and 5% G3) underwent a whole-body ⁶⁸Ga-DOTATOC PET-MRI examination 60 minutes after the injection of a mean activity of 60,2 MBq. The MR study protocol comprised the acquisition of a T1w 3D VIBE sequence (pre- and post-contrast), a T2w HASTE and a diffusion-weighted EPI sequence. Two readers evaluated the following datasets 1. whole-body MRI including DWI, 2. ⁶⁸Ga-DOTATOC PET-MRI without DWI regarding (1) lesion detection, (2) lesion conspicuity (4-point ordinal scale) and (3) diagnostic confidence (5-point ordinal scale). Wilcoxon's signed-rank test was used to determine the significance of differences between the ratings.

Results: ⁶⁸Ga-DOTATOC PET-MRI correctly detected 70 malignant lesions. Among them, MRI-DWI enabled correct identification of 59 malignant lesions. Additionally, ⁶⁸Ga-DOTATOC PET-MRI exhibited a significant higher conspicuity (PET-MRI: 2.93 ± 0.75; MRI+DWI: 2.27 ± 0.99) and diagnostic confidence (PET-MRI: 4.59 ± 0.60; MRI+DWI: 4.09 ± 0.88) in the detection of malignant lesions (p<0.01). Furthermore, ⁶⁸Ga-DOTATOC PET-MRI and MRI-DWI showed an equivalent performance in the detection of benign lesions.

Conclusion: Our results demonstrate the superiority of ⁶⁸Ga-DOTATOC PET-MRI in detecting malignant lesions when compared to MR-DWI alone, underlining its superior potential for whole-body staging of patients with NETs when compared to MR-DWI.

B-1457 08:47

Whole body low-dose CT-study combined with model based iterative reconstruction algorithm for follow-up of oncologic patients: image quality and dose deduction

D. Ippolito¹, I. Salemi¹, C. Talei Franzesi¹, C. Maino¹, L. Riva², A. de Vito¹, C. Massimo¹, T. Giandola¹, S. Sironi³; ¹Monza/IT, ²Missaglia/IT, ³Bergamo/IT

Purpose: To compare radiation dose and image quality of low-dose CT protocol combined with iterative model-based reconstruction algorithm (IMR) with standard-dose CT approach combined with hybrid-iterative reconstruction algorithm (iDose) for follow-up of oncologic patients.

Methods and Materials: Ninety-nine patients with known oncological diseases who underwent, during their clinical follow-up, both low dose CT performed on 256-row scanner, with 100 kV and automated mAs modulation (depending on patient weight), and standard-dose CT performed on 256-row scanner, with 120 kV and automated mAs modulation, were enrolled. Images were reconstructed with IMR for the first CT examination and iDose algorithm for the second CT examination. We evaluated density values in liver and spleen and signal-to-noise ratio (SNR), along with image noise, dose parameters and diagnostic quality with 4-point scale.

Results: Noise of images expressed as SD values, measured in liver and spleen, was significantly lower in IMR images (liver 12,09 vs 17,10, p<0,001) whereas SNR was statistically higher (liver 8,55 vs 4,99, p<0,001) compared to iDose reconstruction. Volumetric-Computed-Tomographic-Dose-Index (CTDIvol) and Dose-Length-Product (DLP) were significantly lower in IMR compared to iDose reconstruction (DLP 499,9 vs 872,55 mGy*cm, p<0,001), with overall dose reduction of 42,71%. 4-point scale qualitative analysis did not reveal any significant differences in terms of diagnostic quality (p=0,04).

glands in all patients. Mean shear wave velocity (SWV) in m/s was compared between the patients and healthy volunteers using Student's t-test.

Results: The SWV values of parotid glands did not show a statistically significant difference between the patients with SS and the healthy volunteers (p> 0.05). The SWV values of both submandibular glands showed statistically significant differences between two groups (p< 0.001). The AUROC curves were 0.65 (95% CI: 0.55-0.75) for right submandibular gland and 0.64 (95% CI: 0.55-0.74) for left submandibular gland. The best threshold values were 1.7 and 1.8; sensitivity 63% and 57%, specificity 57% and 67% for the right and left submandibular glands, respectively. The mean SWV values of submandibular glands in both sides showed a moderate correlation with each other (r=0.46, p<0.001).

Conclusion: The steady inclination in technological advances of ultrasound elastography is promising to provide better diagnostic values in process. In current condition, our findings suggest that SWE have a moderate ability to the diagnosis of patients with SS.

B-1454 09:42

Visualisation of the maxillary nerve using a micro-surface coil and three-dimensional double-echo steady state with water excitation sequence

G. Hong, M. Zou, Z. Yang; Guangzhou/CN (zoumsh@mail2.sysu.edu.cn)

Purpose: To display the courses, divisions and lengths of main segments of the maxillary nerve using a small surface coil combined with three-dimensional double-echo steady state with water excitation (3D-DESS-WE) sequence.

Methods and Materials: The maxillofacial region of 49 volunteers were scanned by a small surface coil combined with 3D-DESS-WE sequence. All 77 nerves were evaluated by two neuroradiologists using a 5-point scale (4, excellent; 3, good; 2, fair; 1, poor; and 0, none). The intraclass correlation coefficient (ICC) was used to access interobserver variability. The lengths of maxillary nerve in pterygopalatine fossa (between foramen rotundum and posterior wall of maxillary sinus) was measured. The signal characteristics of the nerves and adjacent structures were analysed. SIR_{NM} (signal intensity ratio of the nerve to superior rectus muscle) were calculated.

Results: In 49 volunteers (77 sides), all 77 maxillary nerve trunks were displayed (100%). Compared with muscles, nerves showed iso-signal intensity (SIR_{NM}=1.10) on 3D-DESS-WE images. Average subjective scores of all small coil 3D-DESS-WE images were close to 3 points (2.56±1.03), and intraclass correlation coefficient (ICC) between two radiologists was 0.91 (p<0.01). The length of maxillary nerve in pterygopalatine fossa (between foramen rotundum and the posterior wall of the maxillary sinus) was 10.81±1.52 mm.

Conclusion: Small surface coil combine with 3D-DESS-WE sequence performed high quality in maxillary nerves MR imaging using MPR, CPR post-processing technology, which are suitable for clinical application.

B-1455 09:50

An audit of the use of ultrasound scanning in investigation of paediatric inflammatory neck masses

P. Gammack, A. Harper, S. Alexander, J. Jones; Edinburgh/UK (pauline.gammack1@nhs.net)

Purpose: This audit was carried out to determine whether first-line ultrasound is necessary for diagnosis and management of children presenting with acute inflammatory neck masses, and aid development of a clinical protocol for such patients.

Methods and Materials: Data was collected regarding patient age, physical findings, symptom duration, ultrasound findings and management using the online 'TrakCare' patient record system.

Results: 73 patients were referred for ultrasound for inflammatory neck masses over 18 months, with an age range 1 month to 12 years 10 months and average age of 3 years 9 months. Of those, 5 (7%) showed an abscess on initial examination and a further 3 showed abscess on subsequent ultrasound. The remaining scans showed either uncomplicated lymphadenitis, lymphadenitis with necrosis/liquefaction, soft tissue inflammation or other non-inflammatory masses such as haemangiomas. Abscess had an average symptom history of 5 days, compared with complicated/uncomplicated lymphadenitis which was diagnosed after average 3 days of symptoms. Most had either fluctuance, erythema or heat on examination. 5 patients underwent subsequent incision and drainage, the remainder were treated either with antibiotics or no treatment. Patients aged 12 months or less were more likely to require incision and drainage.

Conclusion: Ultrasound may not be necessary for a large proportion of such cases, and particularly where symptoms have been present for less than 3 days, where there is absence of fluctuance, erythema and calor and for older children. The new guideline could have a significant impact on the use of ultrasound in such cases.

Conclusion: Automatic tube-current modulation combined with IMR algorithm and low kV setting allows dose reduction of 45,72% in whole body CT imaging without loss of diagnostic quality, thus representing a useful diagnostic approach in reducing dose exposure in oncologic patients who undergo several follow-up studies.

B-1459 09:03

F-18 FDG PET/CT compared to Tc-99m MDP Bone scintigraphy in assessment of metastatic osseous disease in patients with breast cancer and the relation to serum CA15-3 and alkaline phosphatase

H. Nasr¹, N. Alnajashi², A. Alqarni², H. Farghaly³, ¹Cairo/EG, ²Riyadh/SA, ³Assiut/EG (hatemnashr@gmail.com)

Purpose: To assess F-18 FDG-PET/CT compared to Tc-99m MDP bone-scan in assessment of metastatic osseous-disease in breast-cancer patients and the relation to CA15-3 or alkaline-phosphatase serum levels.

Methods and Materials: We reviewed PET/CT and concomitant bone-scans for 37 patients (age 55.38±13.08 years; 36 females) with known metastatic breast-cancer to bone. A visual semi-quantitative metastatic osseous-score was developed after dividing skeleton into 7-zones. Metastatic osseous-score (MS) was calculated for PET/CT (PMS) and bone-scans (BMS). McNemar-test was used to test which study is showing more lesions. ROC analysis used to define the cutoff-values for CA15-3 that best predict additional value for PET/CT over bone scan.

Results: Metastatic skeletal lesions were matched in 20 patients (54.1%). In 13 patients (35.1%) more metastatic burden were detected on PET/CT. In 4 patients (10.8%) more intense lesions were detected on bone-scan (p=0.049). Most of additional lesions on PET/CT were osteolytic/predominantly medullary (new lesions). Lesions with higher uptake on bone-scan were sclerotic with low FDG (non-active healed/healing). CA15-3 was positively correlated to PMS (r=0.386;p=0.018) but not to BMS (r=-0.027;p=0.874). Differently alkaline-phosphatase was positively correlated to both PMS(r=0.389;p=0.017) and BMS(r=0.363;p=0.027). Cutoff-value CA15-3 >47U/ml best predicted additional findings on PET/CT compared to bone-scan (sensitivity, specificity, PPV, NPV and accuracy of 61.5%, 79.2%, 61.5%, 79.2% and 73% respectively (p=0.013)).

Conclusion: FDG-PET/CT is more sensitive in detecting metastatic osseous lesions and tends to identify new osteomedullary lesions. Higher CA15-3 correlates to metastatic osseous burden on PET/CT but not on bone-scan and predicts more metastatic osseous involvement on FDG-PET/CT compared to bone-scan.

B-1460 09:11

Comparison of capability for TNM stage assessment among whole-body MRI and PET/MRI at different field strength and FDG-PET/CT in non-small cell lung cancer

Y. Ohno¹, K. Aoyagi², M. Yui², Y. Kishida¹, S. Seki¹, T. Yoshikawa¹, T. Murakami¹, ¹Kobe/JP, ²Otawara/JP (yosirad@kobe-u.ac.jp)

Purpose: To prospectively and directly compare TNM stage assessment capability among whole-body MRI and PET/MRI at 1.5 and 3T MR systems and FDG-PET/CT in non-small cell lung cancer (NSCLC) patients.

Methods and Materials: 104 consecutive pathologically diagnosed NSCLC patients (62 men, 42 women; mean age 71 years) prospectively underwent whole-body MRI at 1.5T and 3T systems, integrated PET/CT, and surgical, pathological and/or follow-up examinations. Final diagnoses of T, N and M factors and clinical stage in each patient were determined according to all examination results. Then each factor and clinical stage were visually assessed on both whole-body MRIs, PET/MRIs and PET/CT with contrast-enhanced brain MRI. Kappa statistics were used to determine agreements for assessment of all factors and clinical stage with final diagnoses, and McNemar's test was used to compare each diagnostic accuracy among all methods.

Results: On each factor and clinical stage assessments, agreements between all methods and final diagnosis were substantial or almost perfect (0.60<k<0.98). Diagnostic accuracies of N factor and clinical stage on whole-body MRI as well as PET/MRI at both field strengths were significantly higher than those of PET/CT (p<0.05).

Conclusion: Whole-body MRIs and PET/MRIs at 1.5T and 3T systems have significantly better potential for N factor and clinical stage assessments than PET/CT in NSCLC patients.

Does PET/MR improve lesion detection in oncology: a prospective uncentre study in 1003 examinations

B.M. Schaarschmidt¹, O. Martin², J. Kirchner², J. Grueneisen¹, P. Heusch², M. Forsting³, G. Antoch², K. Herrmann¹, L. Umutlu¹, ¹Essen/DE, ²Düsseldorf/DE

Purpose: To investigate if positron emission tomography/magnetic resonance (PET/MR) imaging improves lesion detection and characterization and reduces radiation exposure in oncological tumour staging in comparison to PET/computed tomography (PET/CT).

Methods and Materials: A total of 1003 oncological whole-body examinations in 918 patients (mean age 57.8y, 400 female, 518 male) were included in this prospective single-centre study. In all patients, PET/CT was performed prior to PET/MRI. A consensus reading was performed for both examinations by board-certified nuclear medicine physicians and radiologists. Analyses of additional lesions and missed lesions in PET/MR compared to PET/CT as well as indeterminate findings in PET/CT that could be classified by PET/MR were performed. Furthermore, the effective dose of PET/MR as well as full- and low-dose PET/CT was analysed. Lesion detection between PET/MR and PET/CT was compared using McNemar's test. Mean effective doses were analysed using paired t tests. p<0.001 indicated statistical significance.

Results: Additional lesions were detected in 26.3% (264/1003) of all examinations by PET/MR. This resulted in a TNM change in 2.9% (29/1003). Only in 2.9% (29/1003) cases, lesions were missed by PET/MR that were visible in PET/CT, resulting in a TNM change in 0.5% (5/1003). Indeterminate findings in PET/CT could be classified by PET/MR in 11.1% (111/1003). Radiation exposure could be significantly reduced by PET/MR by 83.2% compared to full-dose PET/CT and by 36.1% compared to low-dose PET/CT (p<0.001, respectively).

Conclusion: In comparison to PET/CT, PET/MR leads to improved lesion detection and reduced radiation exposure, which might be especially beneficial in paediatric patients.

Prospective comparison of whole-body MRI and ⁶⁸Ga-PSMA PET/CT for the detection of biochemical recurrence of prostate cancer

L.M. Sawicki¹, C. Buddensieck¹, J. Boos¹, J. Kirchner¹, T. Ullrich¹, R. Rabenalt¹, P. Albers¹, G. Antoch¹, H. Hautzel¹, ¹Düsseldorf/DE (Linomorris.sawicki@med.uni-duesseldorf.de)

Purpose: To assess whole-body MRI (wb-MRI) for detection of biochemical recurrence of prostate cancer (PCa) after curative treatment in comparison to ⁶⁸Ga-PSMA PET/CT.

Methods and Materials: 30 patients (mean age: 64.9±8.8 years) with newly documented biochemical recurrence of PCa (mean PSA 2.11 ± 1.97 ng/ml) following curative therapy prospectively underwent both wb-MRI including a dedicated pelvic imaging protocol and PET/CT with 167±35 MBq ⁶⁸Ga-PSMA within 10.4±9.6 days. PET/CT and MRI were separately evaluated regarding PCa lesion count, type, localization, and diagnostic confidence (3-point scale; 1-3) by two physicians. The reference standard was based on histopathology results, PSA following targeted salvage irradiation, and follow-up imaging. Lesion-based and patient-based detection rates were compared using chi-square test. Differences in diagnostic confidence were assessed by Welch test.

Results: A total of 58 PCa lesions were detected in 22/30 patients in the study cohort. ⁶⁸Ga-PSMA PET/CT detected 57/58 (98.3%) lesions in 21/30 (70%) patients, while wb-MRI detected 15/58 (25.9%) lesions in 13/30 (43.3%) patients. The higher detection rate of ⁶⁸Ga-PSMA PET/CT was statistically significant both on a per-lesion (p=0.001) and per-patient (p=0.039) basis. In 8/30 (26.7%) patients no relapse was detectable with both modalities. Except for one local recurrence in the former prostate fossa that was exclusively detected by wb-MRI, all lesions detected by wb-MRI were also detectable on ⁶⁸Ga-PSMA PET/CT. Additionally, ⁶⁸Ga-PSMA PET/CT offered superior diagnostic confidence in identifying PCa lesions (2.7±0.6 vs. 2.3±0.6, p=0.011).

Conclusion: ⁶⁸Ga-PSMA PET/CT significantly outperformed wb-MRI for the detection of biochemical recurrence in PCa patients after curative treatment.

B-1463 09:35

Whole body MR imaging and MR-guided biopsy in initial diagnosis and follow-up of paediatric malignancies: comparison with other imaging modalities

T. **Woerner**, A. Buecker, G. Schneider; *Homburg/DE*
(*Tobias.Woerner@uks.eu*)

Purpose: 79 paediatric oncologic patients underwent whole body MRI for staging and follow-up. When necessary biopsy of tumours was performed under MR guidance for histologic proof of primary tumours or for proof of recurrence or metastases. Results were compared with established staging procedures incl. PET.

Methods and Materials: 389 whole body examinations in 79 patients were performed on either a 1.5 or 3 T scanner (Siemens, Aera/VIDA) 24 lymphoma, 37 solid tumours including neuro-, nephro- and hepatoblastoma as well as 18 pts. with different types of sarcoma were evaluated. Protocol included T1w sequences pre- and post-CM (0.05 mmol/kg BW MultiHance) and in the hepatobiliary phase, DWI, transversal T2w TSE sequences and a coronal whole-body STIR-sequence. If indicated MR-guided biopsy of tumours/metastases or recurrent disease was performed to acquire tissue samples.

Results: Differences between MRI and CT were seen regarding the higher number of detected small lung metastases (<3 mm) on CT. Advantages for WB-MRI were seen in follow-up of T-cell Lymphoma, in which MRI could show PET-negative residual disease under chemotherapy and in local staging of sarcoma. MRI facilitated detection of recurrent tumours and restaging in solid tumours, especially in Ewing-sarcoma.

Conclusion: WB-MRI can correctly stage and diagnose a variety of malignant tumours in paediatric patients and allows for accurate patient management during therapy including MR-guided biopsy. Advantages of established imaging methods were only seen for detection of small lung metastases on pulmonary CT, however differences did not result in a change of patient management.

Utility of 3T MRI whole-body DWI in onco-imaging for the detection of metastasis: comparison with PET/CT

D.H. **Vijayakumar**¹, M.M. Kulkarni², ¹Bangalore/IN, ²Mumbai/IN
(*deepti202@gmail.com*)

Purpose: To evaluate the role of whole-body diffusion-weighted MRI in onco-imaging for the detection of metastasis using 3 Tesla MRI and compare its accuracy with PET/CT.

Methods and Materials: A prospective study of total of 35 patients with histopathologically proven primary malignancy or metastasis who underwent both whole-body diffusion-weighted MRI and PET/CT within 15 days of each other with no surgical or medical intervention in between. Whole-body diffusion-weighted MRI along with fast m-DIXON sequence was performed on Philips Ingenia 3 T machine. Reformatted and source images were analysed for lesions showing restricted diffusion, suggesting metastasis. Data were tabulated on the basis of presence or absence of metastasis in various regions, number of lesions and correlated with 18 FDG PET/CT.

Results: High correlation on Pearson's correlation test and very good agreement on Kappa's test was found between DWIBS and PET/CT in detecting skeletal, lung and liver metastasis. On a case-based analysis, our study showed 94.9% sensitivity and 95.4% accuracy as compared to PET/CT. On a lesion- based analysis, 87.5% sensitivity and 85.8% accuracy was found in whole-body DWIBS as compared to PET/CT.

Conclusion: Whole-body DWIBS with a high b value of 1000s/mm² is comparable to the current gold standard in detection metastases, i.e. PET/CT and can be used as a screening modality as it is quick and safe. DWIBS is excellent for the detection of brain metastases, which are generally missed on PET/CT.

B-1465 09:51

Impact of spectral imaging in patients suspected for occult cancer: a study of 93 patients

M.B. **Andersen**¹, D. Ebbesen², J. Thygesen³, M. Kruis⁴, F.R. Rasmussen³, ¹Roskilde/DK, ²Viborg/DK, ³Aarhus/DK, ⁴Copenhagen/DK
(*mibrandersen@gmail.com*)

Purpose: To investigate the diagnostic impact and performance of spectral dual-layer detector CT in cancer compared to CE-CT.

Methods and Materials: In a national workup program for occult cancer ninety-three patients prospectively enrolled had a contrast-enhanced Philips IQon Spectral CT scan. The readings were performed with and without spectral data available. A minimum of 3 months between interpretations were implemented to eliminate recall bias. The sequence of reads for the individual patient was randomised. Readers were blinded for patient identifiers and

clinical outcome. Two radiologists with 9 and 33 years of experience performed the readings in consensus. If disagreement, a third specialist radiologist with 11 years of experience determined the outcome of the reading.

Results: Significantly more (probable) cancer findings were identified on the spectral reading (six vs. one, p=0.03). Eight probable cancer findings on CE-CT were excluded as cancer on spectral CT. In thirty-four possible cancer findings, spectral added to the diagnosis in nineteen cases. For the possible cancer findings, spectral information was strongly correlated with a difference between the spectral and conventional reading (P<0.001). Hundred and four benign lesions were found on CE-CT and spectral datasets (multiple lesions per patient could be present). In the conventional readings, the radiologists were entirely certain about the benignity in 60% of the cases and in the spectral readings in 89% of the cases (p<0.0001).

Conclusion: In conclusion, we find that access to spectral data adds to find (probable) cancer or exclude the diagnosis. Furthermore, it increases the radiologists' certainty about benign lesions.

Gadoxetic acid-enhanced liver MR can predict tumour recurrence after curative treatment for small single hepatocellular carcinoma

D. **Lee**, J. Lee; *Seoul/KR* (*dhlee.rad@gmail.com*)

Purpose: To determine significant predictive factors of tumour recurrence after curative treatment for single nodular HCCs ≤ 3cm.

Methods and Materials: This retrospective study was approved by the institutional review board. A total of 373 patients with single nodular HCCs ≤ 3cm who underwent pre-treatment gadoxetic acid-enhanced MR followed by hepatic resection (n=143) or radiofrequency ablation (RFA) (n=230) were included. We analysed their clinicopathological and MR features to determine which features may help predict the presence of microvascular invasion (MVI) or recurrence-free survival (RFS). RFS was estimated using Kaplan-Meier analysis and significant predictive MR findings for RFS were evaluated using Cox-proportional hazard regression model.

Results: Non-smooth tumour margins on hepatobiliary phase (HBP) were significantly associated with MVI in 143 patients treated by hepatic resection (P=0.048, odds ratio=2.60 [1.01-6.69]). In addition, non-smooth tumour margins (hepatic resection: P=0.012, hazard ratio [HR]=2.17 [1.19-3.97]; RFA: P=0.019, HR=1.79 [1.10-2.91]) and presence of non-hypervascular HBP hypointense nodules (hepatic resection: P=0.001, HR=3.55 [1.74-7.23]; RFA: P<0.001, HR=2.12 [1.40-3.20]) were significant negative predictive factors of RFS after both hepatic resection and RFA. When high-risk MR findings for recurrence were defined as the presence of non-smooth tumour margins and/or non-hypervascular HBP hypointense nodules, 5-year RFS in patients with high-risk MR findings was significantly lower than in those without after both hepatic resection (31.1% vs. 74.2%, P<0.001, HR=3.56 [1.94-6.55]) and RFA (24.3% vs. 54.6%, P<0.001, HR=2.38 [1.62-3.51]).

Conclusion: Non-smooth tumour margins and the presence of non-hypervascular HBP hypointense nodules were significant predictive factors of tumour recurrence after either hepatic resection or RFA.

B-1467 08:34

Radiomics of gadoxetic acid-enhanced MRI: a predictive biomarker for CK19-positive hepatocellular carcinoma

W. **Wang**¹, Y. Ding¹, L. Yang¹, M. Zeng¹, S.-X. Rao¹, J. Tian²; ¹Shanghai/CN, ²Xi'an/CN (*787356268@qq.com*)

Purpose: To develop and validate a radiomics signature-based model derived from gadoxetic acid-enhanced MR images to preoperatively identify cyokeratin (CK) 19-positive hepatocellular carcinoma (HCC).

Methods and Materials: A cohort of 227 patients with single HCC was classified into a training set (n=159) and a time-independent validated set (n=68). A total of 647 radiomic features were extracted from multi-sequence MR images separately. The least absolute shrinkage and selection operator regression and decision tree methods were utilized for feature selection and radiomics signature construction. A further multivariable regression model was

built incorporating clinical factors and the fusion radiomics signature with significant relation to CK19 expression.

Results: In the whole cohort, 57 patients were positive for CK19 and 170 patients were negative for CK19. Based on 11 and 6 radiomics features extracted in arterial phase and hepatobiliary phase images, a fusion radiomics signature achieved a satisfying performance with an AUC of 0.951 and 0.822 in training and validation datasets. The final combined model integrated serum a-fetoprotein levels, arterial rim enhancement pattern, irregular tumour margin and the fusion radiomics signature, with a sensitivity of 0.818 and specificity of 0.974 in the training cohort and that of 0.769 and 0.818 in the validated cohort. The nomogram based on the combined model showed satisfactory prediction performance in training (C-index: 0.959) and validation (C-index: 0.846) dataset.

Conclusion: The radiomics signature-based model derived from arterial phase and hepatobiliary phase images of gadoxetic acid-enhanced MR imaging can be a reliable biomarker for identifying CK19-positive HCC.

B-1468 08:38

Intra-individual comparison of the MRI contrast agents gadoxetic acid vs gadoteric acid in liver MRI of patients with HCC and underlying cirrhosis

M. Della Seta, F. Colletti, M. Schmelzle, N. Raschzok, B. Hamm, T. Denecke; Berlin/DE (marta.della-seta@charite.de)

Purpose: To the best of our knowledge, the ability of liver-specific contrast agents to produce enhancement characteristics analogous to those obtained with extracellular contrast agents during the early perfusion phases was never confirmed. The aim of our prospective study is to intra-individually compare the two contrast media in patients with HCC and underlying cirrhosis.

Methods and Materials: Twenty-four patients with HCC diagnosis underwent two liver MR examinations at 3T, one with gadoteric acid and one with gadoxetic acid. Quantitative evaluation using regions of interest was performed. Our endpoints were the evaluation of peak maximum enhancement between both contrast agents in the lesion with reference to normal tissue, the evaluation of wash-out, with reference to the healthy liver, and the analysis of signal-to-noise and contrast-to-noise values.

Results: Twenty-three patients had adequate image quality. Relative peak enhancement was significantly higher ($p < 0.001$) for gadoteric acid (176.4±95.9; CI: 215.6-137.2) than for gadoxetic acid (101.7±100.8; CI: 142.9-60.5). The wash-out of gadoteric acid was significantly stronger compared to gadoxetic acid (20.5±17.1; CI:27.6-13.5 vs. 7.9±19.4; CI:15.9-0) ($p=0.006$). The CNR after administration of the liver-specific contrast agent and the extracellular contrast agent also showed a significant difference ($p=0.005$). The SNR between the two contrast media did not differ significantly ($p=0.39$).

Conclusion: Gadoteric acid shows a significantly higher relative peak enhancement and a significantly stronger wash-out compared to gadoxetic acid. After the administration of the two contrast media the CNR differs significantly as well. No significant difference in SNR was found between the two contrast agents.

MRI of hepatocellular adenomas: is there an additional value of using Gd-EOB for subtype differentiation?

T.A. Auer¹, C. Grieser², D. Geisel¹, B. Hamm¹, T. Denecke¹; ¹Berlin/DE, ²Bremen/DE (timo-alexander.auer@charite.de)

Purpose: Morphologic and enhancement characteristics to differentiate among hepatocellular adenoma (HCA) subtypes evaluated with gadoxetic acid-enhanced MRI.

Methods and Materials: Sixty-four patients with 100 histopathologically proven HCA examined with gadoxetic acid-enhanced MRI were retrospectively enrolled (standard of reference: surgical resection, n=92; biopsy, n=7). Three radiologists evaluated all MR images regarding morphological features as well as the vascular and hepatocyte-specific enhancement in consensus. Histopathological subgroup analysis was based on the Bordeaux classification (including steatotic (H-HCA), inflammatory (I-HCA), b-catenin (b-HCA) and unclassified (U-HCA) adenomas).

Results: Overall, 29 H-HCA (29%), 41 I-HCA (41%), 6 b-HCA (6%) and 24 U-HCA (24%) were present. For differentiation of HCA subtypes, presence of intralesional fat (H-HCA, n=27; I-HCA, n=5, b-HCA, n=1; U-HCA, n=3), atoll sign (I-HCA, n=25) and a central scar (b-HCA) were significant ($p < 0.001$). For hepatobiliary phase, most HCA were visually found being hypointense (overall: 71%; H-HCA = 96.5%; I-HCA = 53.5%; b-HCA = 80%, U-HCA = 66.6%). Relative enhancement was not significant between the different HCA subtypes ($p=0.674$).

Conclusion: Following the Bordeaux classification, typical morphologic MR appearances of the different HCA subtypes are present and reliable. On hepatobiliary phase, most HCA show hypointensity; however, I-HCA is the most heterogeneous subtype and some present with a characteristic patchy uptake pattern. Combining Gd-EOB behaviour, the qualitative MR characteristics and predisposing risk factors increase sensitivity for a more accurate diagnosis. In our collective, sensitivity increased by combining atoll sign and heterogeneous Gd-EOB-uptake in the diagnosis of I-HCA.

B-1470 08:46

Quantification of hepatic steatosis: evaluation of 4 MRI techniques vs reference method by biopsy

C. Boudinaud, A. Abergel, M. Fontarensky, J. Joubert Zakeyh, L. Boyer, B. Magnin; Clermont-Ferrand/FR (claireboudinaud@msn.com)

Purpose: Given the growing prevalence of obesity and metabolic syndrome, the management of hepatic steatosis is a major issue. We assessed the quantification of hepatic steatosis using 4 different MRI methods, to determine which was the most correlated to the reference method, that is, histological measurement by liver biopsy.

Methods and Materials: Sixty patients requiring liver biopsy in non-tumour tissue, whatever the indication, were included prospectively at Clermont-Ferrand University Hospital between March 2017 and March 2018. In parallel, a liver MRI (1.5T) was performed using 4 different steatosis quantification techniques (3-echo MRImaging, 6-echo MRImaging, 11-echo MRImaging and MRSpectroscopy). Quantitative histological and imaging data were compared. In secondary analyses, we studied the possible influence of alcohol drinking, hepatic iron overload, or the presence of liver fibrosis.

Results: All four MRI techniques were found to have an excellent correlation with histological measurement: 3-echo MRImaging ($r = 0.852$, $p < 0.001$), 6-echo MRImaging ($r = 0.819$, $p < 0.001$), 11-echo MRImaging ($r = 0.818$, $p < 0.001$), and MRSpectroscopy ($r = 0.812$, $p < 0.001$). The presence of alcohol, iron overload or fibrosis did not interfere with reliability, whichever technique was used.

Conclusion: In the evaluation of hepatic steatosis, our study showed a high correlation of the 4 MRI techniques with the histological standard; MRSpectroscopy appearing as the less reliable, 3-echo MRImaging as the highest correlated (this, without compounding factor in a large population).

B-1471 08:50

The value of MRI-PDFF in detecting and grading hepatic steatosis in patients with nonalcoholic fatty liver disease: a meta-analysis

Z. Ye, X. Xiong, J. Chen, L. Cao, T. Duan, Z. Zhang, B. Song; Chengdu/CN (948080771@qq.com)

Purpose: To evaluate the diagnostic performance of magnetic resonance imaging-proton density fat fraction (MRI-PDFF) in detecting and grading hepatic steatosis (HS) in nonalcoholic fatty liver disease (NAFLD) patients.

Methods and Materials: A comprehensive literature search was conducted to identify studies on the diagnostic accuracy of MRI-PDFF for the assessment of biopsy-proven HS. The degrees of HS were histopathologically defined as mild (>5% steatosis), moderate (>33% steatosis) and severe (>66% steatosis), according to nonalcoholic steatohepatitis clinical research network scoring system. Data were extracted to calculate the pooled sensitivity, specificity, positive and negative likelihood ratios, as well as the area under the summary receiver operating characteristic curve (AUC) in each group.

Results: 16 studies with 1277 subjects were included in this meta-analysis. The pooled sensitivity, specificity, positive likelihood ratio and negative likelihood ratio were estimated to be 0.87 (95% confidence interval [CI]: 0.84-0.90), 0.94 (95% CI:0.91-0.97), 12.83(95% CI:5.93-27.78) and 0.13 (95% CI:0.08-0.22) for the detection of mild HS with MRI-PDFF, 0.80 (95% CI:0.76-0.84), 0.91 (95% CI:0.88-0.93), 7.83 (95% CI:5.68-10.80) and 0.21 (95% CI:0.15-0.29) for the detection of moderate HS, and 0.74 (95% CI:0.67-0.80), 0.92 (95% CI:0.89-0.94), 7.05 (95% CI:4.96-10.04) and 0.29 (95% CI:0.18-0.47) for the detection of severe HS, respectively. The AUCs for mild, moderate and severe HS detection were 0.96(95% CI:0.95-0.97), 0.94(95% CI:0.92-0.95) and 0.92(95% CI:0.90-0.94), respectively. Substantial heterogeneity was observed. No publication bias was detected.

Conclusion: MRI-PDFF shows high diagnostic accuracy in detecting and grading HS and may serve as a noninvasive tool for evaluation of HS in NAFLD patients.

B-1472 08:54

Dual-energy CT in patients with fatty liver disease: improved assessment of hypoattenuating liver lesions using virtual monoenergetic imaging

L. Lenga¹, I. Yel¹, C. Booz¹, S.S. Martin², J.-E. Scholtz¹, T.J. Vogl¹, J.L. Wichmann¹, M.H. Albrecht¹; ¹Frankfurt/DE, ²Charleston, SC/US (lukas.lenga@gmail.com)

Purpose: To assess the impact of noise-optimized virtual monoenergetic imaging (VMI+) on delineation and measuring accuracy of hypoattenuating liver lesions in patients with fatty liver disease compared to standard reconstruction.

Methods and Materials: Twenty-eight patients with fatty liver disease and hypoattenuating liver lesions who had undergone unenhanced and contrast-enhanced portal-venous dual-energy CT were included in this retrospective study. In addition to standard linearly-blended M_0.6 reformats, noise-optimized virtual monoenergetic images (VMI+) were reconstructed in 10-keV intervals. Contrast-to-noise ratio (CNR) of the liver parenchyma was analyzed and the best VMI+ series was further subjectively investigated. Image quality and lesion margin demarcation were evaluated. Size measurements of all hypodense lesions (n=61) were performed in a predefined sequence independently two times. Inter- and intra-rater agreement was assessed using Intraclass correlation coefficient (ICC).

Results: The calculated CNR was greatest at 40-keV VMI+ (5.8±3.8 HU), significantly higher compared to standard reconstructions (3.5±1.5 HU) (P<0.001). Furthermore, 40-keV VMI+ provided the best subjective overall image quality (P≤0.194). Margin demarcation of liver lesions was found to be superior for 40-keV VMI+ compared to standard linearly-blended image series (P≤0.001). Inter-observer agreement for lesion measurements was higher for 40-keV VMI+ reconstructions (ICC, 0.87) vs standard images (ICC, 0.69). Intra-observer agreement was greater for 40-keV VMI+ (mean ICC, 0.94), in comparison with linear-blended reconstructions (mean ICC, 0.82).

Conclusion: Noise-optimized VMI+ reconstructions significantly improve contrast and demarcation of hypoattenuating liver lesions in patients with fatty liver disease compared to standard reconstruction, which translates into improved inter- and intra-rater agreement for quantitative size measurements.

CT-based liver surface nodularity score for noninvasive assessment of clinically significant portal hypertension

A. Abou Elkassem¹, A.M.K. Abdel Aal¹, A. Gunn¹, K. Mahmoud¹, S. Lirette², A. Smith¹; ¹Birmingham, AL/US, ²Jackson, MS/US (akamel@uabmc.edu)

Purpose: To evaluate the accuracy of the CT-based liver surface nodularity (LSN) score to detect clinically significant portal hypertension (CSPH) in patients with chronic liver disease (CLD).

Methods and Materials: For this retrospective study, we identified 46 adult patients with HCV, alcoholic or NASH compensated CLD and contrast-enhanced abdominal CT imaging within 6 months of hepatic vein pressure gradient (HVPG) measurements obtained between 2004 and 2018. The LSN score was measured using custom software. Total liver volume, liver segmental volume ratio (segments I-III vs. IV-VIII), splenic length/volume, and portal vein width were measured from the CT images. A HVPG ≥10 mmHg was used to define CSPH. The accuracy for predicting CSPH was assessed by receiver operating characteristics area under the curve (AUC).

Results: CSPH was present in 63% of patients. In patients with HVPG<10 mmHg vs. CSPH, the average LSN scores were 2.23 vs. 2.55 (p<0.001), average splenic volumes were 426 vs. 736 cc (p=0.031), average splenic lengths were 12.8 vs. 14.9 cm (p=0.037), average FIB-4 indices were 3.17 vs. 5.83 (p=0.038), and average MELD scores were 12.0 vs. 16.0 (p=0.041). Other CT metrics did not have a significant difference (p>0.05). The accuracy for predicting CSPH was highest with the LSN score (AUC=0.80) as compared to splenic volume, splenic length, FIB-4 index, and MELD score (AUC=0.69 for each). The probability of having CSPH increased about fivefolds for each standard deviation increase in LSN score (OR: 5.36; 95%CI: 1.69, 17.0; p=0.004).

Conclusion: The CT-based LSN score accurately detects CSPH in patients with CLD.

Clinical significance of pancreatic steatosis: association between pancreatic exocrine insufficiency and organ fat content

M.-L. Kromrey¹, N. Friedrich¹, R.-T. Hoffmann², R. Bülow¹, U. Motosugi³, J.-P. Kühn¹; ¹Greifswald/DE, ²Dresden/DE, ³Yamanashi/JP (marie-luise.kromrey@uni-greifswald.de)

Purpose: To investigate the relationship between pancreatic fat content and depression of pancreatic exocrine function.

Methods and Materials: In 1,458 volunteers (681 men, mean age 52.8 years) receiving whole-body MRI, pancreatic fat content was quantified by proton-density fat fraction (PDFF). Additionally, hepatic, visceral and subcutaneous fat volumes were determined. Association of organ fat content with exocrine pancreatic function measured by faecal elastase (normal function: >200 µg/g, n=1,319; moderate restriction:100-200µg/g, n=110, manifest restriction: <100 µg/g, n=29) was performed using age, gender and BMI-adjusted linear regression models.

Results: Mean pancreatic fat content was significantly higher in subjects with decreased compared to normal faecal elastase levels (9.36±4.95% vs 7.30±3.59%, p<0.01; overall mean: 7.50±3.78%). An inverse association between pancreatic fat and enzyme levels was detected for the whole study population (beta: -7.19 [standard error: 1.39]; p<0.01) as well as in the subgroup with normal function (-4.26 [1.32]; p<0.01), whereas subjects with restriction in exocrine pancreatic function displayed just a trend towards an inverse relation (-1.28 [0.84]; p<0.13). Concerning other fat compartments, linear regression analyses showed no significant associations between hepatic, visceral or subcutaneous fat and faecal elastase.

Conclusion: An inverse relationship between pancreatic fat content and faecal elastase levels suggests an association of pancreatic steatosis with a restriction of pancreatic exocrine function.

B-1475 09:06

T1 mapping of autoimmune pancreatitis as a quantitative outcome biomarker

L. Zhu¹, Z.-y. Sun¹, Z.-y. Jin¹, T.-y. Qian¹, D. Nickel², M. Makowski³, P. Asbach³, B. Hamm³, H.-d. Xue¹; ¹Beijing/CN, ²Erlangen/DE, ³Berlin/DE (zhuliang_pumc@163.com)

Purpose: To investigate the ability of T1 mapping to visualize and quantify the short-term and mid-term improvement of autoimmune pancreatitis with corticosteroid treatment (CST), and to correlate T1 relaxation time of the pancreas with clinical status and serum IgG4 levels.

Methods and Materials: The institutional review board approved this prospective study and all patients provided written informed consent. Pancreatic MR, including native T1 mapping, was performed in 33 AIP patients before and during CST, and in 20 patients without pancreatic diseases (as control). T1 relaxation time of the pancreatic head, body and tail was measured separately in each patient. Clinical symptoms and serum IgG4 level of the patients in the mean time of the MR scan were recorded.

Results: The T1 relaxation time of AIP was significantly elongated compared to normal pancreatic tissue (1124.5±95.7 ms vs 784.3±41.8 ms, p<0.001). After short-term CST (4 weeks) treatment, the T1 relaxation time of AIP already shortened significantly (957.2±97.3 ms, p<0.001), and after mid-term CST (12 weeks), the T1 relaxation time further shortened towards normalization (844.2±71.6 ms, p<0.001). In 27 AIP patients with elevated serum IgG4 at baseline, T1 relaxation time shows positive correlation with serum IgG4 level (r=0.289, p=0.011). In 6 AIP patients with normal serum IgG4 level at baseline, T1 relaxation time shortening was in accordance with or preceded symptom relief.

Conclusion: T1 mapping can be used to evaluate parenchyma inflammation of AIP and quantify response to treatment. It provides a quantitative outcome surrogate for AIP.

B-1476 09:10

Combination of diffusion kurtosis imaging and conventional MRI helps to differentiate fibrotic from inflammatory bowel strictures in patients with Crohn's disease

J. Du, X. Li, L. Huang, S. Huang, Z. Li; Guangzhou/CN (dujinfangchn@163.com)

Purpose: Distinguishing fibrotic from inflammatory strictures is an important clinical requirement. We evaluated the value of diffusion kurtosis imaging (DKI) in combination with conventional MRI for characterising Crohn's disease (CD) strictures using surgical histopathology as a reference standard.

Methods and Materials: 31 consecutive CD patients undergoing conventional MRI and DKI (b values of 0-2000 s/mm²) before surgery were recruited. We observed T2WI hyperintensity and enhancement pattern on conventional MRI, and measured apparent diffusion coefficient (ADC), apparent diffusional kurtosis (Kapp) and apparent diffusion for non-Gaussian distribution (Dapp) on

DKI. A model with combined MRI variables was proposed for characterisation of intestinal strictures, and its performance was validated on 9 new CD patients.

Results: Histologic inflammation scores significantly correlated with T2WI hyperintensity ($r=0.477$, $P<0.001$), ADC ($r=-0.226$, $P=0.044$) but not with enhancement pattern ($r=0.037$, $P=0.746$). A strong correlation of histologic fibrosis scores with Kapp ($r=0.604$, $P<0.001$) was found, followed by Dapp ($r=0.491$, $P<0.001$) and ADC ($r=-0.270$, $P=0.015$). Using T2WI hyperintensity as a predictor, conventional MRI could differentiate mild from moderate-to-severe inflammation with a sensitivity of 0.970 and a specificity of 0.479. Kapp enabled to identify non-mild from moderate-severe fibrosis with a sensitivity of 0.959 and a specificity of 0.781. The MRI strictured classification that combining of T2WI hyperintensity and Kapp moderately agreed with the pathological classification ($\kappa=0.507$, $P<0.001$). In the validation set, there was a moderate agreement between the MRI and the pathological classification ($\kappa=0.530$, $P<0.001$).

Conclusion: Combination of DKI and conventional MRI helps to characterise bowel strictures in CD patients.

B-1477 09:14

Perfusion fraction derived from IVIM-DWI may facilitate differentiation of moderate to severe inflammation in ulcerative colitis

J. Podgórska, K. Pasicz, E. Zagórowicz, A. Mróz, B. Gołębiowski, P. Kus, J. Jasieniak, W. Skrzyński, A. Cieszanowski; *Warsaw/PL* (ipodgo@gmail.com)

Purpose: To determine the efficacy of intravoxel-incoherent motion (IVIM) parameters in assessment of inflammatory activity of ulcerative colitis in reference to histopathological examination.

Methods and Materials: In this prospective study 20 adult patients with ulcerative colitis underwent 3T magnetic resonance diffusion weighted imaging (DWI) with b-values of 0, 10, 30, 50, 75, 100, 150, 200, 500, 900 s/mm² within 1-6 days of endoscopic evaluation with biopsies. The inflammatory activity of bowel segments (rectum, sigmoid, descending, transverse, ascending colon) was graded using a six-grade classification system for inflammation. IVIM-derived parameters (f , D and D^*) calculated from ROIs placed within the bowel wall were correlated with the histopathologic score. T-test was used for comparison and ROC curve analysis was performed.

Results: In total 33 bowel segments were analysed. For comparison two data groups were created: inactive or mild activity (grade 0-2, $n=23$) and moderate to severe activity (grade 3-5, $n=11$). Statistically significant differences between both groups were found in f (mean = 0.19, SD = 0.09 and mean = 0.28, SD = 0.13, $p=0.024$; AUC = 0.723, sensitivity 0.82, specificity 0.59, accuracy 0.67 for cut-off value 0.185) and D (mean = 1.34×10^{-3} mm²/s, SD = 0.36×10^{-3} mm²/s and mean = 1.07×10^{-3} mm²/s, SD = 0.20×10^{-3} mm²/s, $p=0.0083$; AUC = 0.735, sensitivity 0.91, specificity 0.54, accuracy 0.66 for cut-off value 1.24×10^{-3} mm²/s). No significant difference was found in D^* .

Conclusion: IVIM-derived perfusion fraction may facilitate distinguishing moderate to severe inflammation from less active or inactive disease in ulcerative colitis.

B-1478 09:18

Machine learning-based analysis of rectal cancer MRI radiomics for prediction of metachronous liver metastasis

M. Liang, X. Zhao; *Beijing/CN* (lm_1202@163.com)

Purpose: To use machine learning-based MRI radiomics to predict metachronous liver metastases (MLM) of rectal cancer patients at baseline treatment.

Methods and Materials: This study retrospectively analysed 108 patients with rectal cancer (54 in the MLM and 54 in the non-metastasis group). Feature selection were performed in the radiomic feature sets extracted from images of T2WI and venous phase (VP) sequence respectively, and the combining feature set with 2058 radiomic features incorporating T2WI and VP sequences with the least absolute shrinkage and selection operator method. Fivefold cross-validation and two machine learning algorithms (support vector machine, SVM; logistic regression, LR) were utilized for MLM predictive model building. The diagnostic performance of the models were evaluated by ROC curves with indicators of accuracy, sensitivity, specificity and area under the curve (AUC), and compared by DeLong test.

Results: Five, 8, and 22 optimal features were selected from 1029 T2WI, 1029 VP, and 2058 combining features, respectively. Four-group models were constructed using the 5 optimal T2WI features (Model_{T2}), the 8 optimal VP features (Model_{VP}), the combined 13 optimal features (Model_{combined}), and the 22 optimal features selected from 2058 features (Model_{optimal}). In Model_{VP}, the LR was superior to the SVM algorithm ($P=0.0303$). The Model_{optimal} using the LR algorithm showed the best prediction performance ($P=0.0019-0.0081$), with accuracy, sensitivity, specificity, and AUC of 0.80, 0.83, 0.76, and 0.87, respectively.

Conclusion: Radiomics models based on baseline rectal cancer MRI has high potential for MLM prediction, especially the Model_{optimal} using the LR algorithm. Moreover, except for Model_{VP}, the LR was not superior to the SVM algorithm for model construction.

B-1479 09:22

MRI-detected extramural vascular invasion is a strong risk factor in predicting distant metastasis in rectal cancer

P. Tripathi¹, D. Hu¹, M. Zeng², W. Guo², S. Rao², B. Rai¹; ¹Wuhan/CN, ²Shanghai/CN (pratik9_band@hotmail.com)

Purpose: Extramural vascular invasion (EMVI) has been recommended as an independent prognostic factor for poor overall survival rate in rectal cancer. We aimed to evaluate the MRI-detected EMVI (mrEMVI) in predicting (synchronous) distant metastasis in T3 rectal cancer.

Methods and Materials: Histopathologically confirmed T3 rectal cancer patients who underwent preoperative MRI without previous treatment were enrolled for this study. Two blinded radiologists evaluated the location of the tumour, the degree of mesorectal extension and mrEMVI. mrEMVI was further categorized into EMVI positive and EMVI negative in T2-weighted image using mrEMVI scoring system. The results along with other clinical characteristics (age, sex, tumour location, MRI detected the distance of mesorectal extension, lymphatic invasion, perineural invasion, mrEMVI score and CEA) were then correlated with synchronous metastases to determine the risk factors.

Results: Among 180 patients, 38 patients were confirmed to be mrEMVI positive, 142 patients mrEMVI negative. There were a total of 34 patients with synchronous metastasis in which 25 were mrEMVI positive and 9 were mrEMVI negative. Three factors were significantly associated with synchronous metastasis: mrEMVI ($p=0.001$; OR=8.665), histopathological lymphatic invasion ($p=0.001$; OR=12.940) and preoperative CEA ($p=0.026$; OR=4.124). mrEMVI score 4 was more liable for synchronous metastasis ($p=0.044$; OR=9.429) than mrEMVI score 3 in rectal cancer.

Conclusion: There is an intimate relationship between mrEMVI and synchronous metastasis in rectal cancer. mrEMVI positive is an independent risk factor for synchronous distant metastasis in rectal cancer. mrEMVI score 4 is a strong risk factor for synchronous metastasis than mrEMVI score 3 in rectal cancer.

B-1480 09:26

DWI and high-resolution T2WI-volumetry association with lymphovascular invasion and N-stages in resectable rectal cancer

X. Chen, H. Li; *Chengdu/CN* (20shenbaise@163.com)

Purpose: To determine whether diffusion-weighted imaging (DWI)-volumetry and high-resolution T2-weighted imaging (T2WI) MR-volumetry could predict lymphovascular invasion (LVI) and N-stages in resectable rectal cancer.

Methods and Materials: 50 consecutive patients with rectal cancer who underwent radical surgery in 1-week after DWI and high-resolution T2WI were retrospectively identified. Gross tumor volume (GTV) was evaluated on DWI and high-resolution T2WI. Univariate and multivariate analyses were performed to determine whether GTV could predict LVI and lymph node metastasis (LNM). Mann-Whitney U test was performed to compare GTV among N-stages. Cutoffs of GTV were investigated using area under the receiver operating characteristic curve (AUC) analysis for predicting LVI and N-stages.

Results: DWI-GTV and T2WI-GTV increased with LVI ($r=0.750$ and 0.710 , $P<0.0001$, respectively) and increasing of N stage ($r=0.780$ and 0.755 , $P<0.0001$, respectively). Univariate analysis showed DWI-GTV and T2WI-GTV could predict LVI ($P<0.0001$). Multivariate analyses indicated only DWI-GTV as an independent risk factor of LVI ($P=0.005$, odds ratio=1.207) and LNM ($P=0.005$, odds ratio=1.420). The Mann-Whitney U test showed DWI-GTV and T2WI-GTV could distinguish N0 from N1, N0 from N1-2, N0-1 from N2 ($P<0.0001$). DWI-GTV could predict LVI (cutoff, 11.05cm³; AUC, 0.899), and distinguish N0 from N1 (cutoff, 10.86cm³; AUC, 0.865), N0 from N1-2 (cutoff, 10.46cm³; AUC, 0.934), N0-1 from N2 (cutoff, 17.7cm³; AUC, 0.932). T2WI-GTV could predict LVI (cutoff, 13.74cm³; AUC, 0.877), and distinguish N0 from N1 (cutoff, 12.25cm³; AUC, 0.827), N0 from N1-2 (cutoff, 13.36cm³; AUC, 0.911), N0-1 from N2 (cutoff, 20.43cm³; AUC, 0.927).

Conclusion: High-resolution T2WI-GTV and DWI-GTV of resectable rectal cancer were correlated well with the LVI and LNM, but the latter is a potentially more promising non-invasive technique that can help predict the preoperative LVI and distinguishing N-stages.

B-1482 09:30

Prediction of gastric and esophagogastric junction cancer response to neoadjuvant treatment by functional imaging with PCT

J. Kruk-Bachonko, W. Krupski, T. Skoczylas; *Lublin/PL* (asiakruk1@wp.pl)

Purpose: The Perfusion Computed Tomography (P-CT) exam has shown encouraging results for prediction of tumor response to chemotherapy (CHT) and radiochemotherapy (RCT) in gastric and esophagogastric junction cancer.

We studied time course of perfusion parameters values changes in patients treated with neoadjuvant treatment (CHT and RCT). The aim of this study was to prospectively evaluate these findings by using functional perfusion parameters.

Methods and Materials: 59 patients with gastric cancer qualified for systemic treatment (36 patients received chemotherapy and 23 patients received radiochemotherapy) were involved in to P-CT exam. Study protocol involved baseline P-CT exam before neoadjuvant therapy and P-CT after neoadjuvant therapy before surgical treatment. Perfusion-CT exam examined the following parameters: Blood Flow (BF), Blood Volume (BV), Mean Transit Time (MTT) and Permeability Surface (PS). Positive clinical response to neoadjuvant treatment was defined as tumor size reduction 25% or more.

Results: Responders showed a higher baseline BF and BV value than non-responders and showed statistically significant ($p < 0,05$) BF and BV decrease after therapy. Linear regression of tumor size reduction and perfusion parameters showed significant positive correlation between responders' PS ($p < 0,05$) value and tumor size reduction after neoadjuvant therapy. Linear regression showed significant negative correlation between the baseline MTT value ($p < 0,05$) and tumor size reduction after neoadjuvant therapy.

Conclusion: P-CT revealed a positive prediction value of P-CT in early responders and non-responders patients identification. A full evaluation of gastric cancer treatment should include P-CT exam as a standard procedure.

B-1483 09:34

Added value of MRI to endoscopic and endosonographic response assessment after neoadjuvant chemoradiotherapy in oesophageal cancer: a pilot study

S.E. Vollenbrock, J.M. van Dieren, F.E.M. Voncken, S.T. van Turenhout, L.L. Peppelenbosch-Kodach, K.J. Hartemink, B.M.P. Aleman, R.G.H. Beets-Tan, A. Bartels-Rutten; *Amsterdam/NL (s.vollenbrock@nki.nl)*

Purpose: In order to select oesophageal cancer patients after neoadjuvant chemoradiation (nCRT) for organ-preserving treatment instead of surgery, complete response (CR) assessment must be accurate. As endoscopic and endosonographic assessment with biopsies of the primary tumour area and fine needle aspiration (FNA) of lymph nodes is known to result in a high number of false negatives, our aim is to determine the added value of MRI.

Methods and Materials: Twenty-two patients with locally advanced oesophageal cancer underwent MRI (1.5 T, T2W+DWI); b-values 0,200,800 s/mm², endoscopy with biopsies and endosonography with FNA after nCRT. One radiologist scored MRIs using a 5-point score (1=definitely CR, 2=probably CR, 3=inconclusive, 4=probably residual tumour, 5=definitely residual tumour). Histopathology of the resection specimen was the reference standard (Mandard tumour regression grade 1=pathological CR, 2-5=residual tumour). Sensitivity and specificity of residual tumour detection were calculated for endoscopy+endosonography, and for endoscopy+endosonography including MRI.

Results: Three (14%) of 22 patients achieved a pCR. Endoscopy with biopsies and endosonography with FNA found residual tumour in 9 of 19 patients with residual disease (sensitivity 47%). After adding MRI, 17 of 19 residual tumours were assessed correctly (sensitivity 89%). All complete responders had negative endoscopic biopsies (specificity 100%); one was incorrectly assessed as residual tumour on MRI (specificity 67%).

Conclusion: The addition of MRI to endoscopic and endosonographic response assessment improves detection of residual tumour after nCRT in oesophageal cancer patients.

B-1484 09:38

Multiparametric combined FDG-PET/CT and MR imaging to predict response to chemoradiotherapy in rectal cancer: whole tumour versus sub-volume analysis

N.W. Schurink¹, M. Berbee², J.J.M. van Griethuysen¹, W. van Elmpt², M. Maas¹, M.J. Lahaye¹, F.C.H. Bakkers², R.G.H. Beets-Tan¹, D.M. Lambregts¹; ¹Amsterdam/NL, ²Maastricht/NL (n.schurink@nki.nl)

Purpose: To assess the individual and complementary performance of quantitative parameters from pre-treatment multiparametric MRI and FDG-PET/CT to predict treatment response in rectal cancer.

Methods and Materials: A pilot group (n=20) underwent multiparametric MRI (T2W + DWI; b0, 100, 500, 1000) and FDG-PET/CT before neoadjuvant treatment + surgery. Images were anatomically co-registered using rigid + non-rigid registration. Whole-tumour volumes were segmented on T2W-MRI and transferred to the other modalities/sequences; each tumour was additionally divided into 7x7x7mm³ sub-volumes. The following parameters were calculated per-tumour and sub-volume: T2-texture (uniformity/entropy), T2-signal intensity (SI), ADC (mean/max/min/median/10th and 90th percentile), SUV (mean/max/median), and CT-HU. Performance to predict poor response (Mandard TRG3-5) vs. good response (TRG1-2) was calculated using ROC analysis for [1] each individual parameter (whole-tumour), [2] multiparametric combination of the 5 best-performing parameters (whole-tumour), and [3] the proportion (%) of 'poor-response' sub-volumes within the tumour. Sub-volumes

were defined as 'poor response' when ≥ 4 (out of 5) parameters within that sub-volume were indicative of TRG3-5, using a cut-off derived from dichotomisation by median split.

Results: Best single predictive parameters were T2-uniformity (AUC 0.78), T2-SI (AUC 0.70), ADCmax (AUC 0.76), SUVmax (AUC 0.78) and SUVmean (AUC 0.73). Combined multiparametric performance (whole-tumour) was AUC 0.91. The proportion of 'poor-response' sub-volumes resulted in AUC 0.74.

Conclusion: Multiparametric analysis of quantitative MRI and FDG-PET/CT data has potential added value to predict response to neoadjuvant treatment. If there is a potential benefit for performing sub-volume (or voxel-wise) analysis, this needs to be established by further and larger studies; with our current method, we have so far not demonstrated a clear added value.

B-1485 09:42

Rectal wall T2 relative signal intensity: a non-invasive biomarker of gastro-intestinal (GI) toxicity in patients treated with pelvic radiotherapy (RT)

G. Della Vecchia, A. Di Chiara, M. Panzeri, A. Palmisano, A. Esposito, P. Passoni, C. Fiorino, A. Del Maschio, F. De Cobelli; *Milan/IT*

Purpose: GI toxicity is commonly experienced by patients with pelvic neoplasia treated with RT. A non-invasive biomarker of GI toxicity may help patient's management. In Patients with locally advanced rectal cancer (LARC) treated with chemioradiotherapy, GI toxicity is expected for RT direct on rectal wall. Aim was to evaluate the relative modification of T2w rectal wall signal intensity (T2ratio) during and after treatment in relation to the degree of GI toxicity experienced.

Methods and Materials: Sixty-six patients with LARC underwent 1,5 T MRI before, after 6 weeks and at the end of CRT. An ROI was manually drawn on rectal wall and obturator muscle on T2w images at each time point and the relative T2 ratio (Sirectum/SImuscle) calculated. GI toxicity was scored following National Cancer Institute Common Terminology Criteria for Adverse Event in: G0=absent, G1=low, G2=medium, G3=high.

Results: 5 patients resulted G0, 28 G1, 25 G2 e 8 G3. T2 ratio was significantly different only at post CRT (median G0=1.17, G1=2.42, G2=2.36, G3=3.31; $p: 0.041$). A cut-off value of 1.785 was able to predict GI toxicity (G1-3) with 0.82 AUC, 84% and 72% of sensitivity and specificity. A cut-off value $> 2,675$ predicted G3 with 0.75 AUC, 75% sensitivity 60% specificity. No significant difference among T2ratio and GI toxicity was found at before and during CRT.

Conclusion: T2 ratio could be a helpful non-invasive biomarker of GI toxicity, that could be apply in other setting of pelvic RT.

Brain CT with 64- and 16-slice CT scans: comparison of image quality and radiation dose with standard protocols

M.M. Abuzaid¹, W. Elshami¹, A.A. Suliman², C. Kappas³; ¹Sharjah/AE, ²Alkharj/SA, ³Larissa/GR (mabdelfatah@sharjah.ac.ae)

Purpose: The purpose of this study was to compare radiation dose and image quality of 16- and 64-MDCT scanners during brain procedures.

Methods and Materials: CT scan parameters and patient data were collected for 40 patients who underwent routine brain scan protocol. Average values of CT DIvol, DLP and effective dose (ED) were calculated and compared for the two scanners. Three radiologists evaluate independently image quality using a 5-point scale, as well as select a preferable image.

Results: The DLP and effective dose values are higher for 64-slice CT (1160 mGy/cm and 2.55 mSv) versus 16-slice CT (670 mGy/cm and 1.47 mSv), The p value was less than 0.05, which is statistically significant. In terms of image quality, 64CT scanners images scored higher than 16CT scanner with average scores of 4.5 and 4.0, respectively. In preferred image selection, radiologists preferred the 64CT scanner images in 15 out of 18 image sets (83%), significance of $p < 0.01$.

Conclusion: The high number of detectors produces high image quality and increases the amount of radiation dose received by the patients. Optimizing of scanning protocol leads to ensure that patient dose is within the level of acceptance limits.

B-1487 10:38

Physicians knowledge and perceptions of radiation dose and inherent risks in computed tomography examinations

M. [Gharbi](#), F. Aouini, H. Kamoun; *Tunis/TN (manel.gharbi88@yahoo.fr)*

Purpose: Integrating CT into routine care has improved patient health care dramatically. Despite these great medical benefits, there is concern about the potential radiation-related cancer risk. Consequently, dose reduction and radiation protection is a topic of scientific concern. The purpose of this study was to evaluate the knowledge of physicians prescribing CT examinations on the radiation protection of patients.

Methods and Materials: This descriptive study was performed from the 22nd January to the 12th February 2018 at the military hospital of Tunis. A questionnaire was distributed to all clinician on medical staff. Several questions related to their prescription pattern and their knowledge of radiation protection.

Results: We identified 94 physicians. 73 of them (77.7%) responded to our questionnaire. The mean of professional experience was 8 years. 42.5% of clinicians prescribing CT examinations were interns and resident and 57.7% were senior doctors. While 80.8% of physicians claimed that they considered the risks from exposure to ionizing radiation when prescribing a CT examination, only 16.4% informed their patients about those risks. Knowledge of the radiation dose delivered during CT evaluation of the abdomen and pelvis was poorly understood and the risks related to small doses of radiation were grossly underestimated. Finally, only 19.2% of clinicians had received training with regards to radiation protection.

Conclusion: In the present study, knowledge gaps concerning computed tomography radiation doses and associated health risks are evident. It seems that only the attendance of a radiation protection course has a positive influence on the physician's level of knowledge.

B-1489 10:54

Adaptive statistical iterative reconstruction for computed tomography of the spine

M. [Tsuda](#); *Yonago/JP (joey.no.1@hotmail.co.jp)*

Purpose: To evaluate the effect of adaptive statistical iterative reconstruction technique for sagittal CT of the spine.

Methods and Materials: An improved adaptive statistical iterative reconstruction algorithm (ASiR-V) was used in this study. Sagittal planes of all images were reformatted to 2.0 mm thickness, and were reconstructed using filtered back projection (FBP), blending 50%, and 100% levels of ASiR-V (ASiR-V₅₀, ASiR-V₁₀₀, respectively). Subjective image quality was assessed on a five-point scale by three radiographers. We assessed the images of 32 patients. For objective assessment, modulation transfer function (MTF) was measured using a custom phantom to estimate z-axis resolution. Noise power spectrum (NPS) was measured using a cylindrical water phantom and 2.0-mm thick axial images to evaluate image noise.

Results: There were significant subjective differences in each reconstruction; ASiR-V₁₀₀ was scored the highest. There were no enhancements in degeneration of z-axis resolution using ASiR-V in all contrast images. NPS curves demonstrated that ASiR-V was less efficient for reducing image noise.

Conclusion: ASiR-V effectively improved image noise and image quality for sagittal CT of the spine.

B-1490 11:02

CT scan chest: a new approach to lung cancer

A. [Bernardo](#), F. Gonçalves, M.O. Fernandes; *Lisbon/PT (abernardo@hospitaldaluz.pt)*

Purpose: Demonstrate the evolution of the radiation's dose reduction with the use of new technologies; Compare radiation dose's applied in TC Thorax screenings with the European Guidelines on Quality Criteria for Diagnostic Radiographic Images (EGQCRI).

Methods and Materials: A sample of 157 cases was used - 122 performed with the *SOMATOM Force CT* (Siemens Healthcare AG) and 35 performed with the *SOMATOM Emotion 16 TC* (Siemens Healthcare AG); *Syngo Plaza* (Siemens Healthcare AG) was used to consult images and the radiation's dose. Results were recorded on Excel sheets, as well as the respective means and the standard deviations; We compared the results obtained with the t-Student statistical test between the TC Low dose's of *SOMATOM Emotion 16* and *SOMATOM Force* using the SPSS program; Radiation dose values were compared between the *TC SOMATOM Force* and the reference values present in the EGQCRI.

Results: It was verified that there is a statistically significant difference between the parameters of radiation doses between the different equipment used ($p < 0.0001$), within a reliable range of 95%, nonetheless maintaining diagnostic quality; When comparing the radiation doses of the *CT SOMATOM Force* with the ones of the EGQCRI, we can see that they are similar in value.

Conclusion: We concluded that new technological approaches about CT have brought a significant radiation's dose reduction, being nowadays equated to the RX Thorax. Several parameters may have an influence on the final image quality and should be adjust to guarantee diagnostic quality on this type of study.

B-1491 11:10

Prophylaxis of contrast-induced nephropathy in computed tomography procedures by use of low-osmolality contrast media and good hydration

H.H. [Mansour](#); *Gaza/PS (husam-RT2007@hotmail.com)*

Purpose: To settle the prophylaxis strategy for reducing the effect of IV contrast on the development of post -CT examination acute injury nephropathy.

Methods and Materials: Cross-sectional study for a total of 60 patients (32 males and 28 females) who received iodinated contrast agents during CT procedures over a period of one month. CIN was defined as a relative increase of >25% or an absolute increase of >0.5 mg/dL in serum creatinine levels 3 days post-CT procedure. Patients who undergo intravenous contrast CT procedures were included in this research to ensure good preparation and follow-up.

Results: Paired t test was used to study the differences between urea and creatinine pre- and post-contrast media. The test revealed no statistically significant differences between urea pre-CT exam (mean= 35.3, SD = 15.2) and post-CT with contrast media (mean= 33.9, SD = 25.4) with $t = 0.52$ and p value= 0.608. Moreover, the study shows that no statistically significant differences between creatinine pre-CT test and post-contrast media CT (mean= 0.96, p value = 0.27) and post-CT with contrast media (mean= 0.95, p value =0.48) with $t = 0.52$ and p value= 0.608.

Conclusion: Low-osmolality contrast media and good hydration pre- and post-IV contrast administration are the preventive approaches to a declination of CIN.

B-1492 11:18

Eye lens protection: new perspective

A.J.C.D. [Cunha](#); *Braganza/PT (altinoc@gmail.com)*

Purpose: Cataract is, according to World Health Organization (WHO), an eye lens opacity which prevents clear vision, being responsible for 51% of world blindness, affecting 20 million people (2010). Most of the cases are related to ageing process or it may develop after eye injuries, inflammation, and some other eye diseases. Food concerns is a quite trendy issue nowadays, so it plays an important role on people daily routine, as they seek for a healthy way of life.

Methods and Materials: Ionizing radiation (IR) is an important source in the generation of free radicals such as superoxide radical and hydroxyl radical, among the various physical/chemical agents; interacts with cells and produces cytotoxic effects. So IR is a proven human carcinogen and cataractogen. The crystalline lens of the eye is among the most radiosensitive tissues in the body. A literature review demonstrates that evidence and the antioxidant and radioprotective effects of several food components, such as Propolis and its component Caffeic Acid Phenethyl Ester (CAPE).

Results: What if we could merge eye lens radiation protection and food? Could it be possible to prevent or reduce radiation-induced cataract by changing food habits or introducing new kinds of foods on our daily routines? Studies shows that after irradiation, cataract rate drop 30 % in Propolis and 40 % in CAPE.

Conclusion: In a near future we will prevent the occupational exposure to ionizing radiation with not only individual protection equipment and but also with individual protection food, changing the radiation protection as we know it.

B-1493 11:26

Development of 3D printed quality control tool for X-Ray beam alignment and collimation evaluation

M.V.L. [Oliveira](#), J. Barros; *Salvador/BR (marcusradiology@gmail.com)*

Purpose: To develop a 3D printed low-cost tool for evaluation of X-ray beam alignment and collimation

Methods and Materials: The study was divided in two phases: 1) 3D printed prototype development and 2) Comparison with commercial test object. A 3D printer was used for developing two objects, with 40% of infill and printed with two filaments: PLA (Polylactic acid) and ABS (acrylonitrile butadiene styrene). Two X-ray equipment (SIEMENS, model MULTIX B) were used for Beam Collimation and Beam Alignment tests. For validation, it was compared with a commercial Collimator / Beam Alignment Test Tool.

Results: The tests performed with the prototype and the standard tool showed deviation of ± 1 cm between the light and radiation field. The Central Ray perpendicularity was evaluated through the coincidence between the rod and the metallic circle. The test of CR alignment held with a standard tool showed the axis perpendicularity of 1.5° while both prototypes presented less than 3° .

Conclusion: The prototypes proved to be an effective tool and easy to handle. The variety of printing materials and the ease on filament acquisition reflect the low cost of production.

B-1494 11:34

Portuguese diagnostic reference levels national survey

J. Santos¹, P.M. Teles², M.C. Sousa¹, G. Paulo¹, J. Venancio², F. Caseiro Alves¹, A. Figueira³, P. Rosario², P. Vaz²; ¹Coimbra/PT, ²Lisbon/PT, ³Porto/PT (joanasantos@estescoimbra.pt)

Purpose: National survey was carried out in Portugal in order to establish national Diagnostic Reference Levels (DRL's) per for specific radiography and CT examinations involving all the societies and the government agency responsible for radiation issues.

Methods and Materials: Exposure parameters and dose values for the most frequent radiography and CT consider the most commune procedure type or clinical information. Data from 10 standard patients per procedure was collected on the participating centres and submitted on the website "NRD Portugal". Equipment brand, technology and quality control details were also obtained.

Results: The majority of the centres revealed that equipment quality control was performed by the manufacture (51%). Data from 1590 standard patients submitted to radiography and CT was analysed. DRL's for specific indications were defined for radiography: chest routine, pelvic arthrosis, standing abdominal, lumbar spine without osteosynthesis material; and for CT: head for trauma, head for stroke, chest routine, high resolution chest, abdomen for liver metastases and trunk. Significant differences were founded for head CT trauma and stroke dose values. However no differences were founded in chest CT dose values for routine and high resolution CT.

Conclusion: This was the first Portuguese national survey promoted that considers clinical information on the most frequent radiography and CT examinations. As expected CT technology can contribute to high dose reduction. The majority of Portuguese DRL's are according to the literature.

B-1495 11:42

FORRM: a pilot research mentoring scheme for radiographers in the UK: what have we achieved? An evaluation

C. Malamateniou¹, F. Mellor², R. Appleyard³, H. McNair¹, K. Knapp⁴; ¹London/UK, ²Bournemouth/UK, ³Sheffield/UK, ⁴Exeter/UK (christina.malamateniou@gmail.com)

Purpose: The programme's main aim was to increase research capacity for Radiography in the UK by formal one-to-one mentoring of radiography practitioners/novice radiographer researchers by senior members of the radiography research community.

Methods and Materials: Twelve mentoring pairs were recruited, matched and supported by mentoring training and three networking and evaluation events. A steering committee facilitated this scheme. An action research qualitative methodology was used and purposive sampling. Written reflective accounts of all mentees and mentors at the end of the 9-month project were collected and focus group discussion notes were kept. Informed consent and research ethics approval was sought at the beginning of the project. Data was analysed using thematic analysis. Descriptive statistics was also used to highlight overall results on key outcomes. This was a pilot study funded by the Society of Radiographers.

Results: The majority of mentoring pairs met their agreed targets; This scheme was able to improve research capacity within radiography in all of the following categories: i) increase research outputs (abstracts, papers, presentations etc), ii) improve career prospects of Radiographer mentees and iii) enhance personal development. Mentees and mentors discussed benefits, opportunities and challenges of the scheme. Important recommendations were discussed for a future launch of the scheme, subject to securing renewed funding.

Conclusion: This pilot scheme was the first formal radiography mentoring scheme to help build research capacity in the UK. There have been many benefits for mentees, mentors and the profession and lessons learned, which will hopefully be applied to a future round.

B-1496 11:50

Dementia patient care in the medical imaging department

R. Challen, L.-F. Low, M.F. McEntee; Sydney/AU (rachelchallen94@gmail.com)

Purpose: People with dementia have difficulties with memory, executive functions and behaviour which pose a challenge during diagnostic imaging. There is abundant literature on the radiographic diagnosis of dementia; however, there is little research on how to best to care for people with dementia during imaging procedures. The aim of this study is to explore the experiences of dementia care in imaging departments through the perspectives of people with dementia, carers, radiographers and student radiographers.

Methods and Materials: This was a cross-sectional qualitative study. Four people with dementia and six carers participated in individual semi-structured interviews; eight academic radiographers and 19 student radiographers participated in focus groups. Interviews and focus groups were transcribed and thematically analysed.

Results: Participants described positive and negative experiences during imaging procedures. Common themes existed among people with dementia, carers and radiographers. Findings were (1) people with dementia and carers had negative experiences such as distress and pain; radiographers experienced stigma and violence. (2) Negative experiences during imaging were associated with disrespected personhood, poor communication, insufficient knowledge of dementia, inappropriate time management, overly stimulating physical environments and exclusion of carers. (3) Departmental protocols that contributed to negative experiences included lack of preparation, lack of dementia protocols, and the use of restraints.

Conclusion: People with dementia and their carers can experience poor care in imaging departments and radiographers can find it difficult working with people with dementia. Radiographers need training about dementia, imaging services can improve their procedures and environment, and work in greater partnership with carers.

A clinically driven new classification for aortic dissections

S. Malekzadeh¹, D. Bodenmann², A. Topolski¹, A.-M. Jouannic¹, S.D. Qanadli¹; ¹Lausanne/CH, ²Frauenfeld/CH (soonazmalakzadeh@gmail.com)

Purpose: To report a new classification for aortic dissections (AD), based on a modified Stanford classification, to consider the aortic arch as a separate entity and integrate patterns influencing treatment strategy notably malperfusion syndrome (MPS). The proposed classification was evaluated in a large population of ADs.

Methods and Materials: All patients with proven de novo acute AD who were admitted to our hospital from 2005 to 2017 were included in this study. All pre-therapy CT angiographies were reviewed and reclassified using the new classification based on three types and four subtypes: Type: A, dissection involving at least the ascending aorta; Type B, dissection involving exclusively the descending aorta; and type C, dissection involving the aortic arch with/without descending aorta. Subtype: 0; absence of MPS; 1, dynamic MPS; 2, static MPS; 3, static and dynamic MPS.

Results: A total number of 228 consecutive patients were included in the study. According to the new classification, AD were distributed as 153 type A, 50 type B (38B0, 5B1, 6B2, 1B3) and 25 type C (18C0, 6C2, 1C3). The new type represented 11% of all ADs. MPS was present in 28% of type C. Treatment strategies in type C included endovascular interventions and surgery in 32% and 12%, respectively.

Conclusion: The new classification is easy to use and feasible in a large group population. It should be helpful driving the decision making process and especially in integrating the latest development in trans-catheter therapies.

B-1498 10:47

Application value of dual-source CT combined with intelligent modulation and iterative reconstruction in aortic dissection imaging

P. Jin; Chengdu/CN (pujin_online@163.com)

Purpose: To explore the clinical application value of second-generation dual-source CT combined with intelligent modulation and iterative reconstruction in emergency aortic dissection imaging

Methods and Materials: 40 emergency patients with clinical suspected aortic dissection were included in this study. Conventional scanning was performed in the conventional group, and large-pitch intelligent modulation and iterative reconstruction were performed in the control group. The mean CT value, mean noise, signal noise ratio, contrast noise ratio, effective radiation dose, image quality and aortic root image quality were evaluated and analyzed

Results: 40 patients successfully completed CT aortic dissection imaging. There was no difference in image quality between the conventional group and the control group ($t=1.283, P>0.05$). The quality of aortic root images in the control group was better than that in the conventional group, and the difference was statistically significant ($\chi^2=22.556, P<0.05$). The mean CT value and mean noise of aorta in the conventional group were slightly higher than those in the control group. However, SNR and CNR in the control group were higher than those in the conventional group, and the difference was statistically significant ($t=-21.042, -15.924, 8.530, 11.495, P<0.05$). The radiation dose of the conventional group was significantly higher than that of the control group, the difference was statistically significant ($t=-12.327, P<0.05$)

Conclusion: The combined intelligent modulation technique and iterative reconstruction technique of dual-source CT large pitch scan can guarantee the image quality and reduce the radiation dose, and can be used as a conventional imaging method of emergency CT aortic dissection.

B-1499 10:55

Role of the cardio-synchronised computed tomography angiography in the dissection of descending thoracic aorta

C. Ruggieri¹, S. Veglia, A. Ruffino, G. Ciccone, A. Evangelista, O. Davini; Turin/IT (*chiara_ruggieri@virgilio.it*)

Purpose: To identify a possible role of the cardio-synchronized computed tomography angiography (CTA) in the dissection of descending thoracic aorta (DTA).

Methods and Materials: We retrospectively analysed 23 exams performed using cardio-synchronized CTA (retrospective gating) in suspected acute aortic syndromes or in chronic thoracic dissections. We measured the total vessel areas (TOTA), and the areas of the true (TLA) and false lumen (FLA) at 2 levels (2 cm below the isthmus and 3 cm above the diaphragm). We made measurements in 2 arterial phases (40% and 75% of the cardiac cycle) and in the venous one (no cardio-synchronized acquisition).

Results: In the venous acquisition the average TLA in mm² (SD) was, respectively, 445 (278) and 410 (267) in the proximal and distal points (intermediate values compared to 40% and to 75% phases). The TLA average (SD) in the 40% and 75% phases was, respectively, 462 (283) and 419 (276) in the proximal site; 436 (269) and 388 (267) in the distal site. So it was significantly larger in the 40% vs 75% phase both in the proximal site (mean difference 42.9, 95% CI: 23.8-62.0, p = 0.0001) and in the distal point (mean difference 47.4, 95% CI: 30.7-64.0), p < 0.0001). No significant differences emerged for the TOTA.

Conclusion: We demonstrated that intimal flap dynamic and lumen variations (essential aspects in the aortic dissection) are significantly affected by the various phases of the cardiac cycle. These data lead to think a possible role of cardio-synchronized CTA in follow-up of DTA dissection.

B-1500 11:03

Thoracic aortic fluid dynamics in bicuspid valve patients: correlations with valvular morphology using 4D-flow magnetic resonance imaging

G. Pambianchi, N. Galea, I. Carbone, F. Cilia, F. Catapano, M. Francone, C. Catalano; Rome/IT (*giacomo.pambianchi@gmail.com*)

Purpose: Evaluate the impact of bicuspid aortic valve (BAV) morphology on the transvalvular flow pattern, aortic flow turbulence and wall shear stress (WSS), using cardiac magnetic resonance (CMR) and 4D-flow imaging.

Methods and Materials: Eighteen healthy BAV patients (aortic diameter ≤ 45mm, lack of severe valvular disease) were studied by CMR on a 3.0T unit (Discovery, GE Healthcare), including cine-MR sequences acquired orthogonal and parallel to the aortic root, contrast-enhanced MR angiography and 4D-flow imaging. In each patient we assessed, valvular morphology (valve phenotype, leaflet length, leaflet asymmetry index), valvular flow characteristics (peak flow velocity, flow jet angle, flow displacement), turbulent flow within the ascending aorta (systolic flow reversal ratio, SFRR) and WSS (total, axial and circumferential) at four different levels of the ascending aorta. All data were correlated by bivariate correlation and linear regression analyses.

Results: RL-BAV patients (n: 12), RN-BAV (n: 4) and RN/RL-BAV (n: 2) demonstrated peculiar phenotype-related flow patterns. Direct correlations between leaflets asymmetry index, flow jet angle (r: 0.603, p: 0.008) and flow displacement (r: 0.712, p: 0.001) were observed. Axial WSS was highly related to flow displacement (r: 0.74, p: 0.004) and SFRR (r: 0.758, p: 0.001). RN-BAV patients showed the greatest ascending aorta diameters (p: 0.008), higher degree of flow displacement (p: 0.022) and SFRR (p: 0.009).

Conclusion: BAV phenotype and leaflets asymmetry are strongly involved in aortic root flow eccentricity generation, in particular, flow displacement and flow angle. These parameters are also correlated to the downstream flow pattern, WSS, SFRR and aortic diameter. A deeper knowledge of the relationship between valve morphology and aortic flow dynamics could ameliorate risk stratification strategy in BAV patients.

B-1501 11:11

Follow-up of thoracic aorta diseases with concurrent evaluation of coronary arteries using wide-detector-coverage CT with low-dose protocol

A.D. Annoni, M.E. Mancini, A. Formenti, G. Muscogiuri, M. Guglielmo, S. Mushtaq, G. Pontone, M. Pepi, D. Andreini; Milan/IT (*andrea.annoni@cclm.it*)

Purpose: To assess evaluability, image quality, radiation exposure and coronary evaluability of a submillisievert CT angiography (CTA) scan protocol of thoracic aorta in follow-up of patients with thoracic aorta diseases.

Methods and Materials: We enrolled 80 patients (32F; BMI 25.4±2.97 kg/m²) referred to our hospital for CTA of the thoracic aorta that underwent CT with 80 kV, new adaptive statistical iterative reconstruction algorithm-V and 40ml of contrast medium. Image quality was assessed using a semi-quantitative four-point Likert scale, by two independent readers. For each patient, attenuation, image noise, contrast-to-noise ratio (CNR) were measured at different aortic levels and at the level of the proximal coronary arteries. Mean effective dose (ED) was calculated.

Results: Mean aortic attenuation for ascending aorta, aortic arch and descending aorta were above 600HU. Mean image noise and CNR for ascending aorta, aortic arch and descending aorta were 38.5±6.9, 35.05±7.1 and 36.9±9.1, respectively, and 17.1±3.3, 17.6±2.0 and 16.8±2.5, respectively. Mean luminal attenuation of proximal coronary arteries was above 360 HU. 459 out of 960 coronary segments were classified as good image quality. Coronary evaluability (number of coronary segments evaluable/total number of coronary segments) in a segment-based model was 83% (790/960 segments). Mean ED was 0.81±0.29mSv.

Conclusion: 80kV CTA of the thoracic aorta using 160mm detector coverage and ASiR-V allows low-dose good quality exams with complementary coronary tree evaluation. Our results gain in importance considering the use of CT for serial follow-up of aortic diseases.

B-1502 11:19

ECG-gated MR angiography at 3T for follow-up after aortic surgery involving the ascending aorta

A. Busse¹, C. Neßelmann¹, A. Hoffman², P.M. Dohmen¹, M.-A. Weber¹, F.G. Meinel¹; ¹Rostock/DE, ²Wuppertal/DE (*anke.busse@med.uni-rostock.de*)

Purpose: To evaluate the feasibility, image quality and diagnostic yield of ECG-gated MR angiography in the post-surgical follow-up of patients after aortic surgery involving the ascending aorta.

Methods and Materials: In this study, we retrospectively analyzed a cohort of 19 patients (median age 60 years, range 38-79 years), who underwent MR angiography for follow-up imaging after replacement of the ascending aorta. Our MRI protocol consisted of an ECG-gated contrast-enhanced MR angiography performed at 3T. Mean examination duration was 24 minutes. All examinations were analyzed by two readers in consensus for image quality at various levels of the aorta on a five-point scale ranging from 1 (non-diagnostic) to 5 (excellent). Diagnostic findings were recorded. We also analyzed whether additional down-stream imaging was performed within one month of the MRI examination.

Results: Subjective image quality was rated as "sufficient" (score 3.1 ± 1.0) for the aortic root and as good to excellent for the ascending aorta (score 4.6 ± 0.7), the aortic arch (4.6 ± 0.8), supra-aortic branches (4.7 ± 0.69) and descending aorta (4.6 ± 0.7). In eight cases (42%), a clinical relevant or new pathology was detected. One patient of this study population underwent re-evaluation with CT within one month of the MRI examination after a repeat surgical procedure.

Conclusion: ECG-gated MR angiography at 3T is feasible and yields good image quality for the detection of post-operative complications after replacement of the ascending aorta. This technique may serve as alternative to CT particularly in younger patients with repeated follow-up.

B-1503 11:27

Real-time patient-specific scan initiation for CT of the thoracic aorta: impact on image quality

F.R. Schwartz¹, J.C. Ramirez Giraldo¹, R. Gutjahr², D. Boll³, D. Marin¹, L. Hurwitz¹; ¹Durham, NC/US, ²Nürnberg/DE, ³Basle/CH (*fidesreginadorotheaann.schwartz@duke.edu*)

Purpose: To assess impact of real-time modulation of scan initiation based on patient-specific haemodynamics on contrast in the thoracic aorta on MDCT.

Methods and Materials: This is a HIPAA-compliant, IRB-approved QI project. Exams were performed on a DS-MDCT scanner (120 kVp, 65-75 mL at 4 ml/sec). Contrast administration was monitored in the ascending aorta (thoracic aorta, TA) and descending aorta (thoraco-abdominal aorta, TAA). The delay prior to initiation of diagnostic scan was modulated by a real-time patient-specific (RTPSM) software, incorporating time to threshold and the slope of the enhancement curve. 120 patients (cohort 1) were scanned using RTPSM triggering of scan delay for TA and TAA exams. A reference cohort of 30 patients (cohort 2) was identified from the same scanner (preceding 12 months), using a fixed diagnostic delay (FD). Patient demographics, average aortic HU values and coefficients of variance (COV) at 1-mm increments from the aortic valve through the diaphragm were collected. Descriptive statistics and Student's t tests were applied.

Results: Protocol distribution was 61 and 39% (TAA/TA) in cohort 1 and 60/40% (TAA/TA) in cohort 2. Average scan delay was significantly longer for TAA (12.4 vs 11 sec; p<0.01) and TA (12 vs 9 sec; p<0.01) exams using RTPSM. Average HU values were significantly higher in the RTPSM cohort (403.1 ± 31.8 vs 372.4 ± 38.1 HU; p<0.01) and COV was significantly reduced using RTPSM (8.1 vs 11.6%; p<0.01).

Conclusion: RTPSM results in higher HU values and better contrast homogeneity throughout the thoracic aorta on MDCT exams.

A preliminary study of CT spectral imaging on patients with aortic dissection using revolution CT

B. Wen; Beijing/CN (www.wyner@163.com)

Purpose: To study the application of CT spectral imaging on patients with aortic dissection.

Methods and Materials: 30 aortic dissection patients were studied: 15 patients were scanned by spectral imaging protocol and 15 patients by routine protocol. The spectral imaging series ranging from 40 to 140 keV (10 keV intervals) were reconstructed. The quantitative image quality indices including signal intensity, noise, SNR and CNR of multiple aortic segments were measured and calculated. The virtual non-contrast images were reconstructed using CTA spectral imaging data and were compared with real non-contrast images. Then the subjective evaluation of image quality between the best monochromatic images and routine datasets was performed by two radiologists independently, and the radiation dose was compared in the two groups.

Results: 480 aortic segments were evaluated with good consistency of two radiologists. In the spectral imaging series, the 40-70 keV reconstruction showed superior SNR levels (+44.3, +33.7, +22.3, +9.1 %) and CNR levels (+36.5, +24.8, +11.6, +1.2%) compared to routine scans. Combined with the subjective evaluation of true and false lumen displays, the 70 keV reconstruction image was considered as the best monochromatic image. The image quality between spectral imaging and routine scans at nearly all aortic segments had no significant difference. The virtual non-contrast images were comparable to the real non-contrast images. The DLP for spectral imaging was lower than the comparison group.

Conclusion: The CT spectral imaging on aortic dissection patient has good clinical application value with reduced radiation dose.

B-1505 11:43

ECG-gated CTA of thorax aorta with extended data postprocessing in ascending aorta aneurism diagnosis

A. Skripnik, V. Fokin, R. Mironchuk, G.E. Trufanov, O. Moiseeva, O. Irtuya, V. Uspenskiy, E. Malev, P. Murtazaliev; St. Petersburg/RU (skripnikalexey@mail.ru)

Purpose: To develop a computed tomography angiography (CTA) scanning protocol with extended data postprocessing for the evaluation of the aortic wall elongation in patients with an expansion of the ascending aorta (AA) of varying degrees.

Methods and Materials: 43 patients (26 men) aged 42 to 76 years with a pre-established diagnosis of AA aneurysm were examined. ECG-gated CTA was performed after bolus intravenous injection of 100 ml of contrast agent (iodine concentration 300 mg/ml). The final systole and diastole phases were determined for each study and the maximum aortic diameter (d) and cross-sectional area (S) of the aorta were evaluated.

Results: The patients were divided into three groups, according to the AA diameter, measured during the diastole phase. The 1st group included 20 patients with d<45 mm (mean 41.06±1.9 mm), the 2nd group - 9 patients with d 45-50 mm (mean 47.03±1.16 mm); 3rd group - 14 patients with d 50-55 mm (mean 52.78±2.67 mm). Mean values of S in the 1st, 2nd, and 3rd groups were 1289±116, 1703±75, and 2096±249 mm², respectively. Distensibility (D) in d and S were calculated as: 1. $D_d = (d_{systolic} - d_{diastolic}) / d_{diastolic}$; 2. $D_S = (S_{systolic} - S_{diastolic}) / S_{diastolic}$. D_d of AA in the 1st, 2nd and 3rd groups were 4.88±0.54, 4.73±0.69 and 2.91±0.34 mm, respectively. D_S of AA in patient of the 1st, 2nd and 3rd groups were, respectively, 8.85±0.95, 7.88±1.36 and 4.98±0.78 mm².

Conclusion: Our CTA scanning protocol with extended data postprocessing allows to evaluate the tensile properties of AA wall in different cardiac cycle phases.

Age at aortic coarctation reconstruction is correlated with aortic vessel wall stiffening: an evaluation of pulse wave velocity and wall shear stress from 4D flow MRI

J.F. Juffermans, I. Nederend, P. van den Boogaard, A.A.W. Roest, J.J. Westenberg, H.J. Lamb; Leiden/NL (J.F.Juffermans@lumc.nl)

Purpose: Uncertainties exists in whether the abnormal haemodynamic situation in coarctation patients before curative reconstruction causes aortic wall deterioration. Therefore, this study evaluated the effect of age at curative

reconstruction on the arterial wall stiffness expressed in pulse wave velocity (PWV) and the 3D wall shear stress (WSS) in CoA patients with curative reconstruction. Additionally, effect of valve morphology was evaluated.

Methods and Materials: 21 patients (13.7±2.6 years) were included, including 14 subjects with a bicuspid aortic valve. Mean time after CoA correction is 12.6±3.0 years. For normal PWV comparison, 19 volunteers (13.3±2.8 years) were included. PWV was determined from two high-temporal 1-directional velocity-encoded acquisitions, for the ascending aorta (AO) plus the aortic arch and the descending AO. The peak WSS was determined from 4D flow MRI for the ascending AO, aortic arch and descending AO.

Results: There were no significant differences between volunteer and patient for neither the characteristics nor the PWV. Correlations were found between age and PWV in both aortic segments (proximal AO: r=-.322, p=.042; descending AO: r=-.361, p=.022). For tricuspid aortic valve (TAV) patients, a correlation was found between age at reconstruction and descending AO PWV (r=-.796, p=.010).

Conclusion: The absence of significant PWV difference between volunteers and patients indicates that curative reconstruction does not result in AO wall stiffening. However, the correlation within TAV patients between the age at curative reconstruction and descending AO PWV suggests that a prolonged period of abnormal haemodynamic exposure may result in increased AO wall stiffening.

Medial meniscal ossicle is associated with medial posterior root tear and ACL tear: a case-controlled multicentric SIMS study of 42 cases

A. Caudal¹, G. Lefebvre², D. Guenoun³, G. Corcos⁴, J.-F. Nisolle⁵, V. Vuillemin-Bodaghi⁴, B. Vande Berg⁵; ¹Nice/FR, ²Lille/FR, ³Marseille/FR, ⁴Paris/FR, ⁵Brussels/BE (caudalmandine@yahoo.fr)

Purpose: To test the hypothesis that medial meniscal ossicle is associated with posterior root tear.

Methods and Materials: The MRI and available radiographs of knees with a medial meniscal ossicle and of a sex- and age-matched control group were collected from 17 imaging centres. Two readers assessed only all SE T1-weighted images and available radiographs to detect the presence of a medial meniscal ossicle. Consensus reading was used as reference standard for the presence of a meniscal ossicle. Two other readers blinded to the presence of a meniscal ossicle by reading only the fat-saturated MR images assessed the presence of meniscal, ligament and cartilage lesions.

Results: After consensus reading, there were 42 knees with a medial meniscal ossicle in 39 men (43.77 yrs +/- 13.59) and 7 women (40.8 yrs +/- 6.1). The frequency of posterior root tear in the study group (62% and 76% for R1 and R2) was higher than that in the control group (11% and 4%, respectively) (p<10⁻⁴). There was no difference in frequency of medial posterior horn and body lesions. The frequency of ACL but not of MCL/PCL lesions was higher in the study than in the control group (p=0.007 and 0.003). The degree of cartilage degradation of the medial compared to the lateral femoro-tibial joint was higher in the study than in the control group (p=0.04 and 0.02).

Conclusion: There is a statistically significant association between medial meniscal ossicle and posterior root tear of the medial meniscus, ACL lesions and medial femoro-tibial cartilage degradation.

Rupture of the anterolateral ligament in complete acute traumatic anterior cruciate ligament tear: new insights into acute pivot shift trauma to the knee

M.T. Mastio¹, A. Duarte Vallejo², J. Raya¹, L. Jazrawi¹, J.T. Bencardino³; ¹New York, NY/US, ²Bogota/CO, ³Great Neck, NY/US (mastio@me.com)

Purpose: To evaluate the prevalence and association of anterolateral ligament (ALL) rupture with other meniscal and ligamentous injuries in patients with complete acute traumatic ACL tears.

Methods and Materials: 57 patients M45:F12, mean age 21 (range:13-34) with acute post traumatic ACL rupture who underwent ACLR between 2011 and 2015 were enrolled in this cohort. Preoperative MRI was reviewed by an experienced (20 years) MSK radiologist for: ALL rupture, MM tear, LM tear, posteromedial corner (PMC) injury, posterolateral corner (PLC) injury, MCL tear, and LCL tear. Odds ratios and their 95% confidence interval were used to

assess the associations of ALL with other injuries in the knee. To rule out confounding factors we used the Cochran Mantel Haenszel method in an analysis stratified by gender and BMI (normal, overweight).

Results: Most commonly reported lesions were of MM 63% and PLC 64%. ALL partial or complete tears and Segond avulsion fracture were reported in 28 patients (49%). Anterolateral lesions were associated with a 10 fold decreased risk of MM tear (odds ratio [OR] = 0.10, 95% [CI]=[0.028, 0.38]) and a 4.6 fold increased risk of LCL tear (OR=4.68, 95% CI=[1.28 17.1]). Neither gender nor BMI were confounding for the associations of ALL with MM and LCL tears. No other statistically significant associations were found.

Conclusion: Failure of the ALL during acute traumatic ACL rupture is often associated with tear of the LCL. This may have a protective effect over the MM due to potential "capsular release" during pivot shift trauma.

B-1509 10:55

Healing of the anterior cruciate ligament following primary repair: a longitudinal DTI study

E. De Smet¹, T. Billiet², C. Heusdens¹, P.M. Parizel¹, P. Van Dyck¹;
¹Edegem/BE, ²Leuven/BE (elinedesmet@hotmail.com)

Purpose: There is a lack of objective biomarkers to guide the appropriate timing for return to sports after anterior cruciate ligament (ACL) surgery. The purpose of this study was to investigate the ability of diffusion tensor imaging (DTI) to monitor ACL healing following primary repair.

Methods and Materials: Twelve patients who underwent primary ACL repair were enrolled prospectively. All patients had clinical and DTI follow-up at 3, 6 and 12 months postoperatively. DTI was acquired at 3T using single-shot SE-EPI (b-values: 0/400/800s/mm², 10 directions; TR/TE: 1300/45ms; voxel size: 1.5x1.5x6.0mm³; FOV 768x768x60mm). Fiber tractography (FT) was performed to delineate the ACL. The posterior cruciate ligament (PCL) served as a control. Fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD), and radial diffusivity (RD) were calculated within the FT volumes. Data were compared using a linear mixed effects model for all repeated measures, and paired t tests between different time points (p<0.05).

Results: All knees were stable at 12 months postoperatively. ACL and PCL FT were feasible at all time points. The ACL showed a significant decrease of FA over time (F=8.29, p=0.0040). Diffusivities of the ACL were most often larger than those in the PCL and showed a decreasing trend over time, reaching significance for AD (MD: F=1.45, p=0.23; AD: F=10.15, p=0.0014; RD: F=0.36, p=0.55). There were no significant changes over time in the PCL.

Conclusion: Our study has shown the ability of DTI to quantitatively monitor healing of the ACL repair. The results indicate incomplete healing at 12 months postoperatively.

B-1510 11:03

Can pre-operative MR imaging findings predict early failure following anterior cruciate ligament reconstruction?

M. Mastio¹, A. Duarte¹, J. Raya¹, L. Jazrawi¹, J.T. Bencardino²;
¹New York, NY/US, ²Great Neck, NY/US (mastio@me.com)

Purpose: To identify markers of early failure of ACL graft reconstruction (ACLR) based on preoperative MRI.

Methods and Materials: We identified 26 patients with early ACLR failure (<2Y) who underwent revision between 2011-2015. Exclusion criteria included graft choice other than autografts (n=4) and non available preoperative MRI (n=3). Nineteen patients with early ACLR failure were included. The control group consisted of 38 subjects who underwent ACLR with a minimum of 2 years of clinical FU and no evidence of graft failure matched by age, sex, BMI and graft type. Preoperative

MRI obtained within 8w (range 1-8w) following initial trauma were blindly reviewed by an experienced musculoskeletal radiologist for intra and periarticular lesions including: anterolateral ligament (ALL) injuries (stretch, partial, complete), medial meniscus tear (MM), lateral meniscus tear (LM) tear, posteromedial corner injury (PMC), posterolateral corner injury (PLC) injury, medial collateral ligament tear (MCL), and lateral collateral ligament tear (LCL). Logistic regression analysis was performed.

Results: Mean time to ACLR failure was 14mo (range, 1-24mo). Mean FU of those in the control group was 38mo (range, 25-61). MM tear was the best predictor of early ACLR failure (Accuracy=66.7%, p=0.08) followed by LM (p=0.13). MM was a significant predictor of ACLR failure (p=0.02) with OR 4.2 and 95% CI). All other variables were not associated with ACLR failure (p>0.20).

Conclusion: MM tears were the best predictor of early failure of ACLR. Thus, preserving the integrity of the MM during ACLR procedure may be crucial in minimizing the risk for early ACLR failure.

B-1511 11:11

Feasibility of lower limb muscle volume estimation during contraction with real-time dynamic MRI: implications to clinical diagnostics

M. Garetier¹, R. Grimandi¹, F. Tissier¹, C. Pons-Becmeur¹, D. Ben Salem¹, B. Borotikar¹; Brest/FR (marc.garetier@wanadoo.fr)

Purpose: Ability to determine volume of a contracted muscle has a diagnostic value. We assessed the volume of thigh muscles during contraction on dynamic MRI using a real-time balanced steady-state gradient echo sequence (True-FISP).

Methods and Materials: Twelve healthy adult volunteers participated in this study after signing an informed consent. An MRI of the mid-thigh region (Siemens Magnetom Avanto^{1.5T}) was acquired on each volunteer supine, using real-time True-FISP sequence (TR=3.6, TE=1.8, number of slices=5, slice thickness=8mm, size pixel=2.08X1.4, time=13sec, time frames=10) during rest and contraction. During dynamic state, volunteers pressed an inflated balloon (150mmHg) placed under the knee joint to achieve a pressure of 200mmHg monitored on manometer. Rectus femoris (RF), vastus lateralis (VL), vastus intermedius (VI), vastus medialis (VM) and biceps femoris long head (BFLH) muscles were manually segmented in image sets of static state and dynamic state at which pressure reached 200mmHg. The segmented cross-sectional areas were used to determine muscle volume within the acquisition field. Static and dynamic state volumes were compared with paired two-sample t test.

Results: The mean volume was estimated during rest and contraction, respectively, at 29.16cm³ and 28.15cm³ for RF, 72.22cm³ and 70.9cm³ for VI, 80.63cm³ and 80.27cm³ for VL, 36.25cm³ and 36.69cm³ for VM, 30.77cm³ and 30.66cm³ for BFLH. No significant difference was found for muscle volume between static and dynamic states (p>0.05), except for RF (p=0.005).

Conclusion: Volume of thigh muscles can be evaluated during contraction on dynamic MRI with real-time sequence, allowing quantification of the muscle deformation during contraction.

B-1512 11:19

Musculoskeletal elastography: exploration of confounders in a challenging field

L. Ruby¹, S.J. Sanabria¹, T. Mutschler¹, K. Martini¹, T. Frauenfelder¹, V. Klingmüller², M. Rominger¹; ¹Zurich/CH, ²Marburg/DE (lisa.ruby@usz.ch)

Purpose: To identify and investigate the quantitative impact of confounders in muscle shear wave elastography (SWE), a challenging field due to anisotropy and nonlinear viscoelasticity of muscle.

Methods and Materials: The influence of region of interest (ROI) size and location, excitation pulse, phantom stiffness, muscle fibre orientation and activation state on shear wave velocity (SWV) was assessed with a GE Logiq E9 in three different test objects: an isotropic elasticity phantom with four certified stiffness values (elasticity phantom), explanted porcine muscle (ex vivo porcine muscle) and stretched and relaxed calf muscles of healthy volunteers (volunteers) in parallel and transverse probe direction to the fibres. Regression analysis was performed to estimate the impact of examined confounders.

Results: For the elasticity phantom, SWV increased with greater stiffness (p<0.001), yet underestimated the true stiffness of all four nominal stiffness values. In healthy volunteers, the main variance-contributing factors were in order of importance muscle activation state, fibre orientation, horizontal ROI size and insertion depth. For the elasticity phantom, ex vivo porcine muscle and volunteers, a higher insertion depth significantly reduced SWV (p<0.05). For both the volunteers and the ex vivo porcine muscle, parallel compared to transverse probe-fibre orientation (p<0.001), muscle stretch (p<0.01) and an increasing horizontal ROI size (p<0.01) led to significantly higher SWV values. The comparison of different Logiq E9 software versions showed significant differences in SWV only for the ex vivo porcine muscle (p<0.001).

Conclusion: ROI location and size, software choice, muscle fibre orientation and activation state are important confounders that significantly influence SWV in muscle.

B-1513 11:27

Quantification of abdominal fat and skeletal muscle tissue at CT: associations between single-slice measurements and total compartment volumes

A. Faron¹, J. Luetkens¹, F.C. Schmeel¹, A. Sprinkart¹, D. Thomas¹; Bonn/DE (anton.faron@ukbonn.de)

Purpose: Body composition is of great prognostic value in several oncologic diseases as well as cardiometabolic disorders. We aimed to investigate the correlations of skeletal muscle mass and abdominal adipose tissue compartments between volumetric measures and area-based measurements to identify a useful landmark for estimation of total compartment volumes.

Methods and Materials: In this retrospective study, volumetric quantifications of paraspinal skeletal muscles (SM) and adipose tissue compartments (visceral adipose tissue, VAT; subcutaneous adipose tissue, SAT) were performed in 50

consecutive patients (26 male; mean age, 63 ± 15 years) who underwent abdominal multislice-CT for diagnostic purposes between 06/2017 and 07/2018. Associations between total volumes of SM, VAT, and SAT with area-based measurements at eight predefined anatomical landmarks (levels B12/L1 to L5/S1; level of the umbilicus, U; level of the radix of the superior mesenteric artery, MSA) were studied using correlation coefficients.

Results: Statistical analysis revealed a strong association of area-based measures of adipose tissue compartments obtained at all studied landmarks with total VAT and SAT volume (VAT: all $r > 0.89$, $P < 0.0001$; SAT: all $r > 0.95$, $P < 0.0001$). The strongest associations with total SM volume were found for area-based measurements obtained at L2/3, L3/4, and MSA ($r > 0.87$, $P < 0.0001$) and were further improved by normalization to volume of interest height ($r > 0.92$, $P < 0.0001$).

Conclusion: Area-based measurements of SM, VAT, and SAT at several anatomical landmarks are strongly associated with total compartment volumes and, therefore, allow for easy and simultaneous assessment of skeletal mass as well as amount of adipose tissue compartments from a single-slice image.

B-1514 11:35

Distribution patterns of intra- and extra-myocellular fat by magnetic resonance imaging in subjects with diabetes, prediabetes and healthy controls from a population-based cohort

L.S. Kiefer¹, J. Fabian¹, S. Rospleszcz², C. Storz¹, C.L. Schlett³, F.W. Roemer⁴, K. Nikolaou¹, F. Bamberg⁵; ¹Tübingen/DE, ²Munich/DE, ³Heidelberg/DE, ⁴Erlangen/DE, ⁵Freiburg/DE (lena.kiefer@med.uni-tuebingen.de)

Purpose: To determine distribution patterns of total, intra- and extramyocellular lipids (IMCL and EMCL) by magnetic resonance imaging (MRI) in subjects with type 2 diabetes mellitus (T2DM), prediabetes and healthy controls.

Methods and Materials: Asymptomatic subjects from the general population were classified with T2DM, prediabetes or healthy controls and underwent multi-echo Dixon MRI (TR 8.90ms, six echo times, flip angle 4°). Total myosteatosis, IMCL and EMCL were quantified as proton-density fat fraction (PDFF) in abdominal skeletal muscle compartments using a standardized segmentation algorithm. Cardiometabolic risk factors were prospectively obtained in a comprehensive health assessment.

Results: Among 337 included subjects (mean age: 56.0years, 56.4% males, 14.5% T2DM, 23.4% prediabetes) intramuscular fat content was highest in obese subjects with T2DM (PDFF_{muscle}: 15.8%, IQR: 11.9-17.0%; IMCL: 7.7%, ICQ: 6.4-8.9%; EMCL: 7.1%, ICQ: 5.4-9.2%). There were significant differences in both IMCL and EMCL between the diabetes status groups, being lowest in non-obese, healthy controls and highest in obese, diabetic subjects (IMCL: 5.5%, IQR: 4.6-6.5%; 7.7%, IQR: 6.4-8.9%; EMCL: 3.6%, ICQ: 2.4-5.3%; 7.1% ICQ: 5.4-9.2%; respectively, $p < 0.001$). After adjustment for age and gender, the association of IMCL and prediabetes, but not T2DM was attenuated (IMCL: $\beta: 0.49$, 95%CI: -0.01-0.99, $p = 0.055$; $\beta: 1.31$, 95%CI: 0.25-2.38, $p = 0.016$; respectively), whereas EMCL remained significantly associated with both prediabetes and T2DM ($p < 0.001$).

Conclusion: There are significant differences in PDFF_{muscle}, IMCL and EMCL between subjects with T2DM, prediabetes and healthy controls. Patterns of intramuscular fat distribution by MRI may, therefore, serve as promising imaging-biomarkers, specifically in early stages of impaired glucose tolerance.

B-1515 11:43

Assessment of skeletal muscle mass by magnetic resonance imaging in a population-based cohort

L.S. Kiefer¹, J. Fabian¹, S. Rospleszcz², C. Storz¹, C.L. Schlett³, F.W. Roemer⁴, K. Nikolaou¹, F. Bamberg⁵; ¹Tübingen/DE, ²Munich/DE, ³Heidelberg/DE, ⁴Erlangen/DE, ⁵Freiburg/DE (lena.kiefer@med.uni-tuebingen.de)

Purpose: To determine skeletal muscle mass parameters and their associations by magnetic resonance imaging (MRI) and bioelectrical-impedance analysis (BIA) in non-obese and obese subjects.

Methods and Materials: Subjects from a population-based cohort underwent anthropometry, BIA (50kHz, 0.8mA) and multi-echo Dixon MRI (TR 8.90ms, six echo times, flip-angle 4°). Abdominal skeletal muscle mass by MRI was quantified as total and fat-free cross-sectional area by a standardised segmentation algorithm and normalised to subjects body height² (AMMI: abdominal muscle mass index).

Results: Among 335 included subjects (median age: 56.0±5.0years, 56.1% males), 95 were classified as obese (BMI≥30kg/m²: 28.4%). AMMI by MRI and BIA-based measures of muscle mass showed a moderate to strong, linear correlation, being stronger in non-obese subjects (non-obese: $r < 0.743$, obese: $r < 0.562$, respectively). AMMI_{Total} was lowest in non-obese females and highest in obese males (2507.5mm²/m² (IQR 2178.0-2790.6mm²/m²), 3359.8mm²/m² (IQR: 3170.9-3773.3mm²/m²), respectively, $p < 0.001$). No significant difference was found regarding AMMI_{Fat-free} between non-obese and obese subjects (1632.3mm²/m² (IQR 1379.0-2029.3mm²/m²), 1605.1mm²/m² (IQR 1407.2-2028.3mm²/m²), respectively, $p = 0.705$). Concerning the ratio of normalised fat-free to total abdominal skeletal muscle mass, normal weight males and

females had a significantly higher AMMI_{Fat-free}/AMMI_{Total} compared to obese, male and female subjects (male: 59.9% (IQR 55.0-68.2%) and 57.0% (IQR 47.6-65.5%), $p = 0.027$; female: 55.9% (50.9-62.6%) and 49.1% (44.4-53.5%), $p < 0.001$).

Conclusion: AMMI_{Fat-free}, AMMI_{Total} and their ratio by MRI based on a standardised segmentation-algorithm may be valid and robust alternatives to BIA in both non-obese and specifically obese subjects, and may, therefore, serve as promising imaging biomarkers for the simple, however, comprehensive assessment of skeletal muscle mass parameters.

Magnetic resonance spectroscopy in muscle tissue and bone marrow to identify that a body was previously frozen and is meanwhile thawed

D. Gascho, J. Heimer, M. Thali, N. Zoelch; Zurich/CH (dominic.gascho@irm.uzh.ch)

Purpose: We investigated the use of non-invasive, in-situ magnetic resonance spectroscopy (MRS) for the identification that a body was previously frozen and is meanwhile thawed.

Methods and Materials: Severed hind legs (study group: n=7) of 14 sheep were measured before and several times after storing in a deep freezer (-20°C). The opposite hind legs (control group: n=7) were kept at room temperature and repeatedly measured. A clinical 3 Tesla MR scanner was used to perform 1H-MRS. Single voxel measurements and spectroscopy-based relaxation time measurements in the muscle tissue and bone marrow were conducted. The Shapiro-Wilk test was used to determine if the data sets were normal distributed. The t-test was used to test whether the study group differs significantly from the control group. The same protocol was applied on humans (n=4), who was stored in the deep freezer during the identification process.

Results: Significant alterations in the relaxation times of lipids in the bone marrow were observed in the study group after freezing and thawing. The peak are ratio between lipids in the bone marrow allowed for a clear identification of a previous frozen state. These post-thawing effects were also indicated in human bone marrow. Alterations in relaxation times of water and peak area ratios were also observed in the muscle tissue, which described the thawing process in accordance to previous investigations in meat science.

Conclusion: Non-invasive in-situ 1H-MRS in yellow bone marrow indicates an approach for the objective detection of a previous frozen state in a meanwhile thawed body.

Autodetection of mass and lymph node in breast mammography images with deep learning method

S. Liang¹, J. Ma¹, C. Xia¹, Y. Deng¹, R. Zhang¹, Z. Yu²; ¹Beijing/CN, ²Zhengzhou/CN (13673666622@126.com)

Purpose: High-density breast is associated with increased risk of breast cancer and makes lesion detection difficult in mammography images. We developed a deep learning algorithm to automatically detect masses and lymph node abnormalities in mammography and investigated the influence of breast density on algorithm performance.

Methods and Materials: A total of 12,510 mammography images were collected from 3,669 patients with both CC and MLO views, of which 2,762 patients came from collaborating hospitals (630 studies for testing, 2,132 for training), 857 patients from the DDSM open dataset (for training), and 50 patients from the INBreast open dataset (for testing). Our algorithm mainly built upon Faster R-CNN. To gain better detection performance, four tricks were applied: image normalisation, data augmentation by flipping, alternating training, and transfer learning.

Results: In the hospital testing dataset, mass detection sensitivity and false-positive rate (FPR) were 83.7% and 13.4%, sensitivities across different breast densities (ACR A to D) were 95.9%, 78.7%, 83.9%, and 77.1%, respectively; lymph node detection sensitivity and FPR were 86.4% and 30%, and sensitivities across different breast densities were 83.3%, 90.5%, 87%, and 86.7%. On the INBreast dataset, mass detection sensitivity and FDR were 94.5% and 48% and sensitivities across different breast densities were 97.6%, 92.7%, 100%, 75%, respectively.

Conclusion: Our deep learning algorithm achieved sensitive mass and lymph node abnormality detection in mammography, especially for mass detection on breasts of lower densities. The algorithm can assist radiologists with breast cancer screening more precisely in future.

Integration of AI into the breast MRI assessment enables objective and accurate diagnosis even by an unexperienced reader

S. [Ellmann](#), M. Dietzel, E. Wenkel, C. Bielowski, R. Schulz-Wendtland, M. Uder, T. Bäuerle; Erlangen/DE

Purpose: Interpretation of breast MRI requires high level of training. It is further limited by observer-related bias, particularly among less experienced readers. We investigated, whether integration of artificial intelligence (AI) into the breast MRI assessment enables objective and accurate diagnosis even by an unexperienced reader.

Methods and Materials: 173 consecutive patients showing 176 suspicious breast lesions (BI-RADS IV/V: n=100/76) upon complementary assessment (clinical examination, mammography, ultrasound) received standardized breast MRI prior to histological verification. Six agnostic, semi-/quantitative MRI parameters were independently assessed by two observers (R1/R2: intermediate/no experience in breast MRI). Interobserver variability was studied by ICC (intraclass correlation coefficient). AI consisting of a polynomial kernel function support vector machine was applied to differentiate benign vs. malignant lesions based on the agnostic MRI parameters. Results were verified by tenfold cross validation. Diagnostic accuracy was evaluated (benign vs. malignant: area under the ROC curve (AUC), alpha=5%).

Results: There were 107 malignant lesions (60.8%). The agnostic parameters showed excellent interobserver variability (ICC: 0.81-0.98) with variable diagnostic accuracy (AUC: 0.65-0.82). Overall performance of AI to differentiate benign from malignant lesions reached AUC=90.1%. Results were integrated into an open-access web application and published online (input: agnostic criteria, output: likelihood of malignancy).

Conclusion: Integration of AI into the breast MRI assessment enabled objective and accurate diagnosis even by an unexperienced reader. Results can be easily validated based on our open-access web application.

Texture features from mammography can predict the characterisation of breast tumours

Y. [Li](#), Y. Cui, J. Zhu, W. Li; Jinan/CN (13631697@qq.com)

Purpose: To explore the feasibility and accuracy of extracting texture features from digital mammograms for predicting benign and malignant breast masses using Radiomics.

Methods and Materials: 192 patients who diagnosed as breast masses (Benign: 92 Malignant: 100) by mammography were enrolled. All breast masses were classified as BI-RADS 3, 4, and 5, and at last confirmed by histopathology. Lesion area was marked with a rectangular frame on the images at the 5M workstation. The rectangular regions of interest (ROI) were segmented and 456 radiomics features were extracted from every ROI. Extracted features were dimensioned by Lasso algorithm. Post-dimension features were classified using Support Vector Machine (SVM). 70% of the data as a training set and the other 30% as a testing set. The reliability of the Classifier was evaluated by the 10-fold cross-validation. The classification accuracy was evaluated by the accuracy, sensitivity and the AUC.

Results: 20 radiomics features that are valuable for diagnosing benign and malignant tumours were screened by Lasso algorithm. 10-fold cross-validation show the accuracy was 92.54%, so the model is stable. In the testing sets, Through SVM model the lasso dimension reduction algorithm, the classifier can achieve an accuracy of 91.44%, a sensitivity of 96.70%, and the AUC of 0.90.

Conclusion: Radiomics techniques can be used to extract texture features from digital mammograms for predicting the characterization of breast tumours. This method offer high accuracy and sensitivity, and it is expected to provide additional diagnostic information to the imaging doctors.

B-1520 10:54

Prediction of benign and malignant breast masses using digital mammograms texture features

Y. Cui, Y. [Li](#), Y. Yin, B. Li, J. Dong, J. Zhu; Jinan/CN

Purpose: To investigate the feasibility and accuracy of texture features extracted from digital mammograms at predicting benign and malignant breast mass using Radiomics.

Methods and Materials: 192 digital mammograms data who diagnosed as breast masses (Benign: 92 Malignant: 100) by mammography were enrolled.

Enrol criteria: breast masses classified as BI-RADS 3, 4, and 5 and at last confirmed by histopathology. Lesion area was marked with a rectangular frame on the Cranio-Caudal (CC) and MedioLateral Oblique (MLO) images at the 5M workstation. The rectangular regions of interest (ROI) was segmented and 456 radiomics features were extracted from every ROI. Extracted features were dimensioned by Lasso and Maximum Relevance Minimum Redundancy (MRMR) algorithm. Post-dimension features were classified using Support Vector Machine (SVM). 70% of the data as a training set and the other 30% as a testing set. The reliability of the Classifier was evaluated by the 10-fold cross-validation. The classification accuracy was evaluated by the accuracy and sensitivity.

Results: Both the Lasso and MRMR screened 20 radiomics features respectively. 10-fold cross-validation show their accuracy were 92.54% and 87.31%, respectively. In testing sets, Through the lasso dimension reduction algorithm, the classifier achieves an accuracy of 91.44% and a sensitivity of 96.70%. Through the MRMR algorithm, the classifier achieves an accuracy of 91.37% and a sensitivity of 90.00%.

Conclusion: Radiomics texture features from digital mammograms may be used for benign and malignant prediction. This method offer better accuracy and sensitivity. It is expected to provide an auxiliary diagnosis for the imaging doctors.

Can image registration support radiologists in breast tomosynthesis image reading?

M. [Costa](#)¹, D. Ermacora¹, S. Pesente¹, G. Simonetti¹, E. Belladonna², M. Tonutti²; ¹Udine/IT, ²Trieste/IT (matilde.costa@tecnologieavanzate.com)

Purpose: This work proposes an image registration approach able to correlate corresponding positions between digital breast tomosynthesis (DBT) images and evaluates its effectiveness for simultaneous and synchronized navigation of multiple images.

Methods and Materials: The proposed registration method supports the correlation between the following images: 2D-synthesized image and 3D image (2Ds-DBT), where the corresponding depth of a 2D point is identified by an out-of-plane pattern (OPP) detector; 3D image and priors (DBT-priors), where corresponding locations are found matching couple of OPPs with an anisotropic feature descriptor; 3D images of different projections (2-view DBT), where corresponding regions in ipsilateral views are matched combining the OPP detector/descriptor with an elastic breast compression model. The target registration error (TRE, expressed as the average distance with reference positions annotated by experts) is evaluated as registration accuracy estimate.

Results: The estimated mean TRE and the percentage of cases below a tolerance (success rate) defined by experts are respectively: 3.4 mm and 97% below 10 mm tested on 215 datasets with a total of 2887 markers for 2Ds-DBT; 6.7 mm and 96% below 10 mm tested on 120 datasets with 980 markers for DBT-priors; 18.3 mm and 96% below 40 mm tested on 101 datasets with 295 markers for 2-view DBT.

Conclusion: We showed that the proposed registration algorithms for DBT images lead to a stable synchronization (success rate of 96%) among multiple images with an acceptable average TRE between corresponding regions. This suggests the feasibility of an interactive synchronization tool between images for a straightforward simultaneous multi-view and multi-image DBT reading.

B-1522 11:10

Machine learning can combine B mode ultrasound and strain elastography features to better characterise BIRADS 3 and 4 lesions

A. [Prakash](#); Jaipur/IN (dr.aparnaprakash@gmail.com)

Purpose: Machine learning uses knowledge from previous dataset and tries to predict future outcome without assuming the usual statistical distribution patterns in data. We evaluate the feasibility of combining the strain ratio and strain elastography score with b mode ultrasound descriptors in predicting a benign or malignant outcome of BIRADS 3 & 4 lesions.

Methods and Materials: IRB approval was obtained and 200 consecutive patients undergoing breast biopsy prospectively included to undergo strain elastography. Of these 37 cases were characterised as BIRADS 3 and 32 as BIRADS 4. A random forest algorithm was trained using the b mode ultrasound descriptors of shape, margin, echogenicity, calcification, acoustic shadowing, surrounding tissue distortion, the final BIRADS description and the Elastography score and Elastography ratio as the predictors and final benign or malignant outcome as the target. A 10 fold cross validation was used because of the small sample size.

Results: The machine learning model was able to predict a malignant outcome in BIRADS 3 & 4 lesions with a sensitivity of 91.30% and specificity of 93.33%. The positive likelihood ratio of the lesion turning out malignant was 15.50 when the model predicted a malignant outcome for BIRADS 3 lesion.

Conclusion: Machine learning algorithms can combine b mode and sonoelastography imaging finding to predict outcome with a high degree of accuracy. However opacity in the functioning of these algorithms need to be removed before their implementation in clinical utilization.

Computer-aided detection of breast masses in dedicated breast CT images using adaptive parenchyma local search and deep learning
 M. Caballo, J. Teuwen, R.M. Mann, I. Sechopoulos; *Nijmegen/NL*
 (Marco.Caballo@radboudumc.nl)

Purpose: To develop an automated detection system for mass-like lesions in unenhanced breast CT images.

Methods and Materials: The proposed system is composed of four main steps. First, the breast parenchyma (including any suspicious mass) is identified using automatic segmentation. Second, a multi-scale candidate selection algorithm based on second-order features is used to discretize the search space. The algorithm identifies possible centers of masses, generating around each center a candidate region whose dimensions adapt to the local size of the parenchyma. Then, a multi-view convolutional neural network extracts texture and shape-related features and classifies these candidate regions (scaled to the same dimensions) as either masses or normal tissue. To handle the skewness in class proportion, the network was trained iteratively by dividing the dataset into multiple batches, each always containing the whole set of masses, and as many different normal examples. Finally, fusion of multi-view information from the detected regions is used for false positive reduction. The system was trained on 75 patient-breast CT images on a patch-basis (43,890 normal, 2,601 masses), and tested on a global-basis on another 20 images.

Results: The developed computer-aided detection system has an average detection sensitivity of 90% at 3 false positives per scan.

Conclusion: Results indicate that the combination of second-order features and deep learning is a promising approach for breast mass detection in unenhanced breast CT images, and will be further evaluated in future with a larger image dataset.

B-1524 11:26

Artificial intelligence CAD system capability to classify breast density by mammography
 E.F. Fleury, P.E.Z. de Assis, F.A. Azevedo, R. Lotufo; *Sao Paulo/BR*
 (edufleury@hotmail.com)

Purpose: Determine an artificial intelligence CAD system capability to classify breast density by mammography.

Methods and Materials: The breast density (BD) pattern of 1.000 mammograms from a retrospective screening setting were determined. The BD were classified using an artificial intelligence CAD system with machine-learning technologies, which classified the breast density according to the BI-RADS 5th edition lexicon, which adopts criteria for evaluating the histogram of fibroglandular density rather than its distribution. The breast density patterns are: a. Almost entirely fat; b. Scattered areas of fibroglandular density; c. Heterogeneously dense; d. Extremely dense. Cranio-caudal incidence was opted for analysis because it presented a better contrast due the best compression of the breast compared to the mediolateral-oblique view, and to have fewer structures that contaminate the images, like pectoral muscle. An observer with 16 years of experience in breast imaging has previously classified the mammograms visually, adopting the same criteria used by the software. Agreement between the CAD and the observer was determined.

Results: The results show good agreement between the CAD system and the observer to classify the BD according to the BI-RADS lexicon, with agreement of 78.3%.

Conclusion: The use of an artificial intelligence CAD system has the potential to be used in clinical practice to classify the BD pattern by mammograms according to the lexicon BI-RADS 5th edition.

B-1525 11:34

Automatic deep learning-based denoising filter for 4D dedicated breast CT perfusion imaging of breast cancer
 M. Caballo, R.M. Mann, I. Sechopoulos; *Nijmegen/NL*
 (Marco.Caballo@radboudumc.nl)

Purpose: To develop a 4D denoising filter for perfusion contrast-enhanced dedicated breast CT imaging.

Methods and Materials: Twenty 4D software phantoms were generated from different real 3D patient dedicated breast CT scans using a previously developed algorithm that simulates dynamic contrast enhancement patterns within the different breast tissues and tumours. All phantoms had a temporal resolution of 10s over 5-min scanning, and were corrupted with noise levels corresponding to acquisitions resulting in average glandular doses per 3D scan of 0.95mGy, 0.7mGy and 0.5mGy. A 4D image denoising deep learning algorithm was developed that first removes the quantum noise from the baseline scan (time zero) using a convolutional neural network, and then recovers the noisy perfusion curves using deep pattern recognition networks which recognize and average similar enhancement patterns throughout the image. The algorithm was trained using 8,000 image patches and 50,000 perfusion signals extracted from 13 pairs of 4D phantoms (noisy and noise

free), and tested on the remaining 7 on a global basis. Signal-to-noise ratio was calculated both in the baseline scan and on perfusion curves, within homogeneous regions.

Results: On average, the signal-to-noise ratio of the baseline scan and of the perfusion curves increased after the filtering (+11.46±1.14dB, +24.34±1.96dB, respectively).

Conclusion: The filter was able to increase the signal-to-noise ratio both spatially and temporally. Future work includes evaluating additional perfusion patterns, incorporating more realistic noise and spatial resolution loss models deriving from 4D breast CT image-acquisition simulations, scatter correction, and testing with real patient 4D images.

B-1526 11:42

Ability of an artificial intelligence CAD system to determine quality control of the mammographic study
 E.F. Fleury, P.E. de Assis, F.A. Azevedo, R. Lotufo; *Sao Paulo/BR*
 (edufleury@hotmail.com)

Purpose: Evaluate the ability of an artificial intelligence CAD system to determine quality control of the mammographic study.

Methods and Materials: Retrospectively evaluation of mammographic quality pattern of 1.000 consecutive screening mammograms in the cranio-caudal and oblique medio-lateral incidences. The mammograms were classified using an artificial intelligence CAD system with the technology of deep-learning that automated classified the quality of the acquired images according to the following criteria: I. Bad Quality; II. Acceptable Quality; III. Good Quality. An observer with 16 years of experience in breast previously classified the mammograms visually, adopting the criteria proposed by the MQSA (Mammographic Quality Standards Act), which assesses: 1. Positioning; 2. Contrast; 3. Artifacts; 4. Blurring. The agreement was determined between the CAD system and the observer.

Results: The agreement between the CAD system and the observer to classify the mammograms quality was good, with 70.0% agreement.

Conclusion: The artificial intelligence CAD system has the potential to be used in clinical practice to determine the quality control of the breast mammograms at screening settings.

B-1527 11:50

Scatter radiation correction in digital breast tomosynthesis with a deep learning convolutional neural network
 A. Rodriguez Ruiz¹, C. Fedon², K. Michielsen³, I. Sechopoulos¹; ¹*Nijmegen/NL*, ²*Trieste/IT*, ³*Leuven/BE*

Purpose: To develop a deep learning convolutional neural network (CNN) that can model the scatter signal in digital breast tomosynthesis (DBT) projections.

Methods and Materials: Homogeneous software phantoms representing different compressed breasts undergoing a cranio-caudal DBT exam were implemented in a Monte Carlo (MC) simulation of a 15° wide / 15 projection DBT scan with 10⁸ photons, yielding the scatter fraction (SF) image estimate of each projection. A CNN was trained to predict these SF images using the MC-simulated SF images of 180 phantoms as ground truth. The mean absolute error (MAE) between the MC-simulated SF and the CNN-predicted SF was computed in 20 other phantoms. The method was evaluated on 140 patient DBT scans (including 20 masses, 22 calcification clusters) by comparing original and scatter-corrected volumes in terms of the signal-difference-to-noise-ratio (SDNR) of the lesions and the area under the receiver operating characteristic curve (AUC) of a commercially-available artificial intelligence CAD system for DBT.

Results: The MAE between the CNN-predicted and the MC-simulated scatter images was less than 1%. The CNN generated scatter images up to 10⁵ times faster than MC simulations (0.01 s versus 130 s). After scatter correction, the SDNR of calcifications increased (+25%, P=0.016), while the SDNR of masses (+6%, P=0.455) and the detection accuracy (+0.03 AUC, 95% CI = [-0.12, 0.17]) remained similar.

Conclusion: A deep learning CNN can predict the scatter image in DBT projections as accurately as a Monte Carlo simulation but in a significantly lower amount of time.

Prospective comparison of transient elastography (1D-TE), shear wave elastography (2D-SWE) and magnetic resonance elastography (MRE) for assessment of liver fibrosis in HCV patients

J. Matos, I. Mussetto, F. Paparo, S. Perugin Bernardi, M. De Cesari, L. Cevasco, G. Cenderello, L. Bacigalupo, G.A. Rollandi; *Genoa/IT* (jfgavinadematos@gmail.com)

Purpose: To assess the agreement among three different stiffness imaging techniques for fibrosis staging in HCV patients. To understand which factors may influence the concordance between the different techniques.

Methods and Materials: This was a prospective study. 93 HCV patients were enrolled from March 2017 to September 2018. Each patient was subjected to three techniques performed by blinded operators on the same day. 77 patients had reliable liver stiffness measurements on 1D-TE, 2D-SWE and MRE. Patients were assigned to three different fibrosis groups using kPa cutoffs recommended in a 2015 consensus statement (group 1: no fibrosis, group 2: moderate fibrosis, group 3: advanced fibrosis or cirrhosis). Techniques were confronted (1D-TE vs MRE, 1D-TE vs 2D-SWE, MRE vs 2D-SWE) to assess agreement (kappa Cohen) and kPa value correlation (Spearman's test). Logistic regression was performed to assess factors that determine disagreement.

Results: Agreement among all three techniques was observed in 64.9% of patients. Complete disagreement was seen in just 2.6%. Inter-rater agreement in assigning correct fibrosis group was good for all three pairs of techniques (1D-TE vs MRE 0.81, 1D-TE vs 2D-SWE 0.66, MRE vs 2D-SWE 0.70). Strong correlation of kPa values was observed for all three pairs of techniques. BMI was the only feature associated with disagreement (OR: 1,17; p: 0,02).

Conclusion: Tested techniques correctly assign patients to the same fibrosis group in the majority of cases. Good agreement and strong correlation was demonstrated between the different techniques in non-invasive assessment of liver fibrosis in HCV patients.

Liver stiffness quantification in patients with non-alcoholic steatohepatitis: comparison of shear wave elastography and transient elastography with liver biopsy correlation

G. Caruana, A. Taibbi, S. Petta, R. Cannella, G. Busè, G. Cutaia, D. Giambelluca, V. Di Marco, T.V. Bartolotta; *Palermo/IT* (rob.cannella@libero.it)

Purpose: To assess the accuracy of liver stiffness quantification in patients with non-alcoholic steatohepatitis (NASH) using shear wave elastography (SWE) in comparison with transient elastography (TE).

Methods and Materials: This is a prospective study performed in a single institution, including 49 patients with histological diagnosis of NASH. The stiffness of the right liver lobe was measured on the same day with two techniques: TE (FibroScan, Echosens), and SWE (RS80A ultrasound system, Samsung Medison). In the SWE evaluation, 11 patients were excluded due to more than 75% measurements fails. Receiver operating curves (ROC), areas under the ROC (AUROC) and 95% confidence intervals (CI) were calculated to assess the accuracy of TE and SWE for the diagnosis of significant fibrosis (F2-F4) and advanced fibrosis (F3-F4). Spearman's rank coefficient (rho) was used for correlation of TE with SWE. A p<0.05 was considered for statistical significance.

Results: 38 patients were included in the final population. Overall 24 (63%) patients had significant fibrosis and 17 (45%) had advanced fibrosis. TE and SWE showed an AUROC of 0.711 (95% CI: 0.545-0.877, p=0.032) and 0.729 (95% CI: 0.562-0.896, p=0.020) for the diagnosis of significant fibrosis. The AUROC for the diagnosis of advanced fibrosis were 0.803 (95% CI: 0.648-0.9580, p=0.002) and 0.811 (95% CI: 0.667-0.955, p=0.001) for TE and SWE, respectively. There was a significant correlation between TE and SWE measurements (rho=0.455, p=0.004).

Conclusion: SWE and TE have both a good accuracy, with a significant correlation, for the diagnosis of advanced fibrosis in NASH-patients.

Comparison of sound touch elastography (STE) and shear wave elastography (SWE) using liver biopsy as 'gold standard' for chronic liver disease assessment

I. Gatos¹, P. Drazinos², S. Yarmenitis³, I. Theotokas¹, A. Soultatos¹, E. Panteleakou¹, P. Zoumpoulis²; ¹Athens/GR, ²Kifissia/GR, ³Marousi/GR (p.zoumpoulis@echomed.gr)

Purpose: Chronic liver disease (CLD) is currently one of the major causes of death and the major cause of hepatocellular carcinoma development. sound touch elastography (STE) that is available in Resona 7 Ultrasound (US) device and is similar to shear wave elastography (SWE), seems promising for CLD diagnosis but needs to be validated. The aim of this study is to compare the diagnostic performance between the STE and SWE for CLD assessment, using Liver Biopsy (LB) as "gold standard".

Methods and Materials: 290 subjects, 68 normal (F0) and 222 with CLD (F1-F4), were included in the study. A B-Mode and Elastographic examination was performed on each patient with Resona 7 and Aixplorer US devices. The STE (Resona 7) and SWE (Aixplorer) measurements were performed on the Right Lobe (RL) of each patient and were compared to LB results according to the Metavir Classification System (F0-F4). Receiver Operating Characteristic (ROC) analysis was then performed for each of the two methods to obtain best cut-off stiffness values.

Results: ROC analysis showed AUC_{STE}=0.9741 and AUC_{SWE}=0.9854 for F=F4 (Cirrhosis), AUC_{STE}=0.9723 and AUC_{SWE}=0.9755 for F≥F3, AUC_{STE}=0.9675 and AUC_{SWE}=0.9662 for F≥F2, AUC_{STE}=0.8889 and AUC_{SWE}=0.9288 for F≥F1 Fibrosis Stages. Best cut-off stiffness values for each method (STE/SWE) were: F=F4: 12.2/13.5 kPa, F≥F3: 9.5/8.7 kPa, F≥F2: 9.15/8.55 kPa, F≥F1: 6.5/6.05 kPa respectively.

Conclusion: Both STE and SWE can differentiate between all Metavir fibrosis stages. SWE seems more reliable in differentiating normals from patients with F≥F1 and Cirrhotic patients (F=F4) but less accurate in diagnosing intermediate stages (F≥F2, F≥F3).

Volumetric iodine density using dual-layer spectral CT for liver fibrosis staging and histopathological correlation

L. Wang, R. Li, F. Yan, J. Qiang, Q. Han, X. Chen; *Shanghai/CN* (15216572203@163.com)

Purpose: To investigate the value of volumetric iodine density (VID) using dual-layer spectral CT for liver fibrosis staging and correlated with histopathological results.

Methods and Materials: Twenty rabbit models of CCl₄-induced liver fibrosis were established and four untreated rabbits served as controls. All of rabbits underwent four-phasic (noncontrasts, arterial phase [AP], venous phase [VP], and equilibrium phase [EP]) enhanced CT using dual-layer spectral CT (IQON). Volumetric iodine density of the liver (VID_{liver}) and aorta (VID_{aorta}) were derived based on whole-liver and whole-aorta volume measurement. Normalized volumetric iodine density (NVID) were determine as ΔVID_{liver}/ΔVID_{aorta}. Fibrosis stage, percentage of sinusoidal area (SA%) and α-SMA staining microvessel area (MVA) were quantified at histopathology. Correlation analysis was performed between NVID and fibrosis stage, SA%, and MVA. Receiver operating characteristic (ROC) analysis was performed for assessing

diagnostic performance of NVID in detection of clinical significant fibrosis ($\geq F2$) and advanced fibrosis ($\geq F3$).

Results: No significant correlation was identified between either NVID_{AP}, NVID_{VP}, and fibrosis stage ($P>0.05$). NVID_{EP} showed significant positive correlation with fibrosis stage ($r=0.667$, $P=0.0004$) and SA% ($r=0.603$, $p<0.001$). There was no significant correlation between NVID_{EP} and MVA ($r=0.2666$, $P=0.2079$). NVID_{EP} had a sensitivity, specificity, and AUROC of 92.9%, 70.0%, 0.796, respectively, for the diagnosis of $\geq F2$ fibrosis; and 100%, 73%, and 0.870, respectively, for the diagnosis of $\geq F3$ fibrosis.

Conclusion: Whole-liver volumetric iodine density using dual-layer spectral CT may be a potential biomarker for liver fibrosis staging.

B-1532 11:02

Reproducibility of shear wave dispersion imaging for evaluation of non-alcoholic fatty liver disease

J. Yoo, J. Lee, H.-J. Kang, S. Ahn; *Seoul/KR (jeongjin527@gmail.com)*

Purpose: To evaluate the intraobserver and interobserver reproducibility of shear wave dispersion imaging (SWDI) for noninvasive evaluation of nonalcoholic fatty liver disease (NAFLD).

Methods and Materials: This prospective study was approved by our institutional review board and informed consents were obtained from all subjects. In group I, 71 patients with suspected or alleged NAFLD underwent grey-scale ultrasound (US) imaging and two sessions of dispersion imaging by one abdominal radiologist. In group II, 19 asymptomatic volunteers underwent grey-scale US and three independent sessions of dispersion imaging by three abdominal radiologists. The visual grade of hepatic steatosis on grey-scale US was scored as 0 (absent) to 3 (severe) by two independent reviewers. Intra-observer (group I) and inter-observer (group II) reproducibilities of dispersion imaging were assessed using intraclass correlation coefficient (ICC). Independent association of variables with dispersion slope was analysed using a multivariate linear regression model.

Results: For intra-observer reproducibility, ICC was 0.955 (95% CI, 0.926-0.973). In the subgroup analysis of group I, higher BMI, higher grade of steatosis on US, presence of LFT abnormality were not associated with reduced ICC values. ICC for inter-observer agreement of three radiologists was 0.800 (95% CI, 0.572-0.916). There were no significant differences in dispersion slope among different visual grades of hepatic steatosis. In the multivariate analysis, elasticity, ALT, and AST were significantly related to the dispersion slope as independent variables ($p<0.001$, $p=0.02$, and $p=0.03$, respectively).

Conclusion: Shear wave dispersion imaging showed excellent intra-observer and inter-observer agreement.

B-1533 11:10

Are there different cut-off values for staging liver fibrosis using 2D-SWE implemented on different systems from the same manufacturer?

I. Sporea, F.B. Bende, A.S. Popescu, R. Sirlu, M. Danila; *Timisoara/RO (isporea@umft.ro)*

Purpose: To evaluate the range of liver stiffness (LS) cut-off values for predicting different stages of liver fibrosis (LF) for 2D-SWE.GE implemented on 3 different systems from GE Healthcare (LOGIQ E9, LOGIQ S8, LOGIQ P9).

Methods and Materials: We re-evaluated three studies performed in our Department evaluating the performance of 2D-SWE.GE using different systems (LOGIQ E9, LOGIQ S8, LOGIQ P9) for predicting different stages of LF, using Transient Elastography (TE) as the reference method. 1. LOGIQ E9 study: included 331 subjects with or without chronic hepatopathies; reliable LSM were obtained with both methods in 303/331 (91.5%) subjects; LF distribution using was: F<2: 91/303 (30.1%); F=2: 31/303 (10.2%); F=3: 37/303 (12.2%); F=4: 144/303 (47.5%). 2. LOGIQ S8 study: included 179 consecutive subjects, with or without chronic hepatopathies; reliable LSM were obtained in 171/179 (95.5%) subjects; LF distribution was: F<2: 51 (29.8%); F=2: 40 (23.4%); F=3: 31 (18.1%); F=4: 49 (26.7%). 3. LOGIQ P9 study: included 234 consecutive subjects, with or without chronic hepatopathies; reliable LSM were obtained in 205/234 (87.6%) subjects; LF distribution was: F<2: 40/131 (30.5%); F=2: 24/131 (18.3%); F=3: 22/131 (16.8%); F=4: 45/131 (34.4%).

Results: The best cut-off values for 2D-SWE.GE for predicting F ≥ 2 , F ≥ 3 and F=4 were: 1. For LOGIQ E9: 6.7 kPa (AUC-0.95, Se-92.7%, Sp-85.5%), 8.2 kPa (AUC-0.97, Se-95%, Sp-89.3%), 9.3 kPa (AUC-0.96, Se-91.7%, Sp-92.5%). 2. For LOGIQ S8: 6.9 kPa (AUC-0.92, Se-85.8%, Sp-90.2%), 8.2 kPa (AUC-0.93, Se-87.5%, Sp-86.8%), 9.3 kPa (AUC-0.91, Se-85.7%, Sp-81.2%). 3. For LOGIQ P9: 6.8 kPa (AUC-0.93, Se-83.5%, Sp-91.2%), 7.6 kPa (AUC-0.94, Se-86.5%, Sp-92.7%), 9.3 kPa (AUC-0.91, Se-75.5%, Sp-92.5%). The LS cut-off range for 2D-SWE.GE implemented on different systems were: for F ≥ 2 : 6.7-6.9 kPa, for F ≥ 3 : 7.6-8.2 kPa and for F=4: 9.3 kPa.

Conclusion: The LS cut-off values for 2D-SWE.GE implemented on different systems for predicting F ≥ 2 , F ≥ 3 and F=4 are quite similar.

B-1534 11:18

Differentiating mild and substantial fibrosis from normal subjects: comparison of diffusion-kurtosis imaging and conventional diffusion-weighted imaging

S. Xie, Q. Li, H. Qi, Y. Cheng, W. Shen; *Tianjin/CN (xiess1989_happy@163.com)*

Purpose: To compare the diagnostic accuracy of liver diffusion-kurtosis imaging (DKI) and conventional diffusion-weighted imaging (cDWI) for differentiating mild and substantial fibrosis from normal subjects.

Methods and Materials: Twenty-seven healthy volunteers (S0) and forty-five patients with pathological proved mild (S1) or substantial (S2) liver fibrosis underwent DWI with multiple b values ($b=0, 1,000, 1,500, 2,000$ s/mm²). Mean apparent diffusion (MD), mean kurtosis (MK) and apparent diffusion coefficient (ADC) of liver parenchyma were measured and compared between patients with mild or substantial fibrosis and normal subjects. The discriminative abilities of DKI and cDWI parameters were analysed and compared by receiver operating characteristic (ROC) curve analysis.

Results: There were significant differences in MD and ADC values between patients with mild or substantial fibrosis and normal subjects (all $P<0.05$). Moreover, MD value was statistically different between S0 and S1 ($P=0.028$), S0 and S2 ($P=0.005$). ADC value was statistically different between S0 and S2 ($P=0.012$). There was no significant difference in MK for all groups ($P=0.646$). In addition, MD and ADC values significant correlated with fibrosis stages ($r=-0.668, -0.341$; all $P<0.01$), and MK have no correlation with fibrosis stages ($r=0.180$; $P=0.130$). AUC for MD and ADC were 0.937 and 0.707 for characterisation of S1-2, 0.817 and 0.658 for characterisation of S2. MD performed better than ADC for the characterisation of S1-2 and S2 (all $P<0.05$).

Conclusion: MD value derived from DKI is feasible to differentiate mild or substantial fibrosis from normal subjects, and offer better performance than ADC derived from cDWI.

B-1535 11:26

Liver fibrosis and inflammation: influence on the 3D multi-echo Dixon parameters in patients with chronic liver diseases

F. Hu, B. Song, R. Yang, M. Wang; *Chengdu/CN (yingxianghu_cmc@163.com)*

Purpose: To evaluate the influence of liver fibrosis and inflammation on the 3D Multi-Echo Dixon (3D ME Dixon) parameters in patients with chronic liver diseases and to determine the diagnostic performance of 3D ME Dixon for the simultaneous assessment of liver steatosis and iron overload.

Methods and Materials: 99 consecutive patients with chronic liver disease underwent confounder-corrected 3D ME Dixon scan at 3.0T MR scanner. Liver biopsy was reviewed in all cases, grading liver steatosis, siderosis, fibrosis, and inflammation. Spearman correlation and multiple regression analysis were performed to determine the relationship between 3D ME Dixon parameters and histopathological features. Receiver operating characteristic analysis was performed to determine the diagnostic performance.

Results: At multivariate analysis, only liver steatosis independently influenced MRI-PDFF values ($R^2=0.800$, $P<0.001$). liver iron overload and fibrosis influenced R^{2*} values ($R^2=0.631$, $P<0.001$). liver R^{2*} values were moderately correlated with fibrosis stages ($r=0.610$, $P=0.000$) in the subgroup with the absence of iron overload. The AUC of MRI-PDFF was 0.989 for the diagnosis of steatosis grade 1 or greater, and 0.986 for grade 2 or greater. The AUC of R^{2*} was 0.815 for identifying iron overload grade 1 or greater, and 0.876 for steatosis grade 2 or greater.

Conclusion: 3D ME Dixon can be used to simultaneously evaluate liver steatosis and iron overload in patients with chronic liver diseases, especially for quantification of liver steatosis. However, liver R^{2*} value may be affected by the liver fibrosis in the setting of chronic liver diseases with the absence of iron overload.

B-1536 11:34

2D MRE liver stiffness values are nearly equivalent for three sequence types across four multi-center drug-development clinical trials

M.S. Middleton¹, W.C. Henderson¹, A.L. Louie¹, R. Myers², S. Djedjos², C. Sirlin³, ¹La Jolla, CA/US, ²Foster City, CA/US, ³San Diego, CA/US (msm@ucsd.edu)

Purpose: To demonstrate equivalence of 2D MRE sequences in four multi-center drug-development clinical trials

Methods and Materials: MRE liver stiffness is an endpoint in many multi-center drug-development clinical trials. Equivalence across sequence types (GRE, SE, SE-EPI) at 3T has been reported in single-center, single-scanner studies. However, to justify interchangeable use in clinical trials, validation of equivalence is needed across different sites and MR scanner types. To accomplish this, 2D MRE sequence results were reviewed for four multi-center drug-development nonalcoholic fatty liver disease (NAFLD) clinical trials (Gilead NCT02854605, NCT02781584, NCT02856555, and NCT02466516).

Liver stiffness differences across these sequences were compared to region-of-interest (ROI) analysis areas, and correlation analysis of liver stiffness differences and analysis areas was performed.

Results: GRE, and either SE or SE-EPI sequences were compared for 58 MRs, for two MR manufacturers and four scanner types. Mean GRE liver stiffness was 0.06 kPa less than the mean for SE and SE-EPI sequences ($p=0.74$). Absolute differences in liver stiffness were weakly correlated with total ROI areas. Absolute differences were greater between GRE and the other sequences for smaller total ROI areas (0.52, 0.41, and 0.29 kPa for <700 Px, 700-2000 Px, and >2000 Px, respectively), but statistical significance was not reached for those comparisons ($p>0.05$).

Conclusion: Liver stiffness values for three 2D MRE sequences show near equivalence for different types of scanners in four large multi-center NAFLD drug-development clinical trials. These data support using these sequences interchangeably in future multi-center clinical trials.

Comparison of sound touch elastography (STE) and vibration-controlled transient elastography (VCTE) using liver biopsy as a reference for diagnosis of chronic liver disease

I. Gatoss¹, P. Drazinos², S. Yarmenitis³, I. Theotokas¹, A. Kanavaki¹, E. Manesis¹, P. Zoumpoulis², ¹Athens/GR, ²Kifissia/GR, ³Marousi/GR (p.drazinos@echomed.gr)

Purpose: Chronic Liver Disease (CLD) is one of the major causes of death nowadays and the major cause of Hepatocellular Carcinoma development. Vibration Controlled Transient Elastography (VCTE), commercially available via Fibroscan ultrasound (US) device, is a well-established imaging method in CLD diagnosis, while Sound Touch Elastography (STE) that is similar to Shear Wave Elastography (SWE), seems promising but needs to be validated. The aim of this study is to compare the diagnostic performance between STE and VCTE using Liver Biopsy (LB) as "Gold Standard".

Methods and Materials: 210 subjects, 60 normal (F0) and 150 with CLD (F1-F4), were included in the study. A B-Mode and Elastographic examination was performed on each patient with Resona 7 and Fibroscan US devices. STE and VCTE measurements were performed on the RL of each patient and measurements were compared to LB (Metavir Stage: F0-F4). Receiver Operating Characteristic (ROC) analysis was then performed for both methods to obtain best cut-off stiffness values.

Results: ROC analysis showed $AUC_{STE}=0.9747$ and $AUC_{VCTE}=0.9808$ for F=F4 (Cirrhosis), $AUC_{STE}=0.9790$ and $AUC_{VCTE}=0.9792$ for F≥F3, $AUC_{STE}=0.9731$ and $AUC_{VCTE}=0.9644$ for F≥F2, $AUC_{STE}=0.8941$ and $AUC_{VCTE}=0.9185$ for F≥F1 Fibrosis Stages. Best cut-off stiffness values calculated were: F=F4: 13.7/11.3 kPa, F≥F3: 9.5/8.7 kPa, F≥F2: 9.15/8.2 kPa, F≥F1: 6.15/6.1 kPa respectively.

Conclusion: Both VCTE and STE can differentiate between all Metavir fibrosis stages. STE is more reliable in differentiating CLD patients with intermediate fibrosis stages (F≥F2, F≥F2) but is less accurate in detecting fibrosis (F≥F1) and diagnosing Cirrhosis (F=F4) than VCTE.

Liver fibrosis staging with Cannon shear wave elastography: comparison with three other non-invasive tools using histologic criteria as a reference standard

S. Byun, J. Lee, J. Min, K. Shin, S. You, K. Cheon, I. Song, K. Kim; Daejeon/KR (pureeyes111@cnuh.co.kr)

Purpose: To investigate the value of Cannon shear wave elastography (C-SWE) in the assessment of liver fibrosis and to compare the diagnostic performance of C-SWE with that of other noninvasive tools.

Methods and Materials: Sixty-eight patients with chronic liver disease underwent liver stiffness (LS) measurements with C-SWE and elastography point quantification (ElastPQ) in the same session by two observers, respectively. All patients were examined using transient elastography (TE) and serologic test. The inter-observer agreements of both techniques were assessed with intraclass correlation coefficients (ICCs). The diagnostic performance in significant fibrosis (F≥2) and cirrhosis was evaluated using the receiver operating characteristics curve (AUC) analysis with histologic criteria as reference standard.

Results: The values with C-SWE were significantly greater than those with ElastPQ ($p < 0.001$). The LS measurements with C-SWE ($r = 0.663$ and 0.651) and ElastPQ ($r = 0.790$ and 0.668) significantly increased as liver fibrosis progressed. The inter-observer agreement was excellent for C-SWE (ICC=0.842) and ElastPQ (ICC = 0.879). The estimated cut-off values with C-SWE for both observers were 8.88 kPa and 9 kPa to detect significant fibrosis and 13.3 kPa and 10.4 kPa to detect cirrhosis; these were higher than those with ElastPQ. For the prediction of liver fibrosis, C-SWE, ElastPQ, and TE showed comparable high diagnostic performance (range of AUC: 0.802-0.958) and significantly better than that of the serologic fibrosis marker test.

Conclusion: C-SWE is a promising noninvasive US-based technique for assessing liver fibrosis and shows high diagnostic performance comparable to that of ElastPQ and TE.

Multiparameter dose monitoring in mammography: the use of combined breast thickness and density determined DRLs

L. Cockmartin, K. Lemmens, A. Jacobs, J. Binst, H. Bosmans; Leuven/BE (lesley.cockmartin@uzleuven.be)

Purpose: To propose a method for improved high dose alerts using breast thickness and density driven diagnostic reference levels (DRLs) for quality improvement in digital mammography (DM).

Methods and Materials: Screening mammograms were collected on 4 DM systems: Siemens Inspiration, Hologic Selenia Dimensions, Fuji Innovality and GE Essential with in each dataset 8045, 507, 1422 and 1372 images respectively. Breast thickness and mean glandular dose (MGD) were extracted from the dicomheaders (DOSE, QaelumNV) while volumetric breast density (VBD) was assessed using VolparaTM. A fixed value DRL (2mGy for 60mm) as well as a DRL curve based on the 95th percentile of the MGD obtained from large patient samples on 71 systems tested in the Belgian breast screening, are plotted on these data. Additionally, data were color-coded for their Volpara Density Grade (VDG) and a curve fit was applied to the four VDG groups separately. Outliers were defined as exceeding the 95th percentile DRL curve, and then also as > 1mGy distance to the density-determined curve fit.

Results: Compared to the use of traditional DRL curves that created 778 (9%) outliers on Siemens, present approach showed only 43 (0.5%) outliers. For Hologic this number dropped to 2 (0.7%), for Fuji Innovality to 4 (0.3%) and for GE Essential to 2 (0.1%). This dose monitoring approach pointed to occasional problems in the high density groups.

Conclusion: Multiparameter dose alerting, using both thickness and density, results in improved selection of cases that need further verification and makes dose monitoring more efficient and relevant.

Accuracy of mammography dosimetry in the era of the European Directive 2013/59/Euratom transposition

G. Gennaro¹, S. Bigolaro¹, M. Hill², R. Stramare¹, F. Caumo¹; ¹Padua/IT, ²Wellington/NZ (gisella.gennaro@ioiv.veneto.it)

Purpose: To evaluate the parameters affecting mammography mean glandular dose (MGD) in the era of the European Directive 2013/59/Euratom transposition, where accurate and personalised dose estimates are of heightened importance.

Methods and Materials: 4028 women who had a mammography examination by one of five mammography units using different detector technologies were included. 16,558 images were processed by a software algorithm that determines breast density (BD) and uses BD to estimate patient-specific MGD. Entrance dose values and half value layers measured for each mammography system within 6 months of imaging were collected to calibrate MGD for equipment performance. Mean MGD values considering BD, without and with calibration data, were compared with manufacturer-reported MGD.

Results: MGD estimated using BD is mostly higher than MGD provided by manufacturers for the studied systems, leading to relative mean MGD differences of 6.6%, 15.3%, 4.4%, 13.5%, -1.7%, for the five mammography units. The average differences between measured and manufacturer-provided entrance doses are small for the five units (-1.3%, -1.4%, -2.61%, 1.2%, 2.6%, respectively), so the additional effect of system calibration is minimal. The inclusion of system calibration in patient-specific MGD estimation results in relative mean differences of 1.0%, 9.7%, 5.9%, 10.6%, and -6.7%, compared to manufacturer-reported MGD respectively, although individual MGD differences as large as 44% were observed, which illustrates the importance of ensuring dose accuracy at the patient level.

Conclusion: Increasing levels of accuracy in mammography dosimetry are possible in the era of the European Directive 2013/59/Euratom transposition, taking into account patient-specific BD and equipment calibration.

First clinical application of spiral breast CT with photon-counting detector: patient-specific radiation dose assessment

N. Salybaeva¹, M. Marcon¹, N. Berger¹, D. Kolditz², C. Steiding², A. Boss¹, H. Alkadh¹; ¹Zurich/CH, ²Erlangen/DE (Natalia.Salybaeva@usz.ch)

Purpose: Dedicated breast CT (BCT) has demonstrated superior image quality compared to digital Mammography (DM) and breast tomosynthesis (BT), however the radiation dose from BCT was higher than the one from DM and BT, especially when referring to the screening settings. The novel BCT scanner equipped with photon-counting detector (PCD) allows for more efficient dose utilization. The aim of the study is to assess the radiation dose from the first clinical application of the BCT with PCD.

Methods and Materials: This study included 17 patients underwent breast CT examination on the first clinical BCT equipped with CdTe detector (Nu-view, Erlangen, Germany). Fixed tube voltage of 60kV and tube current of 25mA were used based on preliminary studies. The individual patient DICOM data together with patient-specific scan parameters were used as an input for Monte Carlo (MC) simulations. The accuracy of the MC simulations was validated against the measurements performed on the same BCT system using ionization chamber in 16-cm CTDI phantom. For each patient the average glandular dose (AGD) was calculated based on the individual 3D dose distribution obtained from MC simulations.

Results: The MC simulation has shown high accuracy comparing to the direct dose measurements, with the mean difference of 4.4%. The average glandular dose ranged from 4.6 to 6.1 mGy, depending in the breast size. The mean ADG was found to be 5.2 mGy.

Conclusion: BCT system with photon-counting detector allows performing breast examinations with full 3D imaging capabilities using the dose comparable to that from two-view DM.

Gadolinium deposits in healthy women undergoing repetitive GDBCA-enhanced breast MRI in the context of high-risk breast cancer screening

B.I. Bennani-Baiti¹, K.B. Krug², D. Giese², K. Weiss², T.H. Helbich¹, P.A.T. Baltzer¹; ¹Vienna/AT, ²Cologne/DE (barbara.bennani-baiti@meduniwien.ac.at)

Purpose: To assess, whether women undergoing contrast-enhanced breast MRI exams in the context of high-risk screening exhibit signal alterations in the dentate nucleus.

Methods and Materials: In this IRB-approved prospective study, 41 healthy women (16 with no previous gadolinium-based contrast agent (GDBCA) exposure and 25 that had >5 GDBCA administrations (range 6-25) in the

context of high-risk breast cancer screening) underwent 3T MRI of the brain, with a dedicated head coil, including T1 mapping and mpRAGE sequences. T1 times and T1 signal intensities were measured for dentate nucleus (ND) and pons, employing Horos software. Ratios of ND to pons were calculated and further statistical analyses were carried out with SPSS and Medcalc.

Results: Spearman's rank correlation revealed no correlation between number of cumulative GDBCA doses and either quantitative T1 times of ND (P=0.4457) or T1 signal intensity ratios of ND to pons (P=0.2885). Similarly, no correlation was found for age and either quantitative T1 times of ND (P=0.1855) or T1 signal intensity ratios of ND to pons (P=0.1653). Multiple regression analysis confirmed these results (P>0.05 for all potential associations of age and cumulative number of GDBCA doses with ND T1 times and ND to pons T1 signal ratios).

Conclusion: The dentate nucleus does not exhibit altered T1 signals after high-cumulative dosages of macrocyclic GDBCAs in healthy women. This indicates that currently employed macrocyclic GDBCAs do not result in Gd deposits in the brain of healthy women participating in a high-risk screening programme for early breast cancer detection.

B-1543 11:02

Mammography positioning errors: a multi-centre study

N. Sharma¹, S. Schofield², M. Fletcher¹, R.L. Hammond³, A. N. Larson³, A.S. Bakken³, E. Handberg³, N.-M. Hopland³, S.E. Iles²; ¹Leeds/UK, ²Halifax, NS/CA, ³Oslo/NO (mo@dal.ca)

Purpose: The objectives of this study are to evaluate agreement between radiologists and radiographers in assessing mammography positioning errors.

Methods and Materials: 672 FFDM studies rejected due to positioning errors were independently reviewed by nine radiographers and one radiologist from three breast imaging centres in Canada, Norway, UK. Readers were provided with a PGMI scale and trained on the use of the image quality review tool (Densitas Inc.). Reviewers evaluated studies for positioning errors including PNL, CC exaggeration, nipple position, skin folds, portion cut-off, patient related artefacts, posterior tissue, pectoralis muscle (position, shape, and thickness), IMF, sagging, positioning on image receptor. Interrater agreement overall and by centre was evaluated using weighted Fleiss' Kappa.

Results: Agreement between readers on individual positioning errors across all centres was slight to moderate (kappas ranging from 0.09 to 0.49), and was only slight for PGMI score (kappa=0.176). Positioning errors with highest agreement between readers within centres included portion cut-off, patient related artefacts, PNL length difference <10mm, portion cut-off, skin folds (kappa=0.88, 0.61, 0.53, 0.52); other positioning errors generally showed slight to fair agreement (kappas < 0.5).

Conclusion: Agreement amongst readers on mammography positioning criteria within and between centres ranges widely; automated image quality assessment may help to improve standardization.

B-1544 11:10

Post-contrast cone-beam breast-CT without the prior pre-contrast scan: can we reduce radiation exposure while maintaining diagnostic accuracy?

S. Wienbeck, U. Fischer, J. Lotz, J. Uhlhig; Göttingen/DE (susanne.wienbeck@med.uni-goettingen.de)

Purpose: To evaluate whether post-contrast Cone-Beam Breast-CT (CBBCT) alone is comparable to the current standard of combined pre- and post-contrast CBBCT regarding diagnostic accuracy and superior regarding radiation exposure.

Methods and Materials: This IRB-approved study included 49 women (61 breasts) with median age 57.9 years and BI-RADS 4/5 lesions diagnosed on mammography/ultrasound in density types c/d breasts. 2 radiologists rated post-contrast CBBCT and pre- and post-contrast CBBCT with subtraction images on the BI-RADS scale separately for calculation of inter- and intraobserver agreement and in consensus for diagnostic accuracy assessment. Sensitivity, specificity and area-under the curve (AUC) were compared via McNemar test and DeLong method, respectively. Subtraction imaging misregistration were measured from 1 (no artefacts) to 4 (artefacts with width >4mm).

Results: A total of 100 lesion (51 malignant; 6 high risk; 43 benign) were included. AUC, sensitivity and specificity showed no significant differences comparing post-contrast CBBCT alone versus pre- and post-contrast CBBCT (AUC: 0.84 vs. 0.83, p=0.643; sensitivity: 0.89 vs. 0.85, p=0.158; specificity: 0.73 vs. 0.76, p=0.655). Inter- and intra-observer agreement were excellent (intraclass correlation coefficient ICC=0.76, ICC=0.83, respectively). Radiation dose was significantly lower for post-contrast CBBCT alone versus pre- and post-contrast CBBCT (median AGD 5.9 mGy vs. 11.7 mGy, p<0.001). High-degree misregistrations were evident in the majority of subtraction images (level 1/2/3/4: 16.9%/27.1%/16.9%/39%), in particular for bilateral exams (3.2%/29.2%/8.3%/58.3%).

Conclusion: Diagnostic accuracy of post-contrast CBBCT alone is comparable to pre- and post-contrast CBBCT in type c/d breasts, while yielding a significant twofold radiation dose reduction.

B-1545 11:18

Local diagnostic reference levels in mammography: setting a maximum/alarm dose in a diagnostic mammography unit using dose monitoring software

R.M.A. Hegazy¹, E.A. Aghahowa², R. Yasin³, A. Eduarte²; ¹Cairo/EG, ²Kuwait/KW, ³Menofia/EG (raniahegazy@hotmail.com)

Purpose: To show feasibility of a dose monitoring software to set an alarm level guided by the local DRLs used in mammography above which it will give a red flag so radiation monitoring team will be alerted to a need for revision of the mammography technique.

Methods and Materials: This is a retrospective study comprising mammographic imaging data for 300 consecutive breasts of variable compositions randomly selected. Data were collected using "DoseWatch™" by GE. Mean glandular dose (MGD) was recorded in relation to patient age, compressed breast thickness (CBT), percentage of glandular tissue (FGL), projection views and skin entrance dose among other imaging parameters. The formula $\text{mean} \pm 1.96 \times \text{SD}$ was used to calculate the MGD range for all patients. The maximum calculated dose was rounded to the nearest whole number. The resultant value was used as an upper threshold above which the dose monitoring software gives a red flag.

Results: MGD was calculated for breast thickness above 50 mm in CC, MLO and 3D tomography in CC view and was found to be 1.32, 1.4 and 1.62 mGy, respectively. Local DRLs for breast imaging was calculated as follows: average MGD CC view = 1.32 minimum = 0.74; maximum = 2.42; alert level = 2 mgy. Average MGD MLO view = 1.4 minimum = 0.92; maximum = 2.42; alert level = 2 mgy. Average MGD TomoCC view = 1.62 minimum = 0.88; maximum = 3.75; alert level = 3 mGy. Data found were well comparable to internationally established results.

Conclusion: A dose monitoring software is an easy and reliable tool to set local DRLs in a busy mammography unit. This can be used to establish local and then national DRLs and to compare with published literature worldwide.

B-1546 11:26

A new technique in mammography: self-compression-survey of patient contentedness

S. Ulus¹, O. Kovan, A. Arslan, P. Elpen, M.E. Aribal; *Istanbul/TR* (silaulus@hotmail.com)

Purpose: Senographe Pristina (GE Healthcare, Chicago, IL) is a next-generation mammography technology that features a self-compression tool allowing patients to manually adjust the degree of breast compression. Purpose of this study is to evaluate the experience of this technology compared to previous examinations with a survey study.

Methods and Materials: The survey studies (12-item questionnaire) subsequent to mammography examinations of 365 patients who underwent screening/diagnostic mammography between April-July 2017 at our centre were reviewed retrospectively. Women who never had a mammography before, who had a previous mammography examination ≥ 2 years ago or who didn't want to use the self-compression device were excluded. 106 women were included.

Results: Patient contentedness was high. 70.8% said it was a better experience compared to previous ones. 84.9% of the participants found the examination comfortable; 75.5% of the participants found the examination more comfortable compared to previous ones. 52.8% of the participants declared they were less anxious compared to previous examinations. 66.9% of the participants declared they found the new design attractive; when compared to previous examinations, 39.7% found it more attractive. 27.3% said the new design decreased anxiety. In the evaluation of impact of patient-assisted compression (PAC) on comfort 80.2% said they found it more comfortable. In the evaluation of impact of PAC on anxiety 64.2% said it decreased anxiety. 72.6% of the participants said the exam was shorter.

Conclusion: Self-compression is a useful technique for decreasing pain during mammography examinations resulting in compliance of women with screening guidelines.

B-1547 11:34

Impact of a radiological consultation on the surgical management of breast cancer patients: a retrospective study of 1114 cases

C. Dratwa; *Paris/FR* (chloedratwa@gmail.com)

Purpose: Evaluate the impact of a radiology image consultation on the surgical strategy in patients with a newly-diagnosed breast cancer.

Methods and Materials: During 2014, 1114 patients with breast cancers (invasive: 87.5%, in situ: 12.5%) underwent an imaging-surgery consultation. Followings parameters were evaluated: missing data in the initial imaging report, number and pathological results of additional breast lesions detected

during this consultation, effects on surgical management, impact on treatment delay and second breast surgeries. Uni- and multivariate analyses were done to identify parameters (clinical, radiological and pathological data) with a significant impact on surgical changes ($p < 0.05$).

Results: BI-RADS category was missing in 4.6% of patients. Cancer size was not evaluated in 126 (11.3%, 63.2% of calcifications vs 3.7% for masses). At consultation, at least one additional lesion was detected in 299 patients (26.8%). Among the 236 patients with percutaneous samplings, 102 lesions were malignant (60 invasives, 42 in situ), 16 at high risk, 114 benign and 4 non-contributive. On 1081 patients with primary surgery, surgical management was modified in 147 (13.6%). Delay for surgery was respected in 95%. Reoperation rate was 7% versus 12.9% in 2013. At univariate analysis, "calcification", BI-RADS categorization omission, unknown size, in situ and lobular subtypes were associated with modified surgical strategies. At multivariate analysis, masses with calcifications and lobular subtype were significantly associated with surgical changes (OR = 1.92 95% CI [1.1-3.24]).

Conclusion: In breast-cancer patients, imaging consultation modified the surgical management in 13.6% without increasing delay for surgery and with a less re-excision rate.

B-1548 11:42

Improving quality assurance in DBT breast screening by visual search monitoring

Y. Chen¹, E. Michalopoulou¹, A.G. Gale¹, D. Bernardi²; ¹Loughborough/UK, ²Trento/IT (Y.Chen@lboro.ac.uk)

Purpose: The current research investigates how experienced DBT radiologists visually inspected FFDM cases.

Methods and Materials: Seven radiologists interpreted 40 normal, benign or malignant cases. Each case comprised FFDM or C-view, and DBT views. The cases were presented on a workstation with dual 5 MP monitors and a remote eye tracker positioned underneath the workstation recorded the participants' visual search behaviour. Participants used their normal breast screening reporting procedure of examining the cases, together with prior mammographic images, and then examined breasts as FFDM and DBT views. Diagnostic reporting data, visual gaze position data and DBT slice scrolling behaviour data were recorded.

Results: Examination of the visual search data indicated that radiologists tended to visually examine large areas of the FFDM views to locate potential suspicious areas and then use the DBT views to 'drill down' across image slices to examine their details. Out of 119 total examinations, 25 cancers were missed on the malignant cases. Scrolling behaviour data demonstrated that individuals who correctly recalled a malignancy spent 56s whilst a missed cancer was evidenced by quickly scrolling through the range of slices where the abnormality existed for only 22 seconds. Participants spent on average 1:10s on successfully recalled malignant cases and 1:08s on malignant cases which were not successfully recalled (two-tail paired t test, $p = 0.294$, n.s.).

Conclusion: FFDM images were searched to establish initial potential areas of interest which were then examined in detail using DBT slices. This strategy could improve quality assurance in breast cancer screening trainees.

B-1549 11:50

Diagnostic performance of low dose contrast-enhanced dual energy mammography in comparison to contrast-enhanced MRI

P. Clauser¹, P.A.T. Baltzer¹, P. Kapetas¹, R.A. Woitek¹, F. Leone², K. Pinker-Domenig¹, M. Weber¹, M. Bernathova¹, T.H. Helbich¹; ¹Vienna/AT, ²Milan/IT (paola.clauser@meduniwien.ac.at)

Purpose: To compare the diagnostic performance of a low-dose contrast-enhanced dual-energy mammography (CEDEM) system with breast contrast-enhanced magnetic resonance imaging (CE-MRI) in women with unclear or suspicious findings on conventional imaging.

Methods and Materials: The ethics committee approved this prospective, monocentric study and all patients gave written informed consent. Women with unclear or suspicious findings on conventional imaging and no contraindications for CEDEM or CE-MRI were invited to participate in the study. Included in the final analysis were women with a histological diagnosis (standard of reference). Three off-site, blinded readers evaluated the images according to BI-RADS lexicon in a randomized order, each in two separate reading sessions. Detection rate, sensitivity, specificity, negative and positive predictive values (NPV, PPV) were calculated and compared with multivariate statistics.

Results: Included were 80 patients (mean age 54.3 years, standard deviation 11.2) with 93 lesions (32 benign, 61 malignant). Detection was higher with CE-MRI (92.5%-94.6%) than with CEDEM (79.6%-91.4%, $P = 0.038$). This was related to a higher detection for benign lesions with CE-MRI. No differences in sensitivity (CEDEM 65.6%-90.2%; CE-MRI 83.6%-93.4%, $P = 0.086$) and NPV (CEDEM 59.6%-71.4%; CE-MRI 63.0%-76.5%, $P = 0.780$) were found. Specificity was higher with CEDEM (46.9%-96.9%) than with CE-MRI (37.5%-53.1%, $P = 0.001$). PPV was higher with CEDEM (76.4%-97.6%; CE-MRI 73.3%-77.3% $P = 0.007$). Accuracy of CEDEM was as good as CE-MRI (75.3%-76.3%

versus 72.0%-75.3% respectively, $P=0.514$).

Conclusion: CEDEM showed high detection rate for malignant lesions. Sensitivity and accuracy of CEDEM were as good as CE-MRI, with a higher specificity. CEDEM shows the potential to reduce unnecessary biopsy.

Advanced imaging technique in diagnosis of Parkinson's disease: quantitative MRI mapping of substantia nigra

M.V.M. Micelli¹, A. Corridore¹, S. Torlone¹, L. Panebianco¹, P. Cerrone¹, M. Martino², P. Sucapane¹, A. Splendiani¹, C. Masciocchi¹; ¹L'Aquila/IT, ²Rome/IT (micelli.mvm@gmail.com)

Purpose: Parkinson's disease (PD) is characterised by a degeneration of the dopaminergic neurons in the substantia nigra (SN). Susceptibility-weighted imaging (SWI) shows an abnormal signal intensity inside SN-pars compacta (SNpc) in PD patients. The aim of the study is to assess T1- and T2-values inside SNpc in PD patients.

Methods and Materials: 35 PD patients and 20 sex- and age-matched subjects, without movement disorders, underwent HR-SWI and a synthetic sequence using a 3.0T MRI scan and a 32 phased-array head coil. MRI software automatically generated quantitative maps and T1-, T2- and proton density values were obtained using a manual region of interest (ROI) on SNpc by two-blinded neuroradiology. Analysis of covariance was conducted to analyse the T1-, T2- and proton density values and interobserver agreement was evaluated by calculating the kappa coefficient from the mean kappa pairwise scores.

Results: HR-SWI showed a loss of the swallow-tail sign in all PD patients (15 cases were monolateral); no degenerations were identified in control group. Quantitative MRI mapping showed T2 (ms) and R2 (1/s)-values to be statistically different between PD and controls ($p<0.002$), in detail (mean \pm SD): R2-values: 15.5 ± 1 vs 12.9 ± 1 (PD vs controls), T2-values: 67.3 ± 7.5 vs 76.8 ± 5.1 (PD vs controls). Proton density- and T1-values were not statistically different. Interobserver agreement was higher in quantitative MRI mapping (100%) than HR-SWI (85%).

Conclusion: T2-mapping is an objective method in quantifying the hypointensity inside SN. It could discriminate patients affected by Parkinson's disease due to the capability to assess pathological changes inside nigral neurons.

B-1551 10:38

Executive network integrity predicts sarcopenia in patients with Parkinson's disease

C.Y. Lee, Y.-S. Chen, P.-C. Chen, C.-H. Lu, W.-C. Lin; Kaohsiung/TW (rose80113@hotmail.com)

Purpose: Sarcopenia in Parkinson's disease (PD) patients is significantly associated with morbidity and mortality as disease progression. However, an analysis of clinical severity and brain change, such as white matter (WM) alteration in PD patients with sarcopenia (PDSa), is still limited. A better understanding of associated factors with sarcopenia could provide a focused screen and early intervention in PD patients.

Methods and Materials: 52 PD patients and 19 healthy participants accepted dual-energy X-ray absorptiometry to measure the body composition. Using diffusion tensor imaging, the difference of WM integrity was measured between PDSa and without sarcopenia (PDNSa). Multivariate analysis was performed to explore the relationship between clinical factors, WM integrity and sarcopenia in PD patients.

Results: 21 PD patients (40.4%) exhibited sarcopenia. Compared to PDNSa, PDSa had lower fractional anisotropy accompanied by higher radial diffusivity and/or higher mean diffusivity in fronto-striato-thalamic circuits including bilateral cingulum, left superior longitudinal fasciculus, left genu of corpus callosum, and right anterior thalamic radiation, which prominently participate in the executive function. In addition, decreased muscle mass was associated with worse WM integrity in these regions. Further multiple linear regression

analysis revealed that worse WM integrity in left cingulum, right anterior thalamic radiation, together with gender (male) were independent risk factors for predicting sarcopenia in PD patients.

Conclusion: WM alterations in the executive functional network, such as fronto-striato-thalamic circuits, might be an important risk factor for ongoing sarcopenia in PD. These patterns of WM damage imply the underlying aetiology and provide a marker to predict the development of sarcopenia for comorbidity early prevention.

B-1552 10:46

Treatment of essential tremor (ET) and Parkinson disease (PD) tremor with MRgFUS: preliminary results from 21 patients in a single centre

F. Bruno, M. Micelli, L. Panebianco, F. Arrigoni, M. Varrassi, A. Catalucci, P. Sucapane, A. Ricci, C. Masciocchi; L'Aquila/IT (federico.bruno.1988@gmail.com)

Purpose: To report our experience in the treatment of ET and PD tremor using MRgFUS thalamotomy.

Methods and Materials: In the period February-September 2018, we enrolled 21 patients (12 males, 9 females, mean age 64.6 years) with disabling and refractory tremor (11 ET, 10 PD tremor, mean duration of symptomatology 10.4 years) who were subjected to unilateral Vim ablation using MRgFUS. Clinical evaluation was performed using the Fahn-Tolosa-Marin scale (FTM) for tremor and the QUEST score for quality of life, assessed before treatment, immediately after treatment and with follow-up at 1 month and 3 months. Instrumental MRI follow-up was performed at the same follow-up periods. Sonication parameters were recorded in all procedures.

Results: Treatment was effective (substantial and immediate reduction of tremor) in 20 out of 21 patients (95.2%). FTM scores decreased from mean values of 33.4 before treatment to 14.7 immediately after treatment. In patients followed-up at 1 month (10 patients), the clinical evaluation showed a minimal increase in the mean FTM values due to the reappearance of tremor in 4 patients (mean FTM 16.4 vs. 14.7). At 3 months (6 patients), we found a substantial stability of treatment effects. Quality of life evaluation showed substantial improvement (73.2% reduction of the QUEST scores). Temporary side effects and complications (dysarthria, perioral paresthesias, limb weakness) occurred in 3 patients.

Conclusion: In our experience with a relatively small number of patients and a short follow-up, MRgFUS thalamotomy resulted in a safe and effective treatment option for tremor in ET and PD patients.

B-1553 10:54

Functional connectivity alterations of dorsal premotor cortex subregions in Parkinson's disease

B. Sigl¹, C. Jockwitz², C. Mathys³, S. Eickhoff², C.J. Hartmann¹, C. Rubbert¹, B. Turowski¹, S. Caspers², J. Caspers¹; ¹Düsseldorf/DE, ²Jülich/DE, ³Oldenburg/DE (benjamin.sigl1988@gmail.com)

Purpose: Parkinson's disease (PD) is associated with impairments in motor and cognitive function. Areas of the dorsal premotor cortex (PMd) "6d1-3" are mediators between motor and cognitive networks. We used resting state functional connectivity (RSFC) to investigate PD-related changes of these areas.

Methods and Materials: RSFC was assessed in 40 PD patients under dopaminergic medication ("ON") and after >12h withdrawal ("OFF") and in 40 matched healthy controls (HC). Microstructurally defined areas 6d1-3 within PMd were used as seed regions. We tested for group differences in whole-brain RSFC (PD-OFF/ON vs HC) and for correlations with UPDRS-III score.

Results: There was RSFC-decline in PD-OFF compared to HC for left area 6d1 and 6d2 with right 6d1 and right dorsomedial prefrontal cortex respectively. The latter normalized under medication. Connectivity increase was found for right area 6d3 with bilateral pre- and postcentral regions in PD-ON. We found negative correlation of UPDRS-III with RSFC of right areas 6d2 and 6d3 with left 6d1 in PD-OFF, and of left area 6d2 with bilateral dorsolateral prefrontal cortex in PD-ON, and a positive correlation for RSFC between right 6d3 and bilateral central region.

Conclusion: Distinct RSFC-changes of PMd areas in PD reveal their differential involvement in PD pathology. Connectivity loss within the premotor cortex and with dorsolateral prefrontal cortex are probably directly related to PD symptoms such as motor planning, sensorimotor transformation and cognitive motor control. RSFC-increase of right 6d3 with sensorimotor areas in PD-ON might indicate a dopamine-induced compensation for motor impairment through increased cognitive motor control.

B-1554 11:02

DMN-neuronal activity pattern in patients with PD in early stages

E. Seliverstova, Y. Seliverstov, R. Konovalov, M. Krotenkova, S. Illarionshkin; Moscow/RU (eselivers@yahoo.com)

Purpose: To assess pattern of neuronal activity within default mode network (DMN) in patients with Parkinson's disease (PD) in early stages comparing to healthy controls.

Methods and Materials: We have examined and compared 3 independent right-handed groups (25 patients with PD in early stage, 15 females, mean age 60.2, in pharmacological treatment; 16 newly diagnosed PD patients, 9 females, mean age 55.3; 21 healthy volunteers, 14 females, mean age 48.2) underwent 1.5 T resting-state fMRI scanning; data were calculated using software GIFT and SPM.

Results: We have observed multidirectional changes in neuronal activity within DMN in examination groups of patients, reduction and extension of activation in different DMN areas. But we observed unique equal pattern - significantly greater areas of spontaneous neuronal activity in right/left precuneus [$pFWECorr < 0.05$; $T > 5$] and significant reduction of activation in the right inferior parietal lobule in both groups of PD patients (in pharmacological treatment and newly diagnosed PD patients) versus healthy volunteers [$pFWECorr = 0.037$; $T = 4.7$]. This area is involved in visual-spatial perception (disturbed in PD patients); area changes correlated with decrease in MoCA score and increase in UPDRS ($p < 0.05$).

Conclusion: We have found certain changes of the activation pattern within DMN in patients with early stage PD, including multidirectional changes in neuronal activity in DMN areas in groups of patients, and same significantly changes in both precuneus and right inferior parietal lobule. Our findings may indicate the ongoing neurodegenerative process, reflect neuroplasticity phenomena and be demonstration of functional intercommunication, and functional connectivity as compensatory mechanisms in neurodegeneration.

B-1555 11:10

Resting state functional MRI connectivity comparison between Alzheimer's disease and Parkinson's disease dementia: a sub-analysis

P.A. Harman¹, C. Law², M. Johnson³, S. Pardhan¹, I.Q. Grunwald¹, K. Ramavathu⁴; ¹Chelmsford/UK, ²Stanford, CA/US, ³Southend-on-Sea/UK, ⁴Westcliff on Sea/UK (Kumar.Ramavathu@southend.nhs.uk)

Purpose: Resting state functional MRI (RS fMRI) has been suggested as a potential biomarker for Alzheimer's Disease (AD). However, there is little research into the functional connectivity (FC) patterns of Parkinson's disease dementia (PDD) and no study has sought to directly compare the two. We present a sub-analysis on a set of patients from a larger study which aims to evaluate the use of RS-fMRI in clinical routine, on a 1.5T MRI.

Methods and Materials: As part of an on-going, prospective, observational study, sub-analysis was performed on a small subset of patients. Confirmed PDD patients were age and gender matched to confirmed AD patients. Participants underwent a RS-fMRI scan on a standard 1.5T clinical care MRI and also undertook a neuropsychological battery assessing various areas of cognition. Functional connectivity in regards to clinical characteristics was evaluated along with cognitive profiles.

Results: Analysis showed characteristic differences between the PDD and AD group, specifically regarding the retrieval region in the left executive control network. The AD group had increased levels of connectivity between the retrieval region to left insula and prefrontal cortex regions.

Conclusion: To date we believe this is the first comparison of FC in AD and PDD. A reduction of connectivity from a seed in the left executive control network could represent a distinguishing feature for PDD groups in RS-fMRI data. It seems feasible to incorporate RS fMRI scanning into clinical routine scanning, even on a 1.5T scanner.

B-1556 11:18

3T susceptibility-weighted imaging and Parkinson's disease: new fields in neuroimaging

A. Corridore¹, S. Torlone¹, M. Micelli¹, M. Martino², L. Panebianco¹, P. Cerrone¹, P. Sucapane¹, A. Splendiani¹, C. Masciocchi¹; ¹L'Aquila/IT, ²Rome/IT (antonella.corridore@gmail.com)

Purpose: Aim of the study was to evaluate the morphological features of the Substantia Nigra (SN) in Susceptibility-Weighted Imaging (SWI) sequences in order to assess its reliability in Parkinson Disease (PD) diagnosis and its correlation with neurodegeneration severity.

Methods and Materials: We prospectively evaluated 60 consecutive patients with PD diagnosis, who had been admitted at the Neurological Movements Disorders Ambulatory of our Institution in L'Aquila.

Patients underwent standard brain 3T-MR examination supplemented by SWI sequence for the Nigrosome-1 evaluation; a control group of 20 healthy patients was also provided. Two expert neuroradiologists analysed the SWI images in blind and defined a SN degeneration severity score (mild, moderate and severe). A complete evaluation of the motor function by UPDRS, a

cognitive evaluation by MoCA and an analysis of non-motor disorders by NMSS were performed.

Results: SWI sequences showed accuracy in the disease detection in patients with PD compared to control group ($\chi^2 = 10.31$; $p = 0.001$). A statistically significant correlation ($\chi^2 = 8.22$; $p = 0.016$) between laterality of symptoms and contralateral degeneration of SN pars compacta was depicted. Rigidity and bradykinesia showed a non-statistically relevant association with the contralateral SN degeneration degree. The presence of hallucinations and their severity seem negatively related to the SN hypointensity measured through SWI sequence ($p = 0.015$).

Conclusion: SWI sequence performed in patients with PD represents an efficient support in the differential diagnosis and, potentially, in the monitoring of the disease progression.

B-1557 11:26

Structural integrity impact of focused ultrasound thalamotomy and correlation to behavioural outcomes for tremor disorders

G. Zur, O. Lesman-Segev, I. Schlesinger, A. Eran, I. Kahn; Haifa/IL (gil_zur@yahoo.com)

Purpose: To evaluate white matter changes following MRI-guided focused ultrasound (MRgFUS) ablation of the thalamus and correlate it with treatment successes in essential tremor (ET) and Parkinson's disease (PD) patients.

Methods and Materials: 22 ET and 17 PD patients, candidates for MRgFUS treatment for medication refractory tremor, were recruited and scanned with diffusion tensor imaging (DTI) ($2 \times 2 \times 2$ mm³ resolution, 25 gradients) before the ablation and a day, a week, one-three months, and four months-to-one year following ablation. Diffusivity parameters and fiber tractography measures were extracted. Tremor was evaluated (CRST and UPDRS) at baseline, one month and six months post-ablation.

Results: We found a pattern of decline and recovery in diffusivity measures and fiber tractography in the motor thalamus and throughout the dentato-rubro-thalamo-cortical pathway. The ablation core and the pathway between the red nucleus and motor thalamus did not show full recovery in late follow-up scans ($P < 0.005$). Inverse correlation was found between fractional anisotropy (FA) measured in the motor thalamus a day before or a day following ablation and tremor relief ($R^2 = 0.26$, $P < 0.02$, and $R^2 = 0.37$, $P < 0.005$, respectively). Long-term tremor relief was seen following the treatment.

Conclusion: Long-term white matter damage was found in the ablation core, and in the tract between the thalamus and red nucleus that is in line with the long-term tremor relief, suggesting it may play a role in tremor pathogenesis. Pre-ablation FA values in the motor thalamus correlated with treatment success thus implying its value as a possible biomarker for patient selection.

B-1558 11:34

Lewy body dementia and posterior cortical variant of Alzheimer's disease: distinguishing imaging patterns on FDG PET/CT and ^{99m}Tc-TRODAT SPECT scan

V. Gupta, R. Verma, R. Ranjan, E. Belho, H. Mahajan; Delhi/IN (ethelbelho@gmail.com)

Purpose: To establish differences in imaging patterns of posterior cortical atrophy (PCA), and dementia with Lewy bodies (DLB) on ¹⁸F-FDG PET/CT using ^{99m}Tc-TRODAT scan as the scintigraphic gold standard. This study aims to identify areas of similarities and differences on ¹⁸F-FDG PET imaging between the two.

Methods and Materials: A retrospective analysis of 70 patients clinically suspected of having posterior dementia was done. All patients underwent ¹⁸F-FDG PET/CT scan of the brain and dopamine transporter imaging with ^{99m}Tc-TRODAT-1 SPECT scan on two consecutive days. The studies were analysed both visually and semi-quantitatively. The patients were divided into possible PCA with TRODAT scan normal ($n = 38$) and possible DLB with TRODAT scan abnormal ($n = 32$). The FDG PET/CT uptake patterns were recorded and areas of hypometabolism that were two standard deviations from the mean were considered as abnormal.

Results: All patients had abnormal pattern of FDG uptake on PET. Significantly reduced metabolism was found in parieto-temporal and occipital association cortices and cingulate cortices in PCA patients. DLB patients showed significantly reduced uptake in the visual cortex with variable involvement of parieto-temporal cortices, with significant difference in the regional z scores between PCA and DLB patients. No significant difference was found between z score of occipital association cortex, which showed hypometabolism in both groups.

Conclusion: FDG PET may be useful as a non-invasive diagnostic modality in differentiating the two posterior cortical dementias, despite significant clinical and imaging overlap, with or without additional TRODAT scan.

Analysis the changes of white matter structure with tract-based spatial statistics according to diffusion tensor imaging in Parkinson's disease
C. Chen, J. Cheng; Zhengzhou/CN (chrnchrn812@163.com)

Purpose: To assess the white matter structural changes in patients with Parkinson's disease (PD), using tract-based spatial statistics (TBSS) approach.

Methods and Materials: A total of 88 PD patients and 45 healthy volunteers matched by age and sex were enrolled. DTI were performed on a 3T MAGNETOM Prisma. Data were processed using FSL software. TBSS technique was used to extract the dispersion index values of cellulose skeleton in abnormal white matter, including fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (L1), and radial diffusivity (L23). Independent sample t-test was performed to compare the differences between the two groups. Pearson correlation analysis was applied to reveal the correlation between diffusion index values and clinical indicators.

Results: Compared with healthy volunteers, PD patients presented decreased FA and increased MD, L1 and L23, in the following regions: genu and body of corpus callosum, anterior limb of internal capsule, posterior limb of internal capsule anterior corona radiata, superior corona radiata, left posterior corona radiata and thalamic radiata, right sagittal stratum, external capsule, and superior longitudinal fasciculus. The FA decreased at fornix, while the MD and L23 increases at the anterior limb of internal capsule increased. These findings were positively correlated with disease duration. The L23 of the right anterior limb of internal capsule increased, and it was positively correlated with the unified PD rating scale score.

Conclusion: Extensive structural changes in the white matter of PD patients can be characterised by disruption of projection fibres in the descending pathway, mainly descending from the corpus callosum and posterior thalamic radiata.

B-1560 11:50

The value of MR neurography in the differential diagnosis between amyotrophic lateral sclerosis and multifocal motor neuropathy

M. Kronlage¹, K. Knop², D. Schwarz¹, T. Godel¹, S. Heiland¹, M. Bendszus¹, P. Bäumer¹; ¹Heidelberg/DE, ²Hamburg/DE

Purpose: Differential diagnosis between amyotrophic lateral sclerosis (ALS) and multifocal motor neuropathy (MMN) may be difficult, which has a strong impact on adequate therapy. The purpose of this study was to assess diagnostic accuracy of MR neurography in differential diagnosis of ALS and MMN.

Methods and Materials: Twenty-two patients with ALS and eight patients with MMN underwent MR neurography of upper and lower extremity nerves using high-resolution T2-weighted sequences. MR neurographies of 15 matched healthy subjects served as a control group. Images were independently read by two readers, who rated fascicular lesions and muscle denervation signs and made a final, image based diagnosis while being blinded to the clinical diagnosis. Results were compared with the reference standard of diagnosis according to standard clinical and electrophysiological criteria.

Results: Nerves of patients with ALS either appeared normal or showed mild T2w-hyperintensities without fascicular enlargement, whereas nerve lesions in MMN were characterized by fascicular swellings. Muscle denervation signs were more prominent in ALS compared to MMN. By imaging, 19 of 22 patients with ALS, 7 of 8 patients with MMN and all of the 15 healthy controls were correctly diagnosed, implying a sensitivity of 0.86 (95% CI: 0.67 - 0.95) and a specificity of 1.00 (95% CI: 0.86 - 1.00) for the diagnosis of ALS, as well as a sensitivity of 0.88 (95% CI: 0.53 - 0.99) and a specificity of 1.00 (95% CI: 0.91 - 1.00) for the diagnosis of MMN.

Conclusion: MR neurography may assist differential diagnosis of ALS and MMN.

Screening-like single- and double-reading of DWI for breast cancer detection

F. Pesapane, E. Cassano, A. Rotili, S. Penco, R.M. Trimboli, F. Sardaneli; Milan/IT (filippopesapane@gmail.com)

Purpose: To test diffusion-weighted imaging (DWI) for breast cancer (BC) detection.

Methods and Materials: Single-centre 1.5-T images of 790 breasts in 434 consecutive women (age 49±10, mean ± standard deviation) entered the analysis. Two radiologists with 8- (R1) and 5-year (R2) experience blindly assessed DWI images (b=0 and b=800 s/mm²), with a per-breast recall/no-recall reading. Apparent diffusion coefficient maps were qualitatively evaluated. Double reading (DR) was considered positive even with a single recall. Pathology and follow-up served as reference standard. McNemar and Cohen κ were used.

Results: Per-breast prevalence was 13% (101/790): 65 invasive ductal, 9 invasive lobular, 9 invasive ductal-lobular, 8 in situ ductal, 5 invasive not otherwise specified, 5 other type (median size 18 mm, interquartile range 11-25). Sensitivity was 88/101 (87%, 95% CI 79-93%) for R1, 84/101 (83%, 95% CI 74-90%) for R2, and 94/101 (93%, 95% CI 86-97%) for DR (DR versus R1, p=0.031); specificity 639/689 (93%, 95% CI 91-95%), 613/689 (89%, 95% CI 87-91%), and 603/689 (88%, 95% CI 85-90%), respectively (DR versus R1, p<0.001). For cancers ≤20 mm, ≤15 mm, or ≤10 mm, DR sensitivity resulted 60/65 (92%, 95% CI 83-98%), 39/44 (89%, 95% CI 75-96%), and 26/30 (87%, 95% CI 69-96%), respectively. Interobserver agreement was substantial (κ=0.739).

Conclusion: In this enriched population, DWI showed a high sensitivity, also for small tumours, favourably comparable with that of screening mammography, with an even acceptable specificity. Prospective studies in non-enriched populations are needed for testing DWI in BC screening.

B-1562 10:47

Diffusion-weighted imaging with background suppression in detection of breast malignancies: a non-invasive, non-contrast and non-radiation technique

P. Yadav¹, V. Kulkarni¹, Y. Patil¹, S. Hari²; ¹Pune/IN, ²Manipal/IN (yadavpratiksha@hotmail.com)

Purpose: To evaluate the utility of non-contrast MRI sequences with use of 3-D diffusion-weighted imaging and background suppression in differentiating malignant and benign breast lesions. To evaluate the sensitivity and specificity of the non-contrast MRI and DWI in detection of breast malignancies.

Methods and Materials: This study was IRB and IEC approved and included 68 breast lesions of 57 cases, suspicious for malignancies on mammography and breast ultrasound. All the cases underwent for breast MRI on 1.5 Tesla machine using dedicated breast coil. Multiplanar localizer was applied with 3mm slice thickness. T1WI, T2WI and STIR in axial plane, STIR coronal and sagittal plane. DWI was done with b value 1500 sec/mm². Post-processing was done and ADC calculations were also obtained. All the cases were correlated histopathologically.

Results: The lesions which showed diffusion restriction considered positive whereas lesions did not show restriction considered as benign. DWI with increased b value demonstrates lesions better with background suppression. In 68 breast lesions, 35 (51.4%) were malignant and 33 (48.5%) benign on DWI. Histopathology revealed 37 lesions (54.4%) were malignant and 31 (45.5%) benign. Sensitivity of DWI was 91.6% (95% CI= 77.5, 98.25), specificity 90.62% (95% CI =74.9, 98.02), PPV 91.6% and NPV 90.6%. Mean ADC of malignant lesions was 0.609 ± 0.35 × 10⁻³ mm²/s and benign lesions was 1.732 ± 0.53 × 10⁻³ mm²/s.

Conclusion: When b value increases, signal intensity of the normal breast decreases which demonstrates improved contrast resolution between malignant lesion and normal breast tissue. It is a very useful non-contrast, non-radiation, non-invasive MRI technique.

B-1563 10:55

Diffusion with very high b-value in breast MRI: preliminary results

H. Hamri¹, E. Weiland², M. Scholer¹, Z. Jolibois¹, C. de Bazelaire¹; ¹Paris/FR, ²Erlangen/DE (hamri.hajar@yahoo.fr)

Purpose: To evaluate the diagnostic yield of very high b-value DWI combined with a T2-weighted sequence in breast MRI.

Methods and Materials: In this retrospective study approved by our IRB, breast MRI was performed at 1.5T with an 18 channel breast coil (MAGNETOM Aera, Siemens). Protocol included 2D-T1-FSE, 2D-single-shot-EPI-diffusion-SPAIR with a single b-value of 2500s/mm² (prototype), 3D-T2-SPAIR, and 3D-T1-VIBE-SPAIR dynamic contrast enhanced (DCE) sequences. T1-w, T2-w and T1-w DCE sequences were first analyzed and findings were classified according to the BIRADS lexicon. All findings with high Diffusion signal associated with low T2 signal were classified as suspicious regardless of morphology. All suspicious lesions were biopsied. BIRADS 1-3 lesions had 2 years follow-up. Diagnostic yields were compared using ROC curves.

Results: One hundred and twenty-seven patients (mean 53 yo, range 20-93) with 36 breast cancers and 101 benign lesions or normal breast were included. Higher sensitivity but lower specificity were found with the T1-w, T2-w and T1-w DCE sequences compared with DWI and T2-w sequences (0.972, 0.842 versus 0.889, 0.921 respectively). However, the comparison of ROC curves showed no significant difference (AUC_{T1+T2+T1 DCE}=0.907 and AUC_{DWI+T2}=0.905, p=0.952). DWI and T2-w sequences missed 4 large cancers (>20mm) because of their intense T2-w signal.

Conclusion: Combined analysis of DWI using very high b-value with T2-w sequences reached similar diagnostic yield than standard breast MRI protocol with contrast injection. Further studies combining morphological features and tumor sizes from T1-w and T2-w unenhanced sequences are mandatory.

Evaluation of breast lesions with simultaneous multi-slice DWI in comparison to routine read-out segmented DWI

W. Sanderink¹, J. Teuwen¹, I. Sechopoulos¹, N. Karssemeijer¹, L. Appelman¹, E. Weiland², R.M. Mann¹; ¹Nijmegen/NL, ²Erlangen/DE (wendelien.sanderink@radboudumc.nl)

Purpose: To compare conventional readout-segmented diffusion weighted imaging echo-planar imaging (rs-DWI-EPI) to a prototype Simultaneous Multi-Slice single shot-DWI-EPI (SMS-ss-DWI-EPI) at 3T using b-values of 0 and 800 s/mm², in terms of image quality (IQ), lesion conspicuity, and lesion description.

Methods and Materials: From September 2017 to August 2018, 15 women with known breast cancer or suspicious breast lesions were scanned with the conventional rs-DWI-EPI (resolution: 1.2x1.2x5 mm, TA: 4:23 min) and the SMS-ss-DWI-EPI (resolution: 0.9x0.9x4 mm, TA: 2:45 min) during the same clinical examination on a 3T system. In total, 33 lesions (26 malignant, 5 benign and 2 unknown) were detected on the contrast enhanced series. Two dedicated breast radiologists (4 and 10 years of experience with breast MRI), independently scored both sequences for overall IQ (1: extremely poor to 9: excellent). All lesions were also independently evaluated for conspicuity (1: not visible 2: visible if location is given, 3: visible) and a BIRADS score per lesion (1 to 5) was given.

Results: IQ was significantly higher for conventional rs-DWI-EPI (mean 5.3 ± 1.9), than for SMS-ss-DWI-EPI (mean 3.6 ± 1.7) (p=0.001). Benign lesions had a similar visibility in both sequences. Malignant lesions were significantly better visible in the SMS-ss-DWI-EPI (11/52 reads) (p=0.015). There was no significant difference in BIRADS scores (p=0.228) between the two sequences.

Conclusion: Despite the perceived poorer image quality of the SMS-ss-DWI-EPI sequence, malignant lesions are better visualized using this sequence. The technique might therefore enable lesion detection on unenhanced breast MRI.

B-1565 11:11

Diagnostic performance of region of interest methods in diffusion-weighted imaging of breast lesions: a systematic review and meta-analysis

M. Wielema¹, M.D. Dorrius¹, G.H. De Bock¹, R.M. Pijnappel², M. Oudkerk¹, P.E. Sijens¹; ¹Groningen/NL, ²Utrecht/NL (m.wielema@umcg.nl)

Purpose: The purpose of this systematic review and meta-analysis was to assess the accuracy of different region of interest (ROI) methods in the discrimination of benign from malignant breast lesions in diffusion weighted imaging (DWI) using the apparent diffusion coefficient (ADC), in terms of sensitivity, specificity and area under the SROC curve (AUC).

Methods and Materials: PubMed and EMBASE were searched for studies applying ADC in breast lesions, up to 24-10-2017 (n = 2154). Data were pooled based on 4 ROI method categories: ROI1: whole lesion, ROI2: subtracted whole lesion, ROI3: selected circular regions and ROI4: lowest diffusion selection. The more subjective ROI methods (ROI2, ROI3) excluded necrotic, cystic and hemorrhagic areas. Pooled sensitivity, specificity and AUC of ROIs were calculated. To explore heterogeneity, the following covariables were considered: field strength, lowest b-value, image of ROI drawing, pre-or post-contrast DWI, slice thickness and ADC threshold.

Results: Forty-nine studies (4958 lesions) were included. Pooled sensitivity, specificity and AUC were: 0.85(0.75-0.91), 0.77(0.60-0.89), 0.89(0.86-0.91) for ROI1; 0.92(0.89-0.94), 0.86(0.82-0.88), 0.92(0.89-0.94) for ROI2; 0.90(0.85-0.93), 0.90(0.83-0.94), 0.95(0.93-0.97) for ROI3 and 0.89(0.83-0.93), 0.83(0.79-0.86), 0.87(0.83-0.89) for ROI4, respectively. Significant heterogeneity was found between studies (p<0.001). None of the co-variables could explain the heterogeneity.

Conclusion: Using AUC as an indication of global diagnostic performance, ROI3 exceeded ROI1 and ROI4 (no overlap between ranges). Due to the non-uniformity of the data, however, no single ROI method significantly outperformed in the use of ADC to differentiate benign from malignant. Further standardization of ROI methods is needed to optimize the breast DWI protocol.

B-1567 11:19

Feasibility study of synthetic diffusion-weighted MR imaging in patients with breast cancer by qualitative and quantitative assessment

B. Choi; Changwon/KR (iawy82@gmail.com)

Purpose: To investigate the clinical feasibility of breast synthetic diffusion-weighted imaging (DWI) in patients with breast cancer by assessing diagnostic image quality in comparison with conventional DWI.

Methods and Materials: Thirty-two patients with breast cancer were assessed using both synthetic and conventional DWI with b values of 100, 800 s/mm² (cDWI₈₀₀) and 1500 s/mm² (cDWI₁₅₀₀) before surgery. Synthetic DWI with b value of 1,500 s/mm² (sDWI₁₅₀₀) were generated from conventional DWIs at b values of 100 and 800 s/mm². Image quality assessment was performed using 4-point Likert scale for comparison of sDWI₁₅₀₀, cDWI₁₅₀₀ and cDWI₈₀₀. For quantitative analysis, contrast ratios (CRs) of cancer and glandular tissue were calculated on each DWI. Interobserver agreement was assessed using weighted kappa statistics and intraclass correlation coefficient.

Results: Both sDWI₁₅₀₀ and cDWI₁₅₀₀ showed better normal glandular tissue suppression and lesion conspicuity than DWI₈₀₀ (P<0.05). Although cDWI₁₅₀₀ showed better image quality than sDWI₁₅₀₀ (P<0.005), sDWI₁₅₀₀ and cDWI₁₅₀₀ showed no significant difference of sensitivity for detecting cancer. CRs of cancer and glandular tissue was greater on sDWI₁₅₀₀ than on either conventional DWI (P<0.001).

Conclusion: sDWI of the breast using b value 1500 s/mm² is a feasible option for diagnostic use which can improve conspicuity of cancer with better CRs and background breast tissue suppression compared with cDWI.

B-1568 11:27

MR mammography of suspicious lesions: influence of residual fat signal on diffusion kurtosis imaging

A. Mlynarska-Bujny¹, S. Bickelhaup¹, F. König¹, F. Laun², W. Lederer¹, H. Daniel¹, S. Delorme¹, H.-P. Schlemmer¹, T. Kuder¹; ¹Heidelberg/DE, ²Erlangen/DE, ³Mannheim/DE

Purpose: In diffusion-weighted imaging of breast, not fully suppressed fat can lead to distortion of the quantitative parameters due to the low diffusion coefficient of fat. This work aims to evaluate various fitting models accounting for contamination from residual fat signal.

Methods and Materials: 198 patients with suspicious mammography findings and indication for breast biopsy were involved. DWI scans, before the biopsy, were acquired in one of two study centres (Group A - 1.5T Philips Ingenia, 105 patients; Group B - 1.5T Siemens Aera, 93 patients) using 4 b-values (0, 100, 750 and 1500 s/mm²). ROIs were segmented on the highest b-value slice where the lesion was visible. Fat ROIs were segmented on the contralateral breast. The following curve-fitting models have been compared: 1) diffusion kurtosis equation, describing non-Gaussian distribution; 2) empirically adjusted diffusion kurtosis model with inclusion of unsuppressed fat signal; 3) modified

Intraarticular osteoblastomas: from challenging diagnostic entity to minimally invasive treatment with magnetic resonance-guided focused ultrasound (MRgFUS)

P. Palumbo, F. Arrigoni, C. De Cataldo, M. Ruschioni, L. Zugaro, A. Barile, C. Masciocchi; L'Aquila/IT (palumbopierpaolo89@gmail.com)

Purpose: Intraarticular osteoblastomas location is very uncommon and presents challenging diagnostic difficulties because of the non-specific feature. The purpose of our study was to evaluate the efficacy of MRgFUS in the treatment of intraarticular osteoblastoma.

Methods and Materials: We retrospectively analyzed 6 cases of patients (mean 23,75 years) with an imaging and histological diagnosis of osteoblastomas. All patients were considered eligible for a non-invasive treatment of MRgFUS. Clinical evaluation was performed using VAS score, and a visual score ranging from 0 to 10 was used also to evaluate the functional impairment. Follow-up imaging was performed at 6 and 12 months after the procedure, with both MR and CT exams.

Results: Efficacy of procedure was guaranteed by the temperature obtained in all the regions of the lesion, with a mean temperature of 63°C. Non-significant variation in temperature in the remaining intracapsular region was found. Follow-up imaging after 1 year revealed a significant decrease of bone oedema and synovitis in all cases, with concomitant bone densification. No one shows any precocious onset of osteoarthritis. Clinic follow-up showed a significant decrease in VAS, while functional impairment shows a significant trend depending on the onset of symptoms.

Conclusion: MRgFUS confirmed its high efficacy in the treatment of intraarticular lesion, demonstrated by the complete resolution of pain symptomatology as well as in bone restitutio-ad-integrum, other than by the lack of signs indicating cartilage damage. Unless otherwise stated, completely non-invasive approach with MRgFUS could be considered as first line treatment of intraarticular bone lesion.

Retrospective multivariate analysis of the outcomes of percutaneous thermal ablation of painful bone metastasis in oncological patients

G. Bianchi, F. Arrigoni, P. Palumbo, A. Cortellini, L. Zugaro, K. Cannita, C. Ficorella, A. Barile, C. Masciocchi; L'Aquila/IT (giampaolo.bianchi90@libero.it)

Purpose: The aim of this study is to assess the effectiveness of interventional radiology procedures on quality of life (QoL) in patients with painful bone metastases.

Methods and Materials: A retrospective analysis of 27 consecutive advanced cancer patients, who have been treated with ablation (RFA, CA or MWA) for bone metastases (BM) was performed. Pain intensity variation was evaluated with a Visual Analogue Scale (VAS). Median time to opioid dose escalation, median time to radiological progression of the treated BM and median overall survival (OS) were computed.

Results: 27 patients were evaluated. Axial bones were involved in 22 patients (81.5%) and 17 patients (63%) had a single bone metastasis. Before treatment, 41.1% of patients had a Performance Status (ECOG-PS) of 0-1, while the 51.9% of ≥ 2 ; 40.7% received concomitant bone-oriented treatment (denosumab or zoledronate). 74% of them took concomitant opioid analgesic therapy. Median follow up was 16.5 months. After treatment, 85.2% of patients experienced an improvement in pain intensity (p-value <0,05). Median time to opioid dose escalation was 16.2 months (95%CI: 5.9-26.9; 15 events). Median time to radiological progression of the treated BM was 10.3 months (95%CI:7.6-16.9,16 events) and median OS was 27.2 months (95%CI:8.9-41.2,15 censored patients).

Conclusion: Percutaneous CT-guided thermal ablation led to a significant improvement of the QoL in particular in terms of time to opioid dose escalation. Also median time to radiological progression of the treated BM and median OS seems to be very promising compared to the outcome data known in literature about medical therapy alone.

kurtosis model, with additional factor accounting for signal from fatty area; 4) mono-exponential Gaussian diffusion.

Results: We demonstrated by the analysis of ROC curves, based on logistic regression, that the AUC values obtained for *Model2* [0.86 (95% CI 0.80 to 0.91)] and *Model3* [0.86 (95% CI 0.80 to 0.91)] are significantly higher ($p < 0.03$) than AUC values of *Model1* [0.79 (95% CI 0.72 to 0.86)] and *Model4* [0.77 (95% CI 0.70 to 0.84)].

Conclusion: Kurtosis-based fitting models, adapted to account for residual fat signal, show the potential to better discriminate between benign and malignant lesions than classical kurtosis-based and pure Gaussian diffusion models.

B-1569 11:35

Characterisation of breast parenchyma and cancer during lactation using diffusion tensor imaging

N. Nissan¹, E. Furman-Haran², T. Allweis², T. Menes³, O. Halshtok Neiman⁴, R. Faermann¹, A. Shalmon⁵, M. Gottlieb⁵, M. Sklair⁵, ¹Tel Hashomer/IL, ²Rehovot/IL, ³Tel Aviv/IL, ⁴Kiryat Ono/IL, ⁵Ramat Gan/IL (noam_nissan@hotmail.com)

Purpose: To investigate the utility of DTI parametric maps in characterization of the normal and malignant transformations of the lactating breast.

Methods and Materials: This prospective study was IRB approved and all participants signed an informed consent. Since January 2017, 28 lactating patients (median age and lactation duration: 36y and 6m, respectively) were scanned by diffusion tensor imaging (DTI) together with conventional dynamic contrast-enhanced (DCE) breast-MRI protocol at 1.5T. Indications included newly diagnosed breast cancer (n=11) and screening of high-risk patients (n=17). DTI was acquired using 32 directional diffusion gradients and 0.700s/mm² b values. DTI parametric maps of the principal diffusion coefficients ($\lambda_1, \lambda_2, \lambda_3$), mean-diffusivity (MD), fractional-anisotropy (FA) and maximal-anisotropy index ($\lambda_1-\lambda_3$) were generated and analysed at pixel resolution using a dedicated software granted by permission. Based on the DCE subtraction images, DTI's normal and malignant regions-of-interest (ROIs) were delineated and were statistically evaluated.

Results: The normal fibro-glandular tissue exhibited bi-modal distribution, characterized by a sub-areolar central area with increased diffusivity and reduced anisotropy as opposed to the peripheral areas with relatively lower diffusivity and increased anisotropy, possibly reflecting the respective changes in lactiferous ducts' diameter. All 11 cancers were detected by DTI maps of $\lambda_1, \lambda_2, \lambda_3$ and MD in agreement with DCE, exhibiting substantial contrast compared with the ROIs of the apparently normal tissue of the contralateral breast and fibroglandular tissue of healthy high-risk patients ($p < 0.001$, for all).

Conclusion: DTI maps enabled the characterization of physiological lactation-induced parenchymal changes as well as malignant transformations, with substantial parametric contrast, improving the tumour's conspicuity as revealed by DCE alone.

B-1570 11:43

Breast 1H-MR-spectroscopy to distinguish benign from malignant breast lesions: an updated systematic review and meta-analysis with clinical implications

C. Sodano, P. Clauser, P. Kapetas, T.H. Helbich, P.A.T. Baltzer; Vienna/AT (claudiasodano@hotmail.it)

Purpose: To investigate the diagnostic performance of breast 1H-MR-spectroscopy to distinguish benign from malignant breast lesions and factors influencing sensitivity and specificity by meta-analytic methods.

Methods and Materials: A comprehensive database search using predefined search terms was performed for all articles listed till June 2018. Eligible for this study were publications investigating >10 patients at either 1.5T or 3T for the purpose of distinguishing benign from malignant breast lesions. Both single-voxel and multivoxel techniques were eligible. A reference standard by either histopathological examination or follow-up of >12 months was required. Statistical analysis included pooling of sensitivity and specificity and subgroup analyses based on several covariates including acquisition parameters, field strength and publication date.

Results: Thirty-three studies, including 1404 malignant and 770 benign lesions were included. Most publications reported only diagnostic indices of the choline resonance and not on other metabolites. Pooled sensitivity and specificity were 81.7% (95%-CI: 76-86.3%) and 82.5% (95%-CI 78.3-86.1%), respectively. While neither publication date nor field strength had an effect on diagnostic performance estimates ($P > 0.05$), echo time (TE) had: studies applying $TE \leq 144$ ms reported higher sensitivity (85.6%, 95%-CI: 78.4-90.6%) compared to studies using $TE > 144$ ms (74.9%, 95%-CI 63.4-83.8%) while specificity did not differ.

Conclusion: The diagnostic performance of 1H-MR-spectroscopy to distinguish benign from malignant breast lesions using the choline resonance seems to be higher using shorter echo times. Whether consideration of multiple metabolites increases the diagnostic performance of 1H-MR-spectroscopy has not sufficiently been investigated yet.

Interventional urethral realignment to posterior urethral rupture accompanied by complex pelvic fracture

C.M. Lee, C.H. Jeon, C.W. Kim, H. Kwon, H.M. Cho; *Busan/KR*
(mooya3696@gmail.com)

Purpose: Primary realignment of complete posterior urethral injury is a difficult procedure because of the pelvic bleeding and haematoma formation that occur during complex pelvic fracture. In this article, we report the result of the treatment of posterior urethral rupture by interventional primary urethral realignment performed with fluoroscopy guidance.

Methods and Materials: This retrospective study included 10 patients with traumatic posterior urethral injuries who were treated with urethral realignment from November 2016 to May 2018. All 10 patients were men with the median age of 46.0 years. Technical success rate of urethral realignment, required procedure time, duration of urethral catheterisation, and complications after procedure were investigated.

Results: Urethral realignment was technically successful in 8 of 10 patients (80%). In 2 of 8 patients, Snare catheter was used for passing through the urethral injury site. The median procedure time was 46 minutes (range, 32-69 min). The mean duration of urethral catheterisation after urethral realignment was 63 days (range, 48-94 d). There were no immediate procedure-related complications, although all 10 patients developed varying degrees of symptomatic urethral stenosis after procedure.

Conclusion: Interventional primary urethral realignment is a safe and minimally invasive procedure that can be performed in a patient with posterior urethral rupture accompanied by complex pelvic fracture. Thus, it can be viewed as an effective treatment method that can reduce the frequency of invasive surgical procedures by maintaining urethral continuity early on.

Percutaneous stabilisation of humeral metastatic lesion

A. Al Raaisi, E. Cormier, E. Shotar, M. Drir, F. Clarencon, J. Chiras; *Paris/FR*
(alraisi_arn@hotmail.com)

Purpose: Bony metastases are very common in patients with advanced cancer and pathologic fractures may occur within either lytic or blastic foci. A pathologic fracture of the humeral neck or shaft is commonly treated surgically employing nails, rods, or plate and screws combined with immobilization using an external brace support. Some patients are treated conservatively because of their poor clinical condition and comorbidities. Percutaneous cementoplasty alone is insufficient for stabilization of the fracture. Percutaneous stabilization using dedicated spindles in the management of hip joint lytic lesions demonstrated its effectiveness. In this study, we thought to evaluate the effectiveness of reinforced cementoplasty with spindles for painful and unstable lesions involving the humerus in terms of pain relief and functional recovery.

Methods and Materials: We describe four cases (3 males and one female) of bone malignancies involving the humerus (3 patients with fractures and one patient with no fracture) which were treated by percutaneous insertion of metallic nails through an 8-gauge cannula followed by PMMA bone cement injection in our department from 2016-2018. Procedures were performed under general anaesthesia in two patients and the other two were sedation.

Results: All patients gained full restoration of functionality and pain relief without need for further analgesic therapy. No complications were observed during or after the procedures.

Conclusion: Percutaneous stabilization of humeral fractures is an original minimally invasive technique providing pain relief and effective bone stability was shown to be safe and effective in the treatment of painful bone metastases refractory to conventional therapy.

Percutaneous intervertebral disc coagulation therapy (PDCT) by plasma light: a new method for the treatment of lumbar and cervical disc herniation

C. Zini¹, D. Notaro², G. Sadotti², M. Bellini²; ¹Florence/IT, ²Siena/IT
(zini.chiara@gmail.com)

Purpose: To evaluate the effectiveness, to describe the technique and the advantages of percutaneous intervertebral disc coagulation therapy based on plasma thermal reaction (PDCT).

Methods and Materials: 44 patients (age range: 18-87 years, mean: 52,7) with contained and extruded symptomatic lumbar (n.48) and cervical (n.6) disc hernias in the absence of free fragments causing radiculopathy and without improvement after 6-week of conservative therapy were enrolled. Pre-treatment discography was performed in all the patients. The PDCT system (PLASMA D30, Jeisys Corporation, Seoul, South Korea) was equipped with a diode laser module and 0.4 cm plasma optical fiber; all the treatments were performed under local anesthesia and premedication with antibiotics therapy using fluoroscopic guidance (Innova 3131q, General Electric Healthcare, CT, USA). Before the procedure and 3 months later, the MRI of spine and Visual

Analog Scale (VAS) and Oswestry disability index (ODI) were accomplished

Results: Most patients (n. 36) showed great improvement in symptoms with relevant post-operative VAS scale reduction (p<0,001) and ODI reduction. No major complications occurred. 16 patients referred mild pain or heartburn when the plasma fiber close was to the annulus, symptoms disappeared immediately after treatment.

Conclusion: PDCT can be effective, safe and convenient minimally-invasive decompression methods in selected patients.

B-1576 11:10

Percutaneous CT guided RFA treatment of osteoid osteoma in children and adults: it has high success rate in children too

C. Sahin, Y. Oc, A. Hasanefendioglu Bayrak; *Istanbul/TR*
(cennetsahin2@hotmail.com)

Purpose: Efficacy and safety of Radiofrequency Ablation (RFA) of osteoid osteoma (OO) are demonstrated in many studies. However, there is a hesitation about the use in the pediatrics. Our purpose is to investigate the efficacy and safety of RFA of OO in adults and pediatrics.

Methods and Materials: A total of 114 patients (81 male and 33 female; mean age of 17.9 years; age range 13 month-42 years) had 115 CT-guided RFA between May 2015 and August 2018 with the diagnosis of OO. Of the 114 patients, 63% were children and 37% were adults. The clinical and technical success of the treatment were evaluated by assessing the pain symptom, complication rates and follow-up radiological findings.

Results: All the patients had a favorable immediate pain relief in 24 hours after the procedure. Only one patient (15 y-o; male) had pain relapse in 3 months after RFA and a second RFA was performed. During 19 months follow-up he had no pain. The technical success of the procedure was recorded as 100%. The clinical success was 100% in adults and was 99% in pediatric population. No major complication occurred during neither treatment nor recovery period. Seven minor complications (2 were in pediatrics) were noted which were treated successfully.

Conclusion: The rapid relief of the pain symptoms, low relapse rate and low complication rates demonstrate the efficacy and safety of RFA of OO in both pediatrics and adults. We think that RFA can safely be used as first choice treatment method in pediatrics too.

B-1577 11:18

Balloon vesselplasty vs percutaneous vertebroplasty in chronic compression fractures of the dorsolumbar spine

D.N. Srivastava, A. Monga, K. Madhusudhan, S. Malla; *New Delhi/IN*
(drdeepsrivastava@gmail.com)

Purpose: To evaluate the efficacy of percutaneous vesselplasty in non-traumatic vertebral fractures of the thoracolumbar spine and compare it with percutaneous vertebroplasty.

Methods and Materials: 50 patients with chronic vertebral compression fracture (>12 weeks), severe pain (VAS: more than equal to 7) and disability attributable to the vertebral fracture were included and underwent vertebral augmentation procedure out of which 27 underwent vertebroplasty and 23 underwent vesselplasty. Clinical and imaging follow-up was done for the two groups and evaluated for pain, disability scores, increase in anterior vertebral body height and volume of cement injected. Complication rate was also compared in the two groups.

Results: Mean decrease in pain score was 4.27 in vertebroplasty group and 4.45 in the vesselplasty group. The mean increase in the physical functionality scores was 27.4 in the vertebroplasty group and 35.9 in the other group which was statistically significant (p=0.005). The mean amount of cement injected was 3.84 ml in vertebroplasty group and 4.68 ml in the other group which was significantly higher (p=0.008). The mean change in anterior vertebral height was 0.63 mm in the vertebroplasty group and 2.47 mm in the vesselplasty group which was significantly higher (p<0.001). There was cement leak seen in 34% patients in the vertebroplasty group which was minor and mainly involved the paravertebral and intradiscal regions. In the other group, no intradiscal leak was seen.

Conclusion: Vesselplasty is superior to vertebroplasty in terms of disability scores, increase in anterior vertebral body height, volume of cement injected with low complication rate.

B-1578 11:26

"SpineJack®" percutaneous placement in magerl A2 and A3 traumatic vertebral compression fractures of the thoracolumbar spine

G. Sadotti¹, D. Notaro¹, C. Zini², M. Bellini²; ¹Siena/IT, ²Florence/IT

Purpose: To prospectively evaluate safety and effectiveness of SpineJack® device (SJ) (VEXIM SA Balma - France) to achieve anatomical restoration of traumatic vertebral compression (VCFs) in Magerl A2 and A3 thoracolumbar fractures.

Methods and Materials: 18 patients (16 male; mean age 57 years, age range 27-83 years) with traumatic thoracic (N=12) and the lumbar VCFs (N=7) within 3 weeks from the time of injury classified as Magerl type A2.2 (N=2), A2.3 (N=11) and A3.1 (N=6) were enrolled; exclusion criteria were spontaneous/osteoporotic and neoplastic vertebral fractures, posterior wall involvement of more than 1/3 than of the spinal canal. Visual analogue scale (VAS) score and CT and/or MRI has been performed before and 48 hours, 1 and 6 months after procedure. Technical success was defined as correct placement of SJ implant.

Results: A total of 11 VCFs has been treated with 100% technical success. 1 patient performed at 2 levels in the same session. No major complications related to procedure were registered; asymptomatic cement leakages occurred in 4 patients along fractures lines. All cases showed relevant improvement of symptoms with preoperatively mean VAS score of 7.4 dropped to 1,05, 0,22 and 0,11 within 48 hours, 1 and 6 months respectively. Mean height lift of 8.5 mm has been registered after procedure; 5 VCFs presented height lifting greater than 11 mm.

Conclusion: SJ placement can be effective and safe in traumatic VCFs, leading to immediate and lasting relief of pain and vertebral height recovery.

B-1579 11:34

Intraarticular lumbar facet joint steroid injection vs. medial branch block: which technique ensures better clinical outcome for managing lumbar back pain? A single-centre experience

A. Izzo, M. Varrassi, F. Bruno, G. Bianchi, F. Cobiainchi Bellisari, S. Carducci, A. Giordano, E. Di Cesare, C. Masciocchi; *L'Aquila/IT (izzo@live.it)*

Purpose: To compare the clinical outcome of intraarticular lumbar facet joint (LFJ) steroid injection and lumbar medial branch block (MBB) in the management of LFJ pain.

Methods and Materials: Fifty-seven patients with LFJ pain were recruited on the basis of clinical evaluation and MR-findings and randomly assigned to one of two groups. Twenty-seven patients (Group A) underwent intraarticular LFJ steroid injection. Thirty patients (Group B) were assigned to lumbar MBB. In both procedures, we injected 1.5mL of Ropivacaine with 2mL of Triamcinolone. We assessed the severity of LFJ pain by VAS Score and the disability grade by RMQ Score, before and at 1, 3, 6 months after treatment.

Results: Average values of VAS and RMQ before treatment in Group A were 8.1 and 16.6. The treatment was effective (VAS reduction >50%, RMQ score <9) in 85.2% of patients after 1 month, 77.7% after 3 months, 66.6% after 6 months. Average values of VAS and RMQ before treatment in Group B were 7.8 and 16.1. The treatment was effective in 86.6% of the patients after 1 month, 70% after 3 months, 50% after 6 months.

Conclusion: In this study, both intraarticular LFJ steroid injection and MBB significantly relieved LFJ pain and the positive effects of these techniques persisted for at least 6 months after the procedure. Both procedures showed similar effectiveness in the treatment of LFJ pain at 1 and 3 months, however, intraarticular LFJ steroid injection guaranteed a better clinical outcome after 6 months. We believe that both the techniques are strongly effective in LFJ pain treatment.

B-1580 11:42

Fusion imaging of US and MRI coupled with electromagnetic virtual navigation for periradicular infiltrations of steroids in low back pain: pilot experience of a radiation-free procedure

F. Arrigoni, G. Bianchi, P. Palumbo, S. Mariani, F. Bruno, L. Zugaro, A. Barile, C. Masciocchi; *L'Aquila/IT (arrigoni.francesco@gmail.com)*

Purpose: Low back pain is a disabling condition affecting an increasing number of population. If the source of pain is radicular, it can be decided to proceed to an effective symptomatic treatment, the periradicular steroid injection, which requires the accurate positioning of the needle usually obtained by means of CT or fluoroscopy.

Methods and Materials: Fifteen monolateral periradicular (L4-L5 or L5-S1) injections were performed using a virtual navigation system able to fuse imaging of the lumbar spine obtained by an isotropic volumetric MRI with a real time US. The system couples the imaging obtained with an electromagnetic guide that allows visualising the needle on MR imaging. Prior to drug injection, final position (FP) of the needle's tip (obtained using virtual navigation) was verified with a single CT slide centred on the needle. FP was correct when the needle's tip was in or strictly close to the neural foramen. An operator trained for using the system performed all procedures.

Results: Twelve (80%) FPs were judged correct. Two (13%) FPs were judged inaccurate (incorrect co-registration of MR-US imaging). In one case, it was not possible to reach a correct FP using virtual navigation. No complications occurred.

Conclusion: This pilot study demonstrates the feasibility of this innovative technique for spinal infiltrations. Although additional studies are needed, this technique has multiple advantages that include absence of radiation exposure, excellent imaging guidance (MRI virtually navigated system), multiple infiltrations without need for repeat imaging, and no need for CT suite.

B-1581 11:50

Is the anaesthesia a key factor for the good outcome of bone ablation procedures: a review of the last two-year experience in an MSK interventional centre

A. Izzo, F. Arrigoni, P. Palumbo, F. Bruno, C. De Cataldo, S. Mariani, L. Zugaro, A. Barile, C. Masciocchi; *L'Aquila/IT (izzo@live.it)*

Purpose: The aim of our study is to retrospectively review the outcomes of different anesthetic approaches in bone ablation procedures in order to choose the best option.

Methods and Materials: We retrospectively evaluated 98 ablations performed in the period between January 2016 and July 2018. Three different anesthetic approaches were used: general anesthesia, sedation and loco-regional anesthesia (Brachial Plexus Block, Spinal Anesthesia). To evaluate the outcomes, three parameters were used: procedural technical success, patient comfort (Scale 1-5) and operator comfort (Scale 1-5).

Results: Of 98 ablations, 50 were benign bone lesions, 48 metastatic bone lesions. Overall procedural technical success was 100%. Three cases were of general anesthesia: patient comfort was 5/5 in all cases; operator comfort was in 1 case 5/5, in 2 cases 4/5. Twenty patients underwent sedation: in 3 patients (15%) with benign bone lesion, patient comfort was 1/5 and operator comfort 3/5; in 2 patients (10%) with metastatic bone lesion, patient comfort was 3/5 and operator comfort 4/5. Seventy-five patients underwent loco-regional anesthesia: patient and operator comfort was 5/5 in all cases.

Conclusion: General and loco-regional anesthesia proved itself to be effective, but general anesthesia showed an operator comfort (average value 4.3) lower than loco-regional anesthesia. Sedation showed globally a less effectiveness (75%), especially in benign bone lesions, probably because of their important inflammatory component. In our experience, loco-regional anesthesia is the best anesthetic practice for the treatment of bone lesions. Therefore, we feel that the collaboration with experienced anesthetists who know this procedure is essential.

Machine learning-based analysis of CT radiomics model for the prediction of colorectal metachronous liver metastases

M. Taghavi¹, S. Trebeschi¹, D. Meek², D.M. Lambregts¹, C. Verhoef², J.B. Houwers³, U.A. van der Heide¹, R.G.H. Beets-Tan¹, M. Maas¹; ¹Amsterdam/NL, ²Rotterdam/NL, ³Maastricht/NL (m.taghavi@nki.nl)

Purpose: To develop and validate a CT-based radiomics model for the prediction of metachronous colorectal liver metastases at primary staging with a machine learning algorithm.

Methods and Materials: 91 colorectal cancer (CRC) patients from three centers were included. Two groups were assessed: patients who had no evidence of liver metastasis at primary staging, or during follow-up of at least 24 months (n=67) and patients who had no evidence of liver metastases at primary staging but developed metachronous liver metastases within 24 months after primary staging (n=24). After liver parenchyma segmentation (excluding vessels and benign liver lesions), a large number of radiomics features (n= 7,344) were extracted for each patient by use of an open-source python package (PyRadiomics) on primary staging CT. Patients were divided into training set (n=54) and independent validation set (n=37). To mitigate the risk of overfitting due to the medium sample size, 5-fold cross-validation approach was used for training. Bayesian-optimized random forest with wrapper feature selection was trained on the training set and optimized with sequential model-based optimization.

Results: The area under the curve (AUC) of the machine learning-based radiomics model performance in the training cohort was 0.88 (95%CI: 0.85-0.92), and in the validation cohort it was 0.87 (95%CI 0.82-0.91) with sensitivity 0.88 (95%CI 0.80-0.95) and specificity 0.72 (95%CI 0.63-0.82).

Conclusion: A machine learning-based radiomics analysis of routine clinical CT imaging at diagnosis could provide valuable biomarkers to predict patients at risk for developing colorectal liver metastases.

In-house automatic liver segmentation from CT based on a deep convolutional neural network with data augmentation

J. Witowski, A. Zlahoda-Huzior, M. Stanuch, A. Grochowska, M. Pędzwiat; Krakow/PL (jwitow@gmail.com)

Purpose: To develop and evaluate deep convolutional neural network (CNN) for automatic liver parenchyma segmentation and test differences in training accuracy based on different normalization and augmentation parameters.

Methods and Materials: 21 computed tomography (CT) studies including 11,966 slices of patients qualified for laparoscopic liver resection for oncological purposes were used to develop the network. Ground truth segmentation was performed by experienced radiologist. Data was divided in a ratio of 70% to 30% for training and test data sets, respectively. A standard 2D U-Net architecture was employed to the network. We conducted a series of experiments with the same data, modifying z-score normalization range and data augmentation methods. Batch size of 1; 15% validation data split and 70 epochs were consistently used throughout the study.

Results: Highest Dice similarity coefficient (DSC) of 0.931 on a test set was achieved for a CNN with normalization in range from -200 to 500 HU and 21 augmented CT volumes created with elastic deformations. CNN with no augmentations or normalization scored 0.799 DSC, while CNN with normalization only improved DSC to 0.895. Augmentations based on rotation and translation only did not improve CNN accuracy.

Conclusion: State-of-the-art CNNs are feasible to develop in-house solutions for accurate liver segmentation. Both normalization and elastic transformations were required to achieve best results, with normalization being the most important factor.

Development and validation of a dual-energy CT-based radiomic nomogram for preoperative prediction of lymph node metastasis in patients with gastric cancer

J. Li; Zhengzhou/CN (lijingqingqing@163.com)

Purpose: To develop and validate a dual-energy CT-based radiomic model for the preoperative prediction of lymph node metastasis (LNM) in patients with gastric cancer (GC).

Methods and Materials: A total of 193 pathologically confirmed gastric adenocarcinoma patients who underwent biphasic enhanced scans on a rapid kV-switching DECT were retrospectively enrolled and divided into a training set of 97 patients and a test set of 96 patients. Radiomic features, containing deep learning features and hand-crafted features, were extracted from biphasic and three energy levels (40, 65, 100 keV) images. Quantitative iodine concentration, overall survival (OS) and progression free survival (PFS) were collected. A radiomic predictive nomogram was built by machine learning method in the training set; its performance was evaluated using ROC curve, accuracy, and Harrell's concordance index (C-index) in test set.

Results: The dual phasic, triple energy image-based radiomic signatures were significantly associated with LNM ($P < 0.001$) and demonstrated good performance for discriminating LNM in the test set with AUCs of 0.773 and 0.752 in the training set. The nomogram that incorporated two radiomic signatures, tumour thickness, and CT-reported lymph node status was significantly associated with LNM status ($P < 0.001$), with AUCs of 0.864 in training set and 0.834 in test set. The nomogram also exerted a promising prognostic ability with C-indices of 0.660 ($P = 0.0082$) for PFS and 0.710 ($P = 0.0025$) for OS.

Conclusion: This study provided a new insight into the role of DECT-based radiomic nomogram for the preoperative prediction of LNM and prognosis in GC patients.

B-1585 11:03

Development of a MRI radiomics model for pre-therapeutic evaluation of lymph node metastasis in rectal cancer

S. Hu, C. Xia, W. Peng, Z. Li; Chengdu/CN

Purpose: To establish and validate a radiomics model using MRI data for preoperative assessment of lymph node (LN) metastasis in patients with rectal cancer.

Methods and Materials: A database consisted of 139 patients suffered rectal cancer with/without LN metastasis was divided into training set (41 patients with LN metastasis) and validation set (18 patients with LN metastasis), using 10-fold cross-validation with proportion 7:3. Surgical histopathologic analysis was the reference standard for LN metastasis. Radiomic features were extracted from MRI T2 weighted imaging (T2WI) by Artificial Intelligent Kit (A.K.). One-way ANOVA, rank-sum test, GLM, Spearman, Lasso model were used for feature selection, data redundancy and dimension reduction. The remaining features were included in the model developed by logistic regression

analysis and presented with a radiomics nomogram. The receiver operator characteristics (ROC) analysis was performed to validate the radiomics model curves.

Results: In total, 396 features were extracted and 17 selected features was significantly associated with LN status ($p < 0.05$). After data redundancy and dimension reduction, 3 features including ClusterShade_angle135_offset7, LongRunHighGreyLevelEmphasis_AllDirection_offset1_SD and SurfaceVolumeRatio were used to derive the radscore and develop the prediction model. A nomogram for predicting pathological lymph nodes metastases, with an AUC of 0.769 on the training set and 0.684 on the validation data was successfully plotted.

Conclusion: In this study, we established and validated a radiomics model to diagnose LN metastasis in patients with rectal cancer, which can be a useful and convenient tool to facilitate the preoperative individualized assessment.

B-1586 11:11

Deep learning based radiomics and its usage in prediction for metastatic colorectal cancer

D. Nörenberg¹, T. Huber¹, S. Maurus¹, N. Jäger¹, A. Katzmann², A. Mühlberg², J. Moltz³, V. Heinemann¹, J. Holch¹; ¹Munich/DE, ²Erlangen/DE, ³Bremen/DE (Dominik.Noerenberg@med.uni-muenchen.de)

Purpose: To compare machine learning techniques for predicting tumor growth and one-year overall survival in patients with metastatic colorectal cancer.

Methods and Materials: We employed deep convolutional sparse autoencoders (DCAE) to extract deep features from 473 (tumor growth) / 684 (survival) lesion segmentations of 250 / 192 liver metastases at multiple timepoints in 113 / 104 computed tomography images with contrast of 59 / 45 colorectal cancer patients under first-line therapy after semiautomatic tumor segmentations of colorectal cancer liver metastases and trained a deep convolutional neural network (DCNN) to predict tumor growth and short-term survivors using grouped cross-validation. Metrics were determined using bootstrapping with single lesion segmentations for each patient.

Results: The classifiers using the deep learning algorithm performed with the highest AUC for tumor growth and one-year-survival over prediction based on RECIST diameters of liver metastases or Radiomics (0.662/0.691 with deep learning vs. 0.621/0.587 for RECIST and 0.567/0.562 with Radiomics, respectively) while preserving the highest -coefficient (tumor growth: 0.225 vs. 0.157/0.089; survival: 0.236 vs. 0.221/0.167).

Conclusion: This study demonstrates a deep learning model for predicting tumor growth and one-year overall survival in metastatic colorectal cancer patients using semiautomatic tumor segmentations of liver metastases derived from contrast-enhanced CT images.

B-1587 11:19

A new approach to predict grade of non-functional pancreatic neuroendocrine tumour ≤2 cm: a radiomics nomogram

Y. Bian; Shanghai/CN (bianyun2012@foxmail.com)

Purpose: This study aimed to establish a tumour grade (G) prediction model using radiomics features of multi-slice spiral CT (MSCT) images to accurately predict preoperative grading of non-functional pancreatic neuroendocrine tumours (NF-pNETs) of size ≤ 2 cm.

Methods and Materials: The prediction model was developed in a primary cohort that consisted of 69 patients with clinicopathologically confirmed NF-pNETs, and data was gathered from January 2014 to January 2017. Radiomics features were selected using least absolute shrinkage and selection operator (LASSO) logistic regression algorithm. In multivariable logistic regression analysis, a predictive model was developed; radiomics nomogram was built and its performance assessed. Decision curve analysis (DCA) was performed with training set for clinical usefulness of nomogram estimation. An independent validation cohort contained 46 consecutive patients from February 2017 to December 2017. Of 115 NF-pNETs, 33 were low-grade (G1, n=18) and intermediate-grade (G2, n=15) tumours of size ≤ 2 cm.

Results: The multivariable logistic regression model included arterial and portal venous phase rad-scores. The individualized prediction nomogram showed good discrimination and calibration in the training and validation sets. An AUC of 0.85 can also revealed good discrimination by the nomogram in tumour sizes ≤ 2 cm set. With threshold probability of >5% for a doctor or patient, DCA indicated more net benefit from radiomics nomogram than from "treat all" or "treat none" strategies.

Conclusion: Radiomics nomogram, which incorporates arterial and portal venous phase radiomics scores, is a noninvasive preoperative prediction tool, with favourable predictive accuracy for ≤ 2 cm non-functional pNETs grade.

B-1588 11:27

Development of a multiparametric radiomics combined T2WI and DWI to staging rectal cancer

D. Wen, C. Xia; Chengdu/CN

Purpose: To explore whether radiomics analysis in T2-weighted imaging and Readout-segmented echo-planar diffusion-weighted imaging can help to predict the pathologic staging in rectal cancer.

Methods and Materials: This study prospectively enrolled 524 patients with rectal cancer, which underwent 3.0T MR examinations with both T2WI and DWI sequences. Patients were graded into staging I-II or staging III-IV in accordance with histopathologic findings after surgery. According to 10-fold cross-validation, 70% of this cohort (367 patients) was set as the training cohort, and the others (157 patients) was set as the validation cohort. 396 radiomics features were extracted from T2WI and DWI. The Spearman, Lasso and PCA regression model was exploited for dimension reduction and selection of the feature space. The multivariable logistic regression analysis was adopted to identify the radiomics signature of pathologic staging. The discriminating performance was assessed with the area under receiver operating characteristic curve. The Mann-Whitney U test was adopted for testing the potential correlation of the radiomics signature and the response in training cohorts, and decision curve analysis (DCA) was used for comparing three models.

Results: 14 radiomics features were selected to create the radiomics signature significantly associated with response ($P < 0.001$) after feature dimension reduction. AUC of radiomics signature performance in the training cohort was 0.856, and in the validation cohort was 0.779.

Conclusion: Multiparametric radiomics of rectal cancer, which combined T2WI with DWI, showed a fairly high accuracy in staging of I-II or III-IV rectal cancer.

B-1589 11:35

CT texture analysis in liver fibrosis shows a strong correlation with portal phase enhancement and can predict cirrhosis in decision tree model

P.N. Kaposi, B. Budai, V. Frank, S. Shiriati, A. Folhoffer, M. Abonyi, V. Bérczi; Budapest/HU (kaposipal@gmail.com)

Purpose: CT texture analysis (CTTA) has been successfully used to assess tissue heterogeneity and it may facilitate the diagnosis of liver cirrhosis when utilized in machine learning models.

Methods and Materials: CT scans were retrospectively collected from twenty-seven patients with chronic hepatitis. Examinations were performed with either a 16 (11 cases) or a 64 slice (16 cases) scanner (Philips Healthcare, the Netherlands). The stage of liver fibrosis was determined with shear-wave ultrasound elastography. Contrast-enhanced series in the portal venous phase (PVP) were reconstructed to 5 mm slice thickness with no gap. Anatomical liver segments were labeled manually, and 1112 texture parameters (TP) were calculated for each. TPs were used in a hierarchical cluster analysis (HCA), group comparisons, and in a binary tree prediction model (BTM).

Results: CTTA was performed on 319 anatomical liver segments. A comparison between the two scanners found a significant difference ($p < 0.05$) in 305 TPs. HCA revealed a uniform pattern, which divided segments into two groups. PVP densities showed a significant difference between the two groups in both the 16 (mean±SEM= 108.9±1.69 HU vs. 96.6±1.16 HU, $p < 0.001$) and the 64 slice (mean±SEM= 101.1±1.24 HU vs. 85.2±1.83 HU, $p < 0.001$) sets. Meanwhile, liver stiffness was not significantly different. A BTM was trained on the 16 slice set, and it could predict cirrhosis in segments of the 64 slice set with 92% accuracy.

Conclusion: Contrast enhancement and scanning parameters have a strong influence on TPs. CTTA-based artificial intelligence may achieve success in the detection of liver cirrhosis.

B-1590 11:43

MR imaging of rectal cancer: radiomics analysis to predict hepatic metastases

S. Hu, W. Peng, C. Xia, Z. Li; Chengdu/CN

Purpose: To investigate the value of T2-weighted-based radiomics for prediction of hepatic metastases in patients with rectal cancer.

Methods and Materials: 180 patients with rectal cancer underwent magnetic resonance imaging between March 2016 and February 2018 were prospectively included. 98 patients were confirmed to hepatic metastases by biopsy, surgical histopathologic, CT enhanced imaging or follow up. Using 10-fold cross-validation, all patients were divided into training cohort (125 patients) and validation cohort (54 patients) with proportion 7:3. The Spearman, Lasso and PCA regression models were exploited for dimension reduction and selection of the feature space after texture features extracted by Artificial Intelligent Kit. The radiomics signature of liver metastases was developed by multivariable logistic regression analysis. The discriminating performance was assessed with the area under receiver operating characteristic curve (AUC). The Mann-Whitney U test was adopted for testing the potential correlation of the radiomics signature and the response in training cohorts, and decision

curve analysis (DCA) was used for comparing three models.

Results: A total of 396 features were extracted and two of them were eventually selected to create the radiomics signature significantly associated with response ($P < 0.001$). The radiomics signature showed a good accuracy with an AUC of 0.701 on the training set and 0.652 on the validation data.

Conclusion: T2-weighted-based radiomics for prediction of hepatic metastases from rectal cancer was successfully developed and validated. With a good discrimination performance, this radiomics model could play an important role in the preoperative prediction of liver metastases from rectal cancer.

MR imaging radiomics textures for predicting the gene expression in related to recurrence risks of HCC given by GOLM1, RND1 and SETD7

X. Hu; Chongqing/CN (xianling_hu@foxmail.com)

Purpose: To investigate whether the combination of radiomics and regression model-based classification can predict gene expression signatures of GOLM1, RND1 and SETD7 of HCC preoperatively.

Methods and Materials: 114 pathology confirmed early-staged HCC patients treated with surgical resection were included. All of these patients underwent Gd-EOB-DTPA enhanced MRI examinations. ROIs of the largest slice of each protocol (one unenhanced and 5 enhanced T1-WI MR images) were segmented by graph-based semi-automatic segmentation algorithm using MATLAB. A total of 1650 textures were extracted for each ROI. Three gene expression signatures, GOLM1, RND1 and SETD7 were evaluated using immunohistochemistry. PCA combined with Holm t test was applied to determine the optimal subsets. Logistic regression and ROC were conducted to assess the predictive ability.

Results: The multiple linear regression analyses demonstrated significant associations ($R^2 = 0.14-0.22$, $P < 0.0006$) between features subsets and gene signatures. The yielded ROC curves of each gene signatures with all AUC values (0.76, 0.74, 0.90, 0.90, 0.79, and 0.71) show statistical difference from chance. The prediction models for gene signatures SETD7 tumour and ANTL had the best statistical difference with AUC 0.90, positive predictive values (PPV) 100% and true negative rate (TNR) 100%. Models to predict SETD7 tumour achieved the best classification accuracy (ACC) and negative predictive value (NPV) of both 84%, and RND1 ANTL achieved the best true positive rate (TPR) of 93%.

Conclusion: The study revealed that quantitative HCC MR imaging radiomics could predict gene signatures for preoperatively assessing the risk of HCC recurrence.

Influence of arm positioning on radiation dose during combined thorax and liver CT imaging: a phantom study

O.V. Ivashchenko, J.J. Roelofs, A. van der Most, W.J.H. Veldkamp, I. Hernandez Giron; Leiden/NL (o.ivashchenko@lumc.nl)

Purpose: Impaired shoulder movement is a common morbidity related to various causes. If required, thorax or liver CT of these patients will be performed with 'arms_down', instead of the standard 'arms_up' setup. Only a few studies investigated the influence of arms position during thorax-abdominal CT, partially due to the high cost of fully articulated anthropomorphic phantoms. Here, the effect of arms positioning on patient dose is investigated using affordable in-house-developed arm extensions for the RANDO-phantom.

Methods and Materials: Two anatomically correct phantom arms were constructed as an extension of the RANDO-phantom. Bony parts were created with acrylate-based clay, manually shaped to a typical bony anatomy of the upper limb. Soft tissue was cast on industrial silicon. The attenuation of the phantom materials (Hounsfield units, HU) was compared to patient tissue in CT images. Subsequently, acquisitions were performed selecting the available clinical protocol 'thorax_tumour+liver' in two CT systems: Aquilion-One and Aquilion-Genesis (Canon Medical Systems), with two arm configurations ('arms_up', 'arms_down') and doses were compared in terms of CTDI_{vol} and dose-length-product (DLP).

Results: Attenuation of the arm phantoms [bone: (224±213)HU, soft tissue: (16±29)HU] closely mimicked values of the human arm [bone: (402±359)HU, soft tissue:(12±48)HU]. For the thorax part of the clinical protocol and 'arms_down' configuration, dose increase of 36.5% (DLP↑=23mGy·cm,CTDI_{vol}↑=0.7mGy; AquilionONE) and 19.6% (DLP↑=18.1m mGy·cm,CTDI_{vol}↑=0.6mGy;AquilionONE GENESIS) was observed, compared to the 'arms_up' setup. For the liver part, corresponding dose increases were 26.6% (DLP↑=25.0 mGy·cm ,CTDI_{vol}↑=1.0mGy) and 22% (DLP↑=21.3 mGy·cm,CTDI_{vol}↑=0.9mGy).

Conclusion: In this phantom study, arms positioning during combined thorax-liver CT significantly influenced patient dose (up to 36%).

The effect of scout view length on patient dose from thoracic CT examinations performed with tube current modulation

K. **Perisinakis**, A. Tzedakis, N. Ntoufas, M. Velivasaki, J. Stratakis, J. Damilakis; *Iraklion/GR (kostas.perisinakis@med.uoc.gr)*

Purpose: To investigate the effect of altering the scanogram boundaries, with respect to a standard region to be imaged, on the modulated mA values in thoracic CT examinations.

Methods and Materials: The body region typically imaged in thoracic CT was defined on one adult and four pediatric physical anthropomorphic phantoms. The mean mA per each of the rotations required to image the prescribed image volume was recorded for a modern 128-slice CT system keeping the image volume unchanged but altering the scanogram boundaries symmetrically up to ±10 cm in steps of 2 cm. Monte Carlo methods and five mathematical anthropomorphic phantoms were employed to quantify dose differences between helical CT acquisitions resulting to the same image volume but involving scanograms of different length.

Results: mA modulation was found to be significantly affected when scanogram length was altered with respect to the preset imaged volume. The difference in modulated mA was up to 15% with the highest values recorded for regions close to the imaged volume boundaries. The difference in dose to the radiosensitive organs of thorax was found up to 12% with higher and lower value recorded for thyroid and lung, respectively.

Conclusion: Scanogram length in thoracic helical CT scans performed with mA modulation should cover the entire volume to be imaged plus the overscanning regions at either side to avoid increase of dose to organs close to image volume boundaries such as thyroid.

This project has received funding from the Euratom research and training programme 2014-2018 under grant agreement No. 755523.

B-1594 10:46

Investigation the causes of overscanning in z-axis in thorax, abdominopelvic and thoraco-abdominopelvic CT examinations

O. **Yar**, M.R. Onur, I. Idilman, E. Akpinar, D. Akata; *Ankara/TR (drozanyar@gmail.com)*

Purpose: The aim of this study was to determine the frequency of excessive z-axis coverage of single-phase thorax CT, abdominopelvic CT, thoraco-abdominopelvic CT, stone protocol abdomen CT and pulmonary CT angiography examinations and evaluate the factors that may be associated with overscanning in CT.

Methods and Materials: Between March 1 and April 1, 2018, 2032 CT examinations performed in 1531 cases were included in our study. According to accepted reference points determined for CT examinations, the lengths of over-scanned z-axis were measured. Excessive scan frequency, the ratio of over-scanned length to the acceptable scan length were evaluated according to the gender, age, type of examination, indication of examination, the time of acquisition of the examination, the presence of some factors that may affect the determination of the scan range in topogram, the throughput of CT equipments and the experience of the CT technicians.

Results: While the frequency of over-scanning in z-axis was not significantly different between genders ($p = 0.433$), statistically significant differences in terms of over-scanning in z-axis were obtained between the age groups ($p < 0.001$), types of examinations ($p < 0.001$), indications for examination ($p=0.009$), conditions that may affect determination of the scan range in topogram ($p<0.05$), acquisition time ($p=0.042$) and technician's experience ($p>0.001$).

Conclusion: Overscanning in z-axis is a preventable cause of increased radiation dose in CT. Taking measures for preventable causes of high over-scanning will reduce the effective radiation dose of exposed cases.

B-1595 10:54

Comparison of radiation doses imparted during multidetector CT scanners and cone beam computed tomography for the postoperative, spinal fusion assessment

N. **Guberina**, M. Forsting, A. Ringelstein; *Essen/DE*

Purpose: To assess and compare radiation doses imparted during various, multidetector, single- and dual-source CT scanners (MSCT) as well as cone beam computed tomography (CBCT) for the postoperative examination of spinal fusion of the lumbar spine.

Methods and Materials: Radiation doses were assessed during standardized lumbar spine CT protocols at different MSCT ((I) single-source CT scanner Somatom Definition AS+, (II) 2nd generation of dual-source CT scanner Somatom Definition Flash in single-source technique, (III) 2nd generation of dual-source CT scanner Somatom Definition Flash in dual-source technique (all Siemens Healthcare, Erlangen, Germany)) and at the CBCT Ziehm Vision RFD 3D (Ziehm Imaging GmbH, Nürnberg, Germany), (IV) (a) RFD-3D (Standard) and (b) RFD-3D (L-D). Image quality was examined independently by evaluating various important parameters (pedicle placement, quality control of spinal fusion surgery, and the evaluation of the lumbar spine in case of complications) determined on real patients' examinations. Wilcoxon signed rank test was used to determine statistically significant differences ($p < 0.05$).

Results: In MSCT setting following radiation doses were assessed (CTDI_w; DLP): (I) 8.9mGy; 96.8mGy·cm; (II) 14.2mGy; 153.4mGy·cm; (III) 22.0mGy; 236.2 mGy·cm; in the CBCT setting radiation doses were distributed as follows: (IV) (a) 17.2 mGy; 187.0 mGy·cm; (b) 13.0 mGy; 143.1 mGy·cm. Overall, image quality, was evaluated as good for both, MSCT and CBCT examinations.

Conclusion: Dual-source MSCT scanning involves higher radiation dose for the postoperative examination of spinal fusion of the lumbar spine. Radiation doses are lower during CBCT and single-source MSCT compared to dual-source MSCT lumbar spine examinations while maintaining sufficient image quality.

B-1596 11:02

Effective dose comparison between cone beam CT (CBCT) and MSCT for three types of head examinations

D. **Buytaert**¹, B. Keelson², G. Van Gompel², J. Casselman³, N. Buls², K. Bacher¹; *¹Gent/BE, ²Brussels/BE, ³Bruges/BE (dimitri.buytaert@ugent.be)*

Purpose: To (1) measure and compare organ and effective doses (E) for three types of head examinations with CBCT and conventional MSCT, and (2) to establish CTDI_{vol} to E conversion factors for CBCT.

Methods and Materials: This experimental study included sinus, temporal bone and mandibula CBCT and CT examinations. Images from an Alderson RANDO anthropomorphic phantom were acquired on a Newtom 5G (Newtom, Verona, Italy) CBCT and GE Discovery 750HD (GE Healthcare, Milwaukee, WI, USA) CT device. The phantom was positioned and scanned with clinical standard of care protocols. Organ doses were measured using 160 calibrated TLD dosimeters, of which 148 were positioned inside the first 10 slices of the RANDO phantom. From these organ doses the E was calculated and CTDI_{vol} to E conversion factors were determined.

Results: E values for sinus, temporal bone and mandibula were respectively equal to 105, 238 and 65 µSv on the CBCT device. The respective values calculated for the CT device were 56, 1816 and 743 µSv. The respective CBCT conversion factors from CTDI_{vol} to E were 28.09, 23.90 and 35.46 µSv/mGy, while for CT these conversion factors were respectively equal to 35.47, 34.78 and 56.29 µSv/mGy. For sinus, temporal bone and mandibula the E on CT was respectively a factor 0.53 lower, 7.6 higher and 11.4 higher than on CBCT.

Conclusion: The CT sinus protocol resulted in lower E than the protocol on the CBCT, however the CT temporal bone and mandibula protocols resulted in much higher doses than the CBCT.

Characterisation of patient skin dose in CT imaging

M. **Cabuy**¹, G. Van Gompel², P.D. Deak³, J. de Mey¹, N. Buls²; *¹Jette/BE, ²Brussels/BE, ³Berlin/DE (margo.cabuy@outlook.com)*

Purpose: Investigate the influence of CT acquisition and geometrical parameters on patient skin dose in CT imaging.

Methods and Materials: A Monte Carlo software (ImpactMC) simulating dose distributions was experimentally validated for the scanner geometry (GE Revolution CT). MC experiments were conducted on virtual cylindrical and elliptical phantoms with varying size (diameter 16 and 32 cm; major axis 9.35, 18.7 and 37.8 cm) and position in the CT gantry. In addition, the impact of following acquisition parameters on skin dose were assessed: beam shaping

filter (Medium and Body); tube voltage (70, 80, 100, 120 and 140 kVp); beam collimation (40 and 80 mm). For each condition, the surface skin dose, normalized by $CTDI_{vol}$, was estimated.

Results: The ImpactMC software validation yielded a dose accuracy with variance < 5.5%. For each beam shaping filter, a generalized model of skin dose in function of the patient, geometric and acquisition variables was fitted to the data. The local surface skin dose could be accurately (stdev < 11%) estimated considering only the distance between skin and isocentre. Knowledge of the actual patient position in the gantry, phantom shape, size, tube voltage and beam collimation has only a minor additional impact on the model accuracy (stdev < 3%). For all simulations, an increasing trend in skin dose was observed when the skin approaches the isocentre. The impact of the beam shaping filter is largest at the isocentre (15% difference in skin dose).

Conclusion: Skin dose in CT can be estimated based on CT images and $CTDI_{vol}$ of the CT acquisition.

Coronary calcium scoring in CT with a calcium-aware image reconstruction technique: dose reduction by lowering x-ray tube voltage

R. **Booij**, R.P. Budde, D. Bos, M. Kremer, M. Dijkshoorn, M. van Straten; Rotterdam/NL (r.booij@erasmusmc.nl)

Purpose: To assess the accuracy and dose reduction potential of a reconstruction technique that aims at a constant CT number for calcium when varying tube voltage.

Methods and Materials: A cardiothoracic phantom was scanned in two sessions. First, with a phantom insert containing calcifications varying in size and density at eight tube voltages (70-140 kV). Tube load was adapted by the scanner to maintain the reference image quality defined at 120 kV. Second, 21 ex vivo hearts were scanned at 120 kV and at an automatically selected tube voltage. Images were reconstructed with the standard calcium score kernel (Qr36) and a calcium-aware kernel (Sa36). Agatston score was determined after manual exclusion of lesions caused by noise.

Results: For the phantom insert, CT numbers differed up to 64% for Qr36 and 10% for Sa36 when compared to the reference scan at 120 kV. Similarly, Agatston scores differed up to 40% and 15% for Qr36 and Sa36, respectively. For the ex vivo hearts, the automatically selected tube voltage was always 90 kV instead of 120 kV. Corresponding $CTDI_{vol}$ values were 0.64 mGy and 0.79 mGy, respectively. Agatston scores were up to 300 higher with the new low-dose protocol using Sa36 compared to the reference protocol with Qr36 and 120 kV. However, the clinical impact of this increase seems limited.

Conclusion: A calcium-aware image reconstruction technique allows for consistent CT numbers and comparable calcium scores when lowering kV, resulting in a possible dose reduction of up to 19%.

B-1599 11:26

Dose management in computed tomography using the as-low-as-diagnostically acceptable image quality approach

G. **Widmann**¹, G. Degenhart¹, A. Al-Ekrish², W. Puelacher¹, G. Feuchtnr¹, W.R. Jaschke¹, R. Jacobs³, R. Pauwels³, ¹Innsbruck/AT, ²Riyadh/SA, ³Leuven/BE (gerlig.widmann@i-med.ac.at)

Purpose: For a specific CT examination, the as-low-as-diagnostically acceptable (ALADA) dose for each manufacturer, scanner, protocol, and dose saving technology is usually unknown. Purpose was to develop an ALADA image quality approach which may guide dose optimisation by comparative image quality phantom testing.

Methods and Materials: Spatial resolution, contrast resolution, contrast-to-noise ratio and subjective noise and sharpness scores from a published ALADA clinical craniomaxillofacial trauma reference protocol at $CTDI_{vol}$ 2.66 mGy (80 kV, 40 mA) were compared with the results from two other scanners of a different vendor. Test protocols included fixed settings of 100 kV and 35 mA, 80 kV and 40 mA, and protocol adoptions to achieve doses of around 2.66, and 1.00 mGy. The influence of various sharp and soft kernels, and iterative reconstructions was evaluated.

Results: Doses of around 2.6 mGy could provide similar image quality. 3.08 and 3.44 mGy (100 kV, 35 mA) did not provide significant image quality advantages. Doses of 1.73-1.92 mGy (80 kV, 40 mA) had more noise, while 1.00-1.03 mGy also decreased contrast resolution. Only bone kernel H70h showed similar spatial resolution, but had higher noise than the reference bone kernel. Iterative reconstructions reduced noise and improved contrast-to-noise ratios substantially.

Conclusion: Similar scanner settings may not provide similar doses. Image quality results are largely influenced by convolution kernel and image reconstruction technology. A phantom-based ALADA image quality approach may facilitate protocol optimisation and ensure that patients receive CT examinations with the lowest diagnostically acceptable radiation dose.

B-1600 11:34

Clinical diagnostic reference levels for CT examinations: a prospective multicentre study

H. **Bra**¹, F. Zanca², B. Rizk³, S. Montandon⁴, D. Racine⁵, E. Meicher¹, D. Fournier¹; ¹Sion/CH, ²Heverlee/BE, ³Villars-sur-Glane/CH, ⁴Gland/CH, ⁵Lausanne/CH (hugobene@gmail.com)

Purpose: To establish clinical DRLs (CDRLs) according to BMI in a Swiss multicentre setting.

Methods and Materials: After protocol harmonization and optimization according to clinical indications and BMI (<25;>25), 5310 abdomen and 1058 chest CT examinations (5 Philips scanners) were prospectively collected from February 2017 to June 2018. Local CDRLs per indication (third quartile of the median dose values of each CT modality) were calculated and compared to the new national DRLs (NDRLs). Mann-Whitney tests and Wilcoxon test were used as appropriate (significant difference: p<0.05).

Results: For chest examinations, CDRLs were below or equal to P50 and P75 NDRLs for $CTDI_{vol}$ (range 4.9-6.0 vs 6/7mGy) and DLP (164-209 vs 210/250mGy.cm) in the "all BMI" and BMI<25 groups. For BMI>25 patients, they were higher than P50 and P75 NDRLs for $CTDI$ (range 7.1-7.9 vs 6/7mGy) and DLP (267-321 vs 210/250mGy.cm), suggesting new NDRLs (7mGy, 250nGy.cm) are challenging for overweight population. For BMI< 25 abdomen examinations, local CDRLs were significantly lower than P50 and P75 NDRLs (4.6-7.0 vs 10/11mGy and 226-273 vs 470/540mGy.cm). For BMI>25, CDRLs were lower than NDRLs P75 only (7.1-10.6 vs 10/11mGy and 384-465 vs 470/540mGy.cm), indicating that P75 NDRLs are achievable for BMI >25, but too high for BMI<25 patients. For chest, $CTDI_{vol}$ and DLP variability was larger when considering BMI rather than clinical indication; for abdomen a large variability was observed among indications.

Conclusion: Addressing patient size is relevant when defining DRLs for both chest and abdomen examinations, as clinical indication seems relevant only for abdomen.

Monte Carlo simulation of dual-energy CT systems: initial validation of radiation dose measurements

Y. **Toufique**, O. Bouhali, J.O. Doherty, J. Goracy, I. Delakis; Doha/QA (toufique.yassine@gmail.com)

Purpose: Patient dose measurement and diagnostic reference levels are based on computed tomography dose indices (CTDI), a quantity that can be measured using an ion chamber. The aim of this work is the validation of a numerical Monte Carlo (MC) model of the Definition Flash (Siemens) CT scanner using the GATE (GEANT4 application for tomographic emission) toolkit by the simulation of the measurement process. In addition, a MC model of the x-ray tube, within the CT system was validated by comparing the simulated GATE energy spectrum with a calculated spectrum via SpekCalc software.

Methods and Materials: Experimental CTDI measurements were made in a PMMA body phantom (32 cm) and head phantom (16 cm) using a 100-mm-long pencil chamber, which represents the absorbed dose along the longitudinal z-axis of the scanner measured during a single rotation of the x-ray source. Measurements were performed at five different positions in the phantom (center, 90°, 180°, 270°, 360°).

Results: The comparison between simulated x-ray spectrum and the calculated spectrum shows good agreement. A difference in the K-characteristic x-ray intensity was observed. The relative difference between simulated and measured CTDI values at 70, 80, 100, 120 and 140 kVp was less than 3%.

Conclusion: In this study, we demonstrated that GATE can model a complete CT scanner from the x-ray tube to the absorbed dose (CTDI). Future simulation work will investigate CT dose reduction techniques as well as advanced acquisition methodologies.

B-1602 11:50

Radiation burden of patients with hepatocellular carcinoma from multiple TACE and CT procedures

L. Sukupova; Prague/CZ (lucie.sukupova@gmail.com)

Purpose: The transarterial chemoembolization (TACE) is a high-dose therapeutic procedure, sometimes performed repeatedly, which is accompanied by multiple CT exams during the treatment and follow-up. The aim of this study was to estimate organ and effective doses from TACE and CT procedures for patients who underwent TACE repeatedly.

Methods and Materials: 166 patients underwent 210 TACE during 06/2012-06/2018. 109 patients underwent TACE only once, 40 patients underwent TACE repeatedly (2-5 times). These 40 patients underwent 241 abdomen CT exams (2-11 CT exams) during the treatment and follow-up. The follow-up period lasted up to 4.2 years, median 1.3 years.

The dose estimate of organ and effective doses was performed in PCXMC for TACE and in ImpactDose for CT exams. The actual size, anatomic and dose information was taken from archived images and RDSR or from DICOM headers.

Results: The median/maximum/minimum values of the cumulative organ doses from TACE and CT procedures to the most exposed organs were 1.1/0.3/3.2 Gy to adrenals, 1.7/0.5/5 Gy to kidneys and 1.1/0.3/2.7 to the liver. The highest organ doses in a single procedure were 2.8 Gy to kidneys and 1.2 Gy to the liver. The cumulative effective doses were between 80 and 513 mSv, median 210 mSv.

Conclusion: Organ doses from a single TACE can reach 2.8 Gy for some organs, but this is still remote from the tolerance doses known from radiotherapy. Higher organ and effective doses increase the risk of stochastic effects, but they may be of lower importance in patients with life-threatening HCC.

Visibility of bronchial artery on virtual monoenergetic image and advanced virtual monoenergetic images

T. Nomura, T. Niwa, J. Hashimoto, Y. Imai; Isehara/JP
(yh_4amm1208@yahoo.co.jp)

Purpose: To assess the visibility of bronchial artery on virtual monoenergetic image (VMI) and noise-optimized advanced VMI (VMI+).

Methods and Materials: Eighty-seven patients with oesophageal cancer were scanned on a third-generation 128-slice dual-source CT system before operation. Tube voltages were set to 90 kVp (tube A) and 150 kVp (tube B). Gantry rotation time, pitch, and collimation were 0.25 s, 0.55, and 192 × 0.6 mm, respectively. Images were reconstructed with VMI and VMI+, energy levels at 40-120 keV in 10 keV increments as well as composite image equivalent to CT at 105 kVp. CT attenuation value and contrast to noise ratios (CNR) of bronchial artery on VMI and VMI+ were compared to those on composite image. Subjective analysis was performed by two radiologists in terms of the visibility of bronchial artery.

Results: CT value of bronchial artery on VMI at 40-60 keV, and VMI+ at 40 and 50 keV were significantly higher than that on composite image ($p < 0.05$). CNR on VMI at 40-60 keV was significantly higher than that on composite image ($p < 0.05$); whereas CNR on VMI+ at 40 and 50 keV showed no significant difference to that on composite image. In subjective analysis, both VMI and VMI+ at 40 and 50 keV showed better visualization of bronchial artery than composite image.

Conclusion: VMI and VMI+ at low keV may be useful to visualize bronchial arteries.

B-1604 10:47

The value of multiple quantitative spectrum parameters for assessing the lymph node metastasis of lung cancer with dual-layer detector spectral CT

L. Gao, Y. Hou, Y. Ma, Q. Ma, X. Lu; Shenyang/CN (1242179174@qq.com)

Purpose: To investigate the value of multiple quantitative spectrum parameters for the metastatic lymph nodes in lung cancer using dual-layer detector spectral CT.

Methods and Materials: Thirty-nine patients with lung cancer undergoing dual-phase enhanced scan with dual-layer detector spectral CT were selected. According to pathological findings, sixty-eight lymph nodes were divided into metastatic group (n=37) and non-metastatic group (n=39). Short diameter of lymph nodes, normalized iodine concentration (NIC) and the slope of energy spectrum curve (λ_{HU}) in arterial (AP) and venous (VP) phase were measured and calculated. Receiver operating characteristic (ROC) curves were drawn to confirm the optimum threshold and diagnostic efficiency.

Results: Short diameter of lymph nodes, NIC and λ_{HU} in AP and VP of the two groups all showed significant differences ($P < 0.05$). Moreover, the optimum diagnostic efficiency of AP NIC in metastatic lymph nodes was the largest (AUC_{AP NIC} = 0.843 vs. AUC_{VP NIC} = 0.698; AUC_{AP λ_{HU}} = 0.840 vs. AUC_{VP λ_{HU}} = 0.716; AUC_{short diameter} = 0.736), and its threshold was 0.15mg/dL. The sensitivity and specificity were 89.2% and 69.2%, respectively. When choosing the short diameter of the lymph node ≥ 1 cm as the standard, the sensitivity and specificity were 71.9% and 68.2%, respectively. When the two diagnostic criteria are combined, its sensitivity can be improved to 97.0% and the specificity can be increased to 90.2%.

Conclusion: Multiple quantitative spectrum parameters of dual-layer detector spectral CT imaging provide an effective noninvasive method for accurate evaluation of metastatic lymph nodes in lung cancer. Combining the short diameter of the lymph nodes and AP NIC, the accuracy of the diagnosis can be improved.

B-1605 10:55

Using relationship between pulmonary veins and pulmonary nodules to distinguish benign intrapulmonary lymph nodes from lung cancer on CT

J.L. Barnett¹, I. Pulzato², R. Wilson², S. Padley¹, A.G. Nicholson¹, A. Devaraj¹;
¹London/UK, ²Belfast/UK (ilaria.pulzato@gmail.com)

Purpose: Accurately distinguishing benign intrapulmonary lymph nodes (IPLNs) from small lung cancers is highly desirable in lung cancer screening and for incidentally detected nodules. We aimed to test our hypothesis that IPLNs were more frequently connected to pulmonary veins, compared to lung cancer, and that this could be used to distinguish the two types of nodules.

Methods and Materials: Two radiologists reviewed 62 pathologically confirmed benign intrapulmonary lymph nodes and 61 pathologically confirmed small sized (<15mm) lung cancers and assessed the number and type of pulmonary blood vessels arising from, or terminating within, these nodules. Nodule location and outline and shape were also reviewed.

Results: Connection to a pulmonary vein was significantly more frequent in IPLNs (93.5%) compared to lung adenocarcinomas (21.3%) [$p < 0.001$]. IPLNs were never (0%) associated with pulmonary arteries, but identified in 55.7% of lung cancer nodules. [$p < 0.001$]. The connection to a pleural surface was present in both IPLNs (38.7%) and lung adenocarcinomas (37.7%) [$p = 1.0$].

Conclusion: Connection to a pulmonary vein as opposed to a pulmonary artery can be used in conjunction with other CT signs to identify IPLNs in the setting of small indeterminate pulmonary nodules.

B-1606 11:03

Application of computer-aided diagnosis system based on 3D deep convolutional neural network in lung cancer screening

Q. Meng, J. Ding; Zhengzhou/CN (mengke436@163.com)

Purpose: To evaluate the application value of CAD system based on the novel deconvolution rapid residual CNN lung cancer screening of urban China.

Methods and Materials: The LDCT imaging data of 8850 lung cancer screening volunteers with 1111 nodules of lung from November of 2013 to December of 2017 were evaluated through visual detection (VD) method, CAD method or VD combination CAD method. The detection rate, the missed diagnosis rate and the number of false-positive rate of nodules were observed.

Results: Compared with the VD method, the detection rate of nodules in CAD and VD combined with CAD was significantly increased (80.1% vs 94.2%; 19.9% vs 5.8%, $\chi^2 = 101.65$, $P = 0.00$); the detection rate of nodules in VD combined with CAD method was higher than that of CAD. The number of false-positive nodules detected by CAD method was highest among the three methods. Compared with the VD, the detection rate of lung-RADS classification by CAD and VD combined with CAD was significantly increased ($\chi^2 = 25.083$, 23.449, $p = 0.000$, 0.000). Compared with the VD, the detection rate of types of nodules by CAD or the VD combined with CAD was statistically significant ($\chi^2 = 6.955$, 6.821, $p = 0.031$, 0.033). Compared with VD and VD combined with CAD, the positive prediction rate of lung cancer by CAD was

significantly reduced, the rate of missed diagnosis and the false-positive rate were significantly increased, and the difference was statistically significant (88.2% vs 94.1%, 94.1%, 9.2% vs 2.1%, 2.1%; $\chi^2=14.605$, 14.693, $p=0.002$, 0.002).

Conclusion: The CAD combined with VD method is the preferred method to use in the large-scale LDCT lung cancer screening of urban China.

Deep learning-based CAD may improve detection of pulmonary nodules while preserving a low false-positive rate

J. Lieman-Sifry¹, S. Brouha², A. Yen², E. Weihe², K. Jacobs², M. Horowitz², D. Motiuk², A. Hsiao³; ¹San Francisco, CA/US, ²San Diego, CA/US, ³La Jolla, CA/US (jesse@arterys.com)

Purpose: We investigate the rate at which false positives (FP), defined as a nodule detected by deep learning-based computer aided detection (DL-CAD) not noted by any of four general radiologist readers, are overturned upon subspecialty secondary read to be true nodules.

Methods and Materials: We train and validate a DL-CAD system on standard-dose and low-dose CT scans. The system consists of a high-sensitivity 2D-U-Net-based network and a 3D-VGG-based classifier to reduce the FP rate. To test the DL-CAD system, nodules were identified on 100 scans selected from the NLIST dataset independently by four general radiologists. 3/4 consensus defines a true nodule. Intermediate confidence nodules predicted by the DL-CAD algorithm that were not detected by any of the four general radiologists, which would otherwise be considered "false positives," were presented to five dedicated thoracic radiologists and two fellows as secondary readers. Each FP was reviewed and radiologists assigned their confidence level (0-10) that the prediction was a nodule worth further investigation in a web-based survey. We define FP with average scores of 5 and above as "overturned false positive" nodules.

Results: At operating points of 1.7FP/scan and 0.5FP/scan, 38% of FPs (65/171), and 54% of FPs (26/48) were overturned, respectively. With 260 nodules of 3/4 consensus in the ground truth data, 65 overturned FP suggests that an increase of sensitivity of up to 25% (65/260) could be achieved with use of the DL-CAD system.

Conclusion: A substantial fraction of intermediate confidence lesions from DL-CAD may constitute nodules worth further follow-up.

Analysis of pleural effusion dynamics in patients with pulmonary infarction based on CTPA measurements

M. Kastelic¹, J. Vidmar², K.K. Šifer¹, I. Kocijančič²; ¹Celje/SI, ²Ljubljana/SI (marko.kastelic@gmail.com)

Purpose: There is a lack of studies about pleural effusion dynamics in patients with pulmonary infarction. The aim of this study was to investigate the relationship between possible factors contributing to the development of pleural effusion, its size and time course in patients with pulmonary infarctions.

Methods and Materials: CTPA studies from 103 patients with pulmonary infarction were retrospectively analyzed along with the following data: patient comorbidities, size of pulmonary infarction, location and size of pleural effusion and the time between the onset of clinical symptoms of pulmonary infarction and CTPA study.

Results: A highly statistically significant difference ($p = 0.005$) was found in the mean size of pulmonary infarction in patients with effusion (34.5 cm³) compared to those without it (14.3 cm³). The size of the effusion peaked between 4th - 5th day after the onset of clinical symptoms of pulmonary infarction. In the first 5 days after the onset of clinical symptoms, a highly significant correlation ($p = 0.001$) was found between the size of the effusion and time with an approximate rate of increase in effusion layer of 1.3 mm/12 h.

Conclusion: Patients with a pleural effusion are more likely to have a larger pulmonary infarction than those without it. If present, the effusion can be expected to increase in a relatively slow linear fashion in the first 5 days after the onset of clinical symptoms of pulmonary infarction.

B-1609 11:27

Pulmonary arterial enlargement predicts long-term survival in COPD patients

A. Ezponda Casaiús, J. De Torres, A. Alcaide, A. Campo, J. Bertó, J. González, J. Zulueta, G. Bastarrika Alemañ; Pamplona/ES (aezponda@unav.es)

Purpose: Pulmonary artery enlargement (PAE) is associated with exacerbations in chronic obstructive pulmonary disease (COPD) and with survival in moderate to severe patients. The potential role of PAE in survival prediction has not been compared with other clinical and physiological prognostic markers.

Methods and Materials: In 188 patients with COPD, PA diameter was measured on a chest CT. The following clinical and physiological parameters were registered: age, gender, smoking status, pack-years history, dyspnoea, lung function, exercise capacity, body mass index, BODE index and history of exacerbations in year prior to enrolment. Proportional Cox regression analysis determined the best predictor of all-cause survival.

Results: During a mean follow-up of 83±42 months, 43 patients died. Age, pack-years history, smoking status, BMI, FEV1%, six-minute walking distance, Modified Medical Research Council dyspnea scale (MMRC), BODE index, exacerbation rate prior to enrolment, PA diameter and PAE (diameter ≥30mm) were associated with survival. In the multivariable analysis, age (HR 1.08; 95% CI 1.03±1.12, $p<0.001$) and PAE (HR 2.78; 95%CI 1.35±5.75, $p = 0.006$) were the most powerful parameters associated with all-cause mortality.

Conclusion: In this prospective observational study of COPD patients with mild to moderate airflow limitation, PAE was the best predictor of long-term survival along with age.

B-1610 11:35

Synchrotron phase-contrast imaging of the lung: a proof-of-concept study on porcine lungs in a human-scale chest phantom

W. Wagner¹, F. Wuennemann¹, J. Biederer², P. Konietzke¹, W. Stiller¹, M.O. Wielpütz¹, H.-U. Kauczor¹, G. Tromba³, C. Dullin⁴; ¹Heidelberg/DE, ²Sehheim-Jugenheim/DE, ³Trieste/IT, ⁴Göttingen/DE (willi.wagner@med.uni-heidelberg.de)

Purpose: To prove the applicability of in-line free propagation phase-contrast synchrotron tomography on a human scale using a chest phantom with ventilated fresh porcine lungs.

Methods and Materials: Freshly excised heart and lung explants were positioned in an ARTIChest chest phantom. Artificial lung nodules were induced by injection of 3% agarose gel, containing either 0.5% or 1.0% of a clinical contrast agent with an iodine content of 300 mg/ml. Local areas of interest were imaged with a pixel size of 100 micrometer at the SYRMEP beamline of the Italian synchrotron light source Elettra and compared to standard imaging using a clinical Philips iCT 256 CT scanner.

Results: Synchrotron phase-contrast lung imaging yields a high-resolution depiction of anatomical hallmarks of healthy lungs and artificial lung nodules. Interlobular septa, margins of subsegmental bronchi and pulmonary blood vessels can be visualized in superior detail compared to clinical CT scanners. 33 mGy air kerma were measured using the clinical scanner compared with 13 mGy in synchrotron acquisitions (or 4 mGy with a third of the projections). We achieved a dose reduction by 60 to 88%, respectively.

Conclusion: We demonstrate that synchrotron-based local-area free propagation phase-contrast CT can be performed on a human-scale chest phantom prepped with fresh porcine lungs. Moreover, we demonstrated that improved image quality by PBI allows for a more detailed characterization of anatomical landmarks of healthy lungs and the assessment of artificial lung nodules.

B-1611 11:43

Preoperative multi-detector CT scoring criteria for assessing pericardial, lung, and phrenic nerve invasion of thymoma

S. Lee, S. Yoon; Seoul/KR (eesanghyup@gmail.com)

Purpose: To devise new preoperative multi-detector CT (MDCT) criteria for pericardial, lung, and phrenic nerve invasion of thymoma.

Methods and Materials: We retrospectively reviewed 224 consecutive patients with resected thymoma who underwent a preoperative MDCT scan. Morphologic and ancillary CT findings were evaluated for the invasion of pericardium, lung, and phrenic nerve. Multivariate logistic regression analyses were performed for identifying significant CT findings, and we devised CT scoring criteria for each structural invasion.

Results: On multivariate logistic regression, pericardial invasion was associated with pericardial crossing sign (OR, 60.3 [95%CI, 8.3-438.7]; $p<0.001$), pericardial tail sign (OR, 42.3 [95%CI, 9.6-187.4]; $p<0.001$), and pericardial thickening (OR, 5.2 [95%CI, 1.3-20.4]; $p=0.019$). 2 or higher pericardial invasion score provided the sensitivity/specificity of 76.2%/96.6%. Lung invasion was associated with microlobulation (OR, 33.6 [95%CI, 9.8-114.7]; $p<0.001$), ground-glass opacity at surrounding lung (OR, 11.0 [95%CI, 1.4-88.8]; $p=0.024$), and calcification (OR, 3.4 [95%CI, 1.0-11.6]; $p=0.048$). 3 or higher lung invasion score provided the sensitivity/specificity of 69.6%/96.5%. Phrenic nerve invasion was associated with microlobulation (OR, 16.2 [95%CI, 4.5-58.3]; $p<0.001$), tumour coverage along the course of pericardiophrenic vein (OR, 8.0 [95%CI, 2.2-29.1]; $p=0.002$), mediastinal fat infiltration (OR, 5.3 [95%CI, 1.7-16.9]; $p=0.005$), and calcification (OR, 3.9 [95%CI, 1.1-13.5]; $p=0.030$). 2 or higher phrenic nerve invasion score provided the sensitivity/specificity of 65.2%/94.0%.

Conclusion: Our preoperative MDCT scoring criteria offered reasonable diagnostic accuracies for pericardial, lung, and phrenic nerve invasion of thymoma, which can help accurate assessment of T2 and T3 descriptors.

B-1612 11:51

A reader study in postmortem x-ray dark-field chest radiographs and correlation with conventional x-ray and CT

A.A. Fingerle¹, F. De Marco², K. Willer², P.B. Noel¹, A. Sauter¹, D. Pfeiffer¹, E.J. Rummeny¹, J. Herzen², F. Pfeiffer²; ¹Munich/DE, ²Garching/DE (alexander.fingerle@tum.de)

Purpose: To describe imaging features in x-ray dark-field radiographs, we performed a reader study on postmortem chest x-ray dark-field images to quantify dark-field signal strength, address intra- and interobserver agreement, grade image quality and correlate dark-field signal changes with findings in conventional x-ray and CT images.

Methods and Materials: IRB approval was obtained. 9 human bodies (3 female, 6 male, age range 52-88 years) were imaged with an experimental three-grating asymmetric imaging setup at 70 kVp. Chest x-ray dark-field radiographs and conventional x-rays were simultaneously acquired. CT imaging was performed on a 256-slice MDCT (Brilliance iCT) at 120 kVp. 3 readers evaluated dark-field signal strength in 6 lung regions by visual assessment on a 6-point ordinate scale. Intra- and interobserver agreement were assessed. Image quality was graded. Dark-field signal changes were correlated with findings in conventional x-ray and CT images.

Results: Dark-field signal strength increases from the apex to the base of the lungs, correlating with the amount of lung tissue. Intra- and interobserver agreement were substantial to very good for grading of both dark-field ($r=0.793-0.910$) and conventional ($r=0.772-0.947$) x-ray images. Image quality was graded good (4/6) for dark-field and very good (5/6) for conventional images. Pulmonary infiltrates correlated with areas of reduced dark-field signal.

Conclusion: Our results demonstrate that the dark-field signal shows significant differences depending on lung region and existing pathologies. Furthermore, the dark-field signal can be quantitatively correlated to visual assessment, providing further impetus for clinical studies addressing specific diseases of the lungs.

Comparison of signal intensity ratio, extent and transmuralty between a novel LGE black-blood and standard LGE bright-blood sequences in patients with ischaemic heart disease

G. Muscogiuri¹, M. Gatti², S. Dell'Aversana³, M. Guglielmo¹, A. Baggiano¹, A. Guaricci⁴, M. Pepi¹, G. Pontone¹; ¹Milan/IT, ²Turin/IT, ³Naples/IT, ⁴Bari/IT (g.muscogiuri@hotmail.it)

Purpose: To assess the reliability of a novel dark-blood LGE (DBLGE) technique compared to standard bright-blood LGE (SBBLGE) sequence in patients with ischaemic cardiomyopathy.

Methods and Materials: This prospective study included 78 patients (63.1 ± 12.6 years, 62 males) with clinical history of ischaemic cardiomyopathy who underwent CMR at 1.5T (Discovery MR450w, GE Healthcare, Waukesha, WI) with postcontrast SBBLGE and DBLGE acquisition. Two observers performed the imaging analysis in a double-blinded fashion. The endpoints were a) qualitative and quantitative analyses of signal intensity ratio (SIR); b) n° segments involved; c) transmuralty index (i.e. 0-25%; 25-50%, 50-75% and 75-100%); d) papillary muscle enhancement; e) microvascular occlusion (MVO). A cut-off p value < 0.05 was considered statistically significant.

Results: There were no interobserver variability (all p > 0.05). Subjective image quality in DBLGE compared to SBBLGE was higher for the discrimination between LGE and blood signal (p < 0.001), inferior (p < 0.001) between LGE and myocardium and similar between blood and myocardium (p = 0.56). DBLGE provided higher SIR between LGE and blood signal (1.18 ± 1.15 vs 0.18 ± 0.42; p < 0.001), lower SIR between LGE and myocardium (0.91 ± 4.95 vs 1.96 ± 1.64; p < 0.001) and between blood and myocardium (-0.26 ± 0.71 vs 1.57 ± 1.26; p < 0.001). The n° segments involved was similar (p = 0.08). The transmuralty index was inferior for DBLGE (3.09 ± 1.02 vs 3.30 ± 1.11; p = 0.007). DBLGE was superior in identifying papillary muscle hyperenhancement (25 vs 17 cases; p < 0.001) and inferior in MVO detection (7 vs 12 cases; p < 0.001).

Conclusion: The DBLGE sequences when compared to SBBLGE provided better contrast between LGE and blood pool, seemed to be superior in identifying papillary muscle hyperenhancement, whereas underestimated the transmuralty extension of LGE and the presence of MVO.

B-1614 10:38

Diagnostic accuracy of single-shot two-dimensional multisegment late gadolinium enhancement in ischaemic and non-ischaemic cardiomyopathy

G. Muscogiuri¹, M. Gatti², S. Dell'Aversana³, S. Pica¹, M. Guglielmo¹, A. Baggiano¹, A. Guaricci⁴, G. Pontone¹; ¹Milan/IT, ²Turin/IT, ³Naples/IT, ⁴Bari/IT (g.muscogiuri@hotmail.it)

Purpose: The aim of this manuscript is to assess the reliability of single-shot two-dimensional multi-slice late gadolinium enhancement (2D-MS_{LGE}) compared to standard single slice two-dimensional inversion recovery segmented gradient echo (2D-SS_{LGE}).

Methods and Materials: Sixty-seven patients who underwent clinically indicated cardiac magnetic resonance imaging (CMR) were enrolled. Image quality was assessed using a 4-point scale. Segments positive for LGE were classified as ischaemic or non-ischaemic for 2D-MS_{LGE} and 2D-SS_{LGE}. Interobserver and intraobserver variability was assessed with both sequences. The endpoints were a) detection of myocardial segments involved by LGE; b) classification of LGE as ischaemic and non-ischaemic pattern. Sensitivity, specificity, positive predictive value and negative predictive and diagnostic accuracy values were calculated for the two endpoints.

Results: 2D-MS_{LGE} and 2D-SS_{LGE} were successfully performed in all patients with comparable image quality (1.56 ± 0.59 vs. 1.54 ± 0.58, p = 0.84). For the overall population, 2D-MS_{LGE} correctly identified 1093 out of 1139 myocardial segments involved by LGE [96%; CI95: 95%-97%] as compared to 2D-SS_{LGE}. Similarly, 2D-MS_{LGE} correctly identified 1128 out of 1139 [99%; CI95: 98%-99%] and 1108 out of 1139 [97%; CI95: 96%-98%] of non-ischaemic and ischaemic LGE pattern. Interobserver and intraobserver variabilities for quantification of LGE using 2D-MS_{LGE} were, respectively, 0.98 and 0.99. The acquisition time was shorter for 2D-MS_{LGE} as compared to 2D-SS_{LGE} (2.0 ± 0.5 min vs. 6.0 ± 2.0 min, p = 0.01).

Conclusion: 2D-MS_{LGE} seems to be a reliable tool in both ischaemic and non-ischaemic cardiac disease as compared to 2D-SS_{LGE} with the advantage to require lower scan time and breath-hold.

B-1615 10:46

Left ventricle volumes and function assessment with cardiac magnetic resonance four-dimensional flow imaging

M. Guglielmo¹, A. Baggiano¹, G. Muscogiuri¹, A.J. Guaricci², D. Andreini¹, F. Alamanni¹, M. Pepi¹, G. Pontone¹; ¹Milan/IT, ²Bari/IT (g.muscogiuri@hotmail.it)

Purpose: Aim of this study is to compare 4D flow, echo and CMR quantification of LV volumes and LVEF using CMR SSFP cine sequences as the reference standard.

Methods and Materials: 10 consecutive patients (age: 59 ± 10) with indication to mitral valve plasty (MVP) for severe mitral regurgitation were enrolled. All patients underwent a presurgical assessment of LV end-diastolic (LVEDV), end-systolic (LVESV) volume and LVEF with CMR SSFP cine, 4D flow imaging and TTE. 3 to 5 months after the surgery all the measurements were repeated. Data were analysed using Student's t test, Bland-Altman plots, and intraclass correlation coefficient (ICC).

Results: Subjective image quality was lower for CMR 4D imaging compared to SSFP cine imaging. There was a good correlation between CMR SSFP imaging and both TTE and 4D flow imaging measurements. However, higher LVEDV and higher LVESV were found with CMR SSFP imaging as compared to CMR 4D imaging and TTE both at presurgery and postsurgery evaluations. LVEF was comparable between CMR SSFP imaging, CMR 4D imaging (mean difference with CMR SSFP imaging 2.4%) and TTE (mean difference with CMR SSFP imaging 3.5%). Reproducibility for CMR SSFP imaging was excellent. Reproducibility for echocardiography and 4D imaging was moderate.

Conclusion: CMR 4D flow imaging without contrast media is a new technique that provides an accurate evaluation of LV ejection fraction with a good correlation with CMR SSFP measurements. However, our data show an underestimation of LV volumes with CMR 4D imaging compared to CMR SSFP assessment.

B-1616 10:54

Comparison of standard 3D LGE imaging with novel short inversion time 3D LGE imaging in patients after myocardial infarction

M. Polacin¹, M. Gastl¹, I. Kapos¹, A. Gotschy¹, J. von Spiczak¹, H. Alkadi¹, R. Manka¹; Zurich/CH (Malgorzata.Polacin@usz.ch)

Purpose: Late gadolinium enhancement (LGE) visualizes myocardial scar and fibrosis. After myocardial infarction (MI), subendocardial infarcts can be missed due to poor contrast between the blood pool and subendocardium. The aim of

this study was to evaluate the benefit of 3D LGE imaging using an inversion recovery sequence with a fixed, short inversion time (TI =100 ms) (short 3D LGE) over the standard 3D LGE imaging with an adjusted TI (3D LGE).

Methods and Materials: 3D LGE and short3D LGE (same spatial resolution 1.2 x 1.2 mm², slice- thickness 8 mm; field of view, 350 x 350 mm²) were acquired in 27 patients with MI (8 female, mean age 64.8 ± 12 years) at 1.5T (Achieva, Philips, Best, Netherlands). Two independent, blinded readers evaluated 459 segments (AHA 17-segment model) using a 5-point Likert scale in terms of scar visibility. Contrast- to- noise ratio (CNR) between scar and blood pool was calculated.

Results: 3D LGE showed 98 infarcted segments out of 459 (21.4%), short3D LGE revealed 107 segments (23.3%). Short3D LGE demonstrated a better scar visibility (4.3 vs 2.8, P < 0.01) and better CNR between scar and blood pool (806.7 ± 256 vs. 209.5 ± 149, P < 0.01). Agreement between the readers was moderate for 3D LGE and excellent for short3D LGE (weighted κ = 0.52 vs. 0.78).

Conclusion: Short3D LGE provided a very good scar visualization and could be used additionally to standard 3D LGE imaging, especially in patients with subendocardial scarring and suboptimal nulling of the myocardium.

B-1617 11:02

Cardiac magnetic resonance for response prediction to Levosimendan treatment in patients with acute decompensated heart failure prior to cardiac surgery

A. Wielandner, F. Gremmel, R. Laggner, D. Senn, A. Zuckermann, C. Loewe, D. Beitzke; *Vienna/AT (alice.wielandner@meduniwien.ac.at)*

Purpose: Levosimendan may be used in patients with chronic heart failure and acute left ventricular dysfunction to improve left ventricular (LV) function and reduce LV size. So far, the impact of the myocardial composition on therapy response has not been investigated. Cardiac magnetic resonance (CMR) is a well established method to assess both LV function and composition and therefore may be used to predict treatment response to Levosimendan. This retrospective analyses is aimed to evaluate the impact of myocardial scar burden on the therapy response to Levosimendan in patients with acute decompensated heart failure prior to cardiac surgery.

Methods and Materials: Forty-one patients underwent CMR scan before and immediately after administration of Levosimendan. LV ejection fraction (LVEF) LV end-diastolic and end-systolic volumes (LVEDV / LVESV normalized to body surface), stroke volume (SV), late gadolinium enhancement (LGE) in % of the LV mass as well as proBNP levels were obtained. Patients were additionally grouped presence and absence of LV scar.

Results: There was a decline of LVEF, LVEDV, LVESV, SV and proBNP after Levosimendan administration (mean value before/after: LVEF 28.5 /27.4%, n.s.; LVEDV 131.7/123.6ml/m², p<0.00; LVESV 95.9/86.64ml/m², p<0.00; SV 35.8 vs 33.2ml/m², n.s.; proBNP 6069/4498pg/mL, p<0.00). No significant correlation between scar burden (%) and LVEDV, LVESV and EF changes could be found. Further, sub-group analysis (presence or absence of scar) revealed no significant differences between the groups (p>0.05).

Conclusion: Levosimendan effectively reduces LV size in patients with acute decompensated heart failure. LV scar burden (%) does not influence the therapeutic response.

B-1618 11:10

Noninvasive assessment of myocardial oxygenation after acute myocardial infarction with breath-hold-induced blood oxygen level-dependent imaging

K. Shi, Z.-G. Yang, Y.-K. Guo, S. Huang, X. Li; *Chengdu/CN (kshi0110@qq.com)*

Purpose: Blood oxygen level-dependent (BOLD) imaging is a noninvasive MR technique for determining myocardial oxygenation. In recent years, the safety profile when performing stress status has raised serious concerns in clinical practice. The purpose of this study was to investigate feasibility of breath-hold (BH)-induced BOLD imaging without adenosine administration in acute myocardial infarction (AMI).

Methods and Materials: Seven healthy rabbits were treated with different hypoxia-inhaled gases and adenosine administration, whereas the other seven healthy rabbits with different intervals of BH and adenosine administration. Subsequently, nine AMI rabbits received an optimal interval of BH and compared the diagnostic performance with adenosine administration. Myocardial signal intensity (SI) alterations were monitored when inhaled hypoxia gases, BH manoeuvres, as well as adenosine administration, respectively.

Results: Myocardial BOLD SI increased as inhaled oxygen concentration decreased. BOLD imaging performed when BH lasted from 30 to 60 seconds yielded similar BOLD SI increase (r ranged from 0.40 to 0.62; all P < 0.05) as compared with adenosine administration. Moreover, BH lasted for 30 seconds seems to be optimal to achieve the diagnostic performance with minimal interval (all P > 0.05). When applied 30 seconds' BH in AMI rabbits, it showed significant effectiveness for assessing myocardial response among infarcted,

salvaged and remote myocardium, as compared with adenosine administration (r = 0.89; P < 0.05).

Conclusion: BH-induced BOLD imaging achieves similar diagnostic performance for assessing myocardial oxygenation compared with adenosine administration. It is likely a safer and more tolerable alternative method for AMI patients.

B-1619 11:18

Alterations of the mitral valve vortex ring in ischaemic heart disease: an explorative 4D-flow study

C. Kräuter¹, U. Reiter¹, C. Reiter¹, A. Schmidt¹, A. Greiser², M. Masana³, M.H. Fuchsjäger¹, R. Stollberger¹, G. Reiter¹; ¹Graz/AT, ²Erlangen/DE, ³Barcelona/ES (corina.kraeuter@medunigraz.at)

Purpose: Blood flow into the left ventricle is accompanied by formation of a three-dimensional (3D) vortex ring at the mitral valve leaflets, which is considered to support ventricular filling and diastolic function. The aim of this study was to compare vortex ring properties of patients with chronic ischaemic heart disease (IHD) and healthy controls derived from cardiac magnetic resonance four-dimensional phase-contrast (4D-flow) measurements.

Methods and Materials: 10 subjects (3 IHD patients and 7 age-matched healthy controls) underwent left heart 4D-flow imaging at 3T. Pre-processing of velocity data as well as automated Q-criterion-based extraction and evaluation of 3D mitral valve vortex rings were performed by prototype (4DFlow, Siemens Healthcare) and in-house software. Vortex ring properties in patients and controls were compared by t-test.

Results: In all subjects, vortex rings were present during early and late diastolic filling and dissolved during diastasis. Duration of existence of early diastolic vortex rings was longer in patients compared to controls (226±50ms vs. 150±37ms, p=0.03), whereas their duration of existence did not differ in late diastole (132±27ms vs. 139±20ms, p=ns). Early diastolic peak mean vorticity was lower in patients compared to controls (56±5 s⁻¹ vs. 89±14 s⁻¹, p<0.01), while its delay to mitral valve opening was longer (170±13ms vs. 96±15ms, p<0.01). Late diastolic peak mean vorticity did not reveal differences (61±7 s⁻¹ vs. 74±12 s⁻¹, p=ns).

Conclusion: Early diastolic mitral valve vortex ring formation differs between IHD patients and healthy controls. Vortex ring properties derived from 4D-flow imaging might represent new metrics of diastolic function.

4D- vs 2D-flow imaging in the evaluation of transmitral velocity profiles: comparison with echocardiography

C. Reiter¹, C. Kräuter¹, E. Kolesnik¹, G. Reiter¹, A. Greiser², A. Schmidt¹, D. Scherr¹, M.H. Fuchsjäger¹, U. Reiter¹; ¹Graz/AT, ²Erlangen/DE (Clemens.Reiter@medunigraz.at)

Purpose: Transmitral peak velocity profiles assessed by Doppler-echocardiography represent important markers of diastolic left ventricular function. The purpose of the present study was to evaluate if cardiac magnetic resonance (CMR) four-dimensional phase-contrast imaging (4D-flow) provides better estimates for transmitral velocities than standard two-dimensional phase-contrast measurements (2D-flow) compared with echocardiography, respectively.

Methods and Materials: 53 subjects without signs of heart failure (male/female, 22/31; age, 62±8 years) underwent echocardiography as well as CMR whole-heart 4D-flow imaging and prototype navigator-gated through-plane velocity-encoded 2D-flow imaging in a plane positioned at the tips of opened mitral leaflets. Peak early (E) and late (A) diastolic transmitral velocities were evaluated in compliance with the guidelines for echocardiography, with routine software in case of 2D-flow measurements, and with prototype software from maximum velocities within the transmitral inflow tract in case of 4D-flow measurements. Comparisons of CMR derived E, A and E/A ratios with corresponding echocardiographic parameters were performed by means of correlation and Bland-Altman analysis.

Results: Echocardiographic peak velocities (E=76±15cm/s; A=73±16cm/s) were underestimated more severely by 2D-flow (E=65±12cm/s, p<0.001; A=55±12cm/s; p<0.001) than by 4D-flow measurements (E=73±14cm/s, p=ns; A=67±13cm/s, p<0.001). Echocardiographic E/A ratio (1.08±0.28) differed from 2D-flow E/A ratio (1.26±0.41, p<0.05), the correlation was strong (r=0.61), and the standard deviation of errors was large (SD=0.33). 4D-flow E/A ratio did not exhibit a bias to echocardiography (1.12±0.27, p=ns), the correlation was very strong (r=0.81), and the standard deviation of errors was smaller (SD=0.17).

Conclusion: Compared with echocardiography, CMR 4D-flow is superior to 2D-flow imaging in assessment of transmitral velocity profiles.

Value of CT image texture analysis in the differential diagnosis of benign and malignant parotid tumours

L. Yang, T. Jiang; Beijing/CN (36584269@163.com)

Purpose: To investigate the value of multi-slice spiral CT image texture analysis in differentiating adult benign and malignant parotid gland tumour.

Methods and Materials: Retrospective analysis was carried out in 33 patients with pathologically confirmed parotid gland tumour from August 2013 to April 2018. All patients were proven by pathological findings and underwent conventional and contrast-enhanced CT scan before therapy. According to the pathological findings the patients were divided into benign and malignant groups (22 and 11 cases, respectively). Texture features of the lesions were extracted by manually drawing ROI on the maximum level of tumour in conventional and enhanced CT imaging. The CT texture parameters between BPT and MPT groups were compared. ROC curve analysis was performed regarding the statistically significant parameters and the areas under curve (AUC) were calculated.

Results: CT texture parameter Cluster Shade, Sum entropy; Gray Level Non Uniformity, Large Area High Gray Level Emphasis, Contrast, Zone Entropy, Gray Level Variance, Sum Entropy; Entropy, IDMN, Sum Entropy, Difference Entropy, Gray Level Non Uniformity Normalized, Small Area Low Gray Level Emphasis were significant difference between BPT and MPT group ($P < 0.05$). The best CT texture parameter that differentiated the benign and malignant parotid gland tumour was Sum Entropy of CT venous phase (AUC=0.88, $P < 0.05$). With Sum Entropy ≤ 1.53 as diagnosis threshold in differentiating benign parotid gland tumour, the sensitivity and specificity were 100% and 72.70%, respectively.

Conclusion: There was significant difference in CT texture analysis parameters between benign and malignant parotid gland tumours. CT texture analysis has certain clinical application values in differentiating parotid tumours.

Virtual non-contrast reconstructions derived from DECT cannot replace true native scans in head and neck imaging

A.M.J.L. van Kroonenburgh, S.M.J. van Kuijk, A.A. Jacobi-Postma; Maastricht/NL (anna.van.kroonenburgh@mumc.nl)

Purpose: Virtual non-contrast (VNC) scans from Dual energy CT are thought to reflect True non-contrast (TNC) images and could therefore be used as a substitute to lower radiation dose. The general accepted difference in HU measurement between VNC and TNC is 15 HU points in order to accept VNC as a substitute for TNC. We investigated whether VNC reflects TNC in the head and neck region.

Methods and Materials: From November 2016 until June 2018 forty-seven patients underwent a DECT scan as part of their regular diagnostic work up for primary hyperparathyroidism with TNC, 30 s and 50 s postcontrast DECT scan of the neck. VNC images were calculated from postcontrast scans. Best fit ROIs were placed in thyroid tissue, parathyroid adenoma, lymph node, carotid artery, jugular vein, fat and sternocleidomastoid muscle. VNC densities were compared to TNC. Also difference in VNC 30sec densities and VNC 50sec densities were compared.

Results: Differences in mean density between TNC and VNC of the organs were as follows: Thyroid 54,1 HU ($p < 0,001$); parathyroid adenoma 20,2 HU ($p < 0,001$); Lymph node 22,3 HU ($p < 0,001$); Carotid artery 15,5 HU ($p < 0,001$); Jugular vein 14,4 HU ($p < 0,001$); Fat 61,2 HU ($p < 0,001$); Muscle 11,8 HU ($p < 0,001$). The mean HU value between 30 sec and 50 sec did not differ more than 5 HU.

Conclusion: The mean difference in density measurements exceeds far the limit of 15 HU in thyroid tissue, this possibly reflects the intrinsic iodine of the thyroid. Thus VNC cannot replace TNC in head and neck imaging.

B-1622 11:42

Evaluation of the prognostic value of visually detected cardiac MRI findings in asymptomatic diabetics and healthy volunteers

N. Panagiotopoulos¹, N. Fechrup¹, T.H. Oechtering¹, U. Roggenbuck², K. Nassenstein², J. Barkhausen¹, P. Hunold¹; ¹Lübeck/DE, ²Essen/DE (nikolaos.panagiotopoulos@uksh.de)

Purpose: To evaluate the prevalence and prognostic value of wall motion abnormalities (WMA), late gadolinium enhancement (LGE), and perfusion defects (PD) in cardiac MRI (CMR) in asymptomatic diabetics (D) and non-diabetics (ND).

Methods and Materials: CMRs of 44 diabetics and 228 non-diabetics (64±7y, 32% female, comparable cardiovascular risk) of the Heinz-Nixdorf Recall Study were screened for pathological findings. Primary endpoints (PEP: myocardial infarction, sudden cardiac death) and secondary endpoints (SEP: overall mortality, other vascular diseases) were defined. Distribution of pathologies between diabetics and non-diabetics, and their association with endpoints were analysed using Mann-Whitney-Wilcoxon, Fisher's exact test, and Cox regression.

Results: Diabetics showed more often LGE (D=18%, ND=6%; $p=0.01$), PD (D=23%, ND=9%; $p < 0.01$), and WMA (D=14%, ND=9%; $p=0.12$) than non-diabetics. During the observation period of 10 years, 8/228 non-diabetics, and 3/44 diabetics reached PEPs, while 40/228 non-diabetics, and 12/44 diabetics reached SEPs. A higher percentage of individuals reaching PEP had LGE than those not reaching PEP (D: 33% vs 17%, $p=0.38$, ND: 12% vs 6%, $p=0.32$). Individuals reaching SEP had more often LGE than those not reaching SEP (ND: 13% vs 4%, $p=0.02$; D: 33% vs 10%, $p=0.06$). In diabetics, PD were accompanied by a higher incidence of SEP ($p=0.03$). In non-diabetics, hazard ratio (HR, [confidence interval]) for SEP was increased if LGE or WMA were present (HR_{LGE}=2.2 [0.84;5.70], $p=0.11$; HR_{WMA}=1.4 [0.51;3.70]).

Conclusion: Diabetics presented significantly more pathological CMR findings than non-diabetics. Despite a follow-up period of 10 years and a sizeable cohort of 272 individuals, the small number of reached endpoints did not permit a precise evaluation of the prognostic value of CMR findings.

B-1623 11:50

Prognostic validity of stress cardiac magnetic resonance (CMR) in the intermediate-long term outcome assessment of known-CAD patients

P. Palumbo, E. Cannizzaro, A. Corridore, C. De Cataldo, S. Torlone, M. Di Luzio, A. Di Sibio, E. Di Cesare, C. Masciocchi; L'Aquila/IT (palumbopierpaolo89@gmail.com)

Purpose: The need for a prognostic assessment of CAD patients is continuously increasing. The purpose of our study was to assess the prognostic role of Adenosine Stress CMR compared to CCTA in the outcome of heart patients.

Methods and Materials: 116 known-CAD patients who underwent first Coronary CTA and then stress CMR were selected retrospectively, with an average interval of $2.26 \pm (1.35)$ months between the two examination. Two group analysis was performed according to the imaging-findings (stenosis severity, perfusion defect and LGE) and to the patient history (moderate-to-severe atherosclerotic plaques, stenting or CABG). Primary and secondary end-point was defined (MACE and clinical worsening respectively). The mean follow-up was $38.96 \pm (19.35)$ months.

Results: Among the imaging-findings, a positive logistic regression association between LGE and MACE (Odds ratio 2.16, $p = 0.048$) was detected. A significant Log-Rank test was found between positive CCTA and stress MRI findings patients with MACE. Only perfusion defect showed a significant correlation with clinical worsening (Odds Ratio 5.43, $p = 0.032$), as confirmed by the Log-Rank test which evidence a correlation between clinical worsening with the positive stress MRI alone. No correlation was found between MACE or clinical worsening and patient history.

Conclusion: Our study demonstrates the prevalent role of Stress CMR as a predictive prognostic factor in the outcome of heart patient. Stress CMR may be useful in identifying patients at risk of clinical worsening, even in the absence of major events due to an OMT, and in patients with a non-severe CCTA stenosis.

B-1626 10:46

Machine learning analysis in the prediction of tumour grade and nodal involvement in oropharyngeal and oral cavity squamocellular carcinoma using CT-derived texture features

V. Romeo, R. Cuocolo, L. Ugga, S. Cocozza, F. Verde, S. Dell'Aversana, A. Elefante, S. Staibano, A. Brunetti; *Naples/IT (valeria.romeo@unina.it)*

Purpose: To assess the diagnostic accuracy of CT texture analysis (TA) features in predicting tumour grade and nodal involvement in oropharyngeal (OP) and oral cavity (OC) squamocellular carcinoma (SCC) using a machine learning approach.

Methods and Materials: Forty patients with histologically proven OP (n=7) and OC (n=33) SCC were retrospectively evaluated. Lesions were segmented on contrast-enhanced CT images to extract first, second and higher order TA features. Different feature selection methods and machine learning algorithms were tested to obtain the highest percentage of correctly classified instances for prediction of tumour grade (G2 or G3), nodal involvement (presence/absence of metastatic lymph nodes) and N stage (N1 or N2).

Results: The feature selection method that performed better was k-nearest neighbor algorithm (k-NN) for all groups. Selected features were 1) root mean square and long run emphasis; 2) cluster prominence, dissimilarity, long-run low-gray-level emphasis (LRLGLE) and long-run high-gray-level emphasis (LRHGLE); and 3) range, mean deviation, surface area, high-gray-level run emphasis, short-run high-gray-level emphasis, LRLGLE and LRHGLE for prediction of tumour grade, nodal involvement and N stage, respectively. The k-NN algorithm performed best in all evaluated tasks, with an accuracy of 91.6 ± 14.04% for grade prediction, 85.5 ± 19.19% for nodal involvement and 90 ± 19.82% for N stage.

Conclusion: Machine learning analysis using CT TA may be reliable in predicting tumour grade and nodal involvement in OP and OC SCC, possibly playing a significant role in defining clinical and surgical strategies.

Added prognostic value of pre-treatment MRI texture analysis in patients with primary nasopharyngeal carcinoma

J. Fang, J. Mao; *Guangzhou/CN (197284131@qq.com)*

Purpose: To determine the prognostic value of pretreatment MRI texture analysis for progression-free survival (PFS) in patients with primary nasopharyngeal carcinoma (NPC).

Methods and Materials: Ethical approval by the institutional review board was obtained for this retrospective analysis, and the need to obtain informed consent was waived. This study consisted of 79 patients with primary NPC. Texture analysis of the primary tumour was performed on pretreatment T2-weighted images (T2WIs) and contrast-enhanced T1-weighted images (CE-T1WIs). The Cox proportional hazards model was used to determine the association of texture features, tumour volume and the tumour-node-metastasis (TNM) stage with PFS. Survival curves were plotted using the Kaplan-Meier method. The prognostic performances were evaluated with C-index.

Results: Tumour volume (hazard ratio, 1.054; 95% confidence interval [CI]: 1.016-1.093) and CE-T1WI-based uniformity (hazard ratio, 0; 95% CI: 0-0.001) were identified as independent predictors for PFS (P=0.005; P=0.001). Kaplan-Meier analysis showed that smaller tumour volume (less than the cutoff value, 11.699 cm³) and higher CE-T1WI-based uniformity (greater than the cutoff value, 0.856) were associated with improved PFS (P=0.008; P<0.001). The combination of CE-T1WI-based uniformity with tumour volume and the overall stage estimated PFS better (C-index, 0.794; 95% CI: 0.641-0.947) than the tumour volume (C-index, 0.616; 95% CI: 0.463-0.769) or the overall stage (C-index, 0.627; 95% CI: 0.500-0.754) did (P=0.006; P=0.009).

Conclusion: A texture parameter of pretreatment MRI, CE-T1WI-based uniformity, can be used to improve the estimation of PFS in NPC patients. Texture analysis of pretreatment MRI has added prognostic value for NPC patients.

B-1628 11:02

Application of the IEC3.1 standard of CTDI₁₀₀ to a supine CBCT device

B. Keelson¹, D. Buytaert², G. Van Gompel¹, J. Casselman³, K. Bacher², Y. De Brucker¹, N. Buls¹; ¹Brussels/BE, ²Gent/BE, ³Bruges/BE (bkeelson@etrovub.be)

Purpose: To investigate the feasibility of extending the IEC 3.1 CTDI₁₀₀ as defined by the IAEA to CBCT and compare with device indicated CTDI and an approximation of the "true" CTDI.

Methods and Materials: Weighted CTDI (CTDI_w) measurements of a 16cm diameter dosimetry phantom were obtained on a Newton 5G (Newtom, Verona, Italy) CBCT using a 15x5 cm and 15x12 cm field-of-view (indicated as diameter by height). CTDI_w following the IEC 3.1 definition was computed by multiplying the CTDI_w of a reference collimation (15x5) with the quotient of free-in-air CTDI measurements at the collimation of interest (15x12) and the reference collimation. In addition, to approximate CTDI_∞ ("true" CTDI), CTDI

measurements were performed in a 32 cm long phantom, constructed as a longitudinal combination of two 16 cm diameter phantoms. For the latter measurements, referred to as CTDI₃₀₀, an integration length of 30 cm was used i.e. integrated dose over three adjacent positions with the pencil chamber.

Results: True CTDI_w values were 22mGy/100mAs and 25.8mGy/100mAs for the 15x5 and 15x12 protocols respectively. These values corresponded to an underestimation by the device Indicated CTDI_w values of 57% and 31% for the 15x12 and 15 x 5 protocols respectively. The IEC 3.1 definition however resulted in underestimations of 18 and 14 % for the 15x12 and 15x5 protocols respectively relative to the true CTDI_w.

Conclusion: CTDI using the IEC 3.1 method resulted in reasonable deviations from the "true" CTDI and is recommended to allow for comparison of doses between conventional CT and CBCT.

B-1629 11:10

Texture analysis for differentiating between nasopharyngeal cancer and nasopharyngeal malignant lymphoma on unenhanced CT

H. Tomita, T. Yamashiro, M. Tsubakimoto, G. Iida, S. Murayama; *Nishihara/JP*

Purpose: To investigate a usefulness of texture features in differentiating between nasopharyngeal cancer and nasopharyngeal malignant lymphoma (ML) on unenhanced CT.

Methods and Materials: Thirty nasopharyngeal tumours including 17 nasopharyngeal cancer and 13 nasopharyngeal ML were identified on 18F-FDG PET/CT. All nasopharyngeal cancer and 7 of 13 nasopharyngeal ML were confirmed by endoscopic biopsy. The remaining 6 patients with ML were diagnosed by lymph node biopsy. On unenhanced CT, 36 texture features were calculated following lesion segmentation on the maximum area. Student's t test and the area under the curve (AUC) were measured to compare values for SUVmax, SUVmean, and 36 texture features. Support vector machine (SVM) was constructed to evaluate diagnostic accuracy and AUC of combinations of texture features with 50 repetition of 5-fold cross validation.

Results: Significant differences of SUVmax and SUVmean were not found between nasopharyngeal cancer and nasopharyngeal ML. There were significant differences of texture features as follows: 1 histogram feature (p = 0.0236), 4 grey-level co-occurrence matrix features (p = 0.008-0.03), 2 grey-level run-length matrix features (p = 0.008 and 0.01), 1 neighborhood grey-level different matrix feature (p = 0.006), 2 grey-level zone length matrix features (GLZLM) (p = 0.009-0.012). Maximum AUC of 0.824 were obtained from zone-length non-uniformity in GLZLM. The highest accuracy of the combined texture features using SVM was 79.1% with the AUC of 0.80.

Conclusion: Texture features would provide useful information to discriminate between nasopharyngeal cancer and nasopharyngeal ML on unenhanced CT while SUVmax and SUVmean by PET/CT cannot differentiate them.

B-1630 11:18

Dose optimisation in dual-energy CT imaging of the neck: evaluation of acquisition parameters using a 3D-printed patient phantom

P. Jahnke, B. Hamm, T. Diekhoff; *Berlin/DE (paul.jahnke@charite.de)*

Purpose: To evaluate acquisition techniques for dual-energy computed tomography (DECT) of the neck and to deduce optimal scanning parameters for acceptable image quality at minimal dose.

Methods and Materials: DECT of the neck was performed with 80 and 135 kVp tube voltage on a 320-row CT, using a radiopaque 3D printed phantom for realistic simulation of a patient contrast CT. Tube currents were varied between 40 and 400 mAs for 80 kVp and 5 and 160 mAs for 135 kVp. Virtual blended images (VBI) and virtual monochromatic images (VMI) were reconstructed with all possible pairings (186 in total). Single energy CT (SECT) was performed with 80, 100, 120 and 135 kVp. Hounsfield units (HU), signal-to-noise ratios (SNR) and contrast-to-noise ratios (CNR) were compared between VBIs, VMIs and SECT. Non-linear regression analysis was performed to deduce optimal DECT settings.

Results: 100 and 120 kVp VBI reconstructions overestimated HU slightly (31.68 ± 1.18 HU and 22.03 ± 0.75 HU, respectively). HU of 75 keV VMIs did not differ significantly from 120 kVp SECT. SNR and CNR of VBI were inferior to the corresponding SECT images at similar dose levels. VMI SNR and CNR were highest at 65 keV, but inferior to SECT values at similar dose. Non-linear regression indicates that DECT can achieve approximately 80% SNR and CNR with 120% exposure of the corresponding SECT.

Conclusion: Sequential DECT results in significantly inferior image quality per radiation dose compared to clinical standard SECT. Tube currents should be adapted to the desired DECT information.

Dose reduction in CT imaging of the neck - individual performance and synergetic effects of dose reduction techniques in a clinical context

P. Jahnke, F.B. Schwarz, M. Ziegert, B. Hamm, M. Scheel, T. Diekhoff; Berlin/DE (paul.jahnke@charite.de)

Purpose: To systematically evaluate the clinical performance of automated tube potential selection (ATPS), automated tube current modulation (ATCM), iterative reconstruction (IR) and pitch variation for dose reduction in CT imaging of the neck.

Methods and Materials: A radiopaque 3D printed patient head and neck phantom was used for realistic simulation of clinical neck imaging. 54 CT acquisitions were performed (80-row CT). Three ATCM settings and three fixed tube currents, ATPS and fixed 120 kVp and three pitch settings were systematically combined. Images were reconstructed with filtered back projection (FBP) and IR. In a first reading session, images were rated by three radiologists with an absolute grading. In a second session, a relative grading was performed by ten radiologists with a five-step rating scale. Dose efficiency of the selected acquisition techniques and synergetic effects were analyzed.

Results: Inter-rater reliability was excellent. The highest dose efficiency at acceptable image quality was achieved with ATCM Quality, ATPS, pitch 0.813 and IR. Compared with a clinical standard protocol, the combinations of (ATCM Quality, ATPS, pitch 0.637, IR) and (ATCM Standard, 120 kVp, pitch 0.637, IR) yielded 62% and 58% dose reduction respectively at non-different image quality. ATPS decreased dose more at higher tube currents and was more efficient with IR. FBP required higher tube currents than IR for optimal dose efficiency. Pitch increase added value for IR reconstructed images at fixed tube currents.

Conclusion: Optimal acquisition settings depend on the available dose reduction techniques, which contribute unequally to dose reduction in neck CT imaging.

Dual-layer detector CT angiography in preoperative assessment of carotid body tumours: comparison of virtual monoenergetic and polyenergetic images

Y. Chen, Y. Zhu, H. Liu, K. Xu, S. Yu, T. Su, Z. Zhang, Y. Wang, Z. Jin; Beijing/CN (bjchenyu@126.com)

Purpose: The aim was to investigate the ability of dual-layer CT angiography (DLCTA) in assessment of carotid body tumor (CBT), and comparison of virtual monoenergetic and polyenergetic images.

Methods and Materials: Patients with suspected CBT referred to cervicocerebral CTA were retrospectively reviewed. All examinations were performed using a dual-layer detector CT. Polyenergetic images (120keV) and virtual monoenergetic images (40keV to 120keV with a 10 keV increment) were reconstructed. The feeding arteries, Shamblin type were evaluated based on polyenergetic images. Signals (\pm SD) of the CBT were measured to calculate the SNR. Subjective image quality including visualization of feeding arteries as well as carotid arterial wall were evaluated, using a 4-point Likert scale. Student's t-test and Wilcoxon test were used to determine statistical significance.

Results: 17 patients were included into the study. Feeding arteries included external carotid arteries (ECA, n=1), internal carotid arteries (ICA, n=8) and both (n=8). Shamblin type included I (n=3), II (n=5) and III (n=9). SNR in the virtual monoenergetic images were superior to polyenergetic images at kiloelectron volt levels ranging from 40 keV to 50 keV ($P<0.05$). Visualization of feeding arteries received significantly higher scores at kiloelectron volt levels of 40 keV to 70 keV ($p<0.01$). Visualization of carotid arterial wall was perceived significantly higher at kiloelectron volt levels of 40 keV to 50 keV ($p<0.05$).

Conclusion: Compared to polyenergetic images, virtual monoenergetic images reconstructed from DLCTA at low keV ranging from 40 to 50 keV improve the objective and subjective image quality of CBT.

B-1634 11:42

Are pre-MRI orbital radiographs always necessary in patients with suspected foreign bodies?

A. Foran, M.J. Lee; Dublin/IE (foranat@tcd.ie)

Purpose: To review indications for performing pre-MRI orbital radiograph, to ensure compliance with international guidelines, and to review our protocol for suspected intra-orbital foreign bodies.

Methods and Materials: An audit was performed of all pre-MRI orbital radiographs performed between July 2014 and July 2018, positive findings were recorded as well as patients who proceeded to MRI.

Results: Between July 2014 and July 2018, 286 patients had pre-MRI orbital radiographs. Reasons included occupational exposure (36), a documented history of foreign body (161) and otherwise unspecified history (89). Only 3 patients overall did not proceed to MRI due to the presence of a radiopaque foreign body within the orbit, all of whom had a documented history of foreign body within the eye.

ACR guidelines recommend pre-MRI orbital radiograph only for patients who have had a history of orbital foreign body for which they sought medical attention. We edited our MR questionnaire to reflect these guidelines. Based on our review of the radiographs of the patients who did not proceed to MRI, we deemed that our radiograph protocol was suboptimal, prompting us to change our radiograph protocol. Our plan following implementation of these changes is to re-audit in 3 months time to assess the number of radiographs performed in the interim.

Conclusion: Orbital radiographs were performed in 286 patients, only 3 patients who had an intraorbital foreign body did not proceed to MRI. A new MRI questionnaire reflecting ACR guidelines has been implemented to decrease unnecessary radiographs.

Microflow and resistance index in suspicious lymph nodes

P. De Koekoek-Doll, M.W.M. van den Brekel, W. Vogel, L. Smit, R.G.H. Beets-Tan, M. Maas; Amsterdam/NL (petra.dkd@gmail.com)

Purpose: Ultrasound-guided fine needle aspiration cytology (FNAC) is one of the most important modalities for nodal staging in head and neck cancer. The US vascularity in metastatic lymph nodes (LN) was reported as a sensitive feature. We aim to improve the sensitivity using non-contrast-enhanced slow tissue flow measurement clinical techniques.

Methods and Materials: Prospective study including 123 patients with 217 suspicious nodes. Mean age 62 years (23-87 yrs.). The eL18-4 transducer (Philips) was used for conventional ultrasound (B mode) nodal assessment. Presence of increased peripheral vascularity with microflow imaging (MFI) and measurement of resistance index (RI) values was assessed. FNAC was performed in all nodes and served as the reference standard. Sensitivity and specificity were calculated for capsular vascularisation and the absence of a fatty hilum. Cut-off values for RI were defined.

Results: 100/217 nodes were malignant at cytology. 86/106 (86%) of LN with significant MFI were malignant (sensitivity 86%, specificity 83%, PPV 81%, NPV 84%). Absence of a hilum indicated nodal involvement in 83% (80/96) (sensitivity 80%, specificity 86%, PPV 83%, NPV 83%). Combining an absent hilum and presence of MFI correctly predicted 73/81 (90%) malignant nodes (sensitivity 92%, specificity 75%). The RI yielded a sensitivity of 91% and specificity of 50%, with a cut-off of 0.71. In case of RI<0.6, none of the nodes were malignant.

Conclusion: Extra-capsular vascularisation (microflow) combined with the absence of a fatty hilum has a high diagnostic performance to detect metastatic nodes.

B-1636 10:38

Ability of computed tomography (CT) radiomic features to differentiate lymphomas from thymic masses in the anterior mediastinum

M. Kirienko, G. Ninatti, L. Cozzi, N. Gennaro, F. Ricci, C. Carlo Stella, P. Zucali, A. Chiti, M. Sollini; Milan/IT (gaia.ninatti@st.hunimed.eu)

Purpose: The present study aimed at evaluating the ability of computed tomography (CT) radiomic features to classify anterior mediastinal masses as lymphomas or thymic neoplasms.

Methods and Materials: A cohort of 110 patients diagnosed with either thymic neoplasia or lymphoma with at least one mediastinal localization >4 cm in size, and with baseline non-contrast-enhanced CT imaging available at our institution, was retrospectively studied. The cohort was divided into a training and a validation group. Radiomic textural features (n=41) were extracted from manually segmented CT images using LIFEx software. Statistical analysis was performed using the R platform. Combinations of imaging features were used as predictors in linear discriminant analysis (LDA) with backward stepwise variable insertion to classify the lesions as lymphomas or thymic neoplasms. Pathology was used as reference standard. Scoring metrics included analysis

of the receiver operating characteristic (ROC) curves in terms of area under the curve (AUC), sensitivity, specificity and accuracy.

Results: Fifty-seven patients (27 males, 30 females) were affected by thymic neoplasia (3 thymic carcinoma, 54 thymoma) and fifty-three (20 males, 33 females) by lymphoma (39 Hodgkin's, 12 non-Hodgkin's, 2 ns), median age of 61 and 36 years, respectively. LDA selected 12 CT radiomic features. In the training group, sensitivity, specificity, accuracy and AUC of the model resulted 0.85±0.06, 0.94±0.04, 0.90±0.06 and 0.94±0.06, respectively; in the validation group, sensitivity, specificity, accuracy and AUC resulted 0.73±0.07, 0.83±0.05, 0.77±0.07 and 0.85±0.06, respectively.

Conclusion: CT radiomic features have the potential to differentiate at diagnosis between lymphomas and thymic masses, sparing the use of invasive diagnostic procedures.

Role of diffusion MRI in differentiation of residual/recurrent neck malignancies and post-treatment changes in comparison with histopathology findings

A. Jaiodia, D. Aggarwal, A.S. Rao, R. Aggarwal; *New Delhi/IN* (ankushjaj@gmail.com)

Purpose: Role of diffusion-weighted (DW) MR imaging and ADC mapping in differentiating residual or recurrent neck malignancies from post-operative/post-radiation changes with histopathological/cytological correlation and comparison with PET-CT.

Methods and Materials: Prospective observational study for a year in 62 post-radiation/post-operative patients suspected to have residual/recurrent tumour of neck with lesion diameter more than 5mm measured on MRI.

Results: Mean ADC for recurrent/residual tumours: $1.008 \pm 0.220 \times 10^{-3} \text{mm}^2/\text{s}$ - significantly lower than mean ADC value for post-treatment changes of $1.69 \pm 0.40 \times 10^{-3} \text{mm}^2/\text{s}$ ($p < 0.0001$). The overall diagnostic accuracy, positive predictive value (PPV) and negative predictive value (NPV) of the qualitative assessment for the use of DWI in differentiating tumour recurrence from post-treatment changes were 96.6%, 96% and 83.3%, respectively. Upon quantitative analysis of the DW imaging data, a threshold ADC value of $1.3 \times 10^{-3} \text{mm}^2/\text{s}$ used for differentiating between post-treatment changes and recurrent cancers showed the highest combined sensitivity of 94%, specificity of 83.3%, accuracy of 93.6%, positive predictive value of 95.9%, and negative predictive value of 83.3%.

Conclusion: DW MRI is a promising non-invasive MRI technique used to differentiate recurrent/residual head and neck malignancies from post-treatment changes based on ADC values. Advantage short scanning time; safely added to standard MRI protocol with minimum patient discomfort. Complementary use of DW and PET/CT imaging may increase diagnostic confidence for differentiating recurrent disease from radiation therapy-induced changes after 6-12 months in post-treatment cases.

B-1638 10:54

MRI-based radiomic to assess lipomatous soft tissue tumours malignancy: a pilot study

A. Bouhamama¹, B. Leporq¹, F. Lame², C. Bihane¹, M. Sdika¹, J.-Y. Blay¹, O. Beuf¹, F. Pilleul¹; ¹Lyon/FR, ²Le Gosier/FR (amine.bouhamama@lyon.unicancer.fr)

Purpose: To develop and validate a MRI-based radiomic method to evaluate lipomatous soft tissue tumours malignancy.

Methods and Materials: 81 subjects with lipomatous soft tissue tumours including 40 lipomas and 41 atypical lipomatous tumours or well-differentiated liposarcomas with fat-suppressed T₁w contrast enhanced MR images available were retrospectively enrolled to constitute the database. For each tumor, 87 radiomic features were extracted. A reduction of learning base dimension was performed from relevancy and reproducibility criteria. Next, to predict malignant lesions, a model was prototyped using a linear support vector machine.

Results: After combination with relevancy criterion, 35 features were integrated in the model. To predict malignant tumours, model diagnosis performances were as follow: AUROC = 0.96; sensitivity = 100%; specificity = 90%; positive predictive value = 90.9%; negative predictive value = 100% and overall accuracy = 95.0%.

Conclusion: This work demonstrates that it is possible to assess soft tissue lipomatous tumours malignancy with a routinely used MR acquisition in clinical oncology. These encouraging results need to be further confirmed in an external validation population.

B-1639 11:02

MRI histogram and texture analysis as predictors of response to therapy in head and neck malignancies

R. Balaji, V.K. Anand, G. Krishnamurthi; *Chennai/IN* (ravikanthbalaji@gmail.com)

Purpose: To evaluate the use of histogram and texture analysis of metastatic neck nodes from head and neck squamous cell carcinoma (SCC) using fat-suppressed T2-weighted (Fs-T2WI) and diffusion (DW) imaging for the prediction of response to therapy.

Methods and Materials: Fifty patients with primary squamous cell carcinomas of head and neck region with metastatic nodes (24 well-, 17 moderately and 9 poorly differentiated SCC) were retrospectively analysed. Quantitative parameters with histogram features (relative mean signal, coefficient of variation, kurtosis and skewness) and grey-level co-occurrence matrix (GLCM) features (contrast, correlation, energy and homogeneity) were calculated using Fs-T2WI and DW data with a manual tumour region of interest (ROI).

Results: Relative mean signal and contrast were significantly lower in poorly differentiated SCC (2.3 ± 0.63 , 50.1 ± 12.9) compared to both the moderately (4.6 ± 0.81 , 79.5 ± 9.8) and well-differentiated SCC (3.1 ± 0.69 , 8.7 ± 14.5). The homogeneity in poorly differentiated SCC ($2.8 \pm 0.1510-1$) was higher than that in moderately ($2.4 \pm 0.1810-1$) and well-differentiated SCC ($1.9 \pm 0.1710-1$).

Conclusion: Parameters obtained by histogram and texture analysis of Fs-T2WI and DW may be useful for non-invasive prediction of prognosis in metastatic SCC head and neck malignancy.

B-1640 11:10

Lymph node measurement on serial imaging in clinical trials

M. Bagheri, A. Shafiei, F. Farhadi, A.B. Apolo, L.R. Folio, E.C. Jones, R.M. Summers; *Bethesda, MD/US* (mohammad.bagheri@nih.gov)

Purpose: To optimize target node measurement using RECIST-1.1, when they merge or split.

Methods and Materials: We identified target nodes either separated from conglomerate nodes (split node) or merged with other nodes (merged node) over time on serial CT in 261 cancer patients enrolled in clinical trials. Average of short axis diameter changes of three other well-circumscribed nodes was measured as ground truth (surrogate nodes). Merged nodes were grouped: One target node merged with adjacent nodes (Group-1) either linearly(1-A), or non-linearly(1-B). Two target nodes merged (Group-2). Correction factors were calculated based on surrogate changes for merged nodes. Short axis of the largest nodal fragment was compared with RECIST and surrogate for split nodes.

Results: We identified 46 merged (29 group-1, 17 group-2) and 28 split nodes. Nodal size change per RECIST was similar to surrogates in group 1-A, while there was a significant difference in groups 1-B, 2, and split nodes with surrogates ($p < 0.001$). While all surrogate nodes in group 2 enlarged, RECIST indicated a decreased size in 76% of cases. Furthermore, RECIST indicated an increase in size for 60% of split nodes while their surrogates showed a decrease. Calculated correlation factors for merged lesions in groups 1-A, 1-B, and 2 were 1, 0.75, 1.5 respectively. No significant difference was noted between surrogate measurements and our proposed method of applying a correction factor for merged nodes and measuring the largest fragment when node splits.

Conclusion: Our proposed method can improve the accuracy of nodal assessment when they merge or split.

Image briefly: the new aphorism for surveillance in testicular cancer

R. Balaji; *Chennai/IN* (ravikanthbalaji@gmail.com)

Purpose: To study the use of limited MR sequences for assessing relapse in surveillance of patients with testicular tumours.

Methods and Materials: 130 patients with primary testicular germ cell tumours were included in the study from 2013 to 2018. All patients were followed up every year with MR imaging. Imaging of the abdomen and pelvis covering the inguinal regions was performed using a 1.5T scanner (Achieva, Philips Healthcare, The Best, Netherlands). Axial STIR (respiration triggered) and diffusion sequences (DWIBS free breathing) with b values of 0 and 800 s/mm^2 were performed. Imaging was completed in most patients (115) within 12 minutes. 15 patients had breathing difficulties or were claustrophobic and required 15 to 20 minutes.

Results: Relapse usually occurred in the first 2 years after therapy predominantly in the retroperitoneal or pelvic nodes. Out of 130 patients, 21 (16%) developed nodal relapse. MR imaging performed with STIR and diffusion sequences identified affected nodes in all patients who then

underwent image-guided biopsy and histopathological confirmation.

Conclusion: Relapse in testicular cancers almost always involves the retroperitoneal or pelvic nodes. Shortened MR imaging protocols for surveillance in such patients can help replace CT imaging with its attendant radiation hazards.

B-1642 11:26

Conventional ultrasound and ultrasound elastography in non-Hodgkin lymphoma: ultrasound prognostic index compared with the international prognostic index

J. Jiang, M. Chen; *Shanghai/CN (kkxkk12340@163.com)*

Purpose: To explore the predictive value of prognosis for conventional ultrasound (US) and ultrasound elastography (UE) in patients with non-Hodgkin lymphoma (NHL) as ultrasound prognostic index compared with the international prognostic index (IPI).

Methods and Materials: A total of 168 patients with NHL were divided into two groups by IPI. The US and UE features of enlarged lymph node in these patients were analysed retrospectively. Ultrasound prognostic index was developed to compare with IPI in complete response (CR) rate.

Results: 86 patients with IPI 0, 1, 2 were divided into good prognosis group, while others with IPI 3, 4, 5 into poor prognosis group. Correlation analysis indicated significant correlation between IPI and several US and UE features: long axis diameter (L), short axis diameter (S), hilum status, vascular pattern, elastography score ($P < 0.05$). These features were statistically different between two groups ($P < 0.05$). Ultrasound prognostic index score was assessed by these features: $L > 3.2\text{cm}$, $S > 1.2\text{cm}$, absent hilum, peripheral or mixed vascular pattern, elastography score 3 or 4. The sensitivity, accuracy and AUC value were 80.6%, 72.6% and 0.781 when ultrasound prognostic index ≥ 3 was determined to be the cutoff for poor prognosis. CR rate assessed by ultrasound prognostic index in the low-risk range (ultrasound prognostic index 0 or 1) was better than that assessed by IPI in the low-risk range (IPI 0 or 1).

Conclusion: This study suggests the predictive value of US and UE in the prognosis of NHL. Compared with the IPI, ultrasound prognostic index may have a better predictive value in the patients with good prognosis.

B-1643 11:34

Strain elastography ultrasound for lymph node characterisation

A. Malich, C. Kurrat, D. Predel, N. Bang, I. Papageorgiou; *Nordhausen/DE (ansgar.malich@shk-ndh.de)*

Purpose: To evaluate the diagnostic accuracy of strain elastography (SE) in differentiating benign from malignant lymph nodes.

Methods and Materials: The study was retrospective for $n=53$ patients investigated with ultrasound in B-mode and SE in a single session. All patients received either an image-guided stance biopsy or surgical resection, $n=30$ were found with benign inflammatory changes and $n=23$ with a neoplastic condition. Applied elastographic metrics: (1) average tumour strain, (2) average reference fat (REF) strain, (3) ratio tumour/REF (strain ratio) and (4) Tsukuba-Ueno scale.

Results: The Tsukuba-Ueno class of the malignant lymph nodes was on average score above 3/5 compared to lower than 2 of the benign lesions, $p=0.003$, Mann-Whitney rank-sum test. The tumour strain and the strain ratio did not differ significantly between benign and malignant lymph nodes, $p > 0.05$, Mann-Whitney rank-sum test. The sensitivity/specificity (Se/Spe) of the Tsukuba-Ueno scale was 61/73% for a cut-off value of 3, and 87/50% for a cut-off of 2. The strain ratio showed a low prognostic value with an area under curve = 0.58. For a cut-off strain ratio 1.63, the Se/Spe was 65/57% (ROC analysis with Youden statistics).

Conclusion: Strain elastography is a weak surrogate marker to differentiate between inflammation and lymph node malignancy. The Tsukuba-Ueno scale is the only metric that showed a moderate sensitivity.

B-1644 11:42

Absence of vascularisation in thyroid nodules: new ultrasound feature for stratifying their malignancy risk

M. Minotti¹, F. De Piano¹, L. Tofanelli¹, G. Giugliano¹, F. Maffini¹, G. Mauri¹, M. Bellomi¹, L. Preda², E. De Fiori¹; ¹Milan/IT, ²Pavia/IT (laura.tofanelli@unimi.it)

Purpose: To determine if the absence of vascularization in thyroid nodules is an ultrasound feature significantly associated with malignancy.

Methods and Materials: This retrospective study evaluated 155 thyroid nodules (46 benign, 109 malignant) in 110 patients according to the following inclusion parameters: solid thyroid nodules, pre-operative US with colour-Doppler evaluation available, surgery performed at our Institution (November 2012- July 2018). One radiologist with 20 years' experience scored the nodules according to TI-RADS 2017. Vascularity was also evaluated with colour-Doppler as an additional criteria and classified as: absent, peripheral, mixed, peripheral incomplete, diffusely rough. The association of the absence of

vascularization with the risk of malignancy was assessed by sensitivity (SE), specificity (SP), positive predictive value (PPV), negative predictive value (PPN) and diagnostic accuracy (DA).

Results: Thyroid nodules without vascularization were 40/155, 2/46 were benign and 38/109 were malignant. The SE, SP, PPV, NPV and DA values related with the absence of vascularization were respectively 35%, 96%, 95%, 38% and 52.9%.

Conclusion: This study demonstrated that the absence of vascularization, in addition to TI-RADS classification, could be an useful US feature for better stratify the risk of malignancy in thyroid nodules.

Clinical application of 640 slice spiral CT double low enterography in inflammatory bowel disease

X. Pan, M. Guo; *Guangzhou/CN (wfbq@163.com)*

Purpose: To investigate the clinical application of 640-slice spiral CT enterography combined with low tube voltage, low contrast injection rate and dose technique in inflammatory bowel disease.

Methods and Materials: Forty patients diagnosed as Crohn's disease were randomly divided into two groups. Both groups were scanned by 640-slice CT spiral mode. Double low dose group (group A) was scanned by low dose (100KV), contrast injection rate 2.3 ml/s and low contrast volume 0.8 mL/kg. Routine dose group (group B) was scanned by routine dose (120KV), contrast injection rate 3.5 ml/s and contrast volume 1.2 mL/kg. Computed signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. Image quality (bowel wall CT value, noise, SNR and CNR), radiation dose and contrast dose were compared and analyzed between the two groups.

Results: All patients in double low dose group received volume CT index (CTDI_w) about 3.9-8.6 mGy, with an average of 6.3 mGy, significantly less than 25 mGy, and radiation dose significantly reduced ($p < 0.05$). The radiation dose and dose of contrast medium in group A were significantly lower than those in group B ($P < 0.05$). There was no significant difference in image quality scores between the two groups ($P > 0.05$).

Conclusion: In CT enterography, spiral scanning combined with low tube voltage, low flow rate and low contrast agent dosage can clearly display the small bowel and its surrounding structures, and reduce the radiation dose and contrast agent dosage (33%) and adverse reactions without significantly reducing the image quality.

B-1647 10:47

Magnetic resonance enterography: is routine administration of gadolinium-based IV contrast really needed for the assessment of Crohn's disease?

S.J. Sammut, N. Cook, N. Mahmood, R. Balasubramaniam, B. Thomas, A. James; *Stoke-on-Trent/UK (stephen.sammut@uhnm.nhs.uk)*

Purpose: MR enterography (MRE) is well established for diagnosing and monitoring Crohn's disease (CD). Standard protocol includes dynamic contrast-enhanced sequences using gadolinium-based contrast agents (GBCAs). GBCAs have recently come under scrutiny for retention in the brain tissue and hence avoidance is desirable. The purpose of this study was to explore if there was a diagnostic benefit of contrast-enhanced MRE (CEMRE) sequences.

Methods and Materials: We identified 50 cases for retrospective review performed over 3 months (Dec 2017 - Feb 2018) at our University Teaching Hospital. 10 cases were excluded leaving 40 cases. Initial review only included non-CEMRE sequences. Cases were read independently by radiology fellows and then double-read by consultant GI radiologists. The primary outcome was whether the conclusion differed based on CEMRE. A third radiologist arbitrated differences in opinion.

Results: CEMRE added some diagnostic benefit in 5 cases (12.5%). In one case, a third skip lesion was identified. In 3 cases, findings were more conspicuous on CEMRE but the overall conclusion did not change. The final case was felt to be due to poor quality of T2 and DWI sequences. Thus, only in 1 case (2.5%), did the final conclusion change significantly.

Conclusion: In most cases CEMRE added no diagnostic value, though more junior radiologists more often found them useful. Avoiding GBAs increases patient safety, in addition to a cost-benefit and reduced scan time. It is suggested that routine use of GBCA is not required for MRE, but can be used in selective circumstances.

B-1648 10:55

Can diffusion-weighted imaging (DWI) in MR enterography discriminate inflammatory strictures from fibrotic strictures in Crohn's disease?

M. Travali, P. Foti, N.M.G. Ognibene, S. Palmucci, L. Puzzo, G. Inserra, L. Zanoli, S. Parisi, A. Basile; Catania/IT (mario.travali.a34l@gmail.com)

Purpose: Differentiation between inflammatory and fibrotic bowel strictures has relevant implications in therapeutic management of patients with Crohn's disease. The aim of our study is to retrospectively evaluate the capability of magnetic resonance enterography (MRE) conventional and DWI sequences to differentiate fibrotic strictures from inflammatory ones in Crohn's disease.

Methods and Materials: 21 patients with Crohn's disease that underwent surgical resection with pathological confirmation within 3 months from preoperative MRE were retrospectively selected. Two radiologists blinded to histopathology in consensus evaluated the following bowel wall MRE qualitative and quantitative biomarkers at level corresponding to pathological specimens: mural thickness, maximum calibre of pre-stenotic upstream bowel, T1 ratio, T2 ratio, pattern of wall enhancement, DWI apparent diffusion coefficient (ADC). A blinded pathologist scored stricture histological specimens for fibrosis (0-2) and acute inflammation (0-12). MRE findings were correlated with histopathological data representing the reference standard.

Results: Quantitative ADC measurements correlated significantly with fibrosis score ($P < 0.001$), whereas no significant correlation was observed between ADC values and inflammation score ($P = 0.64$). Maximum calibre of pre-stenotic upstream bowel correlated significantly with fibrosis score ($P = 0.0069$), but not with inflammation score. T2 ratio correlated significantly with both fibrosis ($P = 0.023$) and inflammation score ($P = 0.0048$). T1 ratio, mural thickness and pattern of wall enhancement showed no significant correlation neither with inflammation nor with fibrosis score.

Conclusion: Quantitative ADC measurements from DWI sequences could improve the ability of MRE to noninvasively differentiate fibrotic strictures unlikely to respond to medical therapy, therefore requiring surgical treatment, from inflammatory strictures liable to undergo pharmacological treatment.

B-1649 11:03

MRI quantitative parameters of small-bowel perfusion for early diagnosing and assessing activity of Crohn's disease: a preliminary study

Z. Xianying, W. Yinchen; Fuzhou/CN (1571476087@qq.com)

Purpose: To explore the relationship between MRI quantitative parameters such as the volume transfer constant (K^{trans}), the reflux constant (K_{ep}) and the extravascular space volume fraction (V_e) and the change of blood perfusion and permeability of Crohn's Disease (CD), and evaluate the value of small-bowel perfusion for early diagnosing and assessing activity of CD.

Methods and Materials: 48 patients who underwent bowel examination with magnetic resonance enterography (MRE) were recruited. K^{trans} , K_{ep} and V_e of normal and terminal small-bowel were collected and compared. According to Crohn's disease activity index (CDAI), all patients were divided into three groups such as remissive group, mild group and moderate-severe group. The differences of K^{trans} , K_{ep} and V_e among the three groups were compared. The correlations between quantitative parameters and CDAI and small-bowel wall thickness were, respectively, evaluated.

Results: In 48 patients, K^{trans} , K_{ep} and V_e of terminal small-bowel were higher significantly than that of normal bowel ($p < 0.05$) with the most remarkable increase in V_e . There were 13 cases of remissive group, 20 cases of mild group and 15 cases of moderate-severe group. K^{trans} , K_{ep} and V_e of remissive group were lower than active group ($p < 0.05$). With the progress of CD, K^{trans} , K_{ep} and V_e also increased ($p = 0.000$). All quantitative parameters had high positive correlation with CDAI ($p < 0.05$). However, it was not statistically significant in correlation between K^{trans} and small-bowel wall thickness.

Conclusion: MRI quantitative parameters of small-bowel perfusion can reflect the change of blood perfusion and permeability of CD, and have a certain value for early diagnosing and assessing activity of CD.

B-1650 11:11

High spatiotemporal resolution free-breathing quantitative bowel perfusion imaging

V.C. Obmann¹, K. Yang², N. Seyfried², M. Stopchinski², K. Wright², S. Ghodasara², A. Panda², Y. Chen², V. Gulani², Berne/CH, ²Cleveland, OH/US (verena.obmann@insel.ch)

Purpose: To use a free breathing 3D ultra-fast DCE-MRI exam (spiral GRAPPA) for the acquisition of high spatial and temporal resolution imaging to provide quantitative perfusion modelling of the entire bowel in patients with

Crohn's Disease enabling objective assessment of disease status.

Methods and Materials: In this IRB approved prospective study, 11 patients with Crohn's Disease with at least one inflamed bowel segment were included. 50 coronal free-breathing DCE volumes covering the abdomen (temporal resolution 1.6 s, acquisition time 1.5 min) were acquired over a time course of 1.5min with 1.5 mm in-plane resolution and 4 mm uninterpolated slice thickness. Mural multislice ROI were drawn in different segments of the bowel. The single input, single compartment Tofts model was utilized to calculate K^{trans} and v_e . A Mann-Whitney-U test was performed to compare K^{trans} and v_e of different segments.

Results: Median patient age was 31 years (range 19-77 years, M:F=7:5). K^{trans} and v_e values for segments with inflammation were significantly higher compared to unaffected segments ($\Delta K^{trans} = +133\%$ and $\Delta v_e = +106\%$, $p = 0.007$ and 0.004 , respectively). Between active and chronic inflammatory changes there were no significant differences (both, $p = 0.368$).

Conclusion: A free-breathing 3D quantitative perfusion assessment of the bowel which enables high temporal resolved evaluation of the crucial early arterial portions of the bowel contrast enhancement is presented. This technology should be explored for the assessment of early response to therapy.

B-1651 11:19

Ability of diffusion-weighted magnetic resonance imaging to characterise bowel fibrosis depends on the degree of bowel inflammation

X. Li, S. Huang, B. Lu, L. Huang, Z. Li, J. Du, Y.-K. Zhong; Guangzhou/CN (zyingku@163.com)

Purpose: The ability of diffusion-weighted imaging (DWI) to assess bowel fibrosis in patients with Crohn's disease (CD) remains unclear. Another knowledge gap is whether bowel inflammation could have a confounding impact on the apparent diffusion coefficient (ADC) when detecting fibrosis, given that bowel inflammation and fibrosis are always coexistent. This study assessed the role of DWI in characterisation of bowel fibrosis using surgical histopathology as reference standard.

Methods and Materials: Abdominal DWI was performed before elective surgery in 30 consecutive patients with CD. The ADCs in pathologic bowel walls were calculated. Region-by-region correlations between DWI and the surgical specimens were performed to determine the histologic degrees of bowel fibrosis and inflammation.

Results: The ADCs correlated negatively with bowel inflammation ($r = -0.499$, $P < 0.001$) and fibrosis ($r = -0.464$, $P < 0.001$) in 90 specimens; the ADCs in regions of non-fibrosis and mild fibrosis were significantly higher than those in regions of moderate-severe fibrosis ($P = 0.008$). However, there was a significant correlation between the ADCs and bowel fibrosis ($r = -0.641$, $P = 0.001$) in mildly inflamed segments but not in moderately ($r = -0.274$, $P = 0.255$) or severely ($r = -0.225$, $P = 0.120$) inflamed segments. In the mildly inflamed segments, the ADCs had good accuracy with an area under the receiver-operating characteristic curve of 0.867 ($P = 0.004$) for distinguishing non-fibrosis and mild fibrosis from moderate-severe fibrosis.

Conclusion: The ADC only enables accurate detection of the degree of bowel fibrosis in mildly inflamed bowel walls. Therefore, caution is advised when using ADC to predict the degree of intestinal fibrosis.

B-1652 11:27

ADC values of DWI and DWIBS in bowel imaging: when they are consistent and when not?

I. Apine, M. Baduna, R. Pitura, G. Krumina; Riga/LV (dr.ilze.apine@gmail.com)

Purpose: To assess consistency between ADC-DWI and ADC-DWIBS in different bowel filling degree and bowel content in MRE examinations.

Methods and Materials: Patients with no evidence of IBD were scanned with 1.5T MRI system to assess ADC-DWI and ADC-DWIBS in high SI bowel walls at $b = 800$: 1) in small bowels (54 patients) before and after filling with 2.5% mannitol solution, 2) in large bowels (65 patients) at presence of intraluminal faeces, filled with mannitol afterwards. Bowel distention was maintained with 1.5 l of 2.5% mannitol solution orally. Differences between ADC-DWI and ADC-DWIBS were assessed with two-sample t-test.

Results: No statistically significant difference was found between ADC-DWI and ADC-DWIBS in small bowel walls filled with mannitol being 1.95×10^{-3} mm^2/s (SD 0.41) and 1.91×10^{-3} mm^2/s (SD 0.52), respectively ($p = 0.7255$) but statistically significant difference of 25.4% was found in empty bowel loops, in DWI being 1.28×10^{-3} mm^2/s , SD 0.48, and in DWIBS being 1.02×10^{-3} mm^2/s , SD 0.51; $p = 0.0011$. No statistically significant difference between ADC-DWI and ADC-DWIBS was found in large bowel in presence of mannitol being 2.15×10^{-3} mm^2/s (SD=0.42) and 2.06×10^{-3} mm^2/s (SD=0.64) ($p < 0.3642$) whereas statistically significant difference of 23.4% was found in bowel walls in presence of faeces being 1.05×10^{-3} mm^2/s (SD=0.44) for DWIBS and 1.37×10^{-3} mm^2/s (SD=0.4232) for DWI ($p < 0.0001$).

Conclusion: ADC-DWI and ADC-DWIBS differ in presence of media of short T1 value (fat around collapsed bowel and high-viscosity faeces) whereas in abundance of long T1 value background (large amount of mannitol) ADC-DWI and ADC-DWIBS are consistent.

B-1653 11:35

Validation of the simplified magnetic resonance index of activity (sMaRIA) for Crohn's disease without using gadolinium

N. Capozzi¹, A. Fernandez-Clotet², I. Alfaro², I. Ordás², J. Panes², J. Rimola²,
¹Bologna/IT, ²Barcelona/ES (nunziacp@gmail.com)

Purpose: To validate a simplified Magnetic Resonance Index of activity (sMaRIA) based on Magnetic Resonance Enterography (MRE), which does not include gadolinium enhanced sequences, for assessing disease activity and therapeutic response in patients with Crohn's disease (CD).

Methods and Materials: We prospectively included patients with active CD and at least one intestinal segment with severe inflammation at endoscopy (CDEIS>8.5 or presence of ulcers), requiring treatment with a biological TNF-inhibitor. Patients were evaluated by both MRE and ileo-colonoscopy at baseline and at week 46 (wk-46) of therapy with TNF-inhibitor. Ileo-colonoscopy (CDEIS) was considered the gold standard. The sMaRIA was read using T2-w sequences. Comparison between sMaRIA and CDEIS for detecting active/severe lesions and therapeutic response was performed.

Results: Data from 43 patients (236 segments; 51 with ulcers) at baseline and from 37 patients (191 segments; 44 with ulcers) at wk-46 were available. The sensitivities and specificities of sMaRIA for detecting active disease at segment level (sMaRIA≥1) were 80% and 95% (AUC 0.88), and for detecting severe inflammation (sMaRIA≥2) were 80% and 93% (AUC 0.88) respectively. The sensitivity and specificity of sMaRIA for detecting mucosal healing at segment level (sMaRIA<2) were 73% and 93%. There were statistical significant changes (p=0.000) in sMaRIA score between baseline and post-treatment in patients with mucosal healing. The correlation of magnitude of changes between CDEIS and sMaRIA was moderate and significant (r=0.72; p<0.001).

Conclusion: The sMaRIA is a reliable tool that would avoid the use of gadolinium to detect inflammation and assess therapeutic response in luminal CD.

B-1654 11:43

Correlation analysis between magnetisation transfer ratio with collagen area fraction in the surgical specimen of Crohn's disease

S. Huang¹, X. Li¹, Z. Fang¹, J. Lin¹, Z. Zhang², C.C. Sun¹, S. Feng¹, Z. Li¹,
¹Guangzhou/CN, ²Florida, FL/US (codesy@foxmail.com)

Purpose: We aimed to establish a new index in histology, collagen area fraction, to quantify the amount of collagen and to reflect the severity of bowel fibrosis in patients with Crohn's disease (CD), meanwhile for assessing the correlation between magnetization transfer ratio (MTR) and collagen area fraction in the surgical specimen of CD.

Methods and Materials: We analysed the histopathological data and MT imaging of 31 patients with CD undergoing surgical resection. The MTR were measured and the most representative sections of resected segments were stained with Masson trichrome. The collagen area fraction derived from image segmentation using Image J software and semi-quantitative histological fibrosis score (0-4) were simultaneously calculated for the same section to evaluate the severity of bowel fibrosis.

Results: The collagen area fraction strongly correlated with the histological fibrosis score (r=0.733, P<0.001). It proved to be more accurate for diagnosing Crohn's disease strictures (AUC =0.815, P<0.001) compared with the histological fibrosis score (AUC=0.771, P<0.001). High repeatability was observed for the collagen area fraction, with an intraclass correlation coefficient of 0.915. A good correlation between MTR and collagen area fraction was found (r=0.643, P<0.001). Moderate accuracy of MTR was shown (AUC=0.766, P<0.001) for differentiating a collagen area fraction>0.5 from a collagen area fraction≤0.5 in bowel walls.

Conclusion: The collagen area fraction is a reliable index to quantify the severity of bowel fibrosis in the surgical specimen. MTR can be a noninvasive biomarker to detect and grade the bowel fibrosis in patients with CD.

B-1655 11:51

Magnetic Resonance Fingerprinting (MRF) enables simultaneous T1 and T2 mapping of the bowel wall in patients with Crohn's disease

V.C. Obmann¹, W.-C. Lo², N. Seyfried², Y. Jiang², A. Panda², K. Wright²,
K. Ropella-Panagis², V. Gulani², ¹Berne/CH, ²Cleveland, OH/US
(verena.obmann@insel.ch)

Purpose: Magnetic Resonance Fingerprinting (MRF) provides simultaneous mapping of T1 and T2 relaxation times in a single acquisition. To evaluate the feasibility of MRF-derived T1 and T2 measurements in the bowel for the evaluation of inflammatory bowel disease.

Methods and Materials: 33 patients (19:14 M:F) undergoing MR enterography exams at 1.5T were included in this IRB approved study. 3 axial and 3 coronal 2D-MRF slices were acquired through the bowel using a single breath-hold (24s) MRF-FISP sequence (in-plane spatial resolution 1.6x1.6 mm²). Information from weighted clinical images and endoscopy were used to identify affected segments. On T1 and T2 maps, regions of interest (ROIs) were drawn in the wall of small bowel and colon to assess T1 and T2 relaxation times in the bowel wall for each patient. Mann-Whitney-U and Kruskal-Wallis-Test with Dunn-Bonferroni post-hoc-tests were used to assess differences in T1 and T2 values between unaffected, acutely inflamed, and chronically inflamed bowel.

Results: Average age was 32 years (range 12-77 years). There were 11 segments with chronic disease and 16 with acute inflammation. T1 relaxation times allowed differentiation between unaffected segments (1468 ± 314ms, n=47) and inflamed segments (active 1386.0 ± 349.2ms and chronic 1296.8 ± 281ms), p = 0.028. T2 relaxation times further allowed distinction between segments with active (67.5 ± 48.4ms) and chronic fibrotic changes (48.4 ± 21.5ms), p = 0.009.

Conclusion: Initial application of MR Fingerprinting to evaluate the bowel wall is presented, with promising results for quantitative differentiation of normal, chronically disease, and acutely inflamed bowel.

Testicular cancer follow-up: less is more

E. Rud, C.W. Langberg, E. Baco, G. Sandbæk; Oslo/NO (erik.rud@ous-hf.no)

Purpose: Patients are routinely monitored for relapse after primary treatment for testicular germ cell cancer. The Swedish and Norwegian Testicular Cancer Group recommends abdominal MRI instead of CT to reduce the radiation dose. The current MRI protocol is designed to screen retroperitoneal lymph nodes, abdominal organs, and the bony structures from the diaphragm to proximal femur. The aim of this study was to evaluate the rate and location of relapse in patients with testicular cancer.

Methods and Materials: We included all patients that underwent abdominal MRI after treatment of testicular germ cell cancer during the calendar year 2012 and 2017. MRI reports were classified as negative or positive, and positive reports were cross-checked with follow-up imaging and biopsy results. The location of true positive findings was registered according to anatomical site.

Results: During 2012 and 2017, we performed 2315 MRI examinations. Sixteen patients (0.7%, 95% CI: 0.4-1.1) with relapse were detected of which 12 were seminomas and four were non-seminomas. Fourteen (87%) were located in the retroperitoneal lymph nodes, and two occurred in pelvic and inguinal lymph nodes. No metastases occurred in parenchymatous organs or bony structures.

Conclusion: All cases of abdominal relapse occurred in retroperitoneal or pelvic lymph nodes. For this reason, a simpler MRI protocol containing fewer sequences can be used instead of screening all the abdominal organs as well as the bony structures.

B-1657 10:38

Diagnostic performance of contrast-enhanced ultrasound (CEUS) in unclear testicular pathology

M.H. Lerchbaumer, S.R. Marticorena Garcia, M. Kallenbach, B. Hamm,
T. Fischer; Berlin/DE (markus.lerchbaumer@charite.de)

Purpose: Contrast-enhanced ultrasound (CEUS) has been used as an additional imaging technique to conventional ultrasound in order to clarify acute and chronic testicular pathologies. CEUS is easy and fast to perform, overcomes the limitations of gray-scale ultrasonography. The aim of this retrospective single-center analysis is to evaluate the diagnostic performance of CEUS in the assessment of unclear testicular pathology.

Methods and Materials: CEUS examinations of patients with unclear testicular pathologies between 2012 and 2018 were retrospectively analysed. Examinations were performed using B-mode, colour Doppler and CEUS after injection of a second-generation blood pool agent (SonoVue®, Bracco, Milan, Italy). Results were interpreted by an experienced radiologist (EFSUMB level 3).

Results: 43 patients were examined without any adverse reaction, where out 16 patients presented with a tumour lesion (benign and malign). Median tumour size measured by ultrasound was 17.0 mm (IQR, 9.0-44.8) with a correlation coefficient of 0.917 compared to the tumour size in histopathological report (median size: 22.5 mm; IQR, 14.0-41.8). When matched to the histopathological report and clinical follow up, CEUS represented a sensitivity of 92% (95%-CI, 67-97), a specificity of 90% (95%-CI, 74-97), a positive predictive value (PPV) of 80% (95%-CI, 55-93) and a negative predictive value (NPV) of 96% (95%-CI, 82-99).

Conclusion: CEUS is a feasible tool to differentiate between traumatic and inflammatory testicular pathologies. While differentiation between benign and malignant lesions using CEUS due to enhancement is currently difficult, patients with contraindications to other imaging modalities benefit from this method in the daily clinical routine.

B-1658 10:46

The added value of scrotal palpation during testicular ultrasound (US): a technical note

J.P. Zawaideh¹, C. Trambaiolo Antonelli¹, A. Olivero¹, M. Bertolotto², L.E. Derchi¹; ¹Genoa/IT, ²Trieste/IT (jerespz89@gmail.com)

Purpose: Guidelines on performance of scrotal US indicate that "If a palpable abnormality is the indication for the study, this area should be directly imaged". However, a small lesion may be difficult to identify, even when the patient is asked to indicate where it is located. We herewith underline the beneficial role of scrotal palpation carried out by the radiologist during US examination for scrotal masses.

Methods and Materials: We reviewed the US findings in a series of 7 patients in whom US and simultaneous palpation allowed to identify an otherwise non-visible lesion and/or helped to recognize its nature.

Results: In 2 patients an extratesticular lesion was not detected during the "normal" US and could be seen only through the combination of US and simultaneous palpation. In 5 patients palpation gave more information on the lesion, thus leading to its characterization: in 3 it could be displaced during palpation and recognized as a normal appendix testis (2) or as a pedunculated nodule arising from testicular surface (1); in 2 lesions were seen as freely mobile inside the tunica vaginalis, and recognized as "scrotoliths".

Conclusion: Scrotal palpation carried out by the radiologist during US examination for scrotal masses can increase the diagnostic accuracy of the examination, especially in difficult small lesions.

B-1659 10:54

Focal testicular lesions: multiparametric US features and association with histopathology

I. Campo, C. Sachs, R. Bussani, M. Bertolotto, M.A. Cova; Trieste/IT (irenecampo11@gmail.com)

Purpose: Ultrasound features of solid scrotal tumours are often non-specific. US, however, identifies the lesion in the largest number of cases. To illustrate the histopathologic features which determine echogenicity, echotexture, stiffness, and vascularity of different testicular masses.

Methods and Materials: 116 testicular lesions investigated with colour Doppler US for which histological specimens were available for review were considered. 68 lesions had also CEUS, 39 elastography. Imaging features were correlated with histological characteristics.

Results: Most testicular cancers were hypervascular at colour Doppler interrogation (65/116) and with increased consistency at elastography (24/39). 14/23 hypovascular lesions with small vessels at colour Doppler interrogation were hypervascular at CEUS. Seminomas presented with lower echogenicity compared to other cancers (29/35), mixed tumors were heterogeneous. Irrespective of histotype, abundance of stroma was the main factor determining increased echogenicity. Other factors were hyalization, interleaved necrotic areas and tumor nests, atrophic changes of the surrounding parenchyma. Heterogeneous appearance was observed in presence of different histotypes, calcifications, necrotic or fibrotic areas. Lesions were avascular at colour Doppler interrogation if vessels were lacking or were very small. In the latter case, they were vascularized at CEUS. Lesions with abundant stroma were hard at elastography, while necrotic changes caused soft or mixed appearance.

Conclusion: The different histological features of testicular lesions determine their sonographic appearance. US is highly sensitive for detection of testicular lesions, but specificity is low. The different US modes, if taken individually, are non-specific but if used together improve lesion characterization.

B-1660 11:02

Apparent diffusion coefficient and magnetization transfer ratio in predicting successful sperm retrieval after mTESE

A.A. Ntorkou, A. Tsili, A. Goussia, L.G. Astrakas, A. Kaltsas, N. Sofikitis, M.I. Argyropoulou; Ioannina/GR (alexndorkou@hotmail.com)

Purpose: To assess any probable correlation between apparent diffusion coefficient (ADC) and magnetization transfer ratio (MTR) with the presence of spermatozoa retrieved after microdissection testicular sperm extraction (mTESE) in non-obstructive azoospermia (NOA).

Methods and Materials: This retrospective study included 49 consecutive NOA men (mean age: 36.3 years) who underwent scrotal 1.5 T MRI, a day prior to mTESE. Forty five age-matched men (mean age: 35.4 years) were used as controls. The MRI protocol included diffusion-weighted imaging and magnetization transfer imaging. Based on the more advanced histopathologic pattern, NOA testes were classified as follows: group 1, testes with higher Johnsen score (hJS) ≥ 8 ; and group 2, testes with hJS < 8 . The testicular volume (TV), the mean testicular ADC and MTR were measured. Non-parametric statistical tests were used to assess differences in TV, ADC and MTR between: a) NOA men and controls, b) NOA groups and c) NOA testes with positive and negative sperm retrieval.

Results: TV ($P < 0.001$) was reduced and both ADC ($P < 0.001$) and MTR ($P = 0.013$) were increased in NOA testes compared to controls. TV ($P < 0.001$) was reduced and ADC ($P = 0.015$) and MTR ($P = 0.003$) were increased in group 2 compared to group 1. TV ($P < 0.001$) was reduced and both ADC ($P = 0.011$) and MTR ($P = 0.045$) were increased in NOA testes with failed sperm retrieval.

Conclusion: This preliminary study showed that TV, ADC and MTR may be useful for predicting the outcome of mTESE.

B-1661 11:10

MRI diffusion-weighted and shear wave elastography in testis

M.R.V. Pedersen¹, P.J. Osther¹, H. Nissen¹, P. Vedsted², H. Møller², S.R. Rafaelsen³; ¹Veje/DK, ²Aarhus/DK (Malene.Roland.Vils.Pedersen@rsyd.dk)

Purpose: The purpose was to evaluate ultrasound shear wave elastography in combination with the diffusion MRI in testicles with different tissue characteristics.

Methods and Materials: A prospective study, with a total of 132 patients. All patients underwent b-mode ultrasonography including shear wave elastography measurements and an MRI diffusion examination of the scrotum.

Results: 53 patients with normal testicular tissue, 53 patients with testicular microlithiasis and 23 patients with malignant testicular tumours and 3 patients with benign testicular tumors were included.

There was a significant differences in stiffness between patients with testicular microlithiasis (0.78 m/s), normal testicular tissue (0.77 m/s) and patients with a testicular cancer (1.92 m/s) ($p < 0.001$). Similar, there was a statistical significant difference in MRI diffusion values between patients with testicular microlithiasis (0.978) and normal testicular tissue (0.929) and testicular cancers (0.743) ($p < 0.01$).

Conclusion: Patients with testicular microlithiasis had no malignant characteristics measured with shear wave elastography or MRI diffusion. Testicular tumors had higher elastography values, and higher MRI diffusion restriction compared to normal testicular tissue. MRI in combination with Shear wave elastography may be a useful tool to differentiate benign from malignant testicular lesions.

B-1662 11:18

Percutaneous ablation of renal cancer: radiofrequency vs. microwave

I.D. Domínguez Paillacho, J. Mesa Quesada, L.J.J. Zurera Tendero, C. Pulido Carmona, M. Lombardo Galera, M.E. Perez Montilla, J.J. Espejo Herrero; Córdoba/ES (davko61988@gmail.com)

Purpose: To compare the efficacy and safety of renal percutaneous thermoablation of renal cancer by radio frequency (RF) and microwave (MWs).

Methods and Materials: We retrospectively reviewed the malignant renal tumours treated with RF (RITA system) and MWs (AMICA system) in our centre in the last 12 years. Control was performed one month after treatment to check if there was a tumour remnant and follow-up every 6 months to detect recurrence.

Results: We identified 54 lesions in a total of 44 patients. 26 patients had histological confirmation by biopsy and in 29 the diagnosis was clinical/radiological. 37 lesions were treated with RF and 17 with MWs. The mean tumour size in the group of MWs was greater than the RF group (36 mm vs 26 mm, respectively, $p = 0.001$). Tumour rest was identified in 8 lesions treated with RF (for which a second intervention was performed), while all ablations were complete with MWs ($p = 0.03$). The mean time of follow-up was 24.7 ± 22 months and no tumour recurrence was detected. 4 patients (9%) developed one or more complications: 3 in the RF group (urinary tract lesion, hepatic subcapsular haematoma, wall abscess and intracystic haemorrhage)

and 1 in the group of MWs (retroperitoneal haematoma) ($p > 0.05$).

Conclusion: Percutaneous renal thermoablation is a safe and effective technique. The group of patients treated with MWs, despite presenting a more unfavourable profile, have obtained better results of complete ablation in a single session compared with the RF group.

B-1664 11:26

In vitro and in vivo quantification of urinary stone volume using attenuation threshold-based optimized ultra-low-dose CT method

N. Rasouly¹, B. Kastler², O. Hélénon², B. Habib Geryes², A. Comte³,
¹Kabul/AF, ²Paris/FR, ³Besançon/FR (nrasouly@gmail.com)

Purpose: To assess in practical clinical settings if an optimised ultra-low-dose protocol is able to follow-up kidney stones of different chemical composition in daily practices using variable threshold-based computed tomography methods.

Methods and Materials: 17 stones of different chemical compositions, sizes and shapes were scanned in an anthropomorphic phantom using ultra-low-dose protocol with variable threshold CT method (30%, 40%, 50%, 60% and 70% of stone attenuation), segmented with 0.625-mm-thick sections, tube voltage of 100 KV and tube current of 75 mAs. A statistical analysis was performed to assess bias and precision of this method in comparison with fluid displacement method as a reference standard.

Results: The ultra-low-dose CT protocol with variable attenuation threshold and 3 different reconstruction algorithms (standard, soft and bone) is an accurate and precise method in stone volume measurement to compare with fluid displacement method as a reference standard. However, notable differences were only observed between the 'Bone' reconstruction algorithm with a threshold of 30% and the 'Standard' reconstruction algorithm with a threshold of 30% as well as the 'Soft' reconstruction algorithm with a threshold of 30%. However, all methods are equivalent in bias and precision.

Conclusion: Variable threshold-based CT method which is derived from attenuation of each stone can be used to quantify urinary stone volume even at ultra-low-dose protocol (equal to one abdominal radiograph) with high level of accuracy and precision which is comparable with the fluid displacement method as a reference standard in estimation of kidney stone volume.

B-1665 11:34

Bladder perivascular epithelioid cell tumour: dynamic CT and MRI analyses of 8 cases with 2-year follow-up

D. Xuesong; Chongqing/CN (duxs1966@126.com)

Purpose: To evaluate the dynamic computed tomography (CT) and magnetic resonance imaging (MRI) characteristics of bladder perivascular epithelioid cell tumour (PEComa) and to improve the diagnosis of bladder PEComa.

Methods and Materials: A retrospective analysis was undertaken of the dynamic CT, MRI characteristics of 8 PEComas diagnosed at histopathology.

Results: The age of the patients ranged from 27 to 50 years (mean 36.3 years). There were more women in this group (5/8). Dynamic CT (6 cases) and MRI (4 cases) demonstrated tumours that were of low density or hypointense on T1-weighted imaging (WI) and hyperintense on T2WI; some were isodense with fat (CT: 3/8; MRI: 2/8). The tumours usually had well-defined borders and were of a regular shape (CT: 8/8; MRI: 8/8). Tumour diameters ranged from 1.5 to 12 cm (mean 4.7 cm). Most tumours (CT: 6/8, MRI: 5/8) enhanced heterogeneously and significantly on arterial and venous phases. Tumours appeared slightly hypodense on delayed CT imaging, although some (4/8) had delayed enhancement. The expression rate of HMB-45 (human melanoma black monoclonal antibody) was 100% (8/8).

Conclusion: Knowledge of dynamic CT, MRI, and clinicopathological characteristics could help improve the diagnosis of PEComa.

B-1666 11:42

Comparative study of MR urethrography, sonourethrography and RGU with VCUG for diagnosis of male urethral strictures

P. Jeon¹, R. Rastogi², A. Agarwal³, Y. Gupta⁴, A. Pushkarna³,¹Gurugram/IN,
²Greater Noida/IN, ³Moradabad/IN, ⁴Faridabad/IN (dr.pawanjoon@gmail.com)

Purpose: The aim of study is to evaluate the role of MRU as the potential imaging tool for evaluation of patients with urethral stricture disease and to compare its efficacy to Sonourethrography and RGU with VCUG.

Methods and Materials: The study included 50 men who were referred to Radiology department with history suggestive of urethral stricture disease. All patients underwent RGU/VCUG followed by Sonourethrography and MRU prior to the surgical intervention. The length of the strictures, their site, presence or absence of spongiofibrosis and any other associated periurethral pathologies were looked for in all the modalities and results were compared.

Results: The mean lengths of short and long segment strictures was 0.96cm +/- 0.42 and 3.57cm +/- 1.99 respectively on MRU, 0.90 +/- 0.38 and 3.60 +/- 2.00 respectively on Sonourethrography and 0.84cm +/- 0.42 and 3.69cm +/- 2.03 respectively on RGU/ VCUG ($p < 0.05$). Four patients of anterior urethral strictures were wrongly diagnosed as short segment strictures on RGU but were correctly diagnosed on MRU and Sonourethrography. In cases of anterior

urethral strictures, no discordance was found between MRU and Sonourethrography.

Conclusion: The study showed that MRU and Sonourethrography were more sensitive to RGU/VCUG in both for the stricture length and associated periurethral pathologies like urethral diverticula and sinus tracts. Also, we were able to have information about presence or absence of spongiofibrosis on MRU and Sonourethrography. However, MRU scores over Sonourethrography in that the latter cannot be used to evaluate posterior urethral pathologies, though both being radiation free imaging modalities.

The forecaster of coronary atherosclerosis: black or white, fat or calcium?

R. Khurana, A. Yadav, T.B.S. Buxi, K.S. Rawat, S.S. Ghuman; New Delhi/IN
(rishabhkhurana88@gmail.com)

Purpose: Occurrence of first-time coronary artery disease (CAD) events is higher than recurrent CAD events. Over the years, coronary calcium score (CCS) has stood as an important risk factor for screening and prognosticating CAD. However, sometimes patients with no coronary calcium escape CAD detection, and present for the first time with a major adverse coronary event. Hence, there exists a need for improved CAD risk assessment and earlier intervention. Regional intrathoracic fat depots: epicardial fat volume (EFV) and pericardial fat volume (PFV) have been implicated as independent risk factors for CAD. Extracoronary calcium (ECC) at aortic and mitral valves, aortic root and descending thoracic aorta can also be assessed.

Methods and Materials: EFV and PFV were quantified in 950 patients using semi-automated technique on 128-slice MDCT coronary angiography and correlated with degree of coronary artery stenosis, CCS estimation, ECC sites and plaque characterization. These correlations were performed in isolation and combination with degree of CAD and the Framingham risk score categories.

Results: Fat volumes and CCS were significantly higher across different CAD severity groups. Subset of patients with CCS=0, detected with CAD, had significantly higher volumes of regional fat than those without CAD. Improved CAD detection was seen when EFV was taken into consideration with CCS.

Conclusion: Regional intrathoracic fat depots are an independent risk factor for CAD. Although CCS is a primary tool for CAD screening, EFV can possibly predate CCS as a CAD risk predictor. Improved cardiovascular risk profiling is achieved by considering EFV together with CCS.

B-1669 10:34

Treatment of chronic myocardial infarction with unmodified stem cells at point of care: a feasibility study on pigs

A.S. Haene¹, M. Ghosn², T. Karim³, J. Vykoukal², D.J. Shah², D. Schulz²,
A. Raizner², C. Schmitz⁴, E. Alt⁵,¹Luebeck/DE, ²Houston, TX/US,
³New Orleans, LA/US, ⁴Munich/DE, ⁵New Orleans, TX/US
(Alexander.Haene@uksh.de)

Purpose: Numerous studies investigated cell-based therapies for myocardial infarction (MI). The mixed results of these studies have established the need for developing innovative approaches for improving cell-based therapy for MI. We tested the hypothesis that after blocking the left anterior descending (LAD) artery of pigs for 180min at time point T0, the delivery of 18×10^6 fresh, unmodified autologous adipose-derived regenerative cells (UA-ADRCs) four weeks after the initial infarction (time point T1) into the temporarily blocked LAD vein results in improved cardiac function and structure at ten weeks after T0 (time point T2).

Methods and Materials: UA-ADRCs isolated from adipose tissue were characterised by flow cytometry. Either cells or saline as control was retrogradely delivered via an over-the-wire balloon catheter placed in the temporarily blocked LAD vein at T1. Effects of UA-ADRCs were assessed immediately before T1 and at T2 by cardiac magnetic resonance (CMR) using steady-state free precession and late gadolinium enhancement imaging, and post-mortem histologic analysis

Results: Blocking the LAD artery for 180 min reduced the mean left ventricular ejection fraction (LVEF) to clinically relevant 35% four weeks after induction of the MI. Unlike the delivery of saline, the delivery of UA-ADRCs showed statistically significant improvements in cardiac structure and function at T2:

increased mean left ventricular mass (+29%), decreased mean relative amount of scar volume of the left ventricular wall (-21%), and increased mean cardiac output (+37%).

Conclusion: The delivery of UA-ADRCs four weeks after MI as performed in this study significantly improves myocardial function and structure.

Prevalence of asymptomatic pacemaker and ICD lead perforation on computed tomography

F.F. Aloufi; Riyadh/SA (faisal-aloufi@hotmail.com)

Purpose: The aim of this retrospective study is to measure the frequency of the pacemaker and ICD lead perforation demonstrated on multidetector computed tomography (CT) that was performed for wide varieties of clinical indications.

Methods and Materials: This study included 500 patients with (285) pacemaker and (215) ICD implants who were referred for different clinical indications over the last 5 years. CT was reviewed by 2 cardiothoracic radiologists for device and tip position. Perforation is considered when the star artefact which presents the tip is outside the cardiac cavity.

Results: 500 patients had right ventricular leads. 17 (3.4%) patients out of 500 patients had a lead perforation. The ICD lead perforation was more common than pacemaker lead perforation. 11 (5%) patients out of 215 versus 6 (2%) patients of 285, respectively. 10 (59%) subjects out of 17 cases of lead perforation were noted in noncardiac CT indications, 2 (12%) subjects out of 17 cases of total lead perforation were noted in CT that were performed for suspicious lead perforation, and 5 (30%) subjects in whom CT was performed for coronary assessment.

Conclusion: ventricular ICD leads perforated more frequently than ventricular pacemaker leads. The interpreting physicians must be familiar and report it. The treating physicians should know this incidental finding of lead perforation is common and no further workup is to be requested, especially if the patient is asymptomatic.

Hybrid ¹²³I-mIBG SPECT/CT cardiac imaging for identification of left atrial ganglionated plexi in patients with atrial fibrillation

N.A. Nikitin, S.M. Minin, I. Mikheenko, D.V. Losik, S.V. Shaiakhmetova, A.B. Romanov; Novosibirsk/RU (n_nikitin@outlook.com)

Purpose: Addition of ganglionated plexi (GP) radiofrequency ablation (RFA) to pulmonary vein isolation (PVI) increases the effectiveness of atrial fibrillation (AF) interventional treatment. Solid-state gamma camera, using radiolabelled noradrenaline analogue ¹²³I-metaiodobenzylguanidine (¹²³I-mIBG), has the potential to image small cardiac sympathetic innervation structures located in left atrium (LA) epicardial surface and corresponding to anatomical locations of GP. The purpose of this study is to image and assess the influence of RFA on cardiac sympathetic innervation patterns in AF patients.

Methods and Materials: 15 paroxysmal AF patients scheduled for PVI underwent ¹²³I-mIBG SPECT imaging using a cardiac dedicated solid-state gamma camera. SPECT tomograms were co-registered with cardiac CT tomograms. Discrete ¹²³I-mIBG uptake areas (DUAs) were identified and marked according to location towards LA walls and PVs ostia. 3D SPECT/CT images with marked DUA sites were imported into CARTO and tested during interventional treatment by high frequency stimulation (HFS). Follow-up ¹²³I-mIBG SPECT imaging was acquired 5-7 days after interventional treatment.

Results: A total of 40 DUAs in LA were identified in 12 patients (3.3±1.49 per patient). Positive HFS response at DUA sites was achieved in 8 (67%) patients. In follow-up images 3 DUAs in the LA were identified (0.25±0.62 per patient; p<0.001 vs baseline). In 10 patients (83%) DUAs were not visualized compared to baseline images.

Conclusion: The cardiac sympathetic innervation patterns in LA can be visualized by discrete ¹²³I-mIBG uptake areas using hybrid SPECT/CT cardiac imaging. RF catheter ablation can precisely and effectively target the identified sympathetic innervation structures in AF patients.

Assessment of right ventricular deformation in end stage renal disease patients by cardiac magnetic resonance tissue tracking

Y. Zhang, Z.-G. Yang, Y.-K. Guo, H. Xu, W. Peng, C. Xia, Z. Li; Chengdu/CN (yizhang524@qq.com)

Purpose: To investigate myocardial deformation of right ventricle and its ability to predict heart failure (HF) in End stage renal disease (ESRD) patients evaluated by cardiac magnetic resonance (CMR) tissue tracking.

Methods and Materials: Fifty-seven consecutive patients with ESRD and 21 age- and sex-matched health controls were prospectively recruited and underwent 3.0T CMR examination. A series of SSFP cine sequence, including 8-12 slices of short axis and horizontal 4-chamber were scanned. The global right ventricle (RV) myocardial strain variables were measured. Then, all patients were followed to assess the HF as a cardiac outcome during 11-30 months.

Results: ESRD patients with reduced right ventricle ejection fraction (RVEF≤45%) (n=6), global peak longitudinal strain (GLS) was significantly decreased comparing with patients with preserved RVEF (RVEF>45%) (n=51) and normal controls (-14.39±5.99% vs. -20.88±4.83%, -14.39±5.99% vs. -23.56±3.65%; respectively, all P < 0.05). After the follow-up, there were 15 patients suffered from HF and 25 free from. Patients suffered from HF, had decreased GLS compared with normal controls (-20.24±5.65% vs. -23.56±3.65%, P<0.05). In patients free from HF, GLS were lower than that in normal controls but without significant difference (-21.71±4.50% vs. -23.56±3.65%, P=0.301).

Conclusion: ESRD patients demonstrated myocardial strain reduction early before they suffer HF, even without change in RVEF. Myocardial strains could work as auxiliary indices to predict RV myocardial deformation in ESRD.

Left ventricular global strain analysis in arrhythmogenic right ventricular cardiomyopathy with or without syncope: a cardiac magnetic resonance imaging study

M.-T. Shen, Z. Yang, K. Diao, L. Jiang, S. Huang, B. Hu, Y. Guo; Chengdu/CN (smt1020@qq.com)

Purpose: To clarify the diagnosis value of left ventricular (LV) strain on feature tracking cardiovascular magnetic resonance (FT-CMR) for arrhythmogenic right ventricular cardiomyopathy (ARVC) patients and to explore the correlation between LV systolic function change with syncope in ARVC patients.

Methods and Materials: CMR was performed in 24 with definite ARVC (11 with syncope, 13 without syncope), 18 with borderline ARVC and 28 healthy controls. Feature-tracking analysis was applied to cine CMR images on a commercial post-processing image station. LV global longitudinal strain (GLS), circumferential strain (GCS) and radial strain (GRS) were defined as the peak strain value within a cardiac cycle.

Results: LV GLS of patients with definite ARVC (-13.05±3.02%), with borderline ARVC (-15.46 ±2.22%) and the controls (-17.35±2.39%) were different among these three groups (all p<0.05). Additionally, in patients with definite ARVC, LV GRS (25.51±5.81% vs 35.89±11.63%), LV GCS (-13.25±2.30% vs -16.35±3.65%), and LV GLS (-11.29±2.40% vs -14.81±2.56%) was statistically significant lower in patients with syncope than those without (p<0.05, respectively), whereas left ventricular ejection fraction (LVEF) (50.14±11.53% vs 53.49±10.35%, p=0.46) and other heart function indexes showed no difference. There was a moderate correlation between the global strains and syncope (GRS: r=-0.41, GCS: r=0.382, GLS: r=0.41; all p<0.001). LV GLS < -13.4% exhibited 79% specificity and 83% sensitivity for predicting the presence of syncope (AUC=0.877).

Conclusion: For definite ARVC patients, syncope was correlated with the reduction of LV systolic function. Global strain could differentiate between controls, definite and borderline ARVC, and predict the presence of syncope.

Quantitative T2 mapping for detecting myocardial oedema and its association with myocardial injury biomarkers in acute myocardial infarction swine models

L. Zhang, Y.-K. Guo, Z.-G. Yang, X.-S. Li, C. Fu, H. Xu, M.-X. Yang, R. Xu, L. Xie; Chengdu/CN (zhanglu_scu2018@163.com)

Purpose: To investigate the ability of T2 mapping for detecting myocardial oedema in swine models with acute myocardial infarction (AMI), and determine the relationship between T2 mapping and myocardial injury biomarkers.

Methods and Materials: The AMI model was induced in 10 swine (surgery of left anterior descending artery occlusion). The cardiac magnetic resonance (CMR) scan was completed within 24 hours post-MI including T2-mapping and late-enhancement with gadolinium (LGE). The T2 value of oedematous myocardium and remote myocardium were obtained by ROI-measurement on T2-mapping images. The infarct size and oedematous size were measured on LGE and T2-mapping images, respectively. We measured myocardial injury biomarkers cardiac troponin I (cTnI), creatine kinase (CK) and creatine kinase isoenzyme MB (CK-MB) at the same time points as the magnetic resonance scanning.

Results: The T2 value of oedematous myocardium was higher than that of remote myocardium (54.90 ± 9.64 ms vs. 39.94 ± 6.89 ms; $P < 0.05$). Measured oedematous size was larger than that of infarct size (0.77 ± 0.24 cm² vs. 0.54 ± 0.24 cm²; $P < 0.05$); A strong correlation was demonstrated between the size of oedematous myocardium and cTnI ($r = 0.897$, $P = 0.039$), but the size of oedematous myocardium has no obvious correlation with CK and CK-MB (all $p > 0.05$).

Conclusion: Quantitative T2 mapping is a valuable for the assessment of myocardial oedema that could be a reliable marker to reflect myocardial injury in AMI, and the size of oedematous myocardium would be higher than LGE size.

Comparison of the incidence of in-stent restenosis and the newly developed plaques after stenting between diabetic and non-diabetic patients: evaluation with DSCT angiography

R. Shi, Z.-G. Yang, Y.-K. Guo, Q. Zhao, Y. Gao, P.-I. Han; *Chengdu/CN (shirui_1121@qq.com)*

Purpose: To evaluate the stents in diabetic mellitus (DM) and non-DM patients and compare the incidence of newly developed plaques in originally plaque-free segments between the two groups after coronary stenting by dual-source CT.

Methods and Materials: Thirty-eight coronary artery disease patients, 21 DM patients and 17 non-DM patients, who scheduled for stenting were consecutively included. The patency of the stent, and the distribution, number and types of newly developed plaques in originally plaque-free segments showed on the preoperative and follow-up coronary CT angiography (CCTA) data were determined.

Results: A total of 375 originally plaque-free coronary segments and 81 stents (DM vs. non-DM: 51 vs. 30) were analyzed. At the follow-up images, 72 stents were patent, 9 stents (DM vs. non-DM: 7 vs. 2, $P > 0.05$) had in stent restenosis (ISR) of less than 50%, and no stent had ISR more than 50%. Thirty-one newly-developed plaques (DM vs. Non-DM: 23 vs. 8, $P < 0.05$) were identified, including 10 calcific plaques, 11 non-calcified plaques, and 10 mixed plaques. There is no statistical difference in the type of new plaques in the two cohorts ($P > 0.05$). But it showed a mild correlation between the presence of plaques and DM ($r = 0.106$, $p < 0.05$).

Conclusion: The application of lipid lowering and antithrombotic therapy after stenting may induce the incidence of ISR both in diabetic and non-diabetic patients, but diabetes may be associated with the incidence of newly developed plaques in originally plaque-free segments, suggesting that these segments in diabetic patients need to be paid more attention to in follow-up period.

The correlation between coronary artery stenosis and myocardial perfusion indexes: a prospective "one-stop" 256-row detector computed tomography study

K. Liu, Z. Li, K. Diao, W. Peng; *Chengdu, Sichuan/CN (634270986@qq.com)*

Purpose: To investigate the effect of different degrees of coronary artery stenosis on the transmural perfusion ratio (TPR) in different segments of the left ventricle using combined CT myocardial perfusion imaging (CTP) and CT angiography (CTA) on 256-row detector CT.

Methods and Materials: Ninety-four participants (M/F: 58/36, 63.7 ± 6.7 years) were prospectively enrolled and underwent "one-stop" CT examination, from which CTA and CTP imaging were automatically derived. Patients with CAD were further stratified into mild, moderate and severe stenosis group. TPR was calculated using CTP on Ziostation2 (Minato-kuTM, Tokyo, Japan). One-way analysis of variance was used to compare TPR between the healthy control and CAD patients of different stenosis severity. Spearman correlation was used to assess the relationship between the degrees of coronary artery stenosis and the TPR of relevant segments.

Results: Totally, 1504 myocardial segments were identified using standardized 17 AHA segments model (except the apex). TPR values of segments subtended by the relevant artery were significantly decreased in CAD groups compared with the healthy control group ($P < 0.05$). There was a negative correlation between left anterior descending artery (LAD) stenosis degree and TPR (basal anterior segment: $r = -0.466$, $p = 0.009$; basal anteroseptal segment: $r = -0.519$, $p = 0.003$; apical anterior segment: $r = -0.439$, $p = 0.015$; apical septal segment: $r = -0.375$, $p = 0.041$).

Conclusion: The TPR acquired through the "one-stop" CT protocol was correlated with the corresponding coronary artery stenosis, making this combined CT scan a promising assessment tool for CAD patients to simultaneously quantify the diseased artery and myocardium.

Cardiovascular magnetic resonance early predictors of unfavourable left ventricle remodelling in patients with acutemyocarditis

A. Palmisano¹, G. Benedetti¹, D. Palumbo¹, G. Peretto¹, R. Faletti², S. Sala¹, M. Gatti², F. De Cobelli¹, A. Esposito¹; ¹Milan/IT, ²Turin/IT (palmisano.anna@hsr.it)

Purpose: Acute myocarditis has a highly variable course ranging from complete recovery to end-stage dilated cardiomyopathy, and predictors of outcome are still largely unknown. Aim of the study was to determine the potential value of short-term CMR for the prediction of adverse left ventricle remodelling.

Methods and Materials: From September 2016 to July 2018, 33 consecutive patients with biopsy-proven acute myocarditis underwent baseline CMR (11 ± 8 days after acute clinical presentation) and short-term CMR (65 ± 10 days from baseline MR). Lake-Louise criteria (LL), T1 and T2 mapping were evaluated at each time point, as well as their modification over time. MR parameters were correlated with left ventricle (LV) end-diastolic volume (EDV) and ejection fraction (EF) at short-term CMR.

Results: The vast majority of patients ($N = 18, 54.5\%$) presented with infarct-like clinical presentation (18, 54.5%), followed by 9 (27.3%) with heart failure, 6 (18.2%) with sudden cardiac death/arrhythmia. At baseline CMR, LV volume was 135 ml with EF 53% with a significant elevation of both LL criteria (T2-ratio: 2.8, Hyperemia: 13%, LGE 6%) and mapping parameters (T1: 1103.79, ECV: 31, T2: 53.95) without differences among clinical presentation ($p > 0.05$). At short-term follow-up, a slight recovery of EF was experimented (56%), and all LL and mapping parameters significantly reduced (T2-ratio: 2.3, Hyperemia: 7%, LGE 4%, T1: 1080, ECV: 28, T2: 51), without differences among clinical presentations. Among all parameters analysed only short-term recovery of T1 mapping was associated to improved LV volume and function (EDV $R = 0.884$, $p < 0.001$, FE%; $R = 0.757$, $p < 0.001$).

Conclusion: Short-term T1 recovery is significantly associated to favourable left ventricle remodelling.

B-1679 11:14

FFR_{CT} vs CAD-RADSTM and its impact on patient management: a retrospective pilot study

S. Braspenning¹, C. Van Mieghem², P. Vanhoenacker³; ¹Edegem/BE, ²Kortrijk/BE, ³Aalst/BE

Purpose: Only few data exist regarding the impact of FFR_{CT} (coronary computed tomography angiography-derived fractional flow reserve), more specifically the added value of FFR_{CT} compared to the CAD-RADSTM score alone. This study sought to examine in retrospect the impact of FFR_{CT} on further patient management, and to generate hypotheses concerning further prospective studies.

Methods and Materials: A total number of 51 patients were included. The sensitivity, specificity, PPV, NPV, LR+ and LR- of two strategies, i.e. CAD-RADSTM score alone vs the combination of CAD-RADSTM with FFR_{CT}, to predict the final clinical decision was calculated. Bland-Altman statistics and concordance correlation coefficient were used for concordance of FFR_{CT} and invasive FFR (iFFR) values. ROC curves for sensitivity and specificity of FFR_{CT} vs iFFR were constructed.

Results: The combination of CAD-RADSTM with FFR_{CT} had a slightly lower sensitivity than CAD-RADSTM alone (72.22 vs 77.78) but a higher specificity (51.72 vs 17.24), PPV (48.15 vs 36.84) and NPV (75.00 vs 55.56) for predicting the final clinical decision, conservative management or revascularization. The correlation between FFR_{CT} and iFFR results was relatively poor (concordance correlation coefficient 0.29). The Bland-Altman plot indicated a systematic bias with underestimation of FFR_{CT} results by 0.05. The ROC curves showed only moderate sensitivity and specificity.

Conclusion: As compared to the CAD-RADSTM anatomical score alone, the combination of CAD-RADSTM with FFR_{CT} proved to be superior for predicting subsequent patient management. When comparing individual FFR_{CT} values with corresponding iFFR data, correlation between these two techniques was rather weak.

B-1680 11:18

Left ventricular function impairment and deformation assessment of post-transcatheter aortic valve implantation (TAVI): a systematic review and meta-analysis

M.-T. Shen, Z. Yang, K. Diao, Q. Zhao, L. Jiang, S. Huang, Y. Guo; Chengdu/CN (smt1020@qq.com)

Purpose: The aim of this study was to elucidate changes in LVEF and left ventricular global longitudinal strain (LV GLS) at different follow-up durations after TAVI by a systematic review and meta-analysis.

Methods and Materials: Studies that provided both pre- and post-TAVI LVEF and LV GLS were included. The rate of change was defined as the variable difference of post- and pre-TAVI divided by pre-TAVI. The pooled GLS, LVEF and rate of change were computed using a fixed- or random-effect model. Subgroup analysis was performed to find possible sources of heterogeneity.

Results: Data were included from 17 studies with a total of 1109 patients, and the follow-up durations ranged from at-discharge to one year. The LVEF and LV GLS improved significantly post-TAVI (LVEF: WMD=3.868%, 95% CI=-2.937 to 4.799, GLS: WMD=-1.922%, 95% CI=-2.372 to -1.473, $p<0.001$, respectively). The pooled rates of changes of LVEF and GLS after TAVI at different follow-up assessments were: short-term (<10 day) (LVEF: ES=0.048, 95% CI=0.023 to 0.073, GLS: ES=0.079, 95% CI=0.048 to 0.110); mid-term (1-6 month) (LVEF: ES=0.022, 95% CI=0.010 to 0.034, GLS: ES=0.063, 95% CI=0.044 to 0.082); and long-term (1 year) (LVEF: ES=0.075, 95% CI=0.053 to 0.097, GLS: ES=0.147, 95% CI= 0.114 to 0.179) ($p<0.001$, respectively). No significant evidence of publication bias or sensitivity analyses was observed.

Conclusion: LV systolic function evaluated by GLS and LVEF on echocardiography improved significantly after TAVI intervention. GLS was more sensitive and could serve as a potential assessment tool for the efficacy of therapeutic interventions and for predicting patient prognosis and clinical outcomes.

B-1681 11:22

Assessment of left ventricular deformation in restrictive cardiomyopathy with preserved ejection fraction by cardiac magnetic resonance tissue tracking

S. Huang, Z.-G. Yang, K. Diao, K. Shi, Y. Gao, M.-T. Shen, Y.-K. Guo; Chengdu/CN (huangshan82833@163.com)

Purpose: To determine left ventricular (LV) deformation in restrictive cardiomyopathy (RCM) using tissue-tracking strain analysis on cardiac magnetic resonance (CMR) imaging and further investigate the relationship between strain parameters and myocardial injury.

Methods and Materials: Forty RCM patients (61.6 ± 1.6 years) with preserved LV ejection fraction (LVEF \geq 45%) and 35 normal controls (51.0 ± 1.6 years) were included. Systolic global radial strain (sGRS), circumferential strain (sGCS), longitudinal strain (sGLS) and diastolic global radial strain rate (dGRSR), circumferential strain rate (dGCSR), longitudinal strain rate (dGLSR) were compared between RCM patients and the normal controls. New York Heart Association functional classes (NYHA) and plasma troponin T levels were recorded for clinical reference.

Results: Diastolic strain rates decreased significantly in RCM patients compared with the controls (dGRSR: -0.95 ± 0.10 vs. -2.14 ± 0.10 ; dGCSR: 0.64 ± 0.06 vs. 1.10 ± 0.04 ; dGLSR: 0.54 ± 0.04 vs. 0.92 ± 0.04 ; all $p<0.001$). And despite with preserved EF, RCM patients demonstrated distinctly lower systolic strains (sGRS: 16.78 ± 1.13 vs. 34.61 ± 1.37 ; sGCS: -11.42 ± 0.59 vs. -19.5 ± 0.45 ; sGLS: 7.81 ± 0.53 vs. 17.27 ± 0.45 ; all $p<0.001$). Elevation in troponin level was correlated with more severe NYHA classes ($r=0.626$, $p<0.001$) and strain parameters including sGRS ($r=-0.600$, $p<0.001$), sGCS ($r=-0.560$, $p=0.001$), sGLS ($r=-0.410$, $p<0.05$) in RCM patients. In addition, the presence of atrial fibrillation was associated with enlarged atrial volume ($r=0.563$, $p<0.001$) in RCM.

Conclusion: CMR-based strain imaging can detect both systolic and diastolic function in RCM patients before LVEF decreased. Impaired systolic strain indices are significantly correlated with myocardial injury.

B-1682 11:26

Diastolic dysfunction in competitive triathletes following a strenuous endurance sports event

J. Stáreková, B. Scherz, M. Avanesov, J.M. Weinrich, K. Müllerleile, U. Radunski, G. Adam, G.K. Lund, E. Tahir; Hamburg/DE (j.starekova@uke.de)

Purpose: The purpose of this study was to analyse left ventricular (LV) diastolic function by cardiac magnetic resonance (CMR) following an endurance competition in triathletes with (LGE+) and without fibrosis (LGE-).

Methods and Materials: 30 asymptomatic male triathletes (45 \pm 10 years) underwent CMR before and 2.1 \pm 1.1 hours after competition. To detect fibrosis, late gadolinium enhancement (LGE) imaging was included in the baseline CMR. Diastolic LV function was determined by early peak-filling rates (EPFR)

and atrial peak-filling rates (APFR) using cine CMR in baseline and post-race studies.

Results: Focal myocardial fibrosis was detected in 10 triathletes. At baseline, APFR was higher in LGE+ compared to the LGE- triathletes (161 ± 34 vs. 121 ± 30 ml/s/m², $P<0.01$). While APFR in LGE- triathletes showed a significant increase (121 ± 30 vs. 163 ± 57 ml/s/m², $P<0.001$), APFR in LGE+ triathletes remained unchanged before and after the competition (161 ± 34 vs. 169 ± 50 ml/s/m², $P=0.75$). EPFR remained unchanged in both groups. There were no significant post-race differences regarding LVEF, LV and RV volumes. However, LGE+ triathletes had higher post-race left atrial volumes (43 ± 9 vs. 34 ± 7 ml/m², $P<0.01$).

Conclusion: Post-race diastolic function in LGE- triathletes was characterised by a significant increase of APFR. In contrast, the LGE+ group did not show any relevant changes coming from already increased baseline values. This suggests exhaustion of left atrial compensatory mechanisms most likely related to impairment of diastolic function in LGE+ triathletes.

B-1683 11:30

Evaluation of coronary arteries with prospectively-ECG-triggered-High-Pitch-CT in patients undergoing TAVI-planning

P. Seitz, S. Gottschling, M. Abdel-Wahab, H. Thiele, M. Borger, D. Holzhey, R.F. Gohmann, C. Kriehoff, M. Gutberlet; Leipzig/DE (patrick.seitz@helios-gesundheit.de)

Purpose: To assess image-quality and grade of stenosis of coronary arteries in preprocedural prospectively-ECG-triggered-High-Pitch-CT in patients referred to transcatheter-aortic-valve-implantation (TAVI) in comparison to invasive-coronary-angiography (ICA).

Methods and Materials: In 100 patients (54 male, mean age 79 ± 5.9 years) a Dual-Source-CT-Scan (Siemens, Definition FLASH) and an ICA was performed. The cardiac scan was performed in prospectively-ECG-triggered-High-Pitch-Mode after application of 70 ml Imeron400 (Flow 3.5 ml/s). Grade of stenosis was evaluated per patient and per segment with Syngo.via (Siemens, VB10B) and was performed by one and in 1/3 of the patients by two blinded observers. Image quality was assessed using a 4-point- (0-3) and grade of stenosis using a 5-point-scale (0-4).

Results: 22% of patients had known coronary heart disease (CHD), in 2 cases a coronary anomaly was detected. Diagnostic image quality (Grade 1-3) could be achieved in 30.3% of segments. Sensitivity (75%), specificity (80.5%), and especially the negative predictive value (NPV) with 98.5% were good in comparison to ICA, but the positive predictive value (PPV) was only 16%. A coronary stenosis $>50\%$ could be ruled out completely in all segments for 3 patients, with an excellent NPV and sensitivity (100%), but low PPV (43.6%) and specificity (8.82%). The inter-rater-agreement per patient was excellent ($\text{Kappa}=1.0$), and moderate ($\text{Kappa}=0.405$) per segment.

Conclusion: Even within the limitations in patients referred to TAVI (high heart rate, coronary calcifications, etc.), a valid evaluation of coronary arteries was possible in 30% of segments using prospectively-ECG-triggered-High-Pitch-CT with a high sensitivity and NPV, and should always be performed, if the image quality is feasible.

B-1684 11:34

Relationship between epicardial adipose tissue and coronary vascular function in patients with normal myocardial perfusion by 82Rb PET/TC

S. Dell'Aversana, A. Ponsiglione, C. Nappi, A. Stanzione, M. Puglia, L. D'Acerno, G. Lassandro, A. Cuocolo, M. Imbriaco; Naples/IT (dellaversanaserena@gmail.com)

Purpose: We assessed the relationship between epicardial adipose tissue (EAT) and coronary flow reserve (CFR) in patients with suspected or known coronary artery disease (CAD) and normal myocardial perfusion imaging (MPI).

Methods and Materials: We retrospectively evaluated 272 subjects referred for suspected or known CAD to stress-rest 82RbPET/CT, showing normal MPI. CAC score was measured according to Agatston method; EAT volume (EATv) was measured in cm³ on unenhanced CT. The ln(CAC+1) score and lnEATv transformation were used to reduce heteroscedasticity. Semi-quantitative perfusion scores (SSS, SRS, and SDS) were automatically calculated. Myocardial perfusion was considered normal when the SSS was ≤ 3 . Absolute myocardial blood flow (MBF) was computed from rest and stress imaging. CFR was defined as the ratio of hyperemic to baseline MBF and considered reduced if < 2 .

Results: 95 (35%) patients showed reduced and 177 (65%) normal CFR. Compared to patients with normal CFR, those with reduced CFR were older (60 ± 11 vs. 67 ± 9 , $P<0.05$) and showed higher ln(CAC+1) (3.9 ± 3 vs. 4.7 ± 3 , $P<0.05$) and lnEATv (4.5 ± 1 vs. 4.7 ± 1 , $P<0.05$). At univariable logistic regression analysis, age, ln(CAC+1) and lnEATv resulted significant predictors of reduced CFR. At multivariable analysis, only age and lnEATv were independently associated with reduced CFR (HR: 1.05 and 1.89 and 95% C.I.: 1.02-1.08 and 1.01-3.54, respectively, $P<0.005$).

Conclusion: In CAD and normal MPI, age and EAT are associated with reduced CFR confirming that cardiac visceral fat may influence coronary vascular function. EAT evaluation may play an important role in identification of coronary vascular dysfunction in patients with normal myocardial perfusion.

B-1685 11:38

Imaging carotid artery-vulnerable plaque with ultrasound and contrast-enhanced ultrasound: correlation of cerebrovascular symptoms with quantitative and multi-parametric indexes

V. Rafailidis¹, I. Chryssogonidis¹, E. Grisan², C. Xerras¹, G.-A. Cheimariotis¹, T. Tegos¹, D. Rafailidis¹, P. Sidhu², A. Charitanti-Kouridou¹; ¹Thessaloniki/GR, ²London/UK (billraf@hotmail.com)

Purpose: To investigate the diagnostic accuracy of quantitative carotid plaque features and a multi-parametric vulnerability index (VI) for the detection of symptomatic plaques, using ultrasound (US) and contrast-enhanced ultrasound (CEUS).

Methods and Materials: This is a cross-sectional observational study of 54 patients (72.2% male, median age 61 years) and 62 carotid plaques (50% symptomatic) examined with US and CEUS. The study lasted for two years (July 2016-July 2018). A VI combined degree of stenosis (DOS), greyscale median (GSM) and a quantitative surface irregularity index (SII) were calculated using both colour Doppler imaging (CDI) and CEUS, thus leading to two VI (VI-CDI and VI-CEUS). The SII was based on manual delineation of plaques with specific software. Mann-Whitney U and T tests were used to compare variables and receiver operating characteristic curves (ROC) analysis for diagnostic accuracy comparison. Level of significance was set at 0.05.

Results: Mean DOS of plaques was 68.9% (SD 12.8%). Symptomatic plaques showed significantly higher DOS ($p < 0.001$), lower GSM ($p = 0.001$), higher SII (both with CDI and CEUS - $p < 0.05$) and higher VI calculated both with CDI ($p < 0.001$) and CEUS ($p < 0.001$). The area under the curve (AUC) for the detection of symptomatic plaques was 0.656 for SII-CDI, 0.690 for SII-CEUS, 0.772 for DOS alone, 0.783 for VI-CDI and 0.802 for VI-CEUS. No allergic reaction to contrast agent was noted.

Conclusion: The VI has superior diagnostic accuracy to DOS alone for the detection of symptomatic plaques, with best accuracy achieved with the SII calculated using CEUS, thanks to improved plaque surface delineation.

Cardiac magnetic resonance with 4D flow imaging for mitral regurgitation severity assessment

M. Guglielmo¹, G. Muscogiuri¹, A. Baggiano¹, A.I. Guaricci², D. Andreini¹, F. Alamanni¹, M. Pepi¹, G. Pontone¹; ¹Milan/IT, ²Bari/IT (g.muscogiuri@hotmail.it)

Purpose: The purpose of this study was to compare CMR 4D flow and SSFP imaging for the assessment of MR severity using the degree of left ventricular (LV) remodeling after surgery as the reference standard.

Methods and Materials: 10 consecutive patients (age: 59 ± 10) with indication to mitral valve plasty for severe mitral regurgitation were enrolled. MR severity was assessed using both CMR SSFP-PC imaging and CMR 4D flow imaging without the use of contrast agents. The pre-surgical estimate of regurgitant severity was correlated with the postoperative decrease in LV end-diastolic volume.

Results: Agreement between CMR SSFP-PC imaging and CMR 4D flow imaging for MR regurgitant volume (RV) was excellent for both pre- ($r = 0.8$, $p < 0.05$, mean difference 5.1mL) and post-surgery ($r = 0.9$, $p < 0.05$) evaluations. There was a strong correlation between post-surgical LV remodeling and MR severity as assessed by CMR 4D flow imaging ($r = 0.81$, $p < 0.005$) that was comparable to CMR SSFP-PC ($r = 0.78$, $p < 0.005$). The average time for MR assessment with CMR SSFP and PC imaging evaluation was 10 minutes, and 2 minutes with CMR 4D flow imaging.

Conclusion: CMR 4D flow imaging without contrast agents allows an accurate and quick evaluation of MR regurgitant volume. There is a strong correlation between MR severity assessed with CMR 4D flow imaging and post-surgical LV remodeling. Indeed, CMR 4D flow imaging may represent an alternative method for MR severity assessment.

White matter hyperintensities volumetric burden in healthy adults: a systematic review and meta-analysis

L. Melazzini¹, M. Codari², M. Zanardo¹, M. Bolchini¹, G.D. Papini², F. Sardaneli¹; ¹Milan/IT, ²San Donato Milanese/IT (marina.codari@grupposandonato.it)

Purpose: To perform the first systematic review and meta-analysis of available studies reporting volumetric WMHs burden in healthy adults.

Methods and Materials: A systematic search on the available literature on this topic published between 2008 and 2018 was performed in September 2018. From each study, data about sample size, patients' age and WMHs burden were retrieved. Using the random-effect model, we calculated the pooled WMH burden, with 95% confidence interval (CI) and modelled standard deviation (SD). Subgroup/meta-regression analyses for assessing age factor and Egger test for publication bias risk were performed.

Results: Twenty-eight studies comprising 30 study parts were included in this systematic review and meta-analysis. Final samples comprised 6998 healthy subjects: mean age 44.7- 84.1 years. Mean WMHs volume ranged from $0.27 \pm 0.51 \text{ cm}^3$ to $15.85 \pm 14.57 \text{ cm}^3$, resulting in high heterogeneity ($I^2 = 99.9\%$, $p < 0.001$). Meta-analysis produced a pooled WMHs volume of 6.484 cm^3 (95% CI $5.246\text{-}7.722 \text{ cm}^3$). Meta-regression analysis between WMHs volume and age showed a positive correlation between WMHs volume and subjects' age, ($\gamma = 0.26x - 11.2$; $R^2 = 0.41$). Visual inspection of funnel plot showed low risk of publication bias, confirmed by the Egger- test ($p = 0.929$) and by Kendall's tau ($p = 0.089$).

Conclusion: Results of our meta-analysis showed high heterogeneity in WMHs burden across the analysed studies. Supporting the impact of age as the main unmodifiable risk factor for WMHs development, a positive correlation between WMHs and age was proved by meta-regression analysis.

B-1688 10:38

Prevalence of incidental intracranial vascular findings in a tri-ethnic population-based study

R. Rehwald¹, S. Moriconi², L. Smith², C.H. Sudre², M.J. Cardoso², J.H. Gillard¹, H.R. Jäger²; ¹Cambridge/UK, ²London/UK (rr538@cam.ac.uk)

Purpose: This study aims to present the prevalence, clinical relevance and updated epidemiology of incidental vascular findings on high-resolution brain magnetic resonance angiography (MRA) in a tri-ethnic UK population-based cardiovascular cohort.

Methods and Materials: The trial was approved by the institutional research ethics committee and all participants gave written informed consent. In the prospective inter-ethnic community-based setting of the Southall and Brent Revisited (SABRE) trial, European, South Asian and African-Caribbean study participants were recruited for 3T high-resolution cerebral time-of-flight MRA (visit 3, 2014-2018). All scans were centrally reviewed for incidental vascular abnormalities by two neuroradiologists independently. The population prevalence with 95% CI were then calculated for the incidental findings overall and for each ethnicity, followed by multigroup comparisons.

Results: A total of 766 subjects (348 female, 45.4%), aged 37-90 years (mean: 72.2 ± 6.6), had an adequate MR scan performed (European: 326, 42.5%; South Asian: 257, 33.6%; African-Caribbean: 179, 23.4%; Other: 4, 0.5%). In 97 of 766 study participants (12.6% [95% CI: 10.5%-15.2%]) incidental vascular findings have been found, of which cerebral aneurysms (37/766; 4.8% [95% CI: 3.5%-6.6%]) and intracranial atherosclerotic stenoses (ICAS) (35/766; 4.6% [95% CI: 3.3%-6.3%]) were most frequently observed, followed by arteriovenous malformations (15; 2.0% [95% CI: 1.2%-3.2%]). ICAS were significantly more frequently observed in South Asians than in Europeans and African-Caribbean ($p = 0.035$).

Conclusion: The prevalence of incidental cerebral aneurysms in a community-based cohort is higher than previously expected. ICAS prevalence significantly differs by ethnicity and might be targeted by population-specific primary risk factor prevention.

B-1689 10:46

Age and gender effects on brainstem MR planimetry

S. Mangesius, A. Hussl, C. Müller, F. Krismer, P. Mahlknecht, M. Schocke, E. Gizewski, W. Poewe, K. Seppi; *Innsbruck/AT*
(stephanie.mangesius@tirol-kliniken.at)

Purpose: MR planimetry of brainstem structures can be helpful for the discrimination of parkinsonian syndromes. The aim of this study was to evaluate age and gender effects on brainstem MR-planimetric measures.

Methods and Materials: MR-planimetric measures including brainstem diameters (midbrain, pons, middle and superior cerebellar peduncle) and areas (pontine and midbrain), the ratios derived from both midbrain-to-pons diameters and areas as well as the Magnetic Resonance Parkinson Index (MRPI) were assessed on 1.5 Tesla-weighted MR images in a large cohort of 97 healthy controls (mean age 62.8 years; SD 10.9 years; female-to-male-ratio = 49:48). Planimetric measures were performed on an imaging database program (IMPAX EE). Gender- and age-related differences of all as well as of combined planimetric measurements were calculated using univariate and multivariate GLMs, and repeated for the population relevant for the differential diagnosis of parkinsonism, aged 50 to 80 years.

Results: Univariate and multivariate analyses showed significant effects of gender on both pontine measurements ($p < 0.05$ for all) with male subjects showing larger measurements, and significant effects of age on midbrain measurements ($p \leq 0.001$ for all) as well as on combined measurements and ratios derived from midbrain-to-pontine measurements ($p < 0.01$ for all). Intriguingly, there were neither gender nor age effects on combined measurements or midbrain diameter in the population aged 50 to 80 years.

Conclusion: Although age and gender might influence single brainstem MR-planimetric measures, our results indicate that there is no need for age- or gender-specific cut-offs for the age group relevant for the differential diagnosis of neurodegenerative parkinsonism.

B-1690 10:54

Automated detection of enlarged perivascular spaces on brain MRI

F. Dubost, H.H. Adams, P. Yilmaz, G. Bortsova, M. Ikram, W.J. Niessen, M.W. Vernooij, M. De Bruijne; *Rotterdam/NL* (gerdabortsova@gmail.com)

Purpose: Enlarged perivascular spaces (PVS) are an emerging biomarker for cerebral small vessel disease. Annotation of PVS is a tedious and error-prone task. An automated method to detect PVS location is introduced.

Methods and Materials: T2 weighted MR images (voxel size $0.49 \times 0.49 \times 0.8$ mm³) were acquired from 2200 subjects from a population-based study. An expert rater quantified PVS in the centrum semiovale and basal ganglia (both on a single slice) and, hippocampi and midbrain (whole volume). A weakly supervised deep learning algorithm based on convolutional network regression was developed. The algorithm was trained to predict the PVS count, but also produces high-resolution heatmaps revealing PVS location and size. The algorithm was trained on 1200 scans with PVS count, and evaluated on 1000 MRI scans with PVS dot annotations. Sensitivity and average number of false positives per scan (FPavg) were computed, and compared to intra-rater ($n=40$) reliability.

Results: The agreement between PVS detections and manual annotations reached sensitivity/FPavg of 0.71/1 for midbrain, 0.70/1.1 for hippocampi, 0.57/1.9 for basal ganglia, and 0.51/5.2 for centrum semiovale. The intra-rater reliability for a smaller subset reached sensitivity/FPavg of 0.77/0.4, 0.79/1.1, 0.72/2.1, and 0.55/4.3, respectively.

Conclusion: For each region, the automated detection of PVS performs only slightly worse than the level of intra-rater agreement. By integrating PVS locations in the analyses, this method may strengthen large clinical studies of enlarged perivascular spaces.

Preliminary study on changes of oxygen uptake fraction in pilots before and after hypoxia exposure

J. Liu¹, W.-S. Zhang², J.L. Cheng¹; ¹Zhengzhou/CN, ²Beijing/CN (tongnuo@yeah.net)

Purpose: The changes of oxygen extraction fraction (OEF) in brain tissue of pilots before and after hypoxic exposure were measured by spin echo EPI sequence on MRI.

Methods and Materials: 35 healthy male pilots were scanned with MR spin-echo EPI sequence (parameters: TR/TE=4000ms/103.3ms, layer thickness 5.0mm, layer number 22, FOV=24cm*24cm, matrix Matrix=96*96, excitation frequency NEX=2, average scanning time 3 minutes and 24 seconds), and then inhaled 14.5% oxygen concentration of hypoxic mixture for 10 minutes. The spin echo EPI sequence was scanned again. Two groups of EPI data were processed by GE workstation Functool software, and OEF maps were obtained. One ROI was set in bilateral temporal cortex and one ROI in bilateral occipital cortex, and the OEF values were measured.

Results: Compared with before hypoxic exposure, the pulse and oxygen saturation of pilots decreased after hypoxic exposure, and OEF increased in bilateral temporal lobe and right occipital lobe cortex. OEF increased significantly in the right temporal lobe and right occipital lobe cortex, but not in the left occipital lobe.

Conclusion: The OEF values of pilots before and after hypoxic exposure could be accurately measured by using spin echo EPI sequence, and the OEF values of right temporal lobe and right occipital lobe cortex were significantly increased after hypoxic exposure.

B-1692 11:10

A resting-state functional magnetic resonance imaging study of hypoxic exposure in pilots

J. Liu¹, W.-S. Zhang², J.L. Cheng¹; ¹Zhengzhou/CN, ²Beijing/CN (tongnuo@yeah.net)

Purpose: The objective of this study was to evaluate the basic changes in brain activity in pilots after hypoxic exposure using resting-state functional magnetic resonance imaging (rs-fMRI) method.

Methods and Materials: Thirty-five healthy male pilots were subjected to rs-fMRI scans, and fractional amplitude of low frequency fluctuation (fALFF) and regional homogeneity (ReHo) approaches were used to analyze their brain functions before and after hypoxic exposure.

Results: Compared to pre-hypoxia conditions, the fALFF was decreased in the bilateral superior temporal gyrus and the right frontal gyrus, and increased in the left precuneus, while ReHo was decreased in the right frontal gyrus after hypoxic exposure.

Conclusion: Hypoxic exposure significantly affected the brain functions of pilots, which may have an impact on their cognitive ability. Furthermore, the sensitivity of ReHo was poorer than fALFF for this set of data.

B-1693 11:18

Preliminary study of hypoxic exposure effect on cerebral blood perfusion of pilots using 3D ASL

J. Liu¹, W.-S. Zhang², J.L. Cheng¹; ¹Zhengzhou/CN, ²Beijing/CN (tongnuo@yeah.net)

Purpose: The objective of this study was to investigate how the cerebral blood perfusion changed in pilots with hypoxic exposure through the measurement of resting cerebral blood flow (CBF) using a 3D pcASL technique.

Methods and Materials: In our study, 35 healthy male pilots were subjected to MRI examinations separately. The low oxygen mixed gas inhaled by participants through a breathing mask was approximate to the air composition at the altitude of 3000m with the oxygen concentration of 14.5%. 3D pcASL images were acquired at both pre-oxygen gas inhalation (pre-OL) and post-low oxygen mixed gas inhalation (post-OL).

Results: Compared with pre-OL, 3D pcASL scan for pilots post-OL showed lower CBF values in various regions, including bilateral superior temporal gyrus, middle temporal gyrus, lingual gyrus, left inferior temporal gyrus, right middle occipital gyrus, inferior occipital gyrus, fusiform gyrus, cuneus and cerebellum.

Conclusion: The cerebral blood perfusion after hypoxic exposure is decreased mainly in the temporal and occipital lobe for the right side, and arterial spin-labeling technique can monitor CBF changes of the pilots in hypoxic exposure.

B-1694 11:26

Evaluating the diagnostic value of different imaging modalities in cerebral venous thrombosis

O. Shafaat¹, F. Faeghi², A. Bagheri¹, M. Rabbani¹, K. Jabbari¹; ¹Isfahan/IR, ²Tehran/IR (omid.shafaat@yahoo.com)

Purpose: Cerebral venous thrombosis (CVT) is a rare condition which is hard to diagnose because it has nonspecific symptoms. It can be potentially fatal if it remains undiagnosed and if the treatment is not started promptly. This study was designed to compare different MRI sequences with susceptibility weighted imaging (SWI) for visualization and evaluation of CVT.

Methods and Materials: Eighteen patients with CVT and eleven control patients without CVT were analyzed using different imaging modalities including MRI, SWI, and Phase-contrast-magnetic resonance venography (PC-MRV). The MR sequences included: T1-weighted spin echo (SE) imaging, T2-weighted turbo spin echo (TSE), T2-weighted SWI and three-dimensional phase contrast MRV.

Results: SWI showed the highest sensitivity, positive predictive value, and negative predictive value for the detection of cortical vein thrombosis (100%) and specificity of all sequences in the diagnosis of cortical veins thrombosis was 100%. The sensitivity of PC-MRV, SWI, T2W, and T1W sequences in the diagnosis of venous sinus thrombosis were 100%, 75%, 50%, and 8.3%, respectively. Specificity and positive predictive value of all sequences in the diagnosis of the venous sinus thrombosis were 100%. The negative predictive value of PC-MRV, SWI, T2W, and T1W sequences in the diagnosis of venous

sinus thrombosis were 100%, 78.6%, 64.7%, and 50%, respectively.

Conclusion: SWI had a high diagnostic value for diagnosing cortical vein thrombosis. PC-MRV was the superior MRI sequence for detecting venous sinus thrombosis. Besides PC-MRV, only SWI reached a sensitivity of over 50% for venous sinus thrombosis, followed by T2W, and T1W.

B-1695 11:34

Radial diffusivity role in classification of patients with antiphospholipid syndrome and "normal" radiological exams

S. Sandiramourty, H. Nguyen Troung Thanh, J. Greffier, A. Larbi, J. Frandon, J.P. Beregi, J.-C. Gris, F. Pereira; *Nimes/FR* (sandiramourty.shridevi@gmail.com)

Purpose: Automatically classify patients with Antiphospholipid Syndrome (APS) without neuroradiological manifestations.

Methods and Materials: Antiphospholipid Syndrome is defined as an autoimmune disease which is associated to thrombosis with common impact on MRI. However non-thrombotic APS patients usually present "normal" routine MRI examinations. So there is an interest to find a way to diagnose them. Diffusion-Tensor MRI (DT-MRI) was performed on 30 women with recurrent pregnancy loss (15 controls [C]; 15 antiphospholipid syndrome patients [APS] with high blood titre of Lupus Anticoagulant or Anti- β 2-Glycoprotein-I antibodies). Acceded with Radial Diffusivity (RD), preceding study has demonstrated microstructural brain disruption in APS patient. Here, RD values were extracted within the significant clusters, in which voxels were considered attributes to perform Hoeffding tree classification. This is an incremental decision-tree learning model that assumes the distribution of data don't change over time. Thus, small samples may be enough for optimal splitting attribute.

Results: A total of 5225 attributes were found significant to produce 96.67% of accuracy (29 instances). Kappa statistics was 0.93, mean absolute error was 0.03 and the relative absolute error was 6.59%. All but one control subject were correctly classified resulting sensitivity of 1 and specificity of 0.93.

Conclusion: Radial Diffusivity index is an efficient attribute to classify patients with Antiphospholipid Syndrome by means of Hoeffding tree algorithms.

B-1696 11:42

MRI alterations in the brachial plexus of ALS patients

S. Gerevini, F. Agosta, E. Spinelli, P. Scamarcia, N. Riva, E. Pagani, A. Quattrini, A. Falini, M. Filippi; *Milan/IT* (gerevini.simonetta@hsr.it)

Purpose: To investigate brachial plexus MRI abnormalities in a large cohort of patients with amyotrophic lateral sclerosis (ALS).

Methods and Materials: Brachial plexus MRI scans were obtained from 43 ALS patients and 12 healthy controls. Nerve roots and limb girdle muscles were evaluated for the presence of signal alterations (T2, T1 and STIR) and volume changes. C5, C6 and C7 roots were delineated on axial, T2-weighted volumetric images. Nerve root volumes and T2-signal intensities were measured. Adipose tissue thickness between trapezius and supraspinatus muscles was measured on T1-weighted images. Quantitative measures were compared using Mann-Whitney U tests. Correlations between clinical and MRI features were assessed using the Pearson correlation test.

Results: At visual inspection, T2 hyperintensity and volume alterations of C5, C6, C7 nerve roots were observed in ALS patients. Muscle signal alterations and bilateral fat infiltration were also observed. The quantitative analysis showed increased T2-signal intensity in C5, C6 ($p < 0.001$) and C7 roots ($p = 0.001$, bilaterally) of ALS patients compared with healthy controls. Patients also showed increased C6 and C7 root volumes (p ranging 0.001-0.02). Adipose tissue thickness between trapezius and supraspinatus muscles was increased in patients ($p < 0.001$, bilaterally). Disease progression rate measured using ALS Functional Rating Scale correlated with T2-signal intensity of left C6 and right C7 ($r = 0.45$, $p = 0.03$; and $r = 0.50$, $p = 0.02$, respectively).

Conclusion: T2 hyperintensity and increased volume of brachial plexus roots likely reflect lower motor neuron and axonal degeneration in ALS, and might represent a tool to monitor disease evolution. Muscle structural abnormalities are consistent with denervation atrophy.

B-1697 11:50

Magnetic resonance imaging evaluation of arteritis and other complications in tuberculous meningitis

S.U.K. Khan; *Gulbarga/IN* (mksadaquat@gmail.com)

Purpose: To evaluate the pattern of infarction and arteritis in tubercular meningitis.

Methods and Materials: Fifty patients with intracranial tuberculosis were subjected to MRI and MRA evaluation. Clinical signs and symptoms, focal deficits and CSF findings were recorded. Presence of exudates, infarction, tuberculomas and hydrocephalus were noted. Sites of exudates and infarction were noted. On intracranial MRA narrowing of middle cerebral artery (MCA), anterior cerebral artery (ACA) and posterior cerebral artery (PCA) were recorded. MRA findings were correlated with clinical and MRI findings.

Results: Fifty patients of aged 2-65 yrs were included. Meningitis was seen in 24 (48%) cases, tuberculomas in 28 (56%), hydrocephalus in 10 (20%), arteritis and infarcts were seen in 7 (14%) cases. Majority of cases (70%) of infarcts in our study were located in MCA territory. Basal ganglia was the most common location 5 (71%) followed by cerebral cortex, parietal 4 (57%), frontal region 3 (43%) and temporal region 3 (43%). On MR angiography MCA was involved in 5 cases, ACA in 4 cases and PCA in 3 cases.

Conclusion: MR imaging plays an important role in detection, localisation and characterisation of arteritis and infarction in tuberculous meningitis. Majority of infarcts (71%) were seen in basal ganglia region. MCA territory was involved in majority (70%) of cases. MR angiography demonstrated narrowing due to vasculitis.

Understanding diagnostic student radiographer attrition in the UK

S.J. McAnulla, K.M. Knapp, S. Ball; *Exeter/UK* (S.J.McAnulla@exeter.ac.uk)

Purpose: Diagnostic student radiographer attrition is approximately 36%; however, little research has been undertaken on this subject. This study explored risk factors for attrition and strategies that enabled these to be overcome.

Methods and Materials: This was a two-phase study. Phase one: data for 579 student diagnostic radiographers (468 completers and 111 non-completers) from three UK universities were analysed. Logistic regression was used to estimate completion based on individual characteristics. Phase two: content analysis of data from an online survey of 168 current UK student diagnostic radiographers.

Results: Phase one: attrition was 19% in these data. Increased age, non-A-level entry qualifications and poor academic performance were discriminators for attrition ($p < 0.005$). Phase two: the challenges reported by the groups identified as being 'at risk' showed that for mature students, external responsibilities/pressures and financial pressures were likely to be the greatest cause of attrition and for younger students academic difficulty and workload were most significant.

Conclusion: Increased age appeared to be the greatest risk factor for attrition. The majority of non A-level entry students were mature and different challenges were reported by mature and younger students. For mature students, study may be compromised to accommodate external pressures. For the younger students, the qualifications may be a factor as many reported academic struggles. Poor academic performance may result from both of these situations, increasing the risk of attrition. For the majority, appropriate support was a factor in students' decisions to continue.

B-1699 14:17

Impact of a CT scan simulator on student learning

G. Photopoulos¹, J.G. Stowe², C. Buissink³, C. O'Halloran², M. Quinn², F. Tschan⁴, R. Verwoolde⁵, A. Dyhre Lia⁵; ¹Halifax, NS/CA, ²Dublin/IE, ³Groningen/NL, ⁴Lausanne/CH, ⁵Oslo/NO (gr627731@dal.ca)

Purpose: Radiographers who have a satisfactory understanding of computed tomography (CT) scan parameters positively impact patient dose and image quality. This study aims to assess the effectiveness of an interactive CT simulation tool on student radiographer learning regarding the relationship between CT scan parameters, patient dose, and image quality.

Methods and Materials: The sample population ($n=30$) chosen from a group of European radiography students was divided evenly into a quality control and intervention group. Every participant from each group was administered a questionnaire, designed to measure understanding of different scan parameters' effects on image quality and radiation dose. The intervention group underwent interactive CT training using a CT simulation tool; the quality control group was a baseline and did not receive any teaching. The next day, the questionnaire was re-administered to each participant.

Results: T test results demonstrate a statistically significant improvement in mean questionnaire scores for the intervention group increasing from 58.00% to 67.78% ($P=0.0000617$), while the quality control group's scores did not change from 61.56% ($P=1.00$). Further analysis demonstrated that the use of the intervention task significantly improved CT questionnaire scores ($P < 0.05$) in both understanding of image quality and patient dose concepts. There was some correlation between time taken to complete the intervention task and

improvement in scores, there was minimal correlation with CT experience, country of university, year of study, and time taken to complete questionnaires. **Conclusion:** The CT simulation tool demonstrates improved student understanding on how CT scan parameters affect patient dose and image quality.

B-1700 14:25

Mapping university skills labs in radiography: students' perspectives

K. Cronin¹, S.S. Ghotra², V. Harsaker³, M. Gillard², J. Fitzgerald¹, I. Kieft⁴, H. Sekkelsten⁵, O. Reynolds¹; ¹Dublin/IE, ²Lausanne/CH, ³Opppegård/NO, ⁴Groningen/NL, ⁵Oslo/NO (kevin.cronin@ucd.ie)

Purpose: Establishing an effective theory and practice relationship is necessary for every radiography student. The effectiveness of a skills lab (SL) is paramount to ensure student radiographers are prepared for clinical placement (CP). This study will map the perspectives of radiography students regarding the SL.

Methods and Materials: This study was a quantitative one with one qualitative element. A paper-based questionnaire was administered to 26 radiography students from Optimax summer school, who were from seven different countries, and the data were compiled in Excel. The questionnaire contained 3 closed questions concerning demographics, 6 closed questions regarding students' own SL, 3 of which were Likert scale questions, and 1 open question inquiring about how SL could be enhanced, according to students.

Results: Students indicated that a competent lab tutor, smaller group size and simulated patient interaction to be important factors in the SL. Additionally, environmental factors (light, temperature) were less important. Students mentioned that their equipment is of a lower standard than CP, but they also said that they feel well prepared for CP. Students found modern equipment not hugely important.

Conclusion: Students indicate that theoretical and practical skills labs prepare them well for CP. However, they suggest that a competent lab tutor and additional time are important factors in the SL.

B-1701 14:33

Active learning of exposure technique in digital radiography

S. Lewis, L.J. Hazell; Johannesburg/ZA (lynne@uj.ac.za)

Purpose: With increasing evidence of exposure creep in digital radiography, radiography students' understanding of exposure technique in digital radiography becomes paramount. Developing strategies to enhance this understanding is necessary. The purpose of this study was to explore active learning to assist in the understanding of related exposure creep in digital radiography.

Methods and Materials: A demonstration was designed to obtain four x-rays of a phantom hand using a constant kilovoltage, focal film distance, focal spot size, four-sided collimation and using the same computed radiography (CR) cassette. Only the milliamperes per second (mAs) was changed for each exposure. Students had to predict the outcome of each exposure prior to the CR cassette being read. After the CR cassette was read, students compared their predicted and the actual outcome. Dose-area products (DAP), exposure indicators and image quality for each exposure were also tabulated. Combining the documented results with theory, students critically evaluated and reported on the effect of mAs in digital radiography.

Results: Students observed that at 120 times the acceptable mAs with 144 times the DAP, a post-processed image would still be diagnostically acceptable. Students found that active learning challenged their understanding of exposure creep in digital radiography. Students predicted outcomes of exposure questioned their comprehension of the theory.

Conclusion: The demonstration allowed students to critically evaluate exposure technique in digital radiography through active learning. It was found to be effective in the understanding of exposure technique, exposure indicators, dose creep and the wide dynamic range in digital radiography.

B-1702 14:41

Integrating CT simulation into radiography undergraduate training

J.G. Stowe, C. O'Halloran; Dublin/IE (caimhe.o'halloran@ucdconnect.ie)

Purpose: The research will investigate the efficacy of integrating a new open-source CT scan parameter simulator into an undergraduate training programme as an active learning tool. Learning will be assessed across the themes of CT image quality and dose in the context of scan and reconstruction parameters. The use of the CT simulator will allow students to investigate the effects of scan parameter manipulation in a safe environment with no risk to patients.

Methods and Materials: A CT scan parameter simulator has been developed through a collaboration effort involving University College Dublin and the Western Norway University of Applied Sciences. This simulator has been successfully piloted as part of the OPTIMAX Research School 2018 in University College Dublin. A statistically significant improvement in performance was found in the pilot study and ethical approval was given to trial

it as part of an overall CT training module in an undergraduate Radiography programme. This semester will see the pilot tested on a cohort of over 50 students where its efficacy as part of an overall training module will now be assessed.

Results: Data from the results of the simulation active learning intervention will be assessed at the end of November using a paired sample T-test to assess if using the CT scan parameter simulation can generate a significant difference in the learning of CT image quality and dose topics.

Conclusion: Results will be available by December 2018 and it is envisaged that this will lead to pan-European trials in 2019.

B-1703 14:49

Peer-assisted learning to improve educational performance in radiography training

J.G.E. Du Plessis; Bloemfontein/ZA (duplesj@cut.ac.za)

Purpose: During a visit to Sweden in 2017, peer-assisted learning (PAL) was identified as an ideal strategy to address the shortcomings of supervision during clinical placement.

Methods and Materials: To explore the impact of PAL, the first cycle of an action research project was implemented in two undergraduate radiography modules at the Central University of Technology, Bloemfontein, South Africa. PAL was excluded in the first quarter of 2018 in the selected modules. After the first assessment in both modules, 'strong' students were identified to act as the mentors of 'struggling' students. A structured PAL strategy was then implemented during pre-scheduled sessions after each assessment and prior to the following assessment. The performance of mentors and mentees for each consecutive assessment was compared with the performance of the previous assessments to measure the impact of PAL.

Results: The results from the implementation of PAL revealed a significant increase in the students' combined average year-end results when compared to the mid-year results. These results also delivered a p value <0.05, showing a significant difference between mid- and year-end results. Surprisingly, all mentors also showed an increase in their own year-end results.

Conclusion: It is evident from the results that PAL, as an academic advising tool, holds the potential to become an integral part of curricula of programmes including clinical training. Due to the advantages evident from the results, the implementation of PAL in radiography curricula and other health science programmes could assist in enhancing success to previously struggling students.

B-1704 14:57

Factors influencing student radiographers' assessment of chest radiograph image quality

S. Heitmann¹, R. Toomey², M. Chen³, P. Pettka¹, M. Molehe⁴, M. Selau Junior⁵, K. Fernandes⁶, K. Davies⁷, J. Pires Jorge⁶; ¹Oslo/NO, ²Dublin/IE, ³Groningen/NL, ⁴Free State/ZA, ⁵Florianópolis/BR, ⁶Lausanne/CH, ⁷Prosperous/IE (soheitmann@gmail.com)

Purpose: Image quality assessment is a critical part of radiography, with the potential to influence patient radiation dose and outcome. Previous studies have shown cultural influences on image quality assessment. This study aimed to determine whether country of education, percentage of degree completed, or weeks of clinical experience influence student radiographers' decisions to accept or reject chest radiographs, with the goal of understanding what influences might shape attitudes to image quality.

Methods and Materials: 23 radiography students from Ireland, Netherlands, Norway and Switzerland were timed while accepting or rejecting 30 chest radiographs on the basis of image quality. Each participant then gave reasons for any rejections. The total time taken, reject rate and reasons for rejection were compared between students in earlier/late stages of their degrees, with more/less clinical experience, and from different countries using Mann-Whitney U and Kruskal-Wallis tests.

Results: None of clinical experience completed, percentage of degree completed or country of education influenced time taken to view the images (p>0.05). Participants with more clinical experience rejected more images than those with less (p=0.03). Swiss students rejected significantly fewer images on the basis of "exposure" than Irish (p=0.04) or Norwegian (p=0.03) students, although overall rejection rates did not differ significantly between countries (p>0.05).

Conclusion: Clinical experience influences student radiographers' assessment of chest x-ray image quality in terms of both rejection rates and reasons for rejection of images. Country of education also influenced reasons for rejection. This implies that cultural differences in clinical practice may shape students' behaviours.

B-1706 15:13

The opinions of American radiography educators on lead shielding use in conventional radiography

A. Wall¹, S.R. Kucharczyk², W. Hennessy³, M. O'Connor¹, J. McNulty¹;
¹Dublin/IE, ²Limerick/IE, ³Hamden, CT/US (alyson.wall@ucdconnect.ie)

Purpose: The requirement for lead shielding in conventional radiography has been questioned in recent years with varying protocols employed across clinical sites. A recent European-based study found lack of consensus in radiography educators' opinions concerning lead shielding use. The current work investigates the standpoint held by American educators on the matter.

Methods and Materials: An online survey was distributed to 608 radiography programme directors across the United States to investigate their opinions on lead shielding use in conventional radiography. Topics covered included: the literature influencing their teachings; whether shielding use is incorporated into student assessments; and observed practice regarding patient shielding in affiliated clinical sites.

Results: From a total of 130 respondents, 122 believed shielding provides the patient with an overall dose reduction with these opinions based on textbooks(60%), journal articles(31.5%) and professional experience(26.9%). Interestingly, 26%(n=34) felt shielding of patients over the age of 50 was unnecessary. Most respondents(73.9%;n=96) place equal importance on breast and gonadal shielding. 70.8%(n=92) indicated that protocols in affiliated clinical sites met the American Registry of Radiologic Technologists and American Society of Radiologic Technologists radiation protection practices, however, 84.6%(n=110) are of the opinion that more emphasis should be placed on breast shielding. 53.8%(n=70) reported that failure to use shielding resulted in automatic failure in clinical assessments while for the remainder, omission is not as severely penalised.

Conclusion: There is general consensus amongst American radiography educators that lead shielding of patients is important, which is reflected in their student assessments to varying degrees.

B-1707 15:21

Simulation-based learning to facilitate clinical readiness in diagnostic radiography: a metasynthesis

L.J. Hazell¹, H. Lawrence¹, H. Friedrich-Nel²; ¹Johannesburg/ZA,
²Bloemfontein/ZA (lynneh@uj.ac.za)

Purpose: The aim of this presentation is to present a metasynthesis to identify the attributes for facilitation of simulation-based learning for clinical readiness in a diagnostic radiography programme in South Africa.

Methods and Materials: A qualitative, metasynthesis was undertaken from the existing literature in English, which was retrieved from databases (Medline, CINAHL, Google Scholar and ScienceDirect). The keywords used were simulation-based learning in radiography, simulation-based education in radiography and simulation-based learning in nursing. The large volume of data was reduced to units of meaning. The metasynthesis used the following steps: develop a review question, develop a search strategy, extraction of themes from the literature, and metasynthesis of themes.

Results: Themes and categories were developed from the literature. Theme 1: an authentic and realistic situation which is relevant to the development of a professional in the context of the profession. Theme 2: building confidence in a safe, reliable and nurturing environment. Theme 3: active participation in a collaborative process.

Conclusion: The metasynthesis revealed three major themes that can be used as a framework to motivate for the use of simulation-based learning in a diagnostic radiography programme to facilitate clinical readiness. The strategies would need to stay true to the framework developed so that simulation-based learning can be designed to fit the contextual needs of this dynamic and unique profession.

Radiation risk from digital breast tomosynthesis screening: a comparison with full-field digital mammography

R.M.K. M. Ali¹, A. England², C.E. Mercer², A.K. Tootell², P.H. Hogg²; ¹Najaf/IQ,
²Salford/UK (P.HOGG@SALFORD.AC.UK)

Purpose: To compare the radiation risk from digital breast tomosynthesis (DBT) screening with that from full-field digital mammography (FFDM) screening.

Methods and Materials: To simulate compressed breasts, two perspex-polyethylene breast phantoms were used, one phantom for compressed breast in craniocaudal position and the other for compressed breast in mediolateral oblique. An adult ATOM dosimetry phantom was loaded with high-sensitivity thermoluminescence dosimeters; the phantom was then positioned on Hologic Selenia Dimensions mammographic machine to imitate DBT and FFDM screening. Organ radiation doses were measured from 4-view DBT screening and 4-view FFDM screening. Organ radiation doses were used to calculate effective dose from one screening session and the effective risk that could arise from a range of national screening programmes.

Results: Mean glandular dose (MGD) for DBT was 3.6mGy; MGD for FFDM was 2.8mGy. For DBT, other organ (e.g. thymus, lungs, salivary glands, thyroid, contralateral breast and bone marrow) radiation dose was also higher than for FFDM. The use of DBT for breast cancer screening increases the effective dose (E) of one screening session by 22%. E for DBT was 0.44mSv; E for FFDM was 0.34mSv. Similarly, the total effective risk during female's lifetime of different screening programmes was increased by 23%.

Conclusion: The use of DBT for breast cancer screening may increase the screening programme achievement and it also increases the radiation dose to screening clients.

B-1709 14:08

What criteria should be considered by radiographers while assessing the image quality of breast implant mammograms?

C. Sá dos Reis¹, I. Gremion², K. Schmidt², N. Richli Meystre²; ¹Perth/AU,
²Lausanne/CH (claudia.sadosreis@curtin.edu.au)

Purpose: To identify the most relevant image criteria that can be applied in the analysis of mammography exams performed in patients with breast implants (BI).

Methods and Materials: The study was conducted in 2 phases: i) literature review to find critical imaging criteria used to assess mammography exams; ii) assessment of 1207 BI mammograms to identify the appropriate criteria. A threshold of 75% of achievement was the cut-off to consider each criterion as applicable to CC, MLO and ML images. Descriptive statistics, chi-square test, independent t test, Pearson correlation were performed.

Results: 24 criteria considering positioning, exposure, sharpness and artefacts were identified during the literature review for normal mammograms. Applying those to BI mammograms, for 37.3% of CC images retroglandular fat was not included. Considering MLO and ML images, the "Pectoral-Nipple-Line" criterion was achieved in 35% of the images. The placement of the implant (retropectoral or retroglandular) or performing Ecklund manoeuvre had significant influence on the visible anatomy (p<0.005). The alignment of the breast in the middle of detector and the detector height (p<0.001) were considered highly relevant, having also impact on the amount of tissue displayed.

Conclusion: Part of the criteria used to assess normal mammograms is not applicable to BI imaging due to implant overlap. The alignment of the image in relation to detector's centre seems to have an impact on the amount of tissue visible to assess. Further studies are necessary to define how many projections, best technique to acquire the images and suitable quality criteria to adequately assess BI mammograms.

B-1710 14:16

The use of different angulation in mediolateral oblique view based on patient anatomy in mammography

A. Bedene, E. Alukic, J. Žibert, N. Mekis; *Ljubljana/SI (erna.alukic@zf.uni-lj.si)*

Purpose: The purpose of this research was to investigate if the quality of imaging in mammography can be maximized for patients with specific anatomy with the use of alternative (35° or 55°) angulation in mediolateral oblique (MLO) projection instead of standard projection with 45° angle.

Methods and Materials: 491 women were included in the study of different constitutional type, who undergone screening mammography at angle of 55° and 35°, and additional imaging (tomography) at an angle of 45°. Slovenian criterion (classification) were used to assess the quality of mammographic images. Three measurements were performed on the mammograms: the width of the pectoral muscle, the retromammary space (fatty tissue) and inframammary part of the breast.

Results: When comparing 45° and 55° angle all three measurements (the width of the pectoral muscle, the retromammary space and inframammary part of the breast) were statistically significant in favour of 55° angulation. 35° angle showed more retromammary and inframammary part of breast compared to the standard angle of 45°, both results were statistically significant. There was no statistically significant difference regarding the display of pectoral muscle between mentioned angulations.

Conclusion: The results showed that the use different angulation in MLO projection showed more diagnostically important breast tissue. We recommend the use of a 35° angle as more appropriate for patients with longer chest and small breasts and the use of a 55° inclination in short-term chest and large breast examiners.

B-1711 14:24

Indications and the outcome of the mammography at Douala General Hospital

N. Narcisse Fidele; *Douala/CM (nana_nar6@yahoo.fr)*

Purpose: This study aimed to list indications and results of mammography and/or breast ultrasounds at Douala General Hospital to determine the proportion of routine mammographic screening.

Methods and Materials: This descriptive cross-sectional study was carried out at Douala General Hospital using pre-established data sheets. The study recruited all patients who met the selection criteria and reported to the radiology and medical imaging department for breast screening using physical examinations, mammography and/or ultrasounds.

Results: The study recruited 372 patients, 96.8% of whom were between 40 and 50 years old. The reasons given for the medical consultation were systematic screening (33.01%), pain (27.18%) and lumps (25.24%). Breast examination by inspection was normal in 87.1% of women, and by palpation in 66.7%. Mammography revealed nodular opacities (18.3%), spiculated images (4.3%) and micro-calcifications (3.2%), while ultrasound identified fibroadenomas (16.48%) and cysts (6.18%). Suspicious lesions (ACR 4 and 5) were discovered in 7.6% of cases by mammography and 8.51% of cases by ultrasound. The results indicated that there was no significant association between the use of clinical examination and mammography ($p = 0.754$). The use of clinical examination alone for breast screening may not be sufficient.

Conclusion: Our findings indicate that in Cameroon, the routine screening mammography accounts for less than one-third (33.1%) of all indications. Benign lesions were most common; however, 7.6% and 8.51% of suspicious malignant lesions were observed using mammography and ultrasound, respectively.

B-1712 14:32

Early detection of breast cancer education via interprofessional E-learning: the EBreast project

E. Metsälä¹, T. Kukkes², K.M. Rannisto³, J. Pires Jorge⁴, A. Henner⁵, B. Ström⁶; ¹Helsinki/FI, ²Tartu/EE, ³Oys/FI, ⁴Lausanne/CH, ⁵Oulu/FI, ⁶Bergen/NO (eija.metsala@metropolia.fi)

Purpose: The project "Education and training in early detection of breast cancer for health care professionals" (EBreast) funded by EU was started in 2015 with the goal of studying and developing health care staff competencies related to early detection of breast cancer.

Methods and Materials: An evidence-based developmental method was applied for education and training in early detection of breast cancer for health care professionals (the EBreast project). The learning modules were evaluated according to the relevance of the content, technical quality and achievement of learning outcomes by health care students and professionals in the five European countries.

Results: Health care staff (biomedical laboratory scientists, midwives, nurses, public health nurses, radiographers) competency needs related to the breast cancer diagnostic chain focused on an interprofessional way of working and patient communication, on technical performance of mammography, and on related further examinations as well as on quality assessment. To achieve

these objectives, the learning material package was developed based on the evidence provided by expert opinion and research results.

Conclusion: Teaching multifaceted health care processes such as the diagnostic process of breast cancer interprofessional education is as means of ensuring client-centred high-quality services to the patient. The core benefit of open access E-learning is easily accessible material, regardless of time zone and geography, creating the opportunity for equity in education and harmonized health care practices in Europe.

B-1713 14:40

Acceptable quality dose for mammography: a guide for practitioners in developing countries

D.Z. Joseph; *Kano/NG (josephdlama@gmail.com)*

Purpose: Acceptable quality dose (AQD) is a reference dose value or suggested standard dose that is used as an optimisation tool capable of producing good quality images in diagnostic radiological examination. The purpose of the study is to evaluate the AQD for mammography in a Nigerian Hospital.

Methods and Materials: The study is a prospective cross-sectional study conducted in a Nigerian teaching hospital, 30 patients who came for mammography examination were enrolled in the study. Thermoluminescent (TLD-LiF) dosimeter chips were used for dose assessment for cranio-caudal and mediolateral oblique views while image quality was assessed using European guidelines. Analysis was carried out using Statistical Package for Social Sciences version 23.0 Chicago, USA.

Results: The result shows an average mean glandular dose (MGD) of 0.63mGy and a mean CBT of 1.95mm. The range of MGD for cranio-caudal view and mediolateral oblique (MLO) were 0.88mGy and 1.67mGy, respectively, and the range ESD for CC and MLO were 0.01-6.03mGy and 0.01-3.47mGy, respectively. Most patients' examinations were within acceptable quality doses with percentage score from 60% to 80% for doses and image quality assessment using European guidelines. Patient dose increased with increase in compressed breast thickness (CBT).

Conclusion: AQD has a number of inbuilt advantages because it considers crucial parameters in radiation dose estimation and useful for the formulation of optimisation guidelines and etiquette for countries and regions globally.

B-1714 14:48

Optimization of radiation doses and image quality for mammography examination

D.Z. Joseph¹, F. Nkubli², N. Christian³; ¹Kano/NG, ²Borno/NG, ³Anambra/NG (josephdlama@gmail.com)

Purpose: The purpose of the study was to evaluate mean glandular dose and compare with reference dose levels and determine the relationship between compressed breast thickness (CBT) and mean glandular dose (MGD). To assess the image quality in comparison with European Guidelines.

Methods and Materials: A total number of 30 dose values and mammogram of the patients was evaluated. IAEA dose survey was used for collecting data from records of mammography examination. Information such as patient age, weight, body mass index, compressed breast thickness and technical parameter (kVp, mAs, tube Filtration) and European Commission Image quality template was used for assessing image quality. Mean glandular dose (MGD) was calculated and statistical package for social sciences was used for analysis. Pearson's correlation was used to determine the relationship between CBT and MGD.

Results: The result shows an average MGD of 0.534 mGy and a mean CBT of 1.95 cm. The range of MGD for cranio-caudal (CC) and medio-lateral oblique (MLO) were 0.00-0.91 mGy and 0.00 - 1.67 mGy, respectively, and the range entrance skin dose for CC and MLO were 0.01-6.01 and 0.01-3.47, respectively. A correlation of 0.484 and 0.052 for CC and MLO respectively was gotten between the CBT and MGD. Image quality criteria fulfilled the requirement of European Guidelines with 80% total score.

Conclusion: The average of MGD was 0.53mGy. The MGD does not depend on the CBT. The images obtained are within acceptable limit

B-1715 14:56

A core curriculum for the breast radiographers working in Italy

S. Pacifici¹, P. Bindinelli², V. Galli³, A. Giacobbe⁴, D. Mariotti⁴, S. Pedilcarco⁵, S. Salimbeni⁶, G. Santucci⁷, D. Severi⁸; ¹Rome/IT, ²Verona/IT, ³Modena/IT, ⁴Forlì/IT, ⁵Milan/IT, ⁶Bologna/IT, ⁷Cesena/IT

Purpose: According with the EU Parliament Resolutions on Breast Cancer, all member States were invited to establish a network of certified and interdisciplinary breast units which meet Eusoma's requirements and quality criteria, in order to ensure that women with breast cancer have the right to be cured in centres that ensure quality and efficacy standards. A characterizing element of the Breast Units is the specialisation of the multi-disciplinary team

members. Eusoma guidelines indicate the Radiographer as a core-team member. Actually, due to the lack of a common European training standard, dedicated breast radiographers don't exist in Italy as in many others European countries. These premises have led to the establishment of the Senonetwork's Radiographers Working Group, in order to contribute to the development of breast radiographers and to support their role in the Italian Breast Units.

Methods and Materials: Review of the literature.

Results: Screening radiographers (mammographer) are distinguished from diagnostic breast radiographers. However, in the perspective of Breast Centres where converge first+second level screening, diagnostic, staging and follow-up, this distinction may be overcome, recognizing a single professional to fit this set-up: the breast radiographer.

Conclusion: Core curriculum of breast radiographers must be ensured after the basic training through courses to be carried out at Breast Centres or Regional Reference Centres, which programme is defined according with the EUSOMA recommendations. Senonetwork's Radiographers WorkingGroup, with the Training WorkingGroup and the Senonetwork's representative of radiology, proposes to harmonise the different proposals in order to promote a homogeneous training for the breast radiographers.

B-1716 15:04

Radiographers' competencies for pain management in mammography

M. Pettersson, E. Metsälä; *Helsinki/FI (eija.metsala@metropoli.fi)*

Purpose: Breast cancer is the most common cancer among women. Mammography is the most widespread method in diagnosing breast cancer and it is used as a screening technique as well as for breast cancer controls. It is widely known that mammography can cause pain, fear and anxiety and that can lead to patients avoiding the examination. The aim of this study was to identify radiographers' pain management competencies and educational needs in mammography and, also to find information to make a local pain management model of care.

Methods and Materials: The data for the thesis was collected with an electronic theme writing form from the radiographers (n=12) of the department of interest. Radiographers participating in the study were selected with discretionary sample. The data was analyzed with inductive content analysis. During the analysis was found such information that there was a need for an additional research question.

Results: Based on the analysis radiographers are aware that mammography can cause pain and they know how to decrease that pain, fear and anxiety. Nevertheless, they don't always associate their competencies with pain management because of non-medical aspect of care. Radiographers feel that they have limited possibilities of pain-relieving during mammography due to the limited time for each patient. The results suggest that radiographers' knowledge about pain management methods should be improved.

Conclusion: Based on the analysis there can be found many educational needs and challenges too. Both educational institution and organization must increase the volume of mammography courses and education.

B-1717 15:12

Women's experience of pain in screening mammography

T. Wathén, K. Paalimäki-Paakki, A. Henner; *Oulu/FI (anja.henner@oamk.fi)*

Purpose: Breast cancer is the most common cancer of women. That is why it is important to detect in early phase with screening. Women are often afraid of mammography due to pain and discomfort. The purpose of this study was to describe women's experience of pain and unpleasant feelings during screening mammography.

Methods and Materials: A questionnaire was given after examination to all women participating in screening mammography in one hospital mammography unit during two weeks: one week in November 2017 (older group was invited to screening) and one week in February 2018 (those coming first time). Data were analysed in Excel.

Results: Totally 167 (61%) women returned the questionnaire, 45% aged 49 to 54 years and 43% 65 to 69 years. 21% participated first time to screening program and more than half of them were afraid of pain in advance. Half of the participants found the examination to be slightly painful and 10% rather painful. Women want to discuss with the radiographer during the examination: what is happening in examination, importance of the compression, impact to the compression force used and about possible feelings of pain. Discussion and friendliness/politeness decreases women's experience of pain. Women prefer counselling for breathing during the compression and kind words from the radiographer instead of pain medication.

Conclusion: Professional radiographer in screening mammography is empathic, peaceful, and kind, listens to the woman and explains the examination process and possibility of pain. It is also important to allow the possibility to ask and tell woman's own opinions and feelings.

B-1718 15:20

Scanxiety in follow-up breast cancer women

S. Pacifici, D. Giudice; *Rome/IT*

Purpose: br />**Methods and Materials:** Review of the literature on both follow-up scans related posttraumatic stress disorders and on the effects of non-empathetic, non-compassionate behaviors.

Results: Beside the uncertainty of the test results, the root of scanxiety is thought to be related to the amount of time that elapses between when the test is performed and the results known. However, scanxiety might not be entirely related to the examinations, but also to patient's approach and lack of compassion from healthcare professionals

Conclusion: As being diagnosed with cancer is hard enough, we need to do all we can do to make the patient journey less stressful .

Cancer care providers and healthcare professionals would seriously consider scanxiety, as it may even cause patients to delay medical examinations and other critical parts of their cancer treatment or post-treatment plan. Breast radiographer's skills should not just related to physics or image acquisition techniques.

Additional skills related to communication, team roles, efficiency, critical thinking and patient experience are strongly recommended, as they allow us to be able to help patients reduce scanxiety.

Additive value of dual energy (DE) acquisition in CT follow-up of endovascular aortic repair (EVAR or TEVAR)

G. Agliata¹, N. Schicci², P. Esposto Pirani¹, C. Tagliati¹, A. Giovagnoni¹; ¹Ancona/IT, ²Fabriano/IT (agliata.g@gmail.com)

Purpose: Evaluating the added value of DE technique acquisition in early endoleak detection in TEVAR/EVAR CT follow-up.

Methods and Materials: 82 patients (55M and 27F; mean age 70±5 years) treated with TEVAR or EVAR, underwent DECT scans using a III generation DECT (Somatom Force, Siemens Healthcare). All the scans were obtained using a standard protocol constituted of an angiographic phase, with a delay assessed through bolus-test technique, and a late DE acquisition with 60 seconds of delay from the angiographic phase. Unenhanced images were obtained from the DE late phase. A radiologist with five year of experience in CT angiography, reviewed the images to detect potential endoleak (and its features, such as localization, extent and supply vessel). Firstly native CT images were evaluated. Then, independently, was performed a post-processing analysis of DE phase dataset and qualitative and quantitative assessment of iodine distribution were performed.

Results: Native CT images evaluation allowed detection of 25 endoleaks (30.5%; 44% type I and 56% type II); post-processing evaluation of DE iodine distribution maps allowed detection of 29 endoleaks (35%; 38% type I; 62% type II).

Conclusion: DE technique acquisition and post-processing analysis increases CT diagnostic value in EVAR/TEVAR follow-up, allowing demonstration of small endoleaks (especially type II ones) unrecognized in native images evaluation.

B-1720 14:08

Prospective single-centre study to evaluate artifacts using CEUS in follow-up after EVAR: possible adverse effects on endoleak detection in comparison with CTA

F. Frenzel¹, R. Kubale², J. Stroeder¹, A. Massmann¹, P. Jagoda¹, A. Bucker¹, P. Minko¹; ¹Homburg/DE, ²Pirmasens/DE (felix.frenzel@uks.eu)

Purpose: The aim of this study is to prospectively detect, categorize and interpret relevance of artifacts of contrast-enhanced ultrasound (CEUS) used in follow-up after endovascular aortic repair (EVAR) for detection of endoleaks and postinterventional control.

Methods and Materials: 76 Patients underwent EVAR between 11/2012-06/2017 including complex cases (n=22) with reconstruction of iliac-bifurcation, chimneys as well as mycotic aneurysms using six different stent graft vendors. Patients were followed up (mean 417 days) with CT-Angiography (CTA)

(n=257) and CEUS (n=135). CEUS was performed blinded to the results of CTA using an Acuson S2000 or S3000 (Siemens Healthcare, Germany) and i.v. application of sulphur hexafluoride (SonoVue, Bracco, Italy). Corresponding pairs of CTA /CEUS examinations were reviewed retrospectively a second time by two experienced radiologists.

Results: 55 patients (9 females; mean age 72.5±8.4) had 97 simultaneous CTA/CEUS examinations. Artifacts were seen in 59% of cases: 22% contrast-agent related, 22% post-interventional, 9% attenuation artifacts, 3% ultrasound scanner- and 3% stent graft-specific artifacts. Endoleaks were detected by CEUS in 56% and by CTA in 48% of cases. Mismatch in detection of endoleaks was observed in 9%, in 4% related to artifacts in CEUS (1 false-negative and 3 false-positive). In 5%, CEUS proved advantageous over CTA through dynamic assessment of late endoleaks or beam hardening artifacts in CTA caused by embolization materials.

Conclusion: CEUS has a high ability to detect endoleaks after EVAR, comparable or even superior to CTA. However knowledge of possible artifacts is essential to interpret imaging during CEUS correctly.

B-1721 14:16

Quantitative analysis of dynamic CTA for the detection of endoleaks after abdominal aorta aneurysm endovascular repair: a feasibility study

M.J. Bauer¹, F. Lavra², M. Scarabello³, M. van Assen⁴, L. Saba², C.N. De Cecco¹, U.J. Schoepf¹; ¹Charleston, SC/US, ²Cagliari/IT, ³Milan/IT, ⁴Groningen/NL (email@bauermaximilian.de)

Purpose: To assess the feasibility of quantitative analysis of dynamic computed tomography angiography (dCTA) for the detection of endoleaks in patients who underwent endovascular repair of abdominal aortic aneurysms (EVAR).

Methods and Materials: Twenty patients scheduled for contrast-enhanced CT angiography (CTA) of the abdominal aorta post-EVAR were prospectively enrolled. All patients received a standard triphasic CTA protocol followed by a dCTA acquisition. In addition to visual assessment of time-resolved images, the dCTA acquisition enabled reconstructions of color-coded maps depicting blood perfusion (dynamic CT perfusion, dCTP). Observers assessed the dCTA and dCTP images for the detection of endoleaks and indicated their diagnostic confidence based on a modified 5-point Likert scale (1 - certain absence, ..., 5 - certain presence of endoleaks).

Results: In total, 9 endoleaks were detected in 7 patients using triphasic CTA as the reference standard. There was complete agreement for endoleak detection between the two techniques on a per-patient basis. Both dCTA and dCTP identified an additional potential endoleak in one patient. Moreover, dCTP demonstrated superior diagnostic confidence for endoleak exclusion compared to dCTA (1.0 [1 - 1] vs 1.5 [1.5 - 1.5], respectively; p < 0.01).

Conclusion: Quantitative analysis of dCTA data in form of dCTP is feasible and can aid in the detection of endoleaks demonstrating a strong correlation with visual assessment of dCTA images. Moreover, our findings suggest that analyzing dCTP imaging data has the potential to increase the endoleak detection rate compared to the assessment of triphasic CTA images as the current clinical standard method.

B-1722 14:24

Flow volume of the abdominal visceral arteries increase after EVAR treatment

M. Sugiyama¹, Y. Takehara², M. Alley³, N. Unno¹, K. Katahashi¹, T. Wakayama⁴, A. Nozaki⁴, S. Naganawa², H. Sakahara¹; ¹Hamamatsu/JP, ²Nagoya/JP, ³Stanford, CA/US, ⁴Hino/JP (m-sugi@hama-med.ac.jp)

Purpose: Endovascular aneurysm repair (EVAR) is widely performed to prevent abdominal aortic aneurysm (AAA) from rupture. EVAR may also repair deformed blood pathway and relieve blood flow energy loss caused by non-laminar flow. This may provide more efficient blood delivery to the visceral arteries. In the present study, we aimed to evaluate the hemodynamic changes of the abdominal visceral arteries after EVAR treatment within AAA patients using 3D cine PC MR imaging (4D-Flow).

Methods and Materials: 10 patients (67 to 80 y.o.) with AAA underwent 4D-Flow covering whole abdominal aorta within the period of 1 year before and after EVAR treatment. All the MR studies were conducted on 3.0T MR imagers. Time resolved contrast enhanced 3D MR angiography was performed for the segmentation of the aorta. The acquired 4D-Flow data was postprocessed using a flow analysis software (Flova II, R'tech, Japan). The flow volume were measured at the cross sections of the following arteries; celiac artery (CA), superior mesenteric artery (SMA), and renal arteries (RA). Each datasets consisted of flow volume data of 20 phases per cardiac cycle. The flow volume of the visceral arteries at each cardiac phase between pre- and post-EVAR condition were statistically analyzed using Wilcoxon's signed-rank test.

Results: Significant increase of the flow volume in CA and SMA were observed at mid-diastole.

Conclusion: Flow volume of the SMA and CA increased after EVAR treatment for the AAA patients. This may be reflecting the repair of blood flow passage by EVAR and more efficient blood delivery.

Cumulative radiation dose from contrast-enhanced CT in follow-up after EVAR

S. Magnani, G. Mauri, G. Di Leo, R.M. Trimboli, D. Poretti, L.M. Sconfienza, F. Sardanelli; Milan/IT (dr.smagnani@gmail.com)

Purpose: To estimate the average cumulative radiation dose deriving from contrast-enhanced computed tomography (CT) examinations in patients treated with endovascular aneurysm repair (EVAR).

Methods and Materials: After Ethics Committee approval, records of 110 patients (105 males, 5 females; age 75±7 years [mean±standard deviation]) who underwent EVAR between March 2000 and May 2008 were retrospectively analyzed. The number of CT scans performed in each patient from March 2000 to May 2015 was retrieved. The mean effective dose deriving from abdominal, thoracic or thoraco-abdominal CT scan was derived from another sample of 30 patients. The patient cumulative effective dose was calculated by summing up all radiation doses from each single examination.

Results: During a median follow-up of 25 months (interquartile range [IQR] 10-69 months), these patients underwent a median of 7 CT scans overall; 4 (IQR 2-8) abdominal scans, 2 (IQR 1-4) thoracic scans, and 4 (IQR 2-5) thoraco-abdominal scans. The median cumulative effective dose was 205 mSv (IQR 126-367 mSv) overall; 18 mSv (IQR 9-36 mSv) for thoracic scans, 132 mSv (IQR 66-264 mSv) for abdominal scans, and 160 mSv (IQR 80-200 mSv) for thoraco-abdominal scans. The maximal cumulative effective dose was 1,166 mSv in a patient who underwent 38 CT examinations during a 54-month follow-up.

Conclusion: Patients treated with EVAR underwent multiple serial CT follow-up examinations, thus receiving a very high cumulative radiation dose.

B-1724 14:40

Low tube voltage and low contrast media volume multidetector CT angiography in evaluation of abdominal aorta in EVAR follow-up: a comparison study

E.G.M. Antonuccio, S.J. Vasquez Cuadra, S.P. Pirillo, L. Tipaldi; Rome/IT (dr.gabrieleantonuccio@gmail.com)

Purpose: To compare ionizing radiation dose delivered, image quality and diagnostic performance of Multidetector CT Angiography (MDCTA) of the abdominal aorta after EVAR and arterial splanchnic vessels in two different acquisition protocols: low tube voltage plus low dose contrast medium (CM) protocol (A) versus conventional protocol (B) in the same patients.

Methods and Materials: 40 Patients (26 M; 14 F) referred to MDCTA of the abdominal aorta in follow-up after EVAR, who had undergone conventional protocol (64-slices scanner; 120-kVp, automatic mA, 100mL iomeprol [400mg iodine/mL] @4mL/sec i.v. - B), were enrolled in our single-center prospective randomized study in order to compare conventional protocol to low dose protocol (64-slices scanner; 80-kVp, automatic mA, 40mL iomeprol [400mg iodine/mL] @4mL/sec i.v. - A).

Results: No significant differences were noted in terms of image quality with either axial source images, multiplanar reconstructions or volume rendering images; no significant differences were found among the two protocols in terms of noise throughout aortic stent or vessels ramifications features, moreover DLP in protocol B (531,3±67,9 mGy-cm) was about 1/3 compared to protocol A (1536,1±233,1 mGy-cm) (p<0,0005).

Conclusion: Reducing simultaneously tube voltage and CM volume determines significative dose reduction to the patient without compromising images quality and diagnostic performance of MDCTA in EVAR follow-up.

B-1725 14:48

Spectral imaging on a 80 mm wide-detector CT with fast kVp switching for follow-up CT angiography after EVAR planning: image quality, radiation dose and ultra-low volume contrast medium

P. Hou; Zhengzhou/CN (houping1221@163.com)

Purpose: To investigate the feasibility of reducing radiation exposure and CM dose in follow-up CTA after EVAR through the joint application of spectral imaging and ASIR-V.

Methods and Materials: The conventional protocol with kV Assist scan and CM volume of 60 ml was applied in control group A. The ultra-low dose protocol which performed GSI scan with CM volume of 0.6 ml/kg was utilized in study group B. Group A included TUE images, arterial phase. While in group B,

VUE images and 60 keV data with 50%ASIR-V set were automatically reconstructed from AP. CT values and CNR of aorta and its branches for TUE and VUE images and AP images were obtained and compared.

Results: No significant difference in image quality was found between TUE 4.32 ± 0.53 and VUE 4.21 ± 0.51 images ($P > 0.05$). VUE images had higher image noise than TUE images ($P < 0.001$). For AP images, group B had equivalent subjective scores and CT values as Group A, whereas they had higher or equivalent CNRs. Group B had 30.3% and 21% reductions on CM volume and injection rate, respectively, than Group A. The effective dose for group A was $20.5 \text{ mSv} \pm 4.2$ and that for group B was $12.6 \text{ mSv} \pm 2.7$.

Conclusion: Monochromatic images of 60keV in spectral aortic CTA can minimize the amount of CM and injection rate but without sacrifice image quality, and VUE images as an alternative to TUE images, can provide comparable image quality and reduced the radiation dosage.

B-1726 14:56

Split-filter dual-energy CT: value of advanced monoenergetic reconstructions for the assessment of vessel stents

E. Appel, C. Thomas, Y. Klosterkemper, J. Aissa, G. Antoch, J. Boos; Düsseldorf/DE

Purpose: To assess the effect of split-filter dual-energy CT advanced virtual monoenergetic reconstructions (VMI) on in-stent lumen visibility and image quality.

Methods and Materials: Nine different peripheral vessel stents were placed in a phantom, filled with iodine and examined using a split filter dual-energy CT scanner. Image reconstructions of linearly mixed images (Au/Sn) for 120kV were performed using three different kernels (I46f, Q33f, D33f). VMI and advanced VMI for ten different virtual photon energy levels (40-130keV) were reconstructed. In-stent lumen diameter, artefact width, image noise and lumen density for all reconstructions were assessed using a semiautomatic software tool. Image quality was assessed through signal-to-noise ratio (SNR) and a 5-point Likert scale (1=poor, 5=excellent). Digital angiography served as reference standard for diameter measurements. Standardization with Z-scores was performed to assess the optimal VMI virtual photon energy level.

Results: Advanced VMI led to the highest overall in-stent lumen diameter at 130keV which was significantly higher than AuSn/I46f (3.7 ± 0.5 vs. 3.4 ± 0.4 ; $p < 0.002$). SNR was comparable between AuSn/I46 at 120keV and advanced VMI at 70 keV (11.4 ± 1.0 vs. 11.6 ± 1.3). Averaged over all reconstructions, both readers reported significantly higher image quality for advanced VMI compared with conventional VMI reconstructions (3.8 ± 1.1 vs. 2.3 ± 1.1 , $p = 0.005$) with optimal subjective image quality for advanced VMI at 80 keV (4.6 ± 0.6). Overall, advanced VMI reconstructions at 70 keV were found to be optimal as determined by the Z-score analysis.

Conclusion: Advanced VMI reconstructions at 70 keV are optimal for the imaging of vessel stents in split-filter dual-energy CT.

B-1727 15:04

Comparison of automated software diameter/square detection with radiologist visual assessment for 70% stenosis on coronary CT angiography

S. Hu, W. Peng, Z. Li; Chengdu/CN

Purpose: To explore the feasibility of software automated detection of coronary 70% stenosis using diameter/square-method in comparison of manual evaluation.

Methods and Materials: Fifty-eight patients both underwent CCTA and invasive coronary angiography were retrospectively included. A binary approach (70% stenosis as a cutoff) was used to grade the stenosis severity. For software, all CCTA data sets were analyzed using GE AW Volume Share 5 (AW4.6) product. Double references were selected and corresponding reference diameter/square values were obtained from an automatic trend analysis of coronary artery. As for human manual analyses, axial images, multiplanar reformations and maximum intensity projections in free double-oblique planes were interpreted. Wilcoxon rank-sum test and McNemar test were performed to compare the differences between two groups.

Results: Of the 58 patients (44 men, mean age 65.16 ± 9.64 years), 179 vessels were analyzed. For both per-patient and per-vessel evaluations, the software square detection revealed best sensitivity (100% and 95.31%, respectively) and negative predictive value (NPV) (100% and 96.91%, respectively). Software diameter detection showed highest specificity (SPE) and positive predictive value (PPV), with SPE of 85.71% and PPV of 90.01% for patient-based analysis, SPE of 93.86% and PPV of 88.71% for vessel-based analysis. The significant differences between human reading and software diameter detection ($P = 0.013$) / square detection ($P < 0.001$) were found.

Conclusion: Compared with human diagnosis, both the diameter and square automated detection algorithm have relatively higher accuracy for diagnosing 70% coronary artery stenosis. AW4.6 tool showed an improved evaluation distinguishing the "severe" stenosis that must be implanted stents.

B-1728 15:12

Non-contrast magnetic resonance imaging in the follow-up after endovascular aortic repair

G. Lastella¹, P.M. Cannò², M. Ali¹, F. Secchi², F. Sardaneli¹; ¹Milan/IT, ²San Donato Milanese/IT (giulia.lastella@unimi.it)

Purpose: The aim of this study is to define the diagnostic accuracy of noncontrast MRI with CT as reference standard in the follow up of patients treated with endovascular aortic repair (EVAR).

Methods and Materials: Forty-two patients after EVAR for aortic and/or iliac arterial aneurysms were prospectively enrolled and underwent MRI and contrast-enhanced CT in the same day between 0,01 and 1,55 years after the implantation. MRI was focused on true fast imaging with steady-state free precession (TRUFI) and half-Fourier-acquisition single-shot turbo spin-echo (HASTE) sequences at the precise level of the vessel where EVAR was implanted. CT was performed before and after iodate contrast injection. Two independent observers reviewed MRI to evaluate the presence of hyperintensity near the EVAR. Then, they evaluated in CT images the presence of endoleak and classified them according to Stanford classification in type I (a,b) and II.

Results: MRI revealed that 11 patients had no hyperintensity, and no one of these had endoleak in CT images. 31 patients presented hyperintensity in MRI, and 19 of these revealed a presence of endoleak (6 type I, 13 type II). Sensitivity, specificity, positive predictive value and negative predictive value were 100% (19/19), 48% (11/23), 61% (19/31) and 100% (11/11) respectively. Positive likelihood ratio was -1.9 and negative likelihood ratio was 0.52.

Conclusion: The absence of hyperintensity near the EVAR in MRI images can exclude the presence of endoleak; nonetheless the hyperintensity can correlate with the presence of endoleak and require CT with iodate contrast to confirm it.

B-1729 15:20

Evaluation of blood pressure variations on CTA geometries of abdominal aortic aneurysms

R.C. Aydin¹, F. Bräu², M. Notohamiprodjo³, J.E. Roos⁴, S. Leng⁵, E.E. Williamson⁵, K. Nikolaou³, C.J. Cyron⁶, R.P. Marcus⁷; ¹Geestacht/DE, ²Munich/DE, ³Tübingen/DE, ⁴Lucerne/CH, ⁵Rochester, MN/US, ⁶Hamburg/DE, ⁷Luzern/CH (roland.aydin@gmail.com)

Purpose: To assess the relationship between blood pressure variations and the abdominal aorta aneurysm geometry using CTA imaging and computational simulation of the mechanical properties of the vessel wall.

Methods and Materials: Fifty adult patients with known abdominal aorta aneurysms underwent contrast enhanced CT-examinations on a 3rd generation dual-source-CT (SOMATOM Force, Siemens Healthcare). Blood pressure was measured upon admission as per the standard protocol, during imaging procedure and at same hours at home following discharge. The mean arterial pressure (MAP) values and its maximal variations were recorded. The impact of these changes in vessel diameter and volume was estimated analytically using an idealized cylinder geometry and stiffness parameters from a range of established aortic wall properties. The aneurysm geometry data and the widest MAP differences were submitted to a finite element analysis to model the changes predicted by the analytical estimate.

Results: The average difference between MAP readings during scanning and at home was 9.1 mmHg (10.8%) with a maximum of 31.2 mmHg (23.7%). This resulted in an aneurysmal difference in diameter of 0.08-0.22% (0.19-0.63% for the maximum MAP difference). Comparing MAP during the imaging process and at hospital admission, the average relative difference was 10.6% (9.4mmHg), with a maximum of 29.5% (27.7mmHg). The difference in the aneurysmal diameter was 0.07-0.21% (0.18-0.60% for the maximum MAP difference).

Conclusion: CTA images of abdominal aorta aneurysms for measurement of its diameter and data from mechanical simulations such as finite elements analysis are insensitive to the timepoint of blood pressure measurement.

Machine learning classification of spinal lesions: compared accuracy of texture parameters extracted by different software

V. Chianca¹, D. Albano¹, R. Cuocolo², C. Messina¹, S. Gitto¹, A. Corazza³, I. Merli¹, A. Brunetti², L.M. Sconfienza¹; ¹Milan/IT, ²Naples/IT, ³Genoa/IT (vitochia@hotmail.it)

Purpose: To compare the accuracy of machine learning (ML) algorithms for classification of spinal lesions based on texture analysis (TA) parameters extracted by different software from unenhanced Magnetic Resonance images (MRI).

Methods and Materials: We retrospectively enrolled 146 patients with 146 spinal lesions (49 benign, 57 metastatic and 40 primary malignant lesions) imaged using MRI. Of them, 117 were histopathologically confirmed after surgery while 29 benign lesions were confirmed by follow-up. Patients were randomly divided in training (n=100) and test groups (n=46), respectively for classification model development and testing. Lesions were manually segmented on T1-weighted and T2-weighted images by drawing a bi-dimensional polygonal region of interest. These were used for first order and texture feature extraction on two software, 3D-Slicer heterogeneity CAD module (hCAD) and Pyradiomics. For each of them, different data subsets, obtained by four feature selection methods were analyzed by 9 ML classification algorithms to evaluate their accuracy in identifying benign vs. malignant lesions and benign vs. primary malignant vs. metastatic lesions.

Results: In the test group, a random forest algorithm correctly classified 89% of lesions as benign or malignant, based on hCAD TA, while a Support Vector Machine could achieve an accuracy of 87% from Pyradiomics TA. For the classification of benign, primary malignant and metastatic lesions, RF models accurately classified 70% of lesions for both TA software.

Conclusion: ML algorithms show good accuracy in spinal lesion classification based on non-contrast MRI exams. Furthermore, feature extraction performed using different software has shown consistent results at subsequent ML analysis.

A triple-classification radiomics model for the differentiation of primary chordoma, giant cell tumour, and metastatic tumour of sacrum based on magnetic resonance imaging

P. Yin, N. Hong; Beijing/CN (yinping915@pku.edu.cn)

Purpose: To develop and validate a triple-classification radiomics model for the preoperative differentiation of sacral chordoma (SC), sacral giant cell tumour (SGCT), and sacral metastatic tumour (SMT) based on T2-weighted fat saturation (T2w FS) and contrast-enhanced T1-weighted (CE T1w) magnetic resonance imaging (MRI).

Methods and Materials: 120 pathologically confirmed sacral patients were retrospectively analysed and divided into a training set (n=83) and a validation set (n=37). Morphology, intensity and texture features were assessed based on formfactor, Haralick, grey-level co-occurrence matrix (GLCM), grey-level run-length matrix (GLRLM) and histogram. Analysis of variance (ANOVA), least absolute shrinkage and selection operator (LASSO), Pearson correlation, random forest (RF), area under the receiver operating characteristic curve (AUC) and accuracy analysis were used to build and validate our model.

Results: The median age of SGCT (33.5, 25.3-45.5) was significantly lower than those of SC (58.0, 48.8-64.3) and SMT (59.0, 46.3-65.5) groups ($\chi^2=37.6$, $P<0.05$). For the differential value, features extracted from joint T2w FS and CE T1w images outperformed those from T2w FS or CE T1w images alone. Compared to CE T1w images, features derived from T2w FS images yielded higher AUC in both training and validating set. The best performance of radiomics model based on joint T2w FS and CE T1w images reached an AUC of 0.773 and an accuracy of 0.711.

Conclusion: Our 3.0T MRI-based triple-classification radiomics model is feasible to differentiate SC, SGCT, and SMT, which may be applied to improve the precision of preoperative diagnosis in clinical practice.

B-1732 14:16

Comparison of radiomics nomograms for the differentiation of sacral chordoma and sacral giant cell tumour based on 3D computed tomography and multiparametric magnetic resonance imaging

P. Yin, N. Hong; Beijing/CN (yinping915@pku.edu.cn)

Purpose: To compare radiomics nomograms based on 3D computed tomography (CT) and multiparametric magnetic resonance imaging (mpMRI) for the preoperative differentiation of sacral chordoma (SC) and sacral giant cell tumour (SGCT).

Methods and Materials: 83 SCs and 54 SGCTs patients with histologically proven were retrospectively analysed. All patients underwent CT [CT and CT enhancement (CTE)] or mpMRI [T1-weighted, T2-weighted, diffusion-weighted imaging (DWI) and contrast-enhanced T1-weighted sequences] scans before surgery. We built six models based on each scan and four nomograms based on fused scans combined with or without clinical data. The area under the receiver operating characteristic curve (AUC) and accuracy (ACC) analysis were used to assess the performance of radiomics models. Decision-curve analysis was used to assess the clinical usefulness of nomograms.

Results: Age, sex and tumour location had significant difference between SC and SGCT ($t_{age}=9.00$, $\chi^2_{sex}=10.86$, $\chi^2_{location}=26.20$, $P<0.01$). For individual scan, radiomics model based on DWI features had the highest AUC of 0.889 and ACC of 0.885 in validating set, followed by CT (AUC=0.857, ACC=0.846) and CTE (AUC=0.833, ACC=0.769). For fused scan, CT fused scan had a better AUC of 0.942 and ACC of 0.880, while MR fused scan achieved a lower performance than individual scan. Clinical-radiomics nomogram based on CT fused scans achieved the highest AUC of 0.948 and ACC of 0.920.

Conclusion: Radiomics model based on CT and mpMRI has a certain predictive value in distinguishing SC and SGCT, but CT fused features are more recommended. Radiomics nomograms perform better when combined with clinical data.

B-1733 14:24

Texture analysis for quantitative evaluation of central lumbar spinal stenosis

F.A. Huber, S. Stutz, I. Vittoria De Martini, M. Mannil, A.S. Becker, S. Winklhofer, J.M. Burgstaller, R. Guggenberger; Zurich/CH (florian.huber@usz.ch)

Purpose: To investigate the use of texture analysis (TA) in detection and grading of lumbar spinal stenosis (LSS) in MRI.

Methods and Materials: 343 images of 82 patients from a nationwide LSS cohort study, undergoing MRI of the lumbar spine due to neurogenic claudication, with a single-level severe central LSS were included (1-5 images of levels L1-S1 per patient). One expert radiologist as reference standard rated LSS according to a standard four-point (normal-severe) and to eight-point Schizas grading scale additionally evaluating epidural fat. Two independent readers analogously performed qualitative ratings and additionally performed TA in all images by placing two regions of interest (ROI): (1) dural sac only, (2) additionally including epidural fat and bilateral recesses. Interreader agreements for qualitative and quantitative parameters were calculated. TA parameters with intraclass correlation $<.75$ were excluded for feature reduction. Remaining features were analysed with machine learning (ML) algorithms (Weka 3) for correlation with LSS grades using test and training data sets and 10-fold cross-validation.

Results: Qualitative ratings showed moderate reproducibility for both LSS classification systems, but high correlation with cut-off cross-sectional area (CSA) $<130\text{mm}^2$ for severe LSS (AUC=.722-.916). For both ROIs, ML-evaluation of TA with a decision tree classifier revealed higher performances for LSS grading compared to qualitative assessments using the reference CSA cutoff, respectively.

Conclusion: Qualitative grading of LSS is moderately reproducible. ML-supported TA reveals highly reproducible quantitative features that increase diagnostic performance for severe LSS detection, with minor impact of grading score and CSA border definition.

B-1734 14:32

Evaluation of osseous cervical foraminal stenosis in spinal radiculopathy using susceptibility-weighted magnetic resonance imaging

G. Engel, Y.Y. Bender, L.C. Adams, S.M. Böker, U.L. Fahlenkamp, G. Diederichs, M. Wagner, B. Hamm, M.R. Makowski; Berlin/DE

Purpose: The aim was to evaluate the diagnostic performance of susceptibility-weighted magnetic resonance imaging (SW-MRI) for the evaluation of osseous foraminal stenosis (FS) of the cervical spine compared to conventional MRI-sequences, using computed tomography (CT) as a reference standard.

Methods and Materials: Twenty-one patients with radiculopathy of the cervical spine were prospectively included. CT and MRI data sets were available for all patients. As standard of reference, 280 neuroforamina of the cervical spine, including 58 stenosis, were identified on CT-images. T1-, T2-

and SW-MRI were performed. The presence of FS was assessed in all sequences. Sensitivity and specificity were calculated and differences in detection rate and severity scoring of FS were tested. CT was used as reference standard for all analysis.

Results: 56 of 58 FS could be correctly identified on SW-MR magnitude images. SW-MRI achieved a sensitivity of 96.6% and specificity of 99.5% for the identification of osseous FS. Conventional T1-weighted MRI sequences achieved a sensitivity and specificity of 43.1% and 100% and T2-weighted MRI sequences a sensitivity and specificity of 65.5% and 99.1%, respectively. The overall detection rate was significantly ($p < 0.05$) higher on SW-MRI. There was no significant difference ($p > 0.05$) in severity scoring compared to CT. T1- and T2-weighted MRI underestimated the degree of osseous FS. Intermodality and interobserver agreement were highest for SW-MRI.

Conclusion: SW-MRI enables the detection of osseous FS of the cervical spine in patients with spinal radiculopathy with a higher sensitivity compared to conventional T1- and T2-MRI sequences, with CT as a reference standard.

Advantages of T2* relaxation time with ultra-short TE on intervertebral disc degeneration

H. Takashima¹, M. Yoshimoto¹, R. Imamura¹, Y. Akatsuka¹, M. Nakanishi¹, M. Yoneyama¹, M. Hatakenaka¹, T. Yamashita¹; ¹Sapporo/JP, ²Tokyo/JP (takashima@sapmed.ac.jp)

Purpose: To investigate the association of intervertebral disc (IVD) degeneration with T2* relaxation time using ultra-short TE (UTE).

Methods and Materials: This study included 50 patients (mean age, 52.5 ± 21.8 years) who underwent lumbar routine MR examination using a 3-T MR system (Ingenia, Philips Healthcare). A 3D UTE sequence with fat suppression was used, which was acquired using a phase-encoded stack of spiral trajectory as the first TE and four gradient echoes. TEs were set at 0.16, 4.6, 9.2, and 13.8 ms. Scanning was performed around the lumbar spine using a sagittal slice orientation. We classified the grade of disc degeneration as I-V in the midsagittal section according to the Pfirrmann classification, and T2* was calculated from all TE images at the level of L2/3-L5/S1. We also evaluated the correlation between the T2* of IVDs and Pfirrmann classification.

Results: The T2-weighted image-based Pfirrmann classification for our patients was as follows: grade II, 62 discs; grade III, 43 discs; grade IV, 67 discs; and grade V, 28 discs. The T2* of grades II, III, IV, and V was 44.9 ± 17.4 ms, 30.6 ± 13.0 ms, 23.3 ± 10.8 ms, and 13.1 ± 13.6 ms, respectively. T2* RT decreased with increasing grade ($r = -0.724$, $p < 0.01$) and was significantly different between grades II-V ($p < 0.05$).

Conclusion: The T2* of IVDs using UTE enabled to identify high IVD degeneration and may, therefore, be useful as a new technique for the MR evaluation of IVD degeneration.

Molecular lumbar intervertebral disc alterations in patients with leg length discrepancy

M. Frenken, D. Abrar, M. Knautz, D. Latz, A. Ljimini, G. Antoch, C. Schleich; Düsseldorf/DE (miriam.frenken@med.uni-duesseldorf.de)

Purpose: Leg length discrepancy (LLD) is a frequent incidental finding during orthopaedic physical examination and could be a predisposing factor for early degenerations of lumbar intervertebral discs or vertebral facet joints. The purpose of this study was to elucidate the effect of LLD on glycosaminoglycan content (GAG) in lumbar discs.

Methods and Materials: 11 patients (25.6 ± 4.3 years) with LLD greater than 10 mm and 14 control subjects (23.9 ± 3.5 years) without LLD were examined using a 3T MR scanner. Morphological T2-weighted sequences in sagittal and transversal orientation and Glycosaminoglycan chemical exchange saturation transfer (gagCEST) sequence were performed. Subjects with bulged or herniated discs were excluded.

Results: Nucleus pulposus-gagCEST values of L5/S1 disc were significantly lower in patients with LLD compared to control group ($p = 0.0008$). For all other disc levels, no significant difference was found.

Conclusion: This study supports the hypothesis that LLD greater than 10 mm could be a predisposing factor for early molecular alterations of lumbar discs of L5/S1. Remarkably, we observed lower gagCEST values of the lumbar disc of L5/S1 caused by LLD even before any morphological pathology could be found.

B-1737 14:56

MR imaging of transitional lumbosacral junction: co-incident or causative factor for the disc degeneration and herniation

K.A. Bhagwat, V. Mahadevappa; Davangere/IN (bhagwatkishan@gmail.com)

Purpose: To identify MR imaging findings and to know the causal relationship between transitional lumbosacral junction and degeneration of the lumbar disc. To identify the significance of the transitional lumbosacral junction

Methods and Materials: The retrospective study was carried out at teaching hospital. 600 cases, over a period of 18 months, who were referred to the department of diagnostic radiology for MRI of Lumbosacral spine, from the department of Orthopaedics, Neurosurgery and other departments, were included in the study. Inclusion Criteria:- 1. Patients of all age groups. 2. Patients with history of low back pain.

Exclusion Criteria:- Patients with metallic implants, cardiac pacemakers, cochlear implants; who are claustrophobic.

Results: In our review of 600 cases, 180 cases were having transitional lumbosacral junction. Out of 180 cases, 91 were male population and 89 were females (M:F Ratio - 1.1: 1). 30 out of 180 cases were of age less than 30 years and the remainder were more than 30 years of age. 128 cases showed sacralization and 52 cases showed lumbarisation. 50% of the disc herniations were found to be at L5-S1 intervertebral disc level. In non-lumbosacral transitional vertebral cases, about 53%, 27% and 20% of the disc herniations were found to be at L4-L5, L5-S1 and L3-L4 cases respectively.

Conclusion: We conclude that there is a causal relationship between the transitional vertebra and degeneration of the disc immediately cephalad to it, whereas in non-lumbosacral transitional vertebral cases, disc herniations were common at L4-L5 disc levels.

B-1738 15:04

Dual-energy computed tomography detects disk injuries in patients with vertebral fractures: a prospective diagnostic accuracy study

M. Pumberger, M. Fuchs, N. Engelhard, K.-G.A. Hermann, M. Putzger, M.R. Makowski, B. Hamm, T. Diekhoff; Berlin/DE (torsten.diekhoff@gmail.com)

Purpose: To evaluate the diagnostic accuracy of dual-energy computed tomography (DECT) in the assessment of disk injury in patients over the age of 50 with vertebral fractures using magnetic resonance imaging (MRI) as the standard of reference.

Methods and Materials: The prospective study was approved by the local ethics committee (EA1/372/14), and all patients gave written informed consent. Patients with suspected fracture underwent DECT and MRI of the spine. Three readers scored the DECT collagen maps for the presence vs. absence of disk injury and MR images according to the Sander classification (0-3). Only disks at risk (target disks) were included in the analysis. Sensitivity and specificity were calculated. Fleiss's κ was used for interrater agreement. Attenuation in Hounsfield units (HU) in DECT was compared between affected and unaffected disks. MRI was used as the standard of reference.

Results: A total of 295 disks in 67 patients were analysed. DECT had .85 sensitivity and .75 specificity. Sensitivity varied with the severity of disk damage (1: .80, 2: .85 and 3: .98). Fleiss's κ was .41 for MRI and .51 for DECT. HU values measured in the DECT collagen maps were lower for disks with injury compared to normal disks (80.3 ± 35.2 vs 97.9 ± 41.0, $p = .0002$).

Conclusion: DECT collagen maps allow identification of disk injury in elderly patients with vertebral fractures and can yield additional diagnostic information compared with conventional CT.

B-1739 15:12

Dose optimisation in spinal computed tomography for planning of scoliosis surgery

Y. Klosterkemper, M. Konieczny, T. Hesper, J. Aissa, G. Antoch, J. Boos; Düsseldorf/DE (Yan.Klosterkemper@med.uni-duesseldorf.de)

Purpose: To assess the potential for dose optimisation in patients with adolescent idiopathic scoliosis (AIS) undergoing preoperative spinal CT.

Methods and Materials: Ten patients with AIS (3 male, 7 female, 18±11 years) were included in this prospective study. CT examinations were performed with automated exposure control (mean CTDIvol 4.1±0.9mGy; DLP: 192±50mGy*cm). Dose reduction to 50%, 20 %, 10% and 5% was simulated using dedicated reconstruction software. Two spinal surgeons blinded to the dose level independently and randomly measured the size of each pedicle for screw size selection. Additionally, the confidence in the measurements was assessed (5=very confident in the measurement, 1=measurement cannot be performed with any confidence). Two radiologists rated the image quality for the assessment of bone and soft tissue structures (5=excellent, 1=non-diagnostic). Bonferroni was used to correct for multiple testing ($p < 0.0125$).

Results: Pedicle length and width measurements were comparable between 100% and 50% reconstructions (36.4mm/4.1mm vs 36.6mm/4.1mm) whereas both measurements decreased with further dose reduction (20%: 36.1mm/4.1mm; 10%: 35.5mm/4.0mm; 5%: 34.6mm/3.9mm). Confidence in the measurements was excellent at 100% and 50% (all ratings of 5) and

decreased with further dose reduction (20%: 4.7; 10%: 3.7; 5%: 2.5). Image quality decreased with decreasing dose (4.9±0.4 for 100 % to 1±0 for the 5% reconstructions; p<0.001, respectively). For bone assessment, image quality was comparable between 100% and 50% reconstructions (4.9±0.4 vs 4.7±0.5). **Conclusion:** Dose of preoperative spinal CT in AIS patients can be reduced to 50% without impairment of pedicle size measurements or surgeons' confidence in planning the operation.

Radiation exposure during radiographic and computed tomography lumbar spine imaging for adults

C. Gernhardt, N. Guberina, M. Burggraf, U. Dietrich, J. Theysohn, M. Forsting; Essen/DE (Christian.gernhardt@uk-essen.de)

Purpose: The purpose of this study was to examine radiation dose levels and image quality of important lumbar spine imaging techniques of major clinical concern.

Methods and Materials: In a retrospective study design 41 patients received both (A) radiographic and (B) computed tomography of the lumbar spine. Patients were examined at the single-source CT-scanner SOMATOM Definition AS+, dual-source SOMATOM Definition Flash and SOMATOM Force between March 2015 and March 2018. Important CT parameters and dose descriptors like CTDI_{vol}, DLP and DAP were examined. Additionally, effective and organ doses were calculated using established radiographic conversion factors and Monte Carlo simulation, following IRCP 103 recommendations. Intermodality comparison of radiation exposure and image quality was performed in this ideally matching patient collective.

Results: The mean effective dose [median, CI] for a standardised lumbar spine imaging is summarized as follows: (A) 0.27 mSv [0.21 mSv, CI 0.15 - 0.36] and (B) 5.56 mSv [4.90 mSv, CI 3.34 - 6.30]. Image quality on a five-pointed Likert-scale is rated as follows: for (I) delineation of spinal disc herniation (A) 0.8 and (B) 3.6; (II) delineation of spinal canal stenosis (A) 2.8 and (B) 4.1; (III) postoperative control, spinal fusion assessment and exclusion of vertebral body sintering (A) 3.1 and (B) 4.2.

Conclusion: This is the first data acquisition of radiation exposure during important lumbar spine imaging techniques in an ideally matching patient collective. The assessment of radiation exposure is crucial for the determination of diagnostic reference levels and choosing the best imaging protocol for clinical questions.

Spinal osseous lesions in tuberousclerosis

F. Düzgün, G. Yilmaz Ovalı, I.S. Örgüç; Manisa/TR (fatihdzgn@yahoo.com)

Purpose: To characterize bone lesions incidentally detected in abdominal and thorax computed tomography (CT) and magnetic resonance imaging (MRI) scans in tuberousclerosis patients.

Methods and Materials: Twenty-three patients were examined retrospectively for the presence of spinal, thorax and abdominal CT or MRI scans performed for other components of tuberousclerosis. Only 7 patients had at least one of the above mentioned studies.

Results: All of six adult patients had sclerotic bone lesions on thoracic, lumbar vertebra, sacrum and iliac bones, which distributed around the subcortical bone surrounding the spinal canal in a specific pattern. No sclerotic bone lesion was determined in the pediatric patient. Lesions were mostly located in posterior elements and sacrum was involved in all patients.

Conclusion: Recognition of sclerotic bone lesions is useful for supporting the clinical diagnosis of tuberousclerosis and differing from osteoblastic metastasis as well.

B-1742 14:17

Application of 3.0T magnetic resonance diffusion tensor imaging in diagnosis of discogenic low back pain

S. Tian, H. Yuan; Beijing/CN (ts@bjmu.edu.cn)

Purpose: The aim of our study is to observe the morphology and integrity of annulus fibrosus by diffusion tensor imaging (DTI), and quantitatively analyse the annulus fibrosus by measuring the apparent diffusion coefficient (ADC) and fractional anisotropy (FA).

Methods and Materials: Patients with recurrent low back pain and healthy volunteers were enrolled in the study over a continuous period of time. The ADC and FA values at the posterior margin of the annulus fibrosus were measured by conventional lumbar MR sequence and axial DTI of L3-S1 levels (3.0T). The responsible intervertebral discogenic low back pain segment was determined by discography. The ADC and FA values were measured at the posterior margin of the annulus fibrosus of the segment.

Results: 30 subjects in the experimental group and 24 subjects in the control group were included in the study. There was no significant difference in demographic parameters and the area of region of interest (ROI) measured manually between the two groups. The ADC value of ROI in the experimental group was significantly higher than that in the control group (9.84±4.01 vs. 6.10±3.17, p=0.0002), and the FA value was significantly lower than that in the control group (0.231±0.150 versus 0.341±0.201, p=0.007).

Conclusion: 3.0T magnetic resonance DTI is instructive for the diagnosis of discogenic low back pain and preoperative localisation of the responsible segment. ADC and FA values can provide objective indicators for intervening intervertebral discogenic low back pain.

B-1743 14:25

Diffusion tensor imaging with quantitative evaluation of sciatic nerve within the pelvis in patients with non-contributory lumbar spine magnetic resonance imaging in radiculopathy

M. Catania¹, G. Foti², A. Beltramello², G. Carbognin², ¹Verona/IT, ²Negrar/IT (fid634iff@studenti.univr.it)

Purpose: Diffusion tensor imaging with quantitative evaluation of sciatic nerve within the pelvis in patients with non-contributory lumbar spine MRI in radiculopathy.

Methods and Materials: 32 consecutive sciatica patients with negative lumbar MRI were studied between October 2016 and February 2018 with DTI sequence of the pelvis (TR/TE 5800/97 ms; b=1000; slice thickness 3.5 mm; directions=20) using a 1.5T scanner (Siemens Aera). DTI data were post-processed by two radiologists blinded to clinical data. Each radiologist placed two ROI on the nerve roots at three different levels within the pelvis on both sides and the mean value was used for further analysis. Clinical findings served as the standard of reference. Diagnostic accuracy values of the FA numbers using ROC curves and relative AUC were calculated. Inter-observer and intra-observer agreements and continuous and categorical variables were calculated. A value of p<0.05 was considered statistically significant.

Results: The lumbar nerve roots were visualized and FA values were calculated in all subjects. The FA values were significantly different between suffering nerve roots (178± 48; range 146-285) and spared side (296±52; range 221-412) with a p value <0.001. The ROC curve analysis revealed an AUC of 0.816 (95% confidence interval: 0.682-0.874). Using a FA of 220 as cutoff to identify suffering nerve roots, the sensitivity, specificity, PPV, NPV and accuracy were 81.8, 95.4, 90.0, 91.3 and 90.9%. The inter-observer and intra-observer agreements were near perfect.

Conclusion: DTI can quantitatively demonstrate the presence of suffering sciatic nerve roots within the pelvis.

B-1744 14:33

Preoperative and postoperative strain elastography, and shear wave elastography findings of the sciatic nerve in patients with unilateral lumbar disc herniation

V. Buruldav¹, U.O. Çelebi¹, M. Ogden¹, M.H. Akgül¹, A. Dogan², M.F. Ozveren¹; ¹Kirikkale/TR, ²Kahramanmaraş/TR (vedoctor@hotmail.com)

Purpose: The aim of this study was to compare preoperative and postoperative findings of the sciatic nerve using B-mode ultrasound (US), strain elastography (SE), and shear wave elastography (SWE) in patients with unilateral lumbar disc hernia.

Methods and Materials: This prospective study was conducted with a pre-test and post-test design. Preoperative and postoperative (one month after surgery) B-mode ultrasound, SE, and SWE findings of the patients who underwent unilateral spinal decompression surgery were compared. The cross-sectional area (CSA) was measured with the direct tracing method using an electronic caliper.

Results: A total of 20 patients (9 males, 11 females) with a mean age of 46.2±13.1 years were included. The CSA, diameter, SWE values of the sciatic nerve were significantly higher in the involved side compared to those of the non-involved side (all p<0.05). Blue and blue-green were the most common

colour codes in the involved side while green and green-yellow-red were the most common colour codes in the non-involved side. The CSA, diameter, and SWE values of the sciatic nerve decreased after surgery in the involved side (all $p < 0.05$), and no difference was determined in the non-involved side (all $p > 0.05$).

Conclusion: Lumbar decompression surgery decreases the sciatic nerve diameter, CSA, and stiffness of the sciatic nerve.

B-1745 14:41

Pilot study on radiomics of peripheral nerves: feasibility of quantitative imaging phenotyping on magnetic resonance imaging

A. Tagliafico, F. Rossi, F. Valdora, M. Grandis, L. Benedetti, B. Bignotti, A. Schenone, C. Martinoli; *Genoa/IT (federossi0590@gmail.com)*

Purpose: To study radiomics features of the peripheral nerve MRI in normal and pathological peripheral nerves.

Methods and Materials: We retrospectively reviewed clinical 1.5T MRI data from January 2016 to January 2018 of 20 adult patients (11 men and 9 women; mean age 54.2 ± 3.7) with peripheral neuropathy and 20 age- and sex-matched controls (12 men and 8 women; mean age 56.4 ± 4.9). Radiomic analysis was done on fast spin echo axial T1-weighted images. Regions of interest (ROIs) were done by two radiologists in consensus. $N=104$ radiomics features were extracted and evaluated. Mann-Whitney U test for unpaired data with 1000 bootstraps samples was used to compare radiomics features of normal and pathological peripheral nerves. Reading time was also estimated.

Results: The pathological group included systemic neuropathies ($n=8/20$), Schwannomas ($n=2/20$), diabetic neuropathies ($n=2/20$), entrapments ($n=5/20$), post-traumatic/post-surgical neuropathies ($3/20$). Statistically significant differences ($p < 0.05$) were found in $n=22/104$ (21%) features. $N=5/22$ features were shape based, $n=7/22$ were first-order features, $n=10/22$ features were grey-level run length matrix (Grlm). Mean time to perform radiomics analysis was 3 ± 45 minutes) hours per patient.

Conclusion: Radiomics analysis in MRI of peripheral nerves is feasible and found differences between normal and pathological nerves in $n=22/104$ features.

B-1746 14:49

Diffusion tensor imaging and tractography acquired with magnetic resonance imaging for preoperative assessment of benign peripheral nerve sheath tumours

B.J. Schwaiger, A.S. Gersing, B. Cervantes, C. Knebel, J. Dangelmaier, D. Pfeiffer, E.J. Rummeny, D. Karampinos, K. Woertler; *Munich/DE*

Purpose: To assess the diagnostic potential of fibre tractography and diffusivity analysis based on diffusion-weighted (DW) sequences for preoperative differentiation of benign peripheral nerve sheath tumours.

Methods and Materials: In 17 patients with histologically confirmed schwannomas and 5 patients with neurofibromas (mean age 41.9 ± 17.1 y, 13 women) 3T MR imaging was performed including a fat-suppressed 3D DW-TSE sequence (TR/TE=1600/33ms; b-values=0;400) comprising 6 diffusion directions for diffusion tensor (DT) imaging analysis. DT were computed from iso-DW images using linear fitting, and fibre tracks were determined. Mean diffusivity was computed from derived Eigenvalues. Fascicle visualization was graded using a four-point scale ranging from poor to very good. Tumour location in relation to nerve fascicles and the number of fascicles were noted. MR imaging findings were compared to analogous intraoperative findings. Agreement of MR and intraoperative findings was calculated using Cohen's kappa.

Results: Fascicle visualization was graded as very good/ good in 82%. Schwannomas were significantly more often located eccentrically (94.1%) than neurofibromas (0%; $P < 0.01$). Tractography revealed fascicles to be significantly more often continuous in schwannomas (88.9%) than in neurofibromas (0%; $P = 0.014$). Mean diffusivity in schwannomas ($1.94 \pm 0.40 \times 10^{-3} \text{mm}^2/\text{s}$) was significantly higher than in neurofibromas ($0.89 \pm 0.21 \times 10^{-3} \text{mm}^2/\text{s}$; $P < 0.001$). Fascicle courses around the tumour as graded on MR and intraoperatively showed a substantial agreement ($\kappa = 0.78$).

Conclusion: Preoperative diffusion-weighted imaging-based fiber tractography and diffusivity analysis accurately differentiated between schwannomas and neurofibromas and showed a high agreement with intraoperative findings and thus could support individual treatment and surgical planning.

B-1747 14:57

Sonographic mapping of brachial plexus and comparison with magnetic resonance imaging and electrophysiological studies

A. Agarwal; *New Delhi/IN (ayushagarwal9.8@gmail.com)*

Purpose: To compare ultrasonography (USG) with MRI and electromyography/nerve conduction studies (EMG/NCV) for evaluating the brachial plexus pathologies.

Methods and Materials: Thirty patients with clinical suspicion of brachial plexus involvement underwent sonography of brachial plexus on both sides.

Magnetic resonance imaging (MRI), the gold standard, was done subsequently and compared with sonography findings. EMG/NCV studies were also compared.

Results: The findings on USG (e.g. thickened hypoechoic nerves, increased surrounding hyperechogenicity) had excellent correlation with MRI (e.g. thickened nerves with increased surrounding hyperintensity on T2/ STIR images) and EMG/NCV studies. Out of 30 cases, 15 cases had abnormal USG findings and MRI was abnormal in 19 cases. In 4 cases where USG was normal, MRI showed the intradural root avulsions and associated pseudomeningoceles which could not be picked up on ultrasound. These findings correlated with NCV/EMG studies in all the cases (100%).

Conclusion: USG is more readily available than MRI and can be done in acute emergency settings. It can also be used for follow-up of patients in brachial plexus injury after initial MRI has been done. Furthermore, USG is the only imaging modality available in patients who have contraindications for MRI. The drawbacks of USG include that it could not demonstrate the intradural root avulsions and associated pseudomeningoceles (in 100% cases). Also, the extent of visualisation of brachial plexus on ultrasound is very good for C5, C6 and C7 roots (100% cases) and limited in C8 root (15 cases: 50%) while T1 root could not be visualised in any case.

B-1748 15:05

High-resolution ultrasound of the superficial sensitive nerves of the arm and the forearm: anatomy, scanning technique and clinical relevance

R. Picasso¹, F. Zaottini¹, F. Pistoia¹, M. Miguel Perez², C. Martinoli¹; *Genoa/IT, ²Barcelona/ES (riccardo.picasso@gmail.com)*

Purpose: The aim of this study was to describe the potential role of high-resolution ultrasound (US) for evaluation of superficial sensitive nerves of the arm and forearm.

Methods and Materials: After US-guided percutaneous latex injection, $n=3$ cadaveric limbs were dissected to identify the course of the medial cutaneous nerve of the arm (MCNA) and the medial (MCNF), lateral (LCNF) and posterior (PCNF) cutaneous nerves of the forearm and determine whether US is able to localize these small nerves. A consecutive series of $n=11$ patients who had sensory disturbances in the territory of the MCNA, MCNF, LCNF and PCNF were examined with US using a 17-5MHz transducer. One patient had prolonged arm compression by a plaster cast, $n=3$ underwent a penetrating injury along the nerve course and $n=1$ had a history of repeated cannulations of elbow veins. Other $n=6$ patients presented with symptoms of superficial neuropathy in absence of any history of trauma.

Results: Cadaveric dissection confirmed that US-guided injections placed latex into and around the MCNA, MCNF, LCNF and PCNF in all specimens. In 10/11 patients, US allowed detection of definite nerve abnormalities. Pathological findings included $n=4$ fusiform neuromas and/or fibrous encasement, $n=3$ schwannomas, $n=1$ neurofibroma, $n=1$ intraneural ganglion cyst arising from the radiocarpal joint and $n=1$ mechanical instability at the elbow level.

Conclusion: High-resolution US can identify the MCNA, MCNF, LCNF and PCNF and characterize their abnormalities providing unique information about these small nerve branches.

B-1749 15:13

Therapeutic implications of ultrasound of peripheral nerves in leprosy

Y. Aswani¹, S. Saifi²; *Udaipur/IN, ²Mumbai/IN (aswaniyashant@gmail.com)*

Purpose: Leprosy and lepra reactions have the same treatment regimen except steroids in the latter. Lepra reactions may be identified on clinical and histopathological grounds. However, they may be clinically silent as well. Neuritis as a result of lepra reactions may cause permanent disability within 24 hours of its onset. The aim of this study is to determine ultrasound criteria to distinguish involvement of peripheral nerves due to leprosy from lepra reactions.

Methods and Materials: It was a retrospective analysis of all new leprosy cases between September 2014 and August 2015 at a tertiary care institute. Leprosy was diagnosed on clinical findings and histopathology of skin lesions. However, lepra reactions were diagnosed on clinical basis only. Nerve ultrasound findings of these patients were analysed (transducer: 6.6- 8.4 MHz, Xario, Toshiba). The studied peripheral nerves were bilateral ulnar, median, lateral popliteal and posterior tibial. Nerve involvement was tabulated as thickening (increase in cross-sectional area), internal echotexture (preserved to lost fascicular architecture) and Doppler signals.

Results: Of 20 patients, 16 were males. The age range was 16 to 53 years. Ulnar nerve was the most commonly involved nerve. Maximum thickening of the nerves was above the osseofibrous tunnels along their course. Both leprotic nerves and nerves involved by lepra reactions were thickened ($p > 0.05$) and had change in internal architecture ($p > 0.05$). Doppler signals were significantly present in lepra reactions (sensitivity: 91.6%; $p < 0.05$).

Conclusion: Nerve ultrasound is an excellent screening modality to differentiate between leprosy and lepra reactions.

B-1750 15:21

Time to replace T2-STIR with diffusion-weighted imaging for visualisation of nerve disorders?

S. [Rajan](#), H. Mahajan, M. Barnwal, V. Mahajan, V. Venugopal; *New Delhi/IN* (drsriramrajan@gmail.com)

Purpose: To determine if diffusion-weighted imaging of nerves can provide additional information or change the diagnosis compared to T2/STIR imaging.

Methods and Materials: 88 MRI scans (48 lumbar plexus, 24 brachial plexus, 16 peripheral nerves) performed on a 3.0T MR750w (GE Healthcare, USA) to assess nerve damage/disease were extracted from PACS, anonymised and segregated into scans with T2w STIR (2.5-5mm/0-1mm gap; TR 5150ms, TE 48ms, TI 187-188ms, bandwidth 62.6 kHz, FOV 24x24, matrix 288x128), structural nerve imaging (SNI) and diffusion-weighted (4mm/1mm overlap, TR 8743, TE 63.5, TI 249.5, bandwidth 250kHz, FOV 40x40cm, matrix 64x128), functional nerve imaging (FNI). Scans were read by a senior specialist radiologist (16 years' experience). Visibility of focal signal abnormality, diffuse signal abnormality, nerve fibre continuity and muscular changes were recorded in each scan (present vs absent). Results from both sets of images were compared and the value of functional nerve imaging was evaluated.

Results: Overall, FNI changed the diagnosis in 58 (66%) cases compared to SNI. The number of cases where the diagnosis changed in lumbar plexus, brachial plexus and peripheral nerves were 36 (75%), 16 (67%) and 5 (31%), respectively. Findings visualised on FNI but not on SNI were focal signal abnormalities (24/27%) and diffuse signal abnormalities (39/45%). Nerve fibre continuity and muscular changes appeared similar on both with no change reported in 82 (93%) and 85 (97%) scans.

Conclusion: Diffusion-weighted imaging of nerves, especially for visualisation of the lumbar and brachial plexus, on 3.0T MR, adds to the diagnosis and could replace T2-STIRw structural imaging.

Evaluation of deep learning software tool for CT-based lung nodule classification

J.T. Murchison, G. Ritchie, D. Senyszak, E.J.R. [van Beek](#); *Edinburgh/UK* (edwin-vanbeek@ed.ac.uk)

Purpose: A new fully automatic deep learning software tool (CAD) was developed to facilitate pulmonary nodule management on chest CT. This study was aimed to assess the clinical performance of the tool for classifying pulmonary nodules.

Methods and Materials: A total of 314 Chest CT scans from unique subjects were selected from the NHS Lothian database. A panel of experienced thoracic radiologists reviewed the CT scans for the presence of pulmonary nodules and subsequently determined the composition (solid or sub-solid). A reference standard for the classification of pulmonary nodules was created based on the majority consensus of the panel.

Results: A total of 325 solid nodules and 57 sub-solid nodules were included in the reference standard. The sensitivity, specificity, positive predictive value and negative predictive value of CAD for determining the composition of solid nodules were 98.8%, 68.4%, 90.7% and 94.7%, and 68.4%, 98.8%, 94.7% and 90.7% for sub-solid nodules, respectively. The accuracy and kappa of CAD for determining the composition (solid vs sub-solid) of a pulmonary nodule was 94.2% and .77.

Conclusion: The CAD software yielded a high accuracy of 94.2% and a kappa score of .77 for determining the composition (solid, sub-solid) of a pulmonary nodule.

Improved pulmonary nodule malignancy prediction with surrounding tissues

K. [Liu](#)¹, W. Tang², C. Xia², Y. Deng², R. Zhang¹, L. Fan¹, Y. Xiao¹, S. Liu¹; *Shanghai/CN, Beijing/CN* (469884218@qq.com)

Purpose: In this paper, we examined the influence of surrounding tissues on nodule malignancy classification.

Methods and Materials: The method combined ResNet and UNet to predict nodule malignancy. Chest CT images containing 942 nodules (325 benign, 617 malignant) were used for training, and another 200 nodules (78 benign, 122 malignant) were collected separately as testing set. The malignancy of all nodules was pathology proven. We resampled the images into 0.6 mm pixel space in all dimensions and processed the images in three ways: (1) small tissue condition, cubes (64*64*64 pixels) with target nodules in the centre; (2) large tissue condition, cubes (96*96*96 pixels) which contained a larger scope of surrounding tissues; (3) without tissue condition, nodules only with no surrounding tissues. We trained and tested three different models with the above data, respectively, and used chi-squared test to compare the results.

Results: The presence of surrounding tissues significantly affected prediction accuracy, $\chi^2 = 8.61$, $p = .013$. Specifically, the large tissue condition produced the highest accuracy of 86%, which was significantly higher than the without tissue condition, $\chi^2 = 8.34$, $p = .004$. Moreover, including surrounding tissues significantly improved malignant nodule sensitivity ($\chi^2 = 19.37$, $p < .001$). Yet, whether surrounding tissues were included or not did not affect specificity ($\chi^2 = 1.29$, $p = .52$).

Conclusion: Our study showed that including surrounding tissues could improve pulmonary nodule classification, especially the sensitivity of malignant nodules. This could provide new directions to radiomics research, where conventional methods segment nodules only.

Automated classification of chest x-rays as normal/abnormal using a high sensitivity deep learning algorithm

V. Venugopal¹, M. Tadepalli², B. Reddy², A. Modi², S. Gupta¹, P. Warier², P. Rao², H. [Mahajan](#)¹, V. Mahajan¹; *New Delhi/IN, Mumbai/IN* (drharshmahajan@yahoo.com)

Purpose: Majority of Chest X-Rays (CXRs) performed globally are normal and radiologists spend significant time ruling out these scans. We present a Deep Learning (DL) model trained for the specific use of classifying CXRs into normal and abnormal, potentially reducing time and cost associated with reporting normal studies.

Methods and Materials: A DL algorithm trained on 1,150,084 CXRs and their corresponding reports was developed. A retrospectively acquired independent test set of 430 CXRs (285 abnormal, 145 normal) was analysed by the algorithm, classifying each X-Ray as normal or abnormal. Ground truth for the independent test set was established by a sub-specialist chest radiologist with 8 years' experience by reviewing every Chest X-ray image with reference to the existing report. Algorithm output was compared against ground truth and summary statistics were calculated.

Results: The algorithm correctly classified 376 (87.44%) CXRs with a sensitivity of 97.19% (95% CI - 94.54% to 98.78%) and specificity of 68.28% (95% CI - 60.04% to 75.75%). There were 46 (10.70%) false positives and 8 (1.86%) false negatives (FNs). Out of the 8 FNs, 3 were designated as clinically insignificant (mild, inactive fibrosis) and 5 as significant (rib fractures, pneumothorax).

Conclusion: High-sensitivity DL algorithms can potentially be deployed for primary read of CXRs enabling radiologists to spend appropriate time on abnormal cases, saving time and thereby cost of reporting CXRs, especially in non-emergency situations. More in-depth prospective trials are required to ascertain the overall impact of such algorithms.

Efficacy and clinical and radiological influencing factors on bone suppression by deep learning algorithm in digital chest radiograph

H. [Moon](#), G.-S. Hong, Y. Byeon, C. Lee; *Seoul/KR* (aslhey92@gmail.com)

Purpose: To determine the efficacy and influencing factors on bone suppression by deep learning algorithm (DLA) in the digital chest radiograph (CXR).

Methods and Materials: Among 4551 patients who underwent CXR and had bone suppression image (BSI) generated by DLA from 2017 to 2018, 400 patients were randomly selected. Two radiologists rated the bone suppression

at each of 2400 lung regions in consensus using 5-point scales from no bony change (score 1) to definite bone removal (score 5). Technical success of DLA on bone suppression was defined as mean score ≥ 4 . The per-patient efficacy of DLA was correlated with patient's clinical and radiological factors (i.e., patient's age, sex, position, rotation degree, inspiration degree, cardiothoracic ratio [CT ratio], presence or absence of lung lesion, and body mass index [BMI]) using multiple logistic regression model and the per-regional efficacy in 6 regions was compared using ANOVA.

Results: The per-patient efficacy of DLA on bone suppression was 67% ($n=268/400$). Bone suppression of DLA was significantly influenced by patient's position (OR: 1.55, 95% CI 1.14-2.15) and presence of lung lesion (OR: 0.51, 95% CI 0.33-0.80), not by patient's age, sex, rotation degree, inspiration degree, CT ratio, and BMI. Per-regional efficacy was significantly differed according the lung regions ($P < 0.0001$).

Conclusion: Patient's position and presence of lung lesion are significant independent influencing factors for BSI generation using deep learning. The efficacy of DLA on bone suppression varies significantly with location.

B-1755 14:32

3D computer-aided CT texture analysis with machine learning: capability to play as second reader for radiological finding assessment in interstitial lung disease

Y. Ohno¹, A. Yaguchi², K. Aoyagi³, D. Takenaka⁴, T. Yoshikawa¹, Y. Kishida¹, S. Seki¹, T. Murakami¹; ¹Kobe/JP, ²Kawasaki/JP, ³Otawara/JP, ⁴Akashi/JP (yosirad@kobe-u.ac.jp)

Purpose: To evaluate the capability of a 3D computer-aided CT texture analysis with machine learning to play as second reader for radiological finding assessment in patients with interstitial lung disease (ILD).

Methods and Materials: 3D computer-aided CT texture analysis software developed by means of machine learning method was tested by thin-section CTs in 81 ILD patients. In each patient, thin-section CT findings were divided into 7 different radiological findings as follows: 1) normal lung, 2) ground-glass opacity (GGO), 3) reticulation, 4) emphysema, 5) nodular lesion, 6) consolidation and 7) honeycomb. Then total 350 lesions were randomly selected, and classified by this software and two board-certified chest radiologists. In addition, final radiological finding at each lesion was determined by consensus of two readers. To determine the inter-observer agreements among both readers and software, kappa statistics were performed. In addition, agreement and accuracy for radiological finding evaluation were also evaluated between software and consensus results.

Results: Inter-observer agreement among both readers and the software were determined as substantial (reader 1 vs. reader 2: $\kappa=0.70$, $p<0.0001$; reader 1 vs. software: $\kappa=0.73$, $p<0.0001$; reader 2 vs. software: $\kappa=0.64$, $p<0.0001$). Agreement between consensus result and the software was also evaluated as almost perfect ($\kappa=0.84$, $p<0.0001$). Accuracy of this software was determined as 79.4%.

Conclusion: 3D computer-aided CT texture analysis with machine learning has a potential to play as second reader for radiological finding assessment in interstitial lung disease patients.

Automatic pulmonary nodule detection in low-dose CT scans using convolutional neural networks based on maximum intensity projection

S. Zheng¹, J. Guo¹, M. Rook¹, X. Cui¹, R.N.J. Veldhuis², M. Oudkerk¹, P.M.A. van Ooijen¹; ¹Groningen/NL, ²Twente/NL (s.zheng@umcg.nl)

Purpose: Despite their potential benefit, computer-aided detection (CAD) systems are not routinely used by radiologists for pulmonary nodules detection in clinical practice. In radiological evaluation, maximum intensity projection (MIP) improves detection of pulmonary nodules. Our objective was to explore if using MIP images as input data could increase automatic detection of lung nodules by using convolutional neural networks (CNNs).

Methods and Materials: The proposed two-dimensional (2-D) CNNs approach utilizes MIP images with different slab thicknesses (5 mm, 10 mm, 15 mm) and 1mm plain multiplanar reconstruction (MPR) images as input, which extracts more discriminative information of nodules from vessels through their morphologies. We used the public LUNA16 dataset collected from seven academic centres to train and test our approach. The dataset consisted of 888 low-dose CT scans with 1186 nodules that were annotated by four radiologists. Nodules larger than 3 mm that were accepted by at least three out of the four radiologists served as the reference standard.

Results: Our proposed approach achieved a sensitivity of 95% for lung nodule detection, which was better than the result (86%) obtained from the MPR images alone. Using the thick MIP images helped detection of small pulmonary nodules (3-5mm), while the network trained with MPR images performed relatively better in localizing large nodules (>10 mm).

Conclusion: The preliminary results show that MIP images can improve the sensitivity of automatic pulmonary nodule detection, which indicates the importance and effectiveness of integrating multi-slab thickness contextual information into 2-D CNNs framework in CT data.

Towards a deep learning model for exhaustive chest x-ray pathology classification

N. Ramanaukas, J. Dementaviciene, J. Armitis, D. Barušauskas, J. Bialopetravicius, G. Rimeika, J. Stankeviciene; Vilnius/LT (naglir@gmail.com)

Purpose: Despite increasing volume of other imaging techniques, chest x-rays (CXR) still make up a large fraction of all radiological studies. Thus, increasing accuracy and productivity of radiologists reading CXRs remains of paramount importance. However, CXRs constitute a stark challenge for computer-aided diagnosis. This is because (i) CXRs are two-dimensional projections of three-dimensional data; (ii) at least three major different types of CXRs exist (i.e., AP/PA/LAT); (iii) many different radiological findings of the lungs, the heart, and the spine are observed from a single CXR; (iv) in clinical practice, additional information besides the image is used to make radiological conclusions. In this work, we attempt to tackle challenges (i)-(iii) by creating a deep learning (DL) model which takes AP/PA images as input, and outputs scores pertaining to 76 different radiological features and their localizations. We leave (iv) for future work.

Methods and Materials: A database of CXR images ($n = 301\ 255$) was used. The data was divided into a training set (70%), a testing set (20%), and a validation set (10%). A single convolutional neural network (CNN) based on Inception was used to construct a model for CXR pathology classification.

Results: Our model achieves average area under receiver operating curve (AUC) of 93%.

Conclusion: We have created a Deep Learning model that covers 76 chest x-ray radiological findings with an AUC value of 93%. This model shows promise for various applications, such as patient triage and pre-generating structured reports.

CT-based radiomics predict immune-therapy response in patients with non-small-cell lung cancer

S. Wang, J. Gong, H. Yu, W. Peng; Shanghai/CN (shengpingwang2007@126.com)

Purpose: To predict the disease control rate (DCR) to immune-checkpoint inhibitors (nivolumab) therapy for non-small-cell lung cancer (NSCLC) patients, we developed a radiomics analysis approach based on computed tomography (CT) images.

Methods and Materials: Twenty-seven staged IV NSCLC patients after failed platinum-based chemotherapy were included. First, the enhanced CT images of these patients were divided into baseline group and one cycle therapy group. Second, we applied a semiautomatic segmentation method to segment the targeted lung nodules and computed 842 quantitative imaging (QI) features from each segmented nodule from CT images. Third, two random forest (RF) classifiers were built using QI features extracted from baseline and therapy CT images, respectively. Then, a Relief feature selection method was used to remove redundant QI features from the initial feature pools. Finally, a leave-one-case-out (LOCO) cross-validation method was applied to train and test the classifiers by using selected features.

Results: Areas under receiver operating characteristic curves (AUC) generated by using baseline and one cycle therapy CT scans were 0.81 ± 0.08 (95% CI: [0.60, 0.94]) and 0.68 ± 0.11 (95% CI: [0.44, 0.86]), respectively. The AUC value yielded by baseline group data was significantly higher than one cycle therapy group data.

Conclusion: This study demonstrates (1) feasibility of predicting the DCR to immune-therapy by using CT-based radiomics analysis and (2) higher performance by applying baseline group CT scans than using one cycle therapy data.

Evaluation of deep learning software tool for CT-based lung nodule detection

J.T. Murchison, G. Ritchie, D. Senyszak, E.J.R. van Beek; *Edinburgh/UK* (*edwin-vanbeek@ed.ac.uk*)

Purpose: A fully automatic deep learning software tool (CAD) was assessed for the clinical performance of detecting pulmonary nodules.

Methods and Materials: CT studies of 273 patients were selected from the NHS Lothian database based on the inclusion criteria for lung screening (age 50-74 years, current or past smokers). A panel of experienced thoracic radiologists was evaluated for the presence of pulmonary nodules, alternately reading without (UNAIDED) and with (AIDED) CAD results. Majority consensus served as the reference standard. One-tailed Welch's t test was used to compare UNAIDED vs AIDED mean sensitivity at $p < 0.05$.

Results: 269 nodules with largest axial diameter between ≥ 5 mm and ≤ 30 mm were included. The sensitivity of UNAIDED and AIDED radiologists was 71.9% (95% CI: 66.0%, 77.0%) and 80.3% (95% CI: 75.2%, 85.0%) ($p < 0.01$) at an average number of false positives per scan (FPR) of 0.11 and 0.16, respectively. In a stand-alone test, the sensitivity of CAD was equivalent to that of UNAIDED radiologists at a FPR of 0.62 and was equivalent to AIDED radiologists at a FPR of 0.88. At a FPR of 1.0 per scan the sensitivity was 82.3%, outperforming both UNAIDED and AIDED radiologists.

Conclusion: The use of CAD yielded a nearly 10% higher sensitivity, compared to readings without CAD, with minimal increase of the false-positive rate. In a stand-alone performance, test the CAD system outperformed radiologists reading with and without the CAD system at an average false-positive rate of 1.0 per scan.

A new architecture of the computer-aided system for lung cancer diagnostics

A.A. Meldo, L.V. Utkin, V.M. Moiseenko, M.A. Ryabinin; *St. Petersburg/RU* (*Anna.meldo@yandex.ru*)

Purpose: To develop a new architecture for computer-aided system in lung cancer diagnostics.

Methods and Materials: Open datasets LIDC, LUNA16 for training the system, own dataset LIRA (lung images resource annotated) for testing the system. A new classification approach based on dimension reduction by means of histograms of chord lengths and radiodensities for every segmented lung nodule. A new approach based on applying the Siamese neural network for non-typical lung nodules. Data processing and training the computer-aided system were carried out using a Supercomputer of Peter the Great, St.Petersburg Polytechnic University.

Results: The following accuracy measures are obtained by applying the first approach (histograms): sensitivity is 93%, specificity is 97% and accuracy is 95%. Accuracy measures by applying the Siamese neural network are recently investigated. A new dataset LIRA is collected, which contains a set of "typical", "non-typical" lung cancer nodules and "non-cancer" lung nodules.

Conclusion: The developed system is effective for detecting the lung nodules. An advantage is the ability of functioning independently on CT equipment. The use of the dimension reduction improves the training and the usage of the system. The proposed Siamese neural network is a perspective tool for differential lung disease detection and allows us to apply small datasets for training.

Fully automatic detection and segmentation of thoracic lymph nodes in MSCT scans of the chest using deep learning

H. Carolus¹, A.-I. Iuga², T. Brosch¹, R. Wiemker¹, T. Klinder¹, D. Maizt², A. Höink², M. Püsken²; ¹Hamburg/DE, ²Cologne/DE (*heike.carolus@philips.com*)

Purpose: Detection of malignant lymph nodes (LN) in CT examinations of cancer patients is indispensable for the correct TNM staging, directly impacting therapeutic decisions. Nevertheless, especially mediastinal and hilar LNs can be easily overlooked due to their small size and comparatively low contrast. To overcome this diagnostic challenge, we propose a deep learning algorithm for LN segmentation in chest CT images.

Methods and Materials: 89 CT scans from a public CT lymph node database (<http://doi.org/10.7937/K9/TCIA.2015.AQIIDCNM>) were analysed. Available landmark annotations of 388 LNs were extended to obtain a significantly more comprehensive and high-quality database suitable for algorithmic training. All visible LNs with a short-axis diameter (SAD) of ≥ 5 mm were segmented semi-automatically yielding a set of 4276 mediastinal, hilar and axillary LNs, i.e. 48 LNs per patient on average. Using these data, a fully convolutional net based on 3D fovea patches was trained with 4-fold cross-validation for automatic

detection and segmentation of thoracic LNs.

Results: For enlarged, clinically relevant LNs (SAD ≥ 10 mm), 78% sensitivity was achieved and 60% for small LNs with 11.8 false-positive detections per volume. No significant performance differences between mediastinal and axillary area were found. In 94.1% of the cases with enlarged LNs, at least one LN is detected as enlarged.

Conclusion: Based on the extensive and rigorous annotations, the proposed 3D deep learning approach achieves state-of-the-art performance for enlarged, potentially malignant LNs. This allows this CAD system to support the radiologists, increasing their detection rate of thoracic LNs and accelerating the diagnostic process.

B-1762 14:00

Diagnostic accuracy of CEUS LI-RADS in characterisation of small liver nodules in patients at risk for hepatocellular carcinoma

J. Huang¹, A. Lyshchik², J.-W. Li¹, Y. Luo¹, J.-B. Liu², Q. Lu¹; ¹Chengdu/CN, ²Philadelphia, PA/US (*51967689@qq.com*)

Purpose: To evaluate diagnostic accuracy of the Contrast Enhanced Ultrasound Liver Imaging Reporting and Data System (CEUS LI-RADS) on hepatocellular carcinoma (HCC) in small focal liver lesions (FLL) in patients at risk for HCC.

Methods and Materials: Patients at risk for HCC presenting with $FLL \leq 20$ mm were enrolled in this study. Each FLL was characterised according to the CEUS LI-RADS and American Association for the Study of Liver Disease (AASLD) 2005 criteria with histology or CE-CT/CE-MRI or more than 12 months' follow-up as reference standard.

Results: Totally 175 nodules in 172 patients were included. The mean nodule size was 16.1 ± 3.4 mm. Totally, 105 nodules were proved HCC by histology. The sensitivity, specificity, positive predictive value (PPV) and positive likelihood ratio (+LR) of CEUS LR-5 and AASLD criteria for the diagnosis of HCC were 73.3% vs. 88.6% ($P < 0.05$), 95.7% vs. 85.7% ($P < 0.05$), 96.3% vs. 90.3% ($P < 0.05$), 17.1 vs. 6.2 ($P < 0.05$), respectively. The rate of HCC in CEUS LR-4 and CEUS LR-M was 50.0 % and 75.0 %, respectively. All cases of intrahepatic cholangiocarcinoma were characterised as LR-M by CEUS LI-RADS while classified as HCC by AASLD criteria.

Conclusion: CEUS LI-RADS performed well in characterisation of small FLLs in patients at risk for HCC. CEUS LR-5 demonstrated exceptionally high specificity, PPV and +LR compared to AASLD criteria for diagnosis of HCC with slightly lower sensitivity. CEUS LR-4 and CEUS LR-M categorisation is highly suspicious for malignancy, but not specific enough for HCC.

B-1763 14:08

Non-invasive imaging diagnosis of hepatocellular carcinoma in patients with both chronic liver disease and a history of extrahepatic primary cancer

M. Cho, C. An, K. Aljoqiman, M.-J. Kim; *Seoul/KR* (*chom974@yuhs.ac*)

Purpose: To evaluate the accuracies of the diagnostic criteria and various features for differentiating between hepatocellular carcinoma (HCC) and liver metastasis in patients at risk for both of them.

Methods and Materials: The study subjects were 59 HCCs and 45 metastases pathologically confirmed between 2008 and 2017 at a single institution in 104 patients with both chronic liver disease (i.e. cirrhosis and chronic hepatitis B) and history of extrahepatic primary cancer. Dynamic contrast-enhanced magnetic resonance imaging or computed tomography images were retrospectively reviewed in consensus by two radiologists, based on Liver Imaging Reporting And Data System (LI-RADS) v2018. Serum tumour markers, tumour multiplicity, and suspicious lymph node metastasis were also evaluated.

Results: Major features had sensitivities of 33.9-88.1% and specificities of 76.3-97.8% for HCC. LR-M features had sensitivities of 76.6-80% and specificities of 86.4-93.2% for metastasis. Elevation of tumour markers for metastasis, tumour multiplicity, and suspicious lymph node were more

frequently observed in metastasis than HCC ($P < 0.034$). The sensitivity and specificity were 69.5% and 95.6% for HCC diagnosis by LR-5, and 85.1% and 89.1% for metastasis by LR-M. One of the two metastases categorized as LR-5 was smaller than 2 cm, and the other was accompanied by tumour multiplicity.
Conclusion: LI-RADS features and diagnostic criteria showed high accuracies in patients at risk for both HCC and metastasis. Radiologic and clinical ancillary findings suggestive of metastasis as warning signs may help minimize the risk of misdiagnosis of metastasis as definitely HCC in this patient group.

B-1764 14:16

A radiomics-clinical model to diagnose hepatocellular carcinoma: prospective comparison with the EASL and LI-RADS (v2018) criteria

H. Jiang, X. Liu, J. Chen, L. Cao, Y. Wei, B. Song; Chengdu/CN
 (hanyu_jiang@foxmail.com)

Purpose: We aimed to develop a multidisciplinary radiomics-clinical diagnostic model for hepatocellular carcinoma (HCC) and to compare its accuracy with the 2018 version of European Association for the Study of the Liver (EASL) and the Liver Imaging Reporting and Data System (LI-RADS) criteria.

Methods and Materials: Ethical approval by the institutional review board and informed consent were obtained for this prospective study. From July 2015 to April 2018, consecutive patients with chronic liver diseases and suspected liver lesions were enrolled and underwent gadoteric acid-enhanced magnetic resonance imaging. We constructed a three-dimensional whole-lesion-based radiomics-clinical nomogram with the least absolute shrinkage and selection operator model and multivariate logistic regression analysis. The diagnostic accuracy of the radiomics-clinical model was validated in an independent cohort and compared with the EASL and LI-RADS criteria, as reviewed by two independent radiologists, with receiver operating characteristic analysis.

Results: A total of 164 nodules in 161 patients were included (mean size 5.41 ± 2.67 cm, 129 HCCs). The sensitivity and specificity of the radiomics-clinical nomogram were 88% and 92% in the training cohort and 69% and 96% in the validation cohort, respectively. These measures were 96% and 60% for the EASL criteria and 92% and 89% for the LI-RADS criteria, respectively. The areas under the ROC curves of the radiomics-clinical model (0.890) and LI-RADS criteria (0.904) were significantly higher than that of the EASL criteria (0.781) ($p < 0.05$ for both).

Conclusion: The radiomics-clinical model demonstrated similar overall accuracy to the LI-RADS criteria with markedly high specificity for HCC in high-risk patients.

B-1765 14:24

Value of targetoid appearance on T2-weighted imaging and signs of tumour vascular involvement for differentiating hepatocellular carcinoma (HCC) from other non-HCC liver malignancies

R. Cannella¹, T.J. Fraum², D.R. Ludwig², A.A. Borhani³, K.J. Fowler⁴, A. Furlan⁵; ¹Palermo/IT, ²Saint Louis, MO/US, ³Pittsburgh, PA/US, ⁴San Diego, CA/US (rob.cannella@libero.it)

Purpose: To evaluate sensitivity and specificity of targetoid appearance on T2-weighted imaging and features of tumour vascular involvement for differentiating HCC from other non-HCC primary hepatic malignancies.

Methods and Materials: This is an IRB-approved retrospective study performed at two large liver transplant centres. The final population included 401 pathologically-proven lesions imaged between 2007 and 2017 with liver protocol contrast-enhanced CT or MRI. The cohort consisted of 172 intrahepatic cholangiocarcinoma and 91 combined hepatocellular-cholangiocarcinoma, with addition of 138 HCCs for control. Two abdominal radiologists (R1; R2) independently reviewed the imaging studies (119 CT; 282 MRI), recording the presence of targetoid appearance on T2-weighted images and features of tumour vascular involvement including: encasement, attenuation, tethering, occlusion, obliteration, and tumour in vein (TIV). Sensitivity and specificity of each feature were calculated for the diagnosis of non-HCC malignancy. The Cohen k test was used to assess the inter-reader agreement.

Results: The sensitivity and specificity of targetoid appearance on T2-weighted images for the diagnosis of non-HCC malignancy were 25.3% and 32.5% (R1; R2) and 98.3% and 97.4% (R1; R2), respectively. Among the features of tumour vascular involvement, those providing the highest sensitivity for non-HCC malignancy were vascular encasement (R1: 33.8%; R2: 38.0%) and obliteration (R1: 26.2%; R2: 32.3%). The highest specificity for non-HCC malignancy was provided by tethering (R1: 100%; R2: 97.1%) and occlusion (R1: 99.3%; R2: 99.3%). The inter-reader agreement was moderate to substantial ($k = 0.430-0.765$).

Conclusion: Targetoid appearance on T2-weighted, vascular tethering and occlusion demonstrated strong inter-reader reliability and high specificity for non-HCC malignancy.

Imaging features of hepatocellular carcinoma: qualitative and quantitative comparisons between hepatobiliary and extracellular contrast-enhanced MRI

J. Son¹, S. Hwang¹, M.-S. Park¹, S. Park², M.-J. Kim¹, J.-Y. Choi¹, K. Han¹; ¹Seoul/KR, ²Goyang/KR (hijwson@yuhs.ac)

Purpose: To compare the major imaging features of HCC on MRI with gadoxetate disodium (hepatobiliary agent, HBA) and gadoterate meglumine (extracellular agent, ECA).

Methods and Materials: Among surgically proven 185 HCCs in 169 patients who underwent liver dynamic MRI with either HBA (n=120) or ECA (n=49), 55 nodules for each of the two contrast media were matched according to the tumour size, Edmonson grade (major and worst), and gross type on pathologic specimen. For qualitative analysis, two board-certified radiologists independently reviewed dynamic enhancement patterns and capsule appearance. For quantitative analysis, the third radiologist measured signal intensity at each phase by placing the region of interest (ROI) for tumour and normal liver parenchyma. The lesion-to-liver contrast (LLC) and lesion-to-liver contrast enhancement ratio (LLCER) were calculated.

Results: On qualitative analysis, delayed phase (DP, 3 min) washout was more frequently seen with HBA (mean=90%, 49.5/55) than ECA (mean=73.6%, 40.5/55) ($p = 0.026$). Capsule appearance was less frequently seen with HBA (mean=37.3%, 20.5/55) than ECA (mean=75.5%, 41.5/55) ($p < 0.001$). On quantitative analysis, the LLC on AP was better with ECA ($p = 0.003$) whereas LLC on DP was better with HBA ($p < 0.001$). The LLCER from unenhanced to AP was higher with ECA ($p = 0.022$) whereas LLCER from PVP to DP was higher with HBA ($p < 0.001$).

Conclusion: The detection of DP washout, LLC on DP, and LLCER from PVP to DP was better with HBA, whereas detection of capsule, LLC on AP, and LLCER from unenhanced to AP was better with ECA.

B-1767 14:40

Radiologic-pathologic correlation of non-hypervascular hypointense nodules on gadoteric acid-enhanced MRI: a multi-centre retrospective observational study

I. Joo, S. Kim, T. Kang, K. Lee, J. Lee; Seoul/KR

Purpose: To assess the distribution of pathologic diagnosis of non-hypervascular hypointense nodules (NHHNs) on gadoteric acid-enhanced MRI (Gd-EOB-MRI) and to determine useful clinical and imaging features for differentiating histologic grades of NHHNs.

Methods and Materials: This multi-centre retrospective study included 334 NHHNs of ≤ 30 mm that were pathologically diagnosed as hepatocellular carcinomas (HCCs) or benign cirrhosis-associated nodules in 298 high-risk patients. Histologic slides of NHHNs were reviewed by central pathologic review to determine the final pathologic diagnosis. Two independent radiologists analysed imaging features, and any discrepancies were resolved by a third reviewer. Clinical and radiologic features were compared according to histologic diagnoses. Logistic regression analysis with generalized estimated equation was performed to find prediction factors to differentiate HCCs from benign nodules.

Results: By central pathologic review, NHHNs were confirmed as progressed HCCs in 147, early HCCs or dysplastic nodules (DNs) with HCC foci in 68, high-grade DN in 92, and low-grade DN or regenerative nodules in 27. According to the histologic categories, nodules were different in clinical and radiologic features: elevation of serum alpha-fetoprotein (≥ 100 ng/mL) was more frequently found in patients with HCCs than those with benign nodules, and MR imaging features including hypointensity on precontrast T1-weighted imaging, hypointensity on portal venous phase, hyper-intensity on T2-weighted imaging, restricted diffusion, and well-defined margin were suggestive of HCCs than benign nodules ($Ps < 0.05$).

Conclusion: NHHNs on Gd-EOB-MRI correspond to the wide spectrum of pathologic diagnoses from RNs to progressed HCCs. Ancillary imaging features are helpful to differentiate HCC from benign cirrhosis-associated nodules.

Diagnostic performance of hepatobiliary phase hypointensity and major imaging features for the diagnosis of HCC in lesions between 10 and 19 mm, and arterial phase hyperenhancement

F. Vernuccio¹, R. Cannella¹, M. Meyer², K.R. Choudhury², M.R. Bashir², A. Furlan³, D. Marin²; ¹Palermo/IT, ²Durham, NC/US, ³Pittsburgh, PA/US (federicavernuccio@gmail.com)

Purpose: To determine the diagnostic performance of hepatobiliary phase (HBP) hypointensity and major imaging features for the diagnosis of hepatocellular carcinoma (HCC) in lesions with arterial phase hyperenhancement (APHE) between 10 and 19mm categorised as LR-3 or LR-

4 in patients at-risk for HCC.

Methods and Materials: In this retrospective dual-Institution study, we included 189 APHE lesions between 10 and 19mm - including 135 LR-3 and 54 LR-4 - in 144 consecutive patients (mean age 58 years). A composite reference standard of pathology and imaging follow-up was used. The diagnostic performance - sensitivity and specificity- of HBP hypointensity and LI-RADS major imaging features for the diagnosis of HCC was assessed and compared using a logistic regression model.

Results: In the overall included lesions, LI-RADS major imaging features showed a specificity of 95%-100% for the diagnosis of HCC, and HBP hypointensity yielded significantly higher sensitivity (84%) but lower specificity (84%) compared to the major imaging features. In LR-3 APHE observations between 10 and 19mm, HBP hypointensity yielded moderately elevated sensitivity (73%) and specificity (85%).

Conclusion: All LI-RADS major imaging features have nearly perfect specificity in APHE lesions between 10 and 19mm, which supports the changes in the LI-RADS v2018 and suggests adding enhancing "capsule" for the upgrade to LR-5 of these lesions. HBP hypointensity significantly improves sensitivity while maintaining moderately high specificity for the diagnosis of HCC in LR-3 APHE lesions between 10 and 19mm, thus justifying the mandatory upgrade of these LR-3 lesions to LR-4.

Predicting progression to hypervascular HCC in hypovascular hypointense nodules on gadoxetic acid-enhanced MR images in patients with chronic liver disease

W.S.R.V. Teerasamit; Bangkok/TH (Mojiamp@gmail.com)

Purpose: To identify the patient characteristics and MR imaging features of hypovascular hypointense nodule on hepatobiliary phase gadoxetic acid-enhanced MR imaging in patients with chronic liver disease associated to progression to hypervascular hepatocellular carcinoma (HCC).

Methods and Materials: The institutional review board approved this retrospective review of total 40 patients with 60 hypovascular hypointense nodules on hepatobiliary phase gadoxetic-enhanced MR images. Univariate and multivariate Cox regression analysis for the hypervascular HCC development were used to define the variables including initial nodule size, cause of cirrhosis, history of locoregional therapy of HCC, fat-containing, signal intensity on T1W, T2W, portal and equilibrium phases of dynamic phase, and DW images. Furthermore, cumulative percentage incidence of hypervascularity and growth rate was calculated by using receiver operating characteristic (ROC) curve.

Results: The prevalence of progression to hypervascular HCC was 45% (27 out of 60). Multivariable Cox analysis of developing hypervascularization was initial nodule diameter more than 1 cm. (P=0.027; HR 2.52; 95% CI: 1.11,5.74) The mean growth rate was significantly higher in subsequent hypervascular nodule than in those without hypervascularization (P < 0.001). Cumulative risk incidence of hypervascularization at 3, 6, 12, 24 months were 5%, 20%, 35%, 44 %, respectively.

Conclusion: Initial nodule diameter more than 1 cm is an independent risk factor for progression to hypervascular HCC in hypovascular hypointensity on hepatobiliary phases in patients with chronic liver disease.

B-1771 15:12

Liver imaging reporting and data system v2018: visualisation rate and diagnostic value of ancillary features favouring malignancy in observations at intermediate and high risk for HCC

R. Cannella¹, F. Vernuccio¹, D. Marin², A. Furlan³, ¹Palermo/IT, ²Durham, NC/US, ³Pittsburgh, PA/US (rob.cannella@libero.it)

Purpose: To assess visualisation rate and diagnostic accuracy of LI-RADSV2018 ancillary features (AFs) favouring malignancy in LR-3 and LR-4 observations on gadoxetate-enhanced MRI.

Methods and Materials: In this IRB-approved retrospective dual-institution study, we included consecutive patients at risk for HCC imaged with gadoxetate-enhanced MRI between 2009-2014 fulfilling the following criteria: i) at least one LR-3 or LR-4 ≥ 1 cm; ii) non-rim arterial phase hyperenhancement; iii) confirmation of benignity or malignancy by pathologic proof or imaging follow-up. Four readers recorded the LI-RADSV2018 AFs favouring malignancy. We compared difference in visualisation rates of AFs between benign lesions and HCCs and calculated sensitivity and specificity of each AF for the diagnosis of HCC. Significance was set at P-value <0.05.

Results: 205 observations were selected in 155 patients including 167 (81.5%) LR-3 and 38 (18.5%) LR-4. There were 126 (61.5%) HCCs and 79 (28.5%) benign lesions. A significantly larger number of AFs favouring malignancy was found in LR-3 and LR-4 that progressed to HCC compared to benign lesions (P<.001 and P=.003). The most common AFs favouring malignancy in HCCs included hepatobiliary phase hypointensity (P<.001), transitional phase

hypointensity (P<.001) and mild-moderate T2 hyperintensity (P<.001). Sensitivity and specificity of AFs for the diagnosis of HCC were 2.4%-76.2% and 86.1%-100%, respectively. Hepatobiliary phase hypointensity yielded the highest sensitivity but the lowest specificity.

Conclusion: LR-3 and LR-4 progressing to HCC have a significantly higher number of AFs favoring malignancy compared to benign lesions. Among all AFs, hepatobiliary phase hypointensity yields the highest sensitivity for the diagnosis of HCC.

Response assessment of HCC after locoregional therapy on gadoxetic acid-enhanced MRI: performance of the LI-RADS TR categorisation and added value of ancillary features

S. Kim, I. Joo, H.-C. Kim, S. Ahn, H.-J. Kang, S. Jeon, J. Han; Seoul/KR (shrimpkim90@gmail.com)

Purpose: To determine the performance of the liver imaging reporting and data system (LI-RADS) treatment response (LR-TR) categorization on gadoxetic acid-enhanced MR imaging (Gd-EOB-MRI) and to investigate the added value of ancillary features (AFs) to the conventional enhancement-based criteria for detecting viable tumours.

Methods and Materials: This retrospective study included 207 patients with Gd-EOB-MRI after locoregional treatment for hepatocellular carcinoma (HCC) and a reference standard for marginal recurrence (viable, n=107; non-viable, n=100). For each treated observation, two independent radiologists assigned treatment response categories (TR-nonviable, TR-equivocal, or TR-viable) according to different criteria: i) LR-TR, ii) TP-included: including transitional phase (TP) for determining washout, iii) AF-applied: applying AFs on hepatobiliary phase, diffusion-weighted imaging, and T2-weighted imaging for the category adjustment. Diagnostic performances of imaging criteria were compared using the McNemar test.

Results: For detecting viable tumours, LR-TR-viable resulted in sensitivities of 64.5% and 39.3%, specificities of 98.0% and 98.0%, and accuracies of 80.7% and 67.6% in reviewers 1 and 2, respectively. TP-included viable and AF-included viable showed significantly higher sensitivities (77.6% and 55.1%; 88.8% and 86.0%) than LR-TR in both reviewers (Ps<0.001), while their specificities (98.0% and 96.0%; 97.0% and 96.0%) were comparable to LR-TR (Ps>0.05). In addition, TR-equivocal was less frequently assigned on AF-applied (1.4% and 7.2%) than LR-TR (18.4% and 35.3%) or TP-included (7.7% and 25.7%) in both reviewers.

Conclusion: LR-TR on Gd-EOB-MRI provides specific diagnosis of viable tumours but shows limited sensitivity. By applying ancillary features in the category adjustment, more sensitive and confident diagnosis of recurred HCC can be achieved.

Comparison of contrast-enhanced modified T1-weighted 3D TSE black blood and 3D MP-RAGE sequences for detection of meningeal enhancement

M.F. Froelich, R. Pons Lucas, E. Coppenrath, W. Sommer, K.M. Treitl, T. Saam, N.N. Sommer; Munich/DE

Purpose: To compare a contrast-enhanced modified T1-weighted 3D TSE black blood sequence (T1-mVISTA) with a 3D gradient echo sequence (MP-RAGE) for the detection of meningeal enhancement in patients with suspected meningitis or meningioma.

Methods and Materials: We consecutively selected subjects with known meningeal affection from 10/2013 to 10/2017 for this retrospective study. All patients underwent T1-mVISTA (0.75-mm isotropic resolution) and MP-RAGE (0.8-mm isotropic resolution) at 3-Tesla after application of contrast agent in random order. Presence of dural and leptomeningeal enhancement, supra- and infratentorial location, side, visual contrast enhancement (VCE), image quality and diagnostic confidence were assessed by an experienced radiologist for both sequences in separate reading sessions three weeks apart. Results were compared utilizing chi-square and Wilcoxon tests for paired two-tailed samples. A p<0.05 was considered statistically significant.

Results: A total of thirty patients (12 female, mean age 22 years) were included in the analysis. 11 patients (36.67%) had a suspected infectious aetiology. T1-mVISTA detected either dural or leptomeningeal enhancement in 30 patients (100% sensitivity), while MP-RAGE showed any meningeal enhancement in 24 patients (80% sensitivity). Diagnostic confidence did not differ significantly in patients showing dural/leptomeningeal enhancement in both sequences (all $p > 0.05$). However, a total of 19 patients showed dural enhancement on MP-RAGE while 21 patients were dural-positive on T1-mVISTA ($p < 0.01$). Furthermore, MP-RAGE showed leptomeningeal enhancement in 15 patients, while T1-mVISTA detected leptomeningeal enhancement in 26 patients, including all MP-RAGE-positive patients ($p = 0.038$).

Conclusion: T1-mVISTA may offer an increased sensitivity compared to MP-RAGE sequences, especially for leptomeningeal enhancement.

B-1774 14:08

Application of half-dose contrast-enhanced T2-fluid-attenuated inversion recovery sequence in brain metastasis

T. Jin; Shanghai/CN

Purpose: To assess the detection rate and image quality of 1/2-dose CE T2-fluid-attenuated inversion recovery (FLAIR) in intracranial metastases, compared with CE-T1-weighted imaging (T1WI).

Methods and Materials: Thirty-three patients with known cancers and brain metastasis underwent pre- and post-contrast sequences including: i) 1/2-dose CE-T2-FLAIR, ii) 1/2-dose CE-T1WI, and iii) full-dose CE-3D-BRAVO sequence scan. The optimum scanning time for 1/2-dose CE-T2-FLAIR was analyzed, and we compared contrast ratio (CR) and the number of parenchymal metastases on three sequences above.

Results: One hundred and forty-one 1/2-dose CE-T2-FLAIR, 88 1/2-dose CE-T1WI, and 123 full-dose CE-BRAVO sequence-enhanced lesions were classified as metastases. When metastases were ring-enhanced or solid-enhanced with a diameter of < 5 mm, the number of metastases detected in 1/2-dose CE-T2-FLAIR was higher than that in 1/2-dose CE-T1WI and full-dose CE-BRAVO. However, if solid-enhanced metastases were ≥ 5 mm, the number of metastases detected in 1/2-dose CE-T2-FLAIR was less than that in 1/2-dose CE-T1WI or full-dose CE-BRAVO. In 77 metastatic lesions which both displayed in three sequences, the median CR was significantly higher using optimized 1/2-dose CE-T2-FLAIR (in phase 2, $CR = 71.6$) than 1/2-dose CE-T1WI ($CR = 11.7$, $P < 0.001$) or full-dose CE-BRAVO sequence ($CR = 18.9$, $P < 0.001$).

Conclusion: Half dose CE-T2-FLAIR has distinct advantage in detecting brain metastases, especially ring-enhanced or small solid-enhanced lesions.

B-1775 14:16

Is synthetic MRI of the brain feasible in a clinical setting? A comparison with standard protocol

G. Corrias, A. Balestrieri, L. Saba; Cagliari/IT (corriasgmd@gmail.com)

Purpose: To investigate Radiologist's satisfaction and image quality using an alternative synthetic MRI (sMRI) protocol in Brain imaging.

Methods and Materials: 30 patients were examined using an MRI scan with a field of 3 Tesla and a 32-channels coil. On the top of the standard brain MRI protocol, two additional sMRI sequences were added: [T2]-multi-TE-FSE2D and [T1]-MP2RAGE-(3D). From these two sequences FLAIR, DIR and fat sat images have been reconstructed on the dedicated workstation with a commercially available software (OLEAnova+, Olea Medical, Paris). One radiologists with 6 years of experience graded T1, T2, DIR and FLAIR from the standard and the experimental protocol on a 5 points scale voting image quality, lesion detection and overall satisfaction. Intra-class correlation coefficient (ICC) and repeatability coefficient (RC) were estimated to evaluate agreement between every pair of sequences.

Results: The results were grouped in two categories (score 1-3, sufficient; score 4-5, insufficient). Concordance with these two groups of scores was above 80% for almost all sequences analyzed except from FLAIR images.

Conclusion: Synthetic MRI would reduce the acquisition time of a brain MRI of 6min:50sec. Image quality, lesion detection and overall satisfaction are not different between the standard protocol and the reconstructed sequences obtained from sMRI.

B-1776 14:24

Diagnostic efficacy and safety of gadoteridol in neuroradiology: qualitative assessment in a large sample of MRI studies at 1.5T

A. Del Poggio, C. Pereira, A. Iadanza, A. Falini, N. Anzalone; Milan/IT (adelpoggio@gmail.com)

Purpose: The suspension of linear gadolinium chelates has restricted the choice in neuroradiological field to the macrocyclic compounds. We prospectively evaluated in a clinical setting the safety and diagnostic accuracy of a macrocyclic compound (gadoteridol).

Methods and Materials: From November 2017 to February 2018 a consecutive cohort of patients undergoing to 1.5T neuroradiological magnetic resonance (MRI) with gadoteridol was prospectively enrolled. Image quality and adverse events associated with contrast administration were assessed. Diagnostic performance compared to histological data or to a control MRI was evaluated in a subgroup of patients with neoplastic disease. Inter-reader agreement (kappa) between two expert neuroradiologists was calculated for the diagnosis of malignancy.

Results: 244 patients (128M/116F; mean age 53.5 ± 17.2 years) were enrolled. Overall, 122 (50%) were diagnosed with oncological pathology. Other diagnoses were inflammatory (43 [17.6%]), vascular (24 [9.8%]), infectious or granulomatous (9 [3.7%]) or 'other' (26 [6.6%]). 30 patients (12.2%) were negative. In all cases the MRI exam was diagnostic. There were two allergic reactions (0.8%), one moderate/severe, in line with the literature. Diagnostic accuracy for the diagnosis of malignancy among the subgroup with neoplastic pathology was 97.3% (95%CI 92.3-99.1) with sensitivity and specificity of 94.3% (95%CI 80.8-99.3) and 98.7% (95%CI 92.8-99.9), respectively. The inter-reader agreement for the diagnosis of malignancy was excellent ($K = 0.85$ [95%CI 0.76 - 0.95]).

Conclusion: Gadoteridol was safe and guaranteed good image quality in a large population. Within the subgroup with neoplastic pathology the diagnostic accuracy for malignancy was 97.3% with sensitivity and specificity of 94.3% and 98.7% respectively.

B-1777 14:32

MRI T1w brain signal intensity and relaxation times in individuals with prior exposure to gadobutrol

M. Saake, A. Schmidle, M. Kopp, J. Hanspach, T. Hepp, A. Nagel, A. Doerfler, M. Uder, T. Baeuerle; Erlangen/DE

Purpose: The purpose was to screen a large MRI population for the number of injected doses of gadobutrol in patients with normal and impaired kidney function and to recall selected individuals for assessment of gadolinium brain retention.

Methods and Materials: The database of the University Hospital Erlangen was searched for patients who received gadobutrol between 2007 and 2017 and not any other intravenous MRI contrast agent. Patients with at least 5 (range 5-20) contrast-enhanced MRI scans and normal kidney function (group 1) and at least 1 (range 1-9) contrast-enhanced MRI scans and impaired kidney function (group 2) were matched with control patients who received no MRI contrast agent before (groups 3 and 4). All individuals from groups 1-4 were invited. In participants, brain MRI was performed: T1w morphology and T1 mapping.

Results: Between 2007 and 2017, over 35.000 patients received up to 26 single doses of gadobutrol only at our institution. Of these, 701, 1239, 94 and 409 patients matched the criteria of groups 1-4, respectively. After recalling 2.444 individuals, we were able to perform brain MRI in 220 individuals (groups 1-4: 76, 84, 25, 35, respectively). No significant differences in T1w signal intensity ratios and T1 ratios were found in the dentate nucleus and globus pallidus between patients of groups 1 and 2 and the matched controls.

Conclusion: Based on the measured ratios, we found no statistical evidence for gadolinium brain retention after administration of multiple doses of gadobutrol in patients with normal and impaired kidney function.

Glutamate concentration changes in response to continuous stimulation

A. Manzhurtsev, P. Menshchikov, M. Ublinskiy, N. Semenova, O. Bozhko, T. Akhadov; Moscow/RU (andrey.man.93@gmail.com)

Purpose: Functional MRS of glutamate (Glu) is of high interest since it is the main excitatory neurotransmitter. There is a problem of separating Glu and glutamine signals in MRS, especially at 3 Tesla. We used TE average to measure local Glu change in response to continuous visual stimulation at 3T.

Methods and Materials: Twelve healthy subjects (18-27 y.o.) were analysed with Philips Achieva dStream 3T and Head-Neck SENSE coil. Video stimulation: monitor, mirror, 8-Hz flashing checkerboard. The spectroscopy voxel (20x40x30 mm) was located in visual cortex. Glu signal was obtained with TE-averaged sequence: TE=35, 45, ..., 185 ms, TR=2000 ms, NSA=16, total averages: 256, t=8.5 min. Spectrum in rest was obtained and then spectrum during visual stimulation. Spectral processing: LCModel, program based on FID-A was written to simulate TEavg brain in vivo spectra; basis set for LCModel was created, Glu/Cr and NAA/Cr values were obtained. The stimulation/rest values on Glu/Cr and NAA/Cr were found and compared with a value of 1 (Mann-Whitney criterion).

Results: Glu peak at 2.35 ppm was perfectly fitted by the simulated basis set. The increase (by 5%, $p < 0.05$) of Glu/Cr was revealed, NAA/Cr remained unchanged.

Conclusion: For the first time, TEavg was used for functional MRS of glutamate. It allowed to confidently observe the growth of Glu at 3 Tesla during continuous visual stimulation, which is in agreement with published data obtained at 7 Tesla. The stability of NAA in this study (that is often reported to be decreased in neuroactivation) might be the manifestation of neuronal adaptation.

B-1779 14:48

Two postprocessing method of diffusion kurtosis imaging in glioma grading

A. Gao¹, J. Bai¹, Y. Zhang¹, J. Cheng¹, Y. Hong²; ¹Zhengzhou/CN, ²Hangzhou/CN (annygao456@163.com)

Purpose: To compare histogram analysis and DKE in glioma grading. **Methods and Materials:** DKI and conventional sequence at 3.0T MR scanner. DKI acquires data with six b values (0-2500 sec/mm²) and uses diffusion encoding in 30 directions, scanned using a SE-EPI sequence. DKE software was used to calculate diffusion parameters FA, MK, and RK and AK. Histogram analysis was based on Matlab platform, which was used to calculate diffusion parameters Kapp and Dapp value based on TRACEW parameter image. Independent-samples T test or Mann-Whitney-Wilcoxon test was used to distinguish glioma grades. The parameters with the best percentile were identified by analysis of the AUC of the receiver operating characteristic ROC analysis.

Results: Grade II(n=21), III(n=13) and IV(n=39) glioma were observed. There were significant difference between high and low grade glioma groups by histogram analysis of the Kapp value of maximum, mean, standard deviation, 75th percentile, 95th percentile, and the Dapp value of minimum, mean, 25th percentile, 50th percentile, 75th percentile, 95th percentile, skewness coefficients. According to the ROC, the highest AUC were found at Dapp minimum value (AUC,0.829), Kapp 75th percentile value (AUC,0.819). However, DKE method proved that MK value is significant higher in III grade glioma than it in II grade glioma (AUC,0.996). When it comes to III and IV grade glioma, MK was significant higher in IV grade glioma than III grade glioma (AUC,0.953).

Conclusion: MK value, calculated by DKE software, is a helpful parameter for identifying glioma II, III and IV grade.

B-1780 14:56

Open-source software multimodal neuroimage processing for presurgical assessment: benefits and comparison to proprietary software

P. Donnelly-Kehoe, A.A. Qieda, G. Pascariello, P.A. Acevedo, M.B. Nallino, A.L. Rodriguez Musso, J. Gomez; *Rosario/AR (ojedaheleg@hotmail.com)*

Purpose: Multimodal neuroimage processing allows an optimum presurgical assessment. Structural sequences are used as anatomical guides, fMRI protocols serve to recognize functional regions and DWI reveal the underlying structural connectivity. Proprietary software exhibit several limitations in the processing of each modality and also in the multimodal integration. This work introduces an open-source based toolbox for the multimodal presurgical assessment with state-of-the-art methods.

Methods and Materials: We developed pipelines to process structural, functional and diffusion MRI. The structural pipeline included an automatic segmentation of neuroanatomic regions; fMRI included the removal of movement and non-neural signals based on independent component analysis. The tractography pipeline removed movement and eddy currents and the neuroanatomical segmentation was used for a standardized tract segmentation. Four clinical cases were processed to compare results with the available proprietary software.

Results: Results obtained by the proposed method showed to be superior to the ones obtained by the proprietary software. Main advantages were: (i) structural segmentation automatically delimits anatomical structures; (ii) noise and artefacts from fMRI and DWI were successfully removed, improving signal to noise ratio; (iii) anatomical and functional information was included in the segmentation of tracts; (iv) multiples fMRI protocols were combined within the same space.

Conclusion: The application in clinical cases showed that our methods allow a more effective presurgical assessment than proprietary software that are commonly used in the clinical practice. In this context, the usage of open-source packages is a better alternative for the neuroimage processing, allowing to know the processes and to improve them.

B-1781 15:04

Clinically-implemented, CAD-assisted decision support system to limit gadolinium injection in patients with multiple sclerosis

M. Bilello, R. Mattay, A. Mamourian; *Philadelphia, PA/US (Michel.Bilello@uphs.upenn.edu)*

Purpose: The growing concern about deposition of free gadolinium in the brain among patients that undergo serial contrast-enhanced MRI studies needs to be addressed. We have implemented a clinical decision support system to limit

contrast injections in patients with multiple sclerosis (MS).

Methods and Materials: The main idea is to inject only when scans demonstrate new lesions. The rationale stems from a study we recently conducted, which revealed that 1) 50% of scans with new lesions had enhancing lesions, 2) 100% of scans with enhancing lesions had new lesions, and 3) 24% of all scans had new lesions. A major component of the system is a CAD program that detects new brain lesions on T2/FLAIR images. Here is the workflow: the 3D FLAIR sequence used by the CAD program is acquired first. Immediately after completion, our clinical 3D lab runs the CAD program, and calls the MR technologist with the results: if there is at least one new lesion, the technologist is to perform a complete contrast-enhanced scan. If not, only the non-contrast part of the scan gets done.

Results: We expect to limit the use of gadolinium injection to about 25% of all our follow-up MS brain scans. With more than 100 such scans per month, we expect to avoid about 75 unnecessary gadolinium injections each month.

Conclusion: Our system limits the use of unnecessary gadolinium injections in MS brain scans. This will address the growing concern of patients, who now receive such injections for all their surveillance scans.

B-1782 15:12

Machine learning-based exploration of extracranial determinants of grey matter volume in the KORA-MRI study

F. Schöppe¹, S. Rospleszcz¹, F. Bamberg², C.L. Schlett³, W. Rathmann⁴, K.-H. Ladwig¹, A. Peters¹, B.B. Ertl-Wagner², S. Stöcklein¹; ¹Munich/DE, ²Freiburg/DE, ³Heidelberg/DE, ⁴Duesseldorf/DE, ⁵Toronto, ON/CA (Franziska.Schoeppe@med.uni-muenchen.de)

Purpose: The aim of this data-driven exploratory study was to identify potential extracranial determinants of grey matter volume (GMV) using a machine learning algorithm.

Methods and Materials: From the prospective cohort from the Cooperative Health Research in the Region of Augsburg, Germany (KORA FF4 study), extracranial variables (n = 58) were obtained in a standardized way and whole-brain GMV (ratio-corrected for intracranial volume) was derived from magnetic resonance imaging (3T, FLAIR). Using a machine-learning approach, we evaluated an elastic net on 1000 splits of training and testing data to identify the most important extracranial factors of GMV.

Results: 293 participants (59% men, 55.4±9.1 years, mean whole-brain GMV 20.5%±1.3) were included in the analysis. 11.9% of the subjects had type 2 diabetes mellitus, 23.2% prediabetes and 64.8% were normoglycemic. From 58 different extracranial variables, four variables were identified to be the most important determinants of whole-brain GMV: age (selected in 1000/1000 splits), glomerular filtration rate (794 splits), diabetes (323 splits) and diabetes duration (122 splits). GMV was lower in participants with diabetes compared to normoglycemic subjects (19.7%±1.6 vs 20.6%±1.2, p<0.001) and decreased with increasing diabetes duration (r = -0.15, p = 0.009). The elastic net model showed better performance compared to a constant linear regression (mean squared error = 1.10 vs. 1.59, p<0.001).

Conclusion: Applying a machine learning approach, elastic net identifies extracranial determinants of GMV and provides information on their relative importance. Our results underline the importance of assessing extracranial variables such as diabetes status upon inclusion of subjects in imaging studies.

B-1783 15:20

Virtual monoenergetic images from spectral detector CT (SDCT) enable radiation dose reduction in unenhanced cranial CT

R.P. Reimer, T.E. Lichtenstein, D. Flatten, D. Maintz, J. Borggreffe, N. Grosse Hokamp; *Cologne/DE (robert.reimer@uk-koeln.de)*

Purpose: Recent studies demonstrated that grey-white-matter-differentiation is improved by means of 65 keV-virtual monoenergetic images (VMI_{65keV}) as compared to conventional images (CI). Our study evaluated, if this enables a reduction of radiation-dose.

Methods and Materials: 115 consecutive patients receiving SDCT of the head between 2/2017 and 6/2017 (age: 55±19yrs, M/W: 56%/44%) were retrospectively included. For routine protocol adjustment, tube current time product was reduced by 10% during the study period, resulting in 60 and 55 patients examined with 320 mAs and 290 mAs, respectively. All other scanning parameters were kept identical (including tube voltage 120 kVp). Regions-of-interest were placed in grey and white matter on CI and copied to identical positions in VMI_{65keV}. Contrast-to-noise ratio (CNR) was calculated. Two radiologists, blinded to the reconstruction technique evaluated grey-white-matter-differentiation on a 5-point Likert-scale. Statistical assessment was performed using ANOVA adjusted for multiple comparisons and Wilcoxon test.

Results: Irrespective of mAs, noise was significantly lower in VMI_{65keV} as compared to CI (VMI_{65keV}/CI, e.g. grey-matter with 290 mAs: 3.1±0.6HU/4.6±0.9HU, p<0.0001). In CI, noise was slightly higher in 290 mAs protocols as compared to 320 mAs (e.g. white-matter: 4.9±0.9HU/4.6±0.8HU, p>0.05). Overall, CNR in VMI_{65keV} was superior to CI irrespective of mAs (p<0.0001). Particularly, VMI_{65keV} with 290mAs showed a higher CNR than CI with 320 mAs. Subjective analysis confirmed better grey-white-matter-

differentiation on VM_{165keV} images, even using 290 mAs.

Conclusion: VM_{165keV} from SDCT allow for radiation-dose reduction in cranial CT. While this proof-of-concept included a radiation-dose reduction of 10%, our data suggest that even greater reduction seems possible.

The accuracy of contrast-enhanced mammography: a retrospective multireader study

M. Calvo Imirizaldu¹, I. González de la Huebra Rodríguez¹, A. Ezponda Casajús¹, J. Etxano², A.M. Elizalde Pérez¹, L.J. Pina Insausti¹; ¹Pamplona/ES, ²Vitoria/ES (igonzalez.6@unav.es)

Purpose: To compare the accuracy of Digital Mammography (DM) and Titanium Contrast Enhanced Mammography (TiCEM).

Methods and Materials: IRB approved study. From October-2017 to June-2018, 80 patients with 120 histologically confirmed lesions were recruited. All of them underwent DM and TiCEM. This is a new technique to perform contrast enhanced mammography using a titanium filter. Three readers, blinded to the final diagnosis, retrospectively evaluated the lesions and classified them into the BI-RADS categories. Reader 1 was an expert with 20-years of experience, Reader 2 was a resident with 3-months of experience and Reader 3 was an intermediate level (3-years). For every case readers assessed the DM images and immediately the TiCEM images. Statistical analysis: ROC curves (STATA 12.0 software) for the complete database and for subgroups (dense and non-dense breasts).

Results: Out of the 120 lesions, 41 were benign and 79 malignant (12 DCIS, 5 ILC, 62 IDC). The AUC's of DM vs TiCEM for Reader 1 were: 0.72 vs 0.86; p<0.001. For Reader 2 were: 0.63 vs 0.80; p<0.001. For Reader 3 were: 0.70 vs 0.79; p<0.001. These data were similar for dense and non-dense breasts. Comparison between the AUC of DM for Reader 1 (expert) vs AUC of TiCEM for Reader 2 (Resident) found significant differences (0.72 vs 0.80; p=0.04).

Conclusion: The accuracy of TiCEM was significantly better for all the readers, in dense and non-dense breasts. The accuracy of a Resident reading a TiCEM study was even better than that of an expert radiologist reading DM.

B-1785 14:08

Contrast-enhanced digital mammography, magnetic resonance imaging and mammography alone: a comparison of diagnostic performance in symptomatic women

W. Tang; Shanghai/CN (tangwei12@fudan.edu.cn)

Purpose: To compare the diagnostic efficiency of contrast-enhanced digital mammography (CEDM), digital mammography (DM) and magnetic resonance imaging (MRI) in symptomatic women.

Methods and Materials: Between March and December 2017, 246 patients with 282 histologically proven lesions all underwent DM, CEDM and MRI. Two radiologists were interpreting all images. The diagnostic performance of each method was assessed by receiver-operating characteristic (ROC) curve. The sensitivity, specificity and accuracy were compared using McNemar's and Fisher's exact test. A Kappa test was used to assess the interobserver agreement.

Results: The area under the ROC curve was lower in the group that underwent DM (Radiologist 1 [R1], 0.829; Radiologist 2 [R2], 0.862) than CEDM (R1, 0.927, P=0.0214; R2, 0.910, P=0.0229) and MRI (R1, 0.939, P=0.0006; R2, 0.925, P=0.0009). However, the difference between CEDM and MRI was not significant (R1, P=0.2262; R2, P=0.2843). The accuracy (R1, 73.8%; R2, 72.4%) and sensitivity (R1, 74.9%; R2, 74.2%) of DM were lower than CEDM (accuracy: R1, 89.7%, P=0.001; R2, 90.8%, P<0.001; sensitivity: R1, 92.1%, P<0.001; R2, 90.8%, P<0.001) and MRI (accuracy: R1, 91.3%, P=0.001; R2, 92.7%, P<0.001; sensitivity: R1, 94.7%, P<0.001; R2, 95.4%, P<0.001). In contrast, no significant difference was observed between CEDM and MRI (accuracy: R1, P=0.744; R2, P=0.660; sensitivity: R1, P=0.602; R2, P=0.759). The interobserver agreement of each method was excellent (k=0.896, 0.929 and 0.882 for DM, CEDM and MRI, respectively).

Conclusion: The diagnostic performance of CEDM and MRI is superior to that of DM in symptomatic women; MRI is slightly better than that of CEDM, but without statistical significance.

B-1787 14:16

Evaluation of single-view contrast-enhanced mammography as potential strategy for screening of patient with high breast cancer risk: a non-inferiority retrospective study

M.B.I. Lobbes, J. Hecker, I. Houben, R. Pluymakers, C. Jeukens, U. Lalji, S. Gommers, J.E. Wildberger, P.J. Nelemans; Maastricht/NL (marc.lobbes@mumc.nl)

Purpose: Many guidelines recommend screening of high-risk women using breast MRI. Contrast-enhanced mammography (CEM) might be an alternative strategy. However, its radiation dose is higher than mammography. As an alternative reading strategy, evaluation of single-view (1V) CEM exams might be considered instead of double-view (2V) readings to lower total radiation dose used per exam.

Methods and Materials: This retrospective observational non-inferiority study evaluates whether use of 1V does not result in an unacceptable worse sensitivity for detecting breast cancer (non-inferiority margin: -10%). All CEM images from May 2013 and December 2017 were included. 1V readings were performed by consensus opinion of three radiologists, with 2V readings being performed after six weeks. Cases were considered 'malignant' if the final score was BI-RADS ≥ 4 , enabling us to calculate sensitivity, specificity and AUC under the ROC curve. Histopathological results or a minimal follow-up of six months served as gold standard.

Results: 368 cases were evaluated. Sensitivity decreased with 9.6% from 92.9% to 83.3% when only 1V was used for evaluation (p=0.0009). The lower limit of the 90% CI around the difference in sensitivity between 1V and 2V readings was -15% and lies below the predefined non-inferiority margin of -10%, and non-inferiority of 1V to 2V reading cannot be concluded. AUC for 1V was 0.861 versus 0.899 for 2V (p=0.0174).

Conclusion: 1V evaluations as an alternative reading strategy to the standard 2V evaluations have a worse overall diagnostic performance and it cannot be recommended as an alternative reading strategy to lower CEM-associated radiation exposure.

B-1788 14:24

Comparison of the intensity and pattern of enhancement on contrast-enhanced spectral mammography between malignant and benign breast lesions

Y. Liu, J. Yu, L. Su; Chengdu/CN (ly0283@yeah.net)

Purpose: To investigate the relationship between histological results and the intensity and pattern of enhancement on contrast-enhanced spectral mammography (CESM).

Methods and Materials: Breast CESM was performed on patients with ACR-BIRADS 4 or above by ultrasound. Two experienced radiologists analysed the images and diagnosed together. Regarding pathology results as the gold standard, an enhancement of breast lesion on CESM as positive result, the diagnostic accuracy of CESM was analysed. The enhancement characteristics of CESM images were qualitatively assessed, including the intensity and pattern of enhancement.

Results: 50 cases were enrolled, in which 29 were malignant and the remaining 21 were benign. The performance of CESM was: sensitivity 100%, specificity 38.1% and area under the ROC curve 0.714. All malignant lesions showed enhancement, and most frequently presented as medium or strong enhancement (24). For these with medium or strong enhancement (30), 24 lesions were malignant. There were 13 cases of benign lesions presented as enhancement; and most frequently as weak enhancement (7). There were 17 malignant lesions and 3 benign lesions with homogeneous enhancement, 12 malignant lesions and 9 benign lesions with heterogeneous enhancement. There was significant difference of the degree of enhancement between benign and malignant groups (P<0.001), but there was no significant difference of the pattern of enhancement between the two (P=0.917).

Conclusion: The specificity of CESM is limited. Medium or strong enhancement on CESM is related to breast cancer, which may help predict the risk of malignancy for suspicious breast lesions.

B-1789 14:32

Propagation-based computed tomography and cone-beam computed tomography of the breast: a comparison of radiological image quality

S. Tavakoli Tabataba¹, P. Baran², Y. Nesterets², S. Pacile³, S. Wienbeck⁴, C. Dullin⁴, F. Arfelli³, S. Lewis¹, G. Tromba³, T. Gureyev², P. Brennan¹; ¹Sydney/AU, ²Melbourne/AU, ³Trieste/IT, ⁴Göttingen/DE (amir.tavakoli@sydney.edu.au)

Purpose: Propagation-based phase-contrast CT (PBCT) and cone-beam breast CT (CBCT) are two cutting-edge techniques for breast cancer imaging. A comparison of the radiological quality of images produced by the two

techniques are presented.

Methods and Materials: PBCT and CBCT were performed on eight formalin-fixed breast tissue samples which were of different sizes and included various types of tumour. The PBCT experiment was conducted at the SYRMEP beamline of the Elettra synchrotron in Trieste, Italy at standard radiation dose of 6 mGy and low dose of 1.5 mGy. The CBCT scans were collected using a Koning Breast-CT machine (CBCT1000) at the University Medical Center Göttingen, Germany at standard radiation dose of 6 mGy. Six medical imaging experts independently compared the images from the two modalities and rated radiological quality for each set of images using a five-point rating scale. Image quality was analysed using visual grading characteristics (VGC) and the area under the curve ($0 \leq AUC_{VGC} \leq 1$) was calculated to measure the difference in the image quality of the two systems.

Results: VGC analysis revealed that the image quality was significantly higher for standard dose PBCT than standard dose CBCT; $AUC_{VGC} = 0.990$ ($p < 0.01$). Moreover, the image quality was significantly higher for low dose PBCT than standard dose CBCT; $AUC_{VGC} = 0.812$ ($p < 0.05$).

Conclusion: PBCT can lead to improvements in radiological image quality of breast images even at lower radiation doses compared to CBCT. PBCT is expected to become a viable method for early diagnosis of breast cancer in the future.

B-1790 14:40

Dedicated breast CT may prevent unnecessary biopsies in women recalled from mammographic screening

R.M. Mann, G. van Spijker, M. Caballo, I. Sechopoulos; *Nijmegen/NL (Ritse.mann@radboudumc.nl)*

Purpose: To assess the potential of dedicated unenhanced breast-CT (BCT) in the clinical work-up of women recalled from mammographic screening.

Methods and Materials: 51 women recalled from screening participated in this ethics board-approved study. All women underwent unilateral unenhanced BCT using a dedicated breastCTsystem (Koning Corp., NY, USA), in addition to the regular clinical work-up (tomosynthesis, and ultrasound for soft tissue findings). BCT images were evaluated by an independent radiologist (BI-RADS ≥ 3 positive). The potential impact of BCT on sensitivity and positive predictive value for biopsy (PPV3) was assessed using the McNemar test. Subgroup analyses were performed for different types of mammographic findings.

Results: Clinical work-up led to biopsy for 26 lesions, (6 malignant, 20 benign, PPV3 23%). BCT was positive in 39 lesions (mean size 11.8 mm, range 3-51 mm), (5 malignant, 34 benign, sensitivity 83%, ns). The missed cancer was located in the axillary tail and therefore outside the BCT field of view. BCT had no impact on the indication to biopsy or not for mass lesions ($n=23$, 7 biopsied, 4 malignant), with findings being consistent with those from mammography. In patients presenting with calcifications ($n=21$, 18 biopsied, 2 malignant) BCT was negative in 7 patients with benign lesions, potentially improving the PPV3 for calcifications from 11% to 18% ($p=0.023$). In women with architectural distortion or focal asymmetry ($n=8$, 0 biopsied) BCT also dismissed the screening findings.

Conclusion: This pilot study suggests that unenhanced BCT may be used to prevent unnecessary biopsies in women recalled for benign calcifications.

Influence of different examination settings on the imaging of microcalcifications in CBCT

C. Neubauer, J. Wolf, J. Neubauer; *Freiburg/DE*

Purpose: The aim of the study was to evaluate the influence of different examination settings on the imaging of microcalcifications in CBCT.

Methods and Materials: 9 imaging phantoms, each with a different number of microcalcifications, were examined in CBCT with 243 different examination protocols. The kV, the mA and the slice thickness were varied. 27 radiologists evaluated 9 examinations of different examination protocols with regard to the number of delimitable microcalcifications and the subjective assessment of image quality. Reference standard for the number of microcalcifications was a consensus reading by two radiologists of mammography and tomosynthesis of the phantoms. A p-value of 0.05 was assumed to be statistically significant.

Results: Examination protocols with a slice thickness of 0.1 and 0.2 were associated with more accurate imaging of the microcalcifications and were rated higher in image quality compared to examination protocols with a slice thickness of 0.4 mm. All other parameters showed no influence.

Conclusion: For a most accurate representation of microcalcification in CBCT, a slice thickness of at least 0.2 mm should be chosen. The adjustment of kV and mA is not essential.

B-1792 14:56

The feasibility of using clinically compatible grating interferometry mammography in breast cancer diagnosis

C. Arboleda¹, K. Lang², Z. Wang¹, T. Köhler³, S. Prevrhal³, C. Leo⁴, S. Forte⁴, R. Kubik-Huch⁴, M. Stamanoni¹; *Villigen/CH, ²Malmö/SE, ³Hamburg/DE, ⁴Baden/CH (carolina.arboleda@psi.ch)*

Purpose: Grating-interferometry mammography (GIM) is an emerging breast imaging technique able to provide phase-contrast (PC) and dark-field (DF) images that may contain information complementary to conventional attenuation-only (AT) images. The purpose of this work was to study the potential diagnostic value of PC and DF images in mastectomies.

Methods and Materials: Fifteen mastectomy samples were measured on a clinic-ready GIM investigational device directly after surgery at a mean glandular dose of 1.8 mGy and 14 sec acquisition time. Three breast radiologists performed a qualitative assessment of the individual appearance of the PC and DF signals for anatomical structures, tumor masses and microcalcifications. The DF signal was further quantified in relation to tumor size and type. Readers also compared tumor visibility in a weighted fusion of all three images (WF) to that in AT images.

Results: DF contrast was pronounced for all microcalcifications and tumor masses, with wider contrast range for masses. While anatomical structures did not provide much DF contrast, their edges were enhanced in PC. Some masses also showed PC edge enhancement. WF images showed a slightly improved tumor visualization compared to AT images.

Conclusion: In this first feasibility study of clinically compatible GIM, it was found that the DF signal was more pronounced for pathological lesions than for anatomical structures, which could have a diagnostically relevant impact, especially for tumors embedded in dense breast tissue. Fused images, incorporating the edge-enhancing effect of the PC signal, contributed to improved image quality when compared to conventional AT images.

B-1793 15:04

Optoacoustic imaging is helpful in predicting breast cancer molecular subtypes

B. Dogan¹, G. Menezes², R. Butler³, E. Neuschler³, P. Lavin⁴, R. Aitchison⁴, L.F. Tucker⁵, P. Otto⁶, S. Grobmyer²; *¹Dallas, TX/US, ²San Antonio, TX/US, ³New Haven, CT/US, ⁴Framingham, MA/US, ⁵Wirtz, VA/US (giselalgm@gmail.com)*

Purpose: To investigate the potential role of optoacoustic imaging combined with conventional grey-scale US (OA/US) in non-invasively diagnosing breast cancer molecular subtypes.

Methods and Materials: In this multi-institutional study, 2105 women with a suspicious breast mass underwent pre-biopsy OA/US scans between 12/2012 and 09/2015. Those diagnosed with invasive breast cancer at biopsy were included in this analysis. Seven blinded readers scored the internal (OAIN) and external (OAEXT) OA/US features of identified cancers. The ratio of total internal to total external OA/US features (RIInt/Ext) was derived. Tumour hormone receptor (ER and PR), HER-2neu status, and available ki-67 (%) were derived from pathology specimens. Analysis of individual OA/US features and tumour molecular subtypes of Luminal A (LumA), Luminal B (LumB), triple negative (TNBC) and HER2 amplified (HER2-E) was performed using ANOVA.

Results: Of 532 patients with available molecular subtypes, 186 (35.0%) were LumA, 244 (45.9%) LumB, 79 (14.8%) TNBC and 23 (4.3%) were HER2+. OAEXT was lower in TNBC compared to LumA ($p < 0.0001$), whereas OAIN was lower in LumA compared to TNBC ($p = 0.031$). The mean RIInt/Ext was significantly higher in TNBC (1.7, SD ± 0.7) compared to LumB (1.3, SD ± 0.5) and LumA (1.2, SD ± 0.5) subtypes ($p < 0.0001$), but not significantly different from HER2 (1.5, SD ± 0.6). RIInt/Ext helped distinguish LumA vs LumB ($p = 0.044$), LumA vs HER2+ ($p = 0.0286$), LumA vs TNBC ($p < 0.0001$), and LumB vs TNBC ($p < 0.0001$).

Conclusion: Functional OA/US features might help non-invasively distinguish breast cancer molecular subtypes, showing promise as a clinical prognostic tool that can facilitate management decisions.

Optoacoustic imaging features correlate with breast cancer clinicopathological prognostic factors

B. Dogan¹, G. Menezes², R. Butler³, E. Neuschler³, P. Lavin⁴, R. Aitchison⁴, L.F. Tucker⁵, P. Otto⁶, S. Grobmyer⁶,¹Dallas, TX/US, ²San Antonio, TX/US, ³New Haven, CT/US, ⁴Framingham, MA/US, ⁵Wirtz, VA/US, ⁶Cleveland, OH/US (giselalgm@gmail.com)

Purpose: To identify the potential role of OA/US as an indicator for breast cancer clinicopathological prognostic markers of grade, Ki-67 and axillary lymph node (LN) metastasis.

Methods and Materials: Patients with primary invasive breast cancer who underwent pre-biopsy OA/US between 12/2012 and 09/2015 in this prospective multi-centre clinical trial were retrospectively reviewed. Blinded 7 readers scored the internal (OAIN) and external (OAE) OA/US features of cancers. The ratio of total internal to total external OA/US feature scores (RInt/Ext) was derived. Histologic grade, Ki-67 labeling index (%), and axillary surgical pathology (negative LN, 1-2 positive, or ≥3+ LN) were correlated with OA/US feature scores. ANOVA tests were used to identify the relationship between OA/US features, prognostic factors and metastatic LN groups. Pearson correlation was used to test correlation of continuous variables.

Results: Overall, 629 patients with 653 invasive cancers were identified. Increasing Ki-67 correlated with all OAIN (p=0.002) features, the highest correlation being with internal haemoglobin score (p=0.0004). Increasing RInt/Ext correlated with increasing Ki-67 index (p<0.0001), while there was moderate correlation with OAE (p=0.03). Grade I cancers had lower OAIN (p=0.0112) than Grade III and lower RInt/Ext (p=0.0033) than Grade II and III cancers. Regarding LN status, both OAIN (p<0.0031) and OAE (p<0.0001) were higher in patients with metastatic LN compared to those with negative LN, while significant OAIN (p=0.0082) and OAE (p=0.0003) differences were identified between LN negative, 1-2 LN and ≥3+ LN patient groups.

Conclusion: OA features correlate with breast cancer clinicopathological prognostic factors of histologic grade, Ki-67, and axillary LN status.

CT staging in newly diagnosed breast cancer: are we adhering to current guidelines?

N.A. Healy, J.A. Tanner, F. Kilburn-Toppin; Cambridge/UK (nualahealy@gmail.com)

Purpose: Published guidelines advocate staging CT for Stage III and IV breast cancer only. The aim of this study was to determine if staging CT scans performed in newly diagnosed asymptomatic breast cancer patients adhered to published guidelines. We also aimed to evaluate the workload generated from additional tests ordered based on staging CTs.

Methods and Materials: A PACS system search generated all body CT staging scans performed at Addenbrooke's Hospital, Cambridge, from January 2014 to March 2018, which included 'breast' in indication or result. Only asymptomatic patients with newly diagnosed breast cancer who had CT imaging performed within 3 months of surgery were included in the study. Patient demographics, imaging findings and pathology results were retrieved from the hospital EPIC system and PACS. Number of additional tests generated by staging CTs and outcomes of these investigations were recorded.

Results: A total of 3001 'breast' CT scans were performed during the time period. Of these, 241 were performed in asymptomatic patients recently diagnosed with breast cancer, with 197 performed pre-operatively and 44 post-operatively. 85 patients (35%) were appropriately staged according to guidelines. Metastases were detected in 27 patients (11%) at diagnosis, 16 (59%) of whom had been correctly referred for staging. 64 patients (30%) who

did not have metastasis required additional imaging on the basis of CT findings.

Conclusion: Many patients are inappropriately referred for staging CT following diagnosis of breast cancer, generating additional imaging in a third of cases, thus increasing the workload of the radiology department.

B-1801 14:08

Can breast MRI aid in predicting high burden axillary disease in patients diagnosed with breast cancer?

N. Healy, F. Kilburn-Toppin, M. Wallis; Cambridge/UK (nualahealy@gmail.com)

Purpose: In cases of low volume axillary disease in breast cancer sentinel node biopsy can be offered over axillary lymph node dissection. The aim of this study was to determine if preoperative breast MRI can predict high burden axillary disease on histology (3 or more abnormal nodes) and compare with US findings.

Methods and Materials: A search of hospital records retrieved all breast MRIs performed from Jan 2015 - Dec 2017. All MRIs performed for local staging of new diagnosed breast cancer with positive axillae were included. A retrospective review of imaging for all patients with a positive axillary status was performed to determine nodal status on MRI and correlate it with sonographic and pathology results.

Results: Of the 1217 breast MRIs, 434 with complete data were performed for local staging of breast cancer. 179 had disease in the axilla, 110 detected pre-operatively and 69 on axillary sampling. 105 of 179 had neo-adjuvant treatment. 23 in the surgery group had 3 or more abnormal lymph nodes on histology; MRI axilla was abnormal in 16/23 (70%) and US abnormal in 13/23 (56%). In the neoadjuvant group 46 had 3 or more abnormal nodes; MRI was abnormal in 39/46 (85%) and US abnormal in 44/46 (96%) cases. These included 19 that had greater than 3 nodes based on fibrosis and MRI predicted axillary disease in 18/19 (95%) cases.

Conclusion: MRI can aid in detection of high axillary nodal burden and may be useful in combination with US at identifying a positive axilla pre-operatively.

B-1796 14:16

Clinical value of 18F-FDG PET/CT for staging elderly and young women with preoperative breast cancer

K. Kubota, T. Fujioka, M. Mori, J. Tsuchiya, U. Tateishi; Tokyo/JP (kbtmrad@tmd.ac.jp)

Purpose: The purpose of this study was to investigate the clinical value of routine 18F-FDG-PET/CT staging for primary breast cancer in the elderly and young patients.

Methods and Materials: Preoperative breast cancer patients under 35 y.o. (young group) and over 75 y.o. (elderly group) who underwent FDG-PET/CT from 2005 to 2017 were recruited. Image findings, clinical stage, the status of lymph node metastasis, the status of distant metastasis and detection of other malignancies were examined.

Results: There were 22 patients (stage 0: 3, I: 7, II: 8, III: 3, IV: 1) in the young group and 107 patients (stage 0: 12, I: 58, II: 33, III: 2, IV: 2) in the elderly group. SUVmax of the breast cancer was significantly higher in the young group than the elderly group (6.4 ± 5.9 vs 3.3 ± 3.1, p=0.0005). The sensitivity, specificity, PPV, and NPV for detecting lymph node metastasis in the young group were 85.7%, 100%, 100%, and 90.9%, respectively. The sensitivity, specificity, PPV, and NPV for detecting lymph node metastasis in the elderly group were 31.8%, 98.8%, 87.5%, and 84.8%, respectively. No other malignancy was found in the young group, whereas other malignancies (2 colon cancer, 1 oesophageal cancer, 2 lung cancers) were identified in 5% (5/107) in the elderly group.

Conclusion: FDG uptake of the young breast cancer was high, and PET/CT showed a high ability to diagnose lymph node metastasis in young patients. Incidental cancer was found in elder patients. Management of PET/CT according to age may be necessary.

B-1797 14:24

Comparative evaluation of strain ratio on sonographic elastography and T2* values on 3Tesla MRI in differentiating malignant from benign axillary lymph nodes in breast cancer

S. Sharma, R. Bansal, S. Jain, P. Sethi; New Delhi/IN (dr.princysethi06@gmail.com)

Purpose: To assess whether strain ratio and T2* values can improve the sensitivity and specificity of differentiating metastatic from benign axillary lymph nodes in breast cancer patients taking histopathology as reference standard.

Methods and Materials: The study was done on 43 patients. A multi-echo transverse T2*W MR sequence was obtained with TE= 0.9- 1.5 ms, TR=37.2 ms and flip angle=25°. Sonographic elastography was done using high frequency linear probe (L3-16 MHz). Manual selection of the region of interest was done on suspicious lymph nodes for calculation of T2* values and strain ratio. ROC curves were obtained for various T2* and strain ratio values in

comparison to histopathological findings as gold standard.

Results: Correlation with histopathology was better with T2* values than strain ratio. The sensitivity and specificity were calculated using cut off values obtained from ROC curve (31.225ms for T2* value and 1.85 for SR) and were 70.37%, 68.75% for strain ratio and 96.29%, 93.75% for T2* value respectively. The positive predictive value and negative predictive value were also assessed, values being higher for T2* than strain ratio. Comparison of areas under ROC curve was statistically significant with p value 0.018.

Conclusion: T2* can be used as a potential biomarker for differentiating metastatic from benign axillary lymph nodes owing to its high sensitivity, specificity and relative ease of performance. Quantitative assessment of changes in T2* values may allow more objective analysis of signal changes with significant differences between benign and malignant lymph nodes, even in case of partial infiltration.

B-1798 14:32

Biopsy-proven ductal carcinoma in situ radiographic features and upgrade rates

L.C.A. Chan, K.H. Wong, P.Y. Tang, K.Y. Tam, K.O. Cheung, C.L. Chiu; Hong Kong/HK (lokchi327@gmail.com)

Purpose: To review the radiographic presentation of biopsy-proven ductal carcinoma in situ (DCIS) by ultrasound-guided core biopsy or stereotactic-guided vacuum-assisted biopsy and their upgrade rates to invasive carcinoma at surgical excision.

Methods and Materials: 142 image-guided core biopsies with the diagnosis of DCIS of 139 patients referred from surgical breast clinic or oncology clinic to a single centre from March 2004 to March 2014, were reviewed. 83 (58.5%) were sonographically visible lesions with or without associated mammographic abnormality and ultrasound-guided biopsy performed. 59 (41.5%) were mammographic detected microcalcification but sonographically occult groups and stereotactic-guided vacuum-assisted biopsy done. Their radiographic features, the biopsy and surgical histopathological results were reviewed.

Results: Majority of the sonographically visible DCIS were seen as a mass lesion (94.0%). They were shown on ultrasound mainly as irregular (78.2%), non-circumscribed (71.8%), hypoechoic (91.0%) masses. A small proportion presented as dilated duct (2.4%) or microcalcification groups (3.6%). The mammographic detected and sonographically occult microcalcification groups were predominantly fine pleomorphic (40.7%) or amorphous (55.9%) microcalcification, ranging from 3 to 25 mm (mean: 8.9 mm) in size. There was no significant difference in the DCIS histologic grades between sonographically visible lesions and mammographic detected only microcalcification groups ($p=0.93$). The subsequent upgrade rate upon surgical excision compared with the sonographic guided core biopsy was significantly higher than of stereotactic-guided vacuum-assisted biopsy (26.7% vs 10.5%, $p=0.027$).

Conclusion: DCIS exhibits various radiological appearance. Upgrade from DCIS to invasive cancer especially based on ultrasound-guided biopsy should be considered in subsequent surgical management.

B-1799 14:40

MRI assessment of axillary lymph nodes after neoadjuvant chemotherapy based on breast cancer subtype

V. Ruggeri, G. Mariscotti, M. Durando, C. Costanza, L. Bergamasco, I. Castellano, P. Fonio; Turin/IT (vruggerim@gmail.com)

Purpose: Breast MRI is routinely used to determine residual breast disease after neoadjuvant chemotherapy (NCT) in locally advanced cancer; however, its role in predicting axillary nodal response is controversial. We investigated the role of breast MRI in predicting residual nodal disease after NCT based on cancer subtype.

Methods and Materials: A retrospective review was completed using our institutional database, including all patients who underwent NCT from January 2011 to May 2018. Patients underwent breast MRI before, during and after NCT. MRI images were reviewed by two dedicated breast Radiologists, blinded to clinical and pathological results. At MRI post-NCT, lymph nodes reported as larger than 1 cm, exhibiting loss of fatty hilum, thickened cortex, or irregular contour were considered pathologic. Lymph node MRI characteristics were compared with surgical pathological findings.

Results: Axillary MRI images after NCT and pathologic findings were available for 83 patients. Residual nodal disease was present in 43 patients (51.8%), 40 (48.2%) had a complete nodal pathologic response. Sensitivity, specificity and positive and negative predictive values of MRI were 62.8%, 80.0%, 77.1% and 66.7%, respectively. A subset analysis by cancer phenotype demonstrated that, for triple negative subtype, MRI had the highest specificity (100%) and positive predictive value (100%). MRI showed a significantly higher sensitivity in HER2 positive than in HER2 negative cancers (90.0% vs 54.4%, $p=0.04$), as well as a higher negative predictive value (91.7% vs 58.3%, $p=0.03$).

Conclusion: Our preliminary results could support the use of MRI post-NCT for assessing axillary nodal response, considering that its reliably might vary based on cancer subtype.

B-1800 14:48

Which factors affect the accuracy of MRI in predicting response and estimating residual disease after neoadjuvant chemotherapy?

H. Ahn, Y. An, J. Baek, Y. Suh, H. Choi; Suwon/KR

Purpose: To evaluate the diagnostic accuracy of breast magnetic resonance imaging (MRI) in predicting pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC), and to determine the factors affecting the accuracy of MRI in evaluation of residual tumour.

Methods and Materials: A total of 88 breast cancer patients who underwent breast surgery after NAC were included in this study. A pCR was defined as the absence of invasive cancer in pathologic specimen, and a clinical CR as the absence of enhancing lesion on post-NAC MRI. The maximal diameter of the residual tumour on post-NAC MRI was compared with the pathologic tumour size. We analysed the accuracy of MRI in predicting pCR, and the factors affecting the size discrepancy of residual tumour between MRI and pathology.

Results: The residual tumour size on MRI strongly correlated to the pathologic tumour size ($r=0.9$, $p<0.001$), and showed greater accuracy in the patients with concentric reduction pattern ($r=0.918$, $p<0.0001$) than the patients with scattered reduction pattern ($r=0.816$, $p=0.0004$). The sensitivity, specificity, diagnostic accuracy and area under the curve (AUC) for predicting pCR with MRI were 93.67%, 66.67%, 90.91% and 0.8017, respectively. The size discrepancy was significantly greater in patients with luminal type ($P=0.0226$), multifocal tumours and non-mass enhancement on pre-NAC MRI ($P=0.0467$).

Conclusion: MRI is an accurate tool for determining pCR and evaluating residual tumour in breast cancer, especially in patients with concentric reduction pattern during NAC. The molecular tumour subtype and lesion morphology on pre-NAC MRI influence the accuracy of MRI in evaluating residual tumour.

B-1802 14:56

Response of breast cancer to neoadjuvant treatment assessed using hyperpolarised ¹³C MRI

R.A. Woitek, M.A. McLean, J. Grist, A. Gill, J. Abraham, F. Gilbert, C. Caldas, K. Brindle, F.A. Gallagher; Cambridge/UK (rw585@cam.ac.uk)

Purpose: Carbon-13 magnetic resonance imaging (¹³C-MRI) following injection of hyperpolarized [1-¹³C]pyruvate was used to determine early response of breast cancer to neoadjuvant treatment.

Methods and Materials: Six patients with treatment naïve breast cancers (4xTNBC, 1xIDC, 1xILC) underwent dynamic ¹³C-MRI at 3T (MR750, GE Healthcare) using an 8-channel ¹³C breast coil following injection of hyperpolarized [1-¹³C]pyruvate using IDEAL encoded spiral chemical shift imaging. One patient with TNBC was rescanned after 21 days of neoadjuvant chemotherapy (NACT) and another one after eight days of NACT plus a PARP inhibitor (NACT+P).

Results: After 21 days of NACT, the summed lactate to pyruvate ratio (LAC/PYR) decreased by 53% alongside a 68% decrease in tumour volume whereas in the patient under NACT+P for 8 days, LAC/PYR increased on spectral (0.068 vs. 0.103) and imaging data (0.038 vs. 0.045) despite stable tumour volume. After seven cycles of chemotherapy, both patients showed complete pathological response. Among all six patients, the summed lactate to pyruvate ratio (LAC/PYR) was significantly correlated with tumour volume ($\rho=0.810$, $p=0.022$; Spearman's correlation).

Conclusion: This study showed that hyperpolarized ¹³C-MRI can be used to assess response to NACT alone but might be limited in detecting very early response to NACT+P. With DNA damaging drugs, such as platinum, DNA repair mechanisms are activated and can deplete the tumour cells' NAD(H) pool, which can limit the hyperpolarized label exchange between ¹³C-pyruvate and ¹³C-lactate. With PARP inhibitors, this depletion may be impaired, preserving the NAD(H) pool maintain a high LAC/PYR ratio at early time points during treatment.

Longterm review of recurrence after breast cancer treatment: data from breast cancer/tumour type analysis

M. Lavens, H. Wildiers, P. Neven, I. Nevelsteen, A. Smeets, M. Keupers, R.M.A. Prevos, A. Laenen, C. Van Ongeval; Leuven/BE (matthias.lavens@telenet.be)

Purpose: Imaging follow-up after breast cancer treatment includes a yearly mammography (MG) and according to the European guidelines an ultrasonography (US). Recurrence rates are useful as a predictive value, but could also serve as data for new guideline recommendations.

Methods and Materials: 8038 women were reviewed (Jan 2000- Jan 2016) on local (ipsilateral breast and local lymph node metastasis) and contralateral (breast only) recurrence. Women were excluded after detection of distant metastasis. Our pathologists used the St-Gallen-tumour type classification to determine BC subtypes.

Pre-surgical marking under CT guidance of no-palpable, non solid/solid/partially solid pulmonary nodules: when and why to use it

I. Campo, S. Cernic, F. Arban, R. Pozzi Mucelli, F. Sacconi, M.A. Cova; Trieste/IT (irenecampo11@gmail.com)

Purpose: To assess the value of pre-surgical CT marking of no palpable, non solid/solid/partially, solid pulmonary nodules to improve the surgical outcome.

Methods and Materials: 29 nodules on 23 patients, identified by diagnostic CT/HRCT between January 2013 and February 2018, assessed during multidisciplinary meetings, were considered suspect (after adequate follow-up and/ or in high-risk neoplastic patients) the same were marked with metal landmarks under CT guidance, prior to thoracoscopic surgery. The safety of the procedure, the type of surgery and the histological pattern of the marked lesions were finally evaluated.

Results: 29 nodules were evaluated, respectively 12 non-solid, 9 partially solid and 8 solid. The average duration of the marking procedure was about 33,5 minutes and the complications found were all of low clinical impact (pneumothorax and alveolar haemorrhage). 100% of the nodules were localized during the surgery. In 18 cases the type of surgery was thoracoscopic, the average surgical time of about 1 hour and 30 minutes and the average duration of hospitalization of 6,6 days. Out of 29 nodules, 21 were found to be neoplastic, 8 of preinvasive type.

Conclusion: Small nodules non-solid, partially solid or solid, considered suspect after multidisciplinary discussion, can be marked safely during the preoperative phase by positioning of metallic markers. This kind of procedure determines an improvement of the surgical outcome (in particular regarding timing and surgical accuracy) and a more precise anatomic-pathological evaluation of the marked lesions.

B-1808 14:25

CBCT-guided hydrogel plug percutaneous deployment before video-assisted thoracoscopic surgical resection

A. Beneventi¹, N. Casamassima¹, A. Muollo², A. Coppola¹, E. Macchi¹, F. Piacentino¹, A. Ierardi³, F. Fontana¹, G. Carrafiello⁴; ¹Varese/IT, ²Busto Arsizio/IT, ³Marsala/IT, ⁴Milan/IT (beneventi.a@gmail.com)

Purpose: Cone Beam Computed Tomography (CBCT)-guided hydrogel plug deployment was recently proposed for prevention of pneumothorax after percutaneous lung biopsies. This is our initial experience of CBCT-guided hydrogel plug positioning for localization of difficult intraoperative lung nodules undergoing video-assisted thoracoscopic (VATS) resection.

Methods and Materials: We retrospectively evaluated the medical notes of 27 consecutive patients undergoing VATS lung wedge resection for surgical biopsy or definitive treatment of 28 small pulmonary nodules (malignant, 82%) between October 2017 and July 2018. Difficult intraoperative nodule recognition was anticipated based on lesion size <10 mm, or depth from pleura: size ratio >1, or ground-glass opacity (GGO), or operating surgeon judgement. All lesions were preoperatively marked by CBCT-guided hydrogel plug. Study endpoints were: post-localization pneumothorax frequency; intraoperative nodule localization rate; successful VATS resection rate.

Results: Mean size of solid nodules (n=24) and GGOs (n=4) was respectively 10.4±3.4 mm and 16.0±6.2 mm. Only one hydrogel plug marking procedure caused clinically relevant pneumothorax (1/28, 4%). All nodules were intraoperatively localized: 25 (89%) by hydrogel plug; 3 (11%) by palpation and pleural puncture hole visible in case of plug displacement. All nodules were completely excised by VATS, without complications.

Conclusion: CBCT-guided hydrogel plug deployment is useful not only to reduce pneumothorax rate, but also to mark challenging lung nodules. Moreover, since this device is used after biopsy procedure, it's not necessary to submit the patients to double puncture.

Results: Sixteen year cumulative incidence of local recurrence was 3.83% for luminal A primary breast cancer subtype, 3.38% for luminal B, 4.78% for Her 2 and 9.73% for Triple Negative (TN) subtype. Extended analysis of TN versus Luminal A showed a four-year hazard ratio (HR) of 4.77 for TN versus 0.51 for luminal A (p<0.001) and an eight-year hazard ratio of 5.14 versus 1.14 (p=0.003). Twelve-year-HR and sixteen-year-HR showed no Triple Negative versus Luminal A difference. Sixteen-year-cumulative-incidence of contralateral recurrence was 5.91% for luminal A subtype and 7.36% for TN (p=0.09). In a sample analysis 88 % of all relapses were detected with the combination of clinical examination, MG and US.

Conclusion: A remarkable higher local recurrence rate of primary Triple Negative and Her2 breast tumours should questioning a dedicated imaging surveillance protocol (MG, US, MRI), particularly the first eight year after diagnosis.

B-1804 15:12

Contrast-enhanced mammography screening women after breast-conserving therapy

D. Avendano¹, M.S. Jochelson¹, K. Pinker-Domenig², M.A. Marino³, J. Gluskin¹, J.S. Sung¹; ¹New York, NY/US, ²Vienna/AT, ³Messina/IT (diliah1@gmail.com)

Purpose: To investigate the added value of contrast-enhanced mammography (CEM) compared to low-energy mammography in routine imaging of breast cancer patients after breast-conserving therapy (BCT).

Methods and Materials: In this HIPAA compliant IRB-approved retrospective single-institution study 427 consecutive asymptomatic breast cancer patients treated with BCT who underwent screening CEM between January 2013 and March 2018 as part of their routine follow up were included. Histopathology was used as the standard of reference.

Results: Ten (2.3%) of 427 patients (854 breasts) were diagnosed with breast cancer during follow-up with 10 lesions: eight with an ipsilateral recurrence and two with contralateral cancer. All 10 (100%) cancers were detected with CEM whereas only 5/10 cancers (50%) were seen with mammography. Sensitivity, specificity, and accuracy of CEM was 100%, 98% and 98% compared to low-energy mammography alone which was 50%, 98% and 97%. The combined interpretation of CEM and low-energy mammography achieved sensitivity and specificity of 100% and 98.7% with an improved accuracy of 98.7%.

Conclusion: Data indicate that CEM is more sensitive than low-energy mammography for breast cancer detection after BCT in the screening setting. Best results are achieved with the combined interpretation of low-energy mammography and CEM.

Does internal mammary artery irradiation for breast cancer make significant difference in diameters of internal mammary artery?

Correlation with computed tomography

G. Durhan, A. Erdemir, S. Sari, M. Gültekin, J. Karakaya, M. Akpınar, F. Yildiz, F. Demirkazık; Ankara/TR (a.gurkan.erdemir@gmail.com)

Purpose: Internal mammary nodal irradiation improves loco-regional control and decreases rates of distant metastasis. However, irradiation accelerates atherosclerosis and may cause stenosis of not only coronary arteries but also internal mammary artery (IMA). IMA has two major importance in patients diagnosed as breast cancer. First, IMA is an excellent conductor for coronary bypass grafting (CABG). Second, IMA is the most common recipient vessel used in free flap breast reconstruction. The aim of study is to investigate radiation effects on internal mammary arteries via computed tomography (CT).

Methods and Materials: Between January 2010 and December 2016, 3612 patients with breast cancer treated with radiotherapy (RT) were reviewed. 239 patients who have appropriate imaging and nodal irradiation were included to the study. Bilateral IMA diameter were assessed via thin-section contrast-enhanced CT. The results of ipsilateral IMA with nodal irradiation compared with the results of contralateral non-irradiated IMA via "independent-samples t test" analysis.

Results: Diameters of "irradiated IMA" were significantly smaller than "non-irradiated IMA" regardless of right or left (p<0.0001). All vascular calcifications were found in irradiated side. Radiation dose was not correlated with vessel calibres and calcifications. Although presence of calcification was found in patients having longer time interval between RT and CT, it did not reach statistical significance. Also, time interval between RT and CT was not correlated with calibre.

Conclusion: Calibres of IMA are decreased due to RT regardless of radiation dose and time interval. Evaluation of vessels via CT before CABG and flap reconstruction can help surgeon to select proper vessel.

CT-guided lung biopsy: a simplified classification and scoring system to assess appropriateness of indication according to nodules' 18-FDG uptake, dimension and localisation

M. Tipaldi¹, G. Orgera¹, F. Laurino², E. Ronconi¹, M. Krokidis³, A. Zolovkins¹, A. Laghi⁴, M. Rossi¹; ¹Rome/IT, ²Eboli/IT, ³Cambridge/UK, ⁴Latina/IT (tipaldi.andrea@gmail.com)

Purpose: To develop a simplified classification and scoring system to predict risk of technical failure in patients undergoing CT-guided transthoracic core needle biopsy (TTNB) according to nodules' characteristics and 18-FDG uptake.

Methods and Materials: CT-guided lung biopsies, performed in our institution from January 2014 to January 2017, were reviewed retrospectively. Lesions were classified into 3 clusters of low (n=72), intermediate (n=118) and high (n=58) technical difficulty on the basis of nodule diameter, distance from the pleural needle access and basal localisation. Technical success, length of procedure, delivered radiation dose and complications were investigated in each cluster and compared with 18-FDG uptake.

Results: Overall technical success was 83% (n=206), 71% (n=196) malignant and 12% (n=30) benign. PET-negative nodules had significant longer procedures (p<0.0001) and delivered dose (p=0.0436) despite fewer successful results (50% vs 92%, p<0.0001) than positive one. Technical failure showed a growing trend from 11% (n=8) in low-difficulty group, 14% (n=16) in the intermediate and 31% (n=18) in the high one, resulting statistically significant (p=0.0043) as well as the increase of procedure length (p=0.0007) estimated delivered dose (p=0.0115) and rate of complications (p=0.0055). High-difficulty PET-negative nodules had the highest technical failure rate amongst all groups (80%), significantly worse than middle- and low-difficulty PET-negative group (p=0.0008).

Conclusion: TTNB of high-difficulty PET-negative nodules is associated with very poor technical success rate and, in this group of patients, other strategies should be considered.

B-1810 14:41

Fusion imaging technique in lung biopsy to demonstrate the correlation between standardised uptake value (SUV) and specimen's diagnostic value

A. Muollo¹, A. Beneventi², E. Macchi², F. Piacentino², C. Floridi³, F. Fontana², G. Carrafiello⁴, C. Fugazzola²; ¹Busto Arsizio/IT, ²Varese/IT, ³Perugia/IT, ⁴Milan/IT (alessandra.muollo29@gmail.com)

Purpose: In the context of a large study about PET/CT-CBCT-guided percutaneous lung biopsies, ten selected patients underwent double bioptic sampling, respectively in the SUV maximum and in the SUV minimum zone of the lesion. Aim of this study was to demonstrate the correlation between SUV value and specimen's diagnostic value.

Methods and Materials: Ten patients with voluminous pulmonary masses (diameter>30mm), characterized by homogeneous uptake of 18F-FDG at PET/CT scan, underwent double percutaneous bioptic sampling (SUV maximum and SUV minimum zone) using PET/CT-CBCT guidance. Diagnostic efficacy rate was calculated. The pathologist reported the percentage of neoplastic cells/flogosis/fibrosis for each sample analysed; furthermore, he evaluated the possibility to draw up a biomolecular profile researching antigens and genetic mutations of lung cancer in the two group.

Results: 9 lesions were malignant, one case was benign (flogistic). Diagnostic efficacy was equal to 100% (10/10) for the SUV maximum group and 70% (7/10) for the SUV minimum group (p=0,21). In the first group the pathologist found major percentage of neoplastic cells, while in the second group flogosis and fibrosis were predominant. The biomolecular profile was obtained in 100% (9/9) of cases for the first group and in 33,3% (2/6) of the second group (p=0,011).

Conclusion: Correlation between SUV value and specimen's diagnostic value was demonstrated. In addition, using fusion imaging PET/CT-CBCT technique for lung lesions biopsy admit to obtain more helpful information from tissue sampling.

B-1811 14:49

The value of core-biopsy of nodules less than 10 mm

P.S. Sánchez; Atibaia/BR (penelope.san@hotmail.com)

Purpose: The objective of our study is to determine the value of core-biopsy of nodules less than 10 mm. The diagnostic accuracy, complication rates with haemoptysis, haemoptysis, thoracic drainage and the impact on patients will be reported.

Methods and Materials: Retrospective, unicentric study, through the review of charts, images and chest tomography reports in an oncology reference centre. Will be analyzed 40 biopsies per fragment, of pulmonary nodules measuring up to 9 mm (ranging from 5 to 9 mm) guided by computed tomography, using needle 18 or 20 G conducted between January 2014 and December 2018. Consent was completed by all patients or their caregivers. At tomographic

images at the time of biopsy were retrospectively reviewed in the standard pulmonary window (width 1500 HU, level 600 HU).

Results: The anatomopathological results will be collected and classified as positive or negative for malignancy, of primary or secondary origin and if they were compatible with the histopathology of the surgical piece when feasible. Negative results will be considered as true negatives when there are histological or microbiological confirmations, or if the lesion disappears or reduces in size or remains stable for at least 2 years of follow-up. Growth of the malignant nodule or surgical confirmation of the malignancy will be considered false negative results. The sensitivity, specificity, and accuracy of the core biopsies will be calculated. The positive and negative predictive values will be calculated for nodules with positive and negative results, respectively. Indices of pneumothorax, haemothorax and pleural drainage will be calculated.

Conclusion: The study showed that the complication rate was similar to that of nodules larger than 10 mm and the biopsy effectiveness rate was equal to that of the larger nodules.

B-1812 14:57

Percutaneous radiofrequency thermal ablation (RFA) of lung neoplasms using a new 15 G internally cooled jet-tip electrode: preliminary results

F. Carchesio, R. Iezzi, A. Posa, T. Congedo, G. Veltri, S. Margaritora, R. Manfredi; Rome/IT (francesca.carchesio@gmail.com)

Purpose: Aim of our study was to assess the safety and feasibility of CT-guided RFA in unresectable lung neoplasms, using a new 15 G internally cooled jet-tip needle.

Methods and Materials: 14 consecutive patients with lung neoplasms (< 4cm), both primary and secondary, unsuitable or refusing surgery, underwent percutaneous CT-guided RFA using a 15G electrode with 3-cm exposed tip. Primary endpoints were the incidence and grade of adverse events and technical success; secondary endpoint was complete response determined using CT and/or FDG-PET performed 6 months after procedure.

Results: A total of 14 nodules were treated (mean diameter: 28mm; range: 12-38mm). All patients underwent technically successful procedure without neither major complications nor intraprocedural death. Mild pneumothorax not requiring a tube drainage placement was registered in 40% of patients while a mild perilesional haemorrhage was registered in all cases. During the follow-up period, a complete response was obtained in 13 of 14 nodules with one partial response requiring a repeated procedure in one patient.

Conclusion: Percutaneous RFA using a 15G internally cooled J-Tip electrode is a safe and feasible treatment for unresectable lung lesions, with a high rate of complete response obtained.

B-1813 15:05

Leaving-tail microcoil localisation for small pulmonary nodules prior to thoracoscopy

T. Su, L. Jin; Beijing/CN

Purpose: To describe standardised interventional protocols of CT-guided localising lung nodules with leaving-tail microcoil prior to video-assisted thoracoscopic surgical (VATS) resection.

Methods and Materials: This study retrospectively included ninety-six patients who underwent preoperative microcoils localisation towards small pulmonary nodules. The location of pulmonary nodule and proper patient's position for microcoil implantation have been documented. The head of microcoil was pinpointed adjacent to the target nodule while its end tail remained above the visceral pleura. After the implantation, CT scan was conducted to assess the depth of the microcoil and its length outside the pleura. The results of CT were compared with observation by VATS within 24 hours. The complications and success rate of implantation were recorded.

Results: CT-guided microcoil implantations were performed targeting 105 pulmonary nodules. The planning access route and implantation site were determined based on the location of the pulmonary nodule, and were followed by an appropriate body position on the CT table. After implantation, CT scan showed the intra-pulmonary depth and extra-pleural length of microcoil were 18.0±6.2 mm (2 to 36 mm), 8.1±6.0 mm (-13 to 26 mm), respectively. During VATS, localisation microcoils from 95 cases (90.5%, 95/105) were visualised that their front-ends were partially inserted and their end tails remained above the visceral pleura. Finally, 104 (99.0%, 104/105) localising pulmonary lesions were successfully resected by VATS and no serious complications occurred in the localisation.

Conclusion: According to the location of lesion in the lungs, the standardised microcoil implantation method is the key to successful preoperative localisation.

Intravoxel incoherent motion diffusion-weighted imaging for the assessment of myocardial fibrosis in hypertrophic cardiomyopathy

R. Wu, R.-Y. Shi, D.-A. An, C.-W. Wu, B. Chen, L. Wu, J. Xu; *Shanghai/CN* (wuyidaoruiui@163.com)

Purpose: To investigate the feasibility and potential of intravoxel incoherent motion (IVIM) to detect the myocardial fibrosis in hypertrophic cardiomyopathy (HCM) patients.

Methods and Materials: Fifty-five HCM patients were enrolled and underwent IVIM diffusion-weighted cardiovascular resonance imaging (DW-CMR). Cine, T1 mapping, IVIM DW-CMR and late gadolinium enhancement (LGE) were performed. Strain, native T1, extracellular volume (ECV), parameters derived of IVIM-CMR (D, D* and f) and LGE analyses were segmented into 16 American Heart Association (AHA) segments and the correlations among these parameters were analysed. According to LGE and ECV, positive regions for myocardial fibrosis were defined as the presence of LGE (LGE+) or ECV \geq 29.6%.

Results: D values were significantly increased in both LGE+ ($1.89\mu\text{m}^2/\text{ms}$; $1.75\mu\text{m}^2/\text{ms}$, $2.04\mu\text{m}^2/\text{ms}$) and ECV \geq 29.6% ($1.84\mu\text{m}^2/\text{ms}$; $1.69\mu\text{m}^2/\text{ms}$, $1.97\mu\text{m}^2/\text{ms}$) group than LGE- ($1.63\mu\text{m}^2/\text{ms}$; $1.56\mu\text{m}^2/\text{ms}$, $1.73\mu\text{m}^2/\text{ms}$) and ECV < 29.6% ($1.61\mu\text{m}^2/\text{ms}$; $1.54\mu\text{m}^2/\text{ms}$, $1.68\mu\text{m}^2/\text{ms}$) group. Compared to LGE- and ECV < 29.6% group, D* ($34.9 \pm 5.5 \mu\text{m}^2/\text{ms}$ vs $55.2 \pm 11.4 \mu\text{m}^2/\text{ms}$, $p < 0.001$; $37.5 \pm 6.9 \mu\text{m}^2/\text{ms}$ vs $59.6 \pm 9.2 \mu\text{m}^2/\text{ms}$, $p < 0.001$, respectively) and f values ($10.8 \pm 1.29\%$ vs $12.5 \pm 1.26\%$, $p < 0.001$; $10.9 \pm 1.1\%$ vs $13.0 \pm 1.00\%$, $p = 0.021$, respectively) were significantly decreased in both LGE+ and ECV \geq 29.6% group. Moreover, significant correlations were demonstrated between IVIM-derived parameters and ECV, as well as strain and strain rate.

Conclusion: IVIM DW-CMR is sensitive to detect myocardial fibrosis and has potential of characterizing the extent fibrosis in HCM patients.

B-1817 14:08

Analysis of strain values in asymmetrical hypertrophic cardiomyopathy: correlations with wall thickness and extent of focal fibrosis

C. De Cataldo, S. Torlone, A. Corridore, P. Palumbo, E. Cannizzaro, F. De Matteis, A. Di Sibio, E. Di Cesare, C. Masciocchi; *L'Aquila/IT* (camilladeca@hotmail.it)

Purpose: To assess Radial (RS), Longitudinal (LS) and Circumferential (CS) Strain values in patients affected by Asymmetrical Hypertrophic Cardiomyopathy (HCM) and their correlation with wall thickening (WT) and extent of focal fibrosis (LGE%).

Methods and Materials: We retrospectively analysed 35 HCM patients with preserved ejection fraction (EF); a control group of 20 healthy patients was provided. We collected Global, Per Planes and Segmental RS, CS and LS values with dedicated software (Cvi42) for each patient. We divided cardiac segments on the basis of WT and LGE%. Statistical analysis with Kruskal-Wallis test, Spearman test and ROC curve was performed.

Results: On a per-patient analysis, we noticed a significant impairment of Global Strain values compared to control group (GLS median -13.6% vs -17.14%; GCS median -17.31% vs -18.44%; GRS median 27.42% vs 41.84%) ($p=0.04$). GRS, GCS and GLS values were positively related to EF but negatively to age and myocardial mass. On a per-segment analysis, we noticed that both hypertrophic and/or enhanced segments and morphologically not affected segments in HCM showed impaired Strain values, with a significant discrepancy between these two groups and compared to control group ($p < 0.000001$), especially for RS values (cut-off=21.77, Sensitivity=75.7%, Specificity=88.75%, AUC=0.858). RS values varied proportionally to WT and LGE%, while LS and CS values were more affected by LGE%.

Conclusion: Although our small specimen size, our experience provides impaired Strain values both in involved segments and apparently not involved segments in HCM, demonstrating the entirety of the disease.

B-1814 15:13

Retrospective analysis of the role of intraparenchymal blood patching and the rate of pneumothorax after percutaneous CT-guided core lung biopsy

R.M. Peitl¹, J. Hetzel¹, H. Bösmüller¹, C. Kloth², M. Horger¹; ¹Tübingen/DE, ²Ulm/DE

Purpose: To assess the rate of biopsy-related pneumothoraces after percutaneous CT-guided lung puncture and to evaluate the impact of intraparenchymal blood patching (IBP) and of other tumour and operator-related risk factors.

Methods and Materials: Retrospective analysis of CT-guided lung biopsies performed at our institution between 01/2003 and 08/2018. The image data of 868 patients were evaluated, of whom 419 received an IBP. The data were analysed for pneumothorax rates, need for thoracic drainage, other risk factors such as lesion size, lesion depth, location within the lungs, needle calibre, number of samples taken and operators' experience.

Results: The pneumothorax rate was significantly lower in the IBP group (10.74%) than in the non-IBP group (15.37%). In both groups, lesions < 3 cm showed a significantly higher rate of pneumothorax ($p < 0.05$); furthermore, pneumothorax rate increased with increasing lesion depth ($p < 0.001$). The rate of pneumothorax was significantly lower ($p < 0.05$) for 17G needles in the IBP group, but not for other calibers. When sampling from the lower lobe, the rate of pneumothorax was significantly reduced by IBP ($p < 0.001$). Only in less experienced operators pneumothorax rate differed from 11.1% with IBP to 24.8% without IBP. When taking >3 samples pneumothorax rate was significantly lower in the IBP group ($p < 0.01$).

Conclusion: The use of IBP significantly reduces the incidence of pneumothorax in CT-guided lung biopsies, in particular, for lesions located deeper in the lungs, when more than 3 samples are taken, when samples are taken from the lower lobe or by less experienced operators.

B-1815 15:21

Gelfoam slurry tract embolisation after computed tomography-guided percutaneous lung biopsy: does it prevent major pneumothorax?

R. Sum, K.K. Lau; *Clayton/AU* (r.r.sum@gmail.com)

Purpose: To assess the efficacy of biopsy tract embolisation using an absorbable gelatin sponge slurry (Gelfoam) in the prevention of major pneumothorax after percutaneous lung biopsy.

Methods and Materials: A retrospective analysis was conducted on 273 patients who underwent computed tomography-guided percutaneous lung biopsy over a 9-year period. Smoking status, underlying medical condition, radiological evidence of emphysema, location and size of the lesion, length of biopsy tract, and presence of a post-biopsy pneumothorax on CT and plain radiograph were recorded.

Results: Gelfoam was used in 166 patients (mean age 71, range 20-96) and not used in 107 patients (mean age 69, range 27-96). Proportions of patients with radiological evidence of emphysema were similar (63.6% and 67.5% in the non-Gelfoam and Gelfoam groups, respectively). The most commonly used needle size was a 20-gauge coaxial needle. There was no significant difference in pneumothorax complications in either group on immediate post-biopsy CT ($p=0.06$) and 4 hours post-biopsy plain radiograph ($p=0.24$). The need for an intercostal catheter to treat a major pneumothorax was significantly higher when Gelfoam was not used (OR=0.1328, $p=0.01$) - 9 patients (8.4%) in the non-Gelfoam group required an intercostal catheter while only 2 patients (1.2%) required this in the Gelfoam group.

Conclusion: There is no significant difference in the rates of developing a pneumothorax when a gelatin sponge slurry was used for biopsy tract embolisation. However, gelfoam reduced the likelihood for necessitating an intercostal catheter for the treatment of a major pneumothorax.

B-1818 14:16

MRI characteristics and clinical outcomes of hypertrophic cardiomyopathy with infarct-like late enhancement

L. Li, S. Zhao; Beijing/CN (tyyxilu@126.com)

Purpose: The purpose of our study is to evaluate the prevalence, cardiac magnetic resonance (CMR) features and prognostic value of infarct-like LGE in HCM.

Methods and Materials: From 1411 HCM patients confirmed by CMR, 57 patients in group A (age 47.70±13.29 years; 71.9% males) and 413 patients in group B (age 45.65±13.43 years; 68.1% males) were compared in terms of clinical and CMR findings. Event-free survival and Cox regression analyses were also performed in this study.

Results: The prevalence of infarct-like LGE was approximately 11.61% (57/491). LVEF was lower in group A than in group B [55.77±16.07 vs 66.90±8.50, $p<0.001$]. Compared to group B, group A had larger LVEDVi (73.28±27.61 vs 64.77±16.79 ml/m², $p=0.027$), LVESVi [26.67 (18.35-41.50) vs 20.52 (15.80-25.73), $p<0.001$] and more extensive LGE extent [18.20% (8.25-28.93) vs 8.51% (5.02-14.90), $P<0.001$]. Group A showed higher annual cardiovascular (8.71% vs 1.17%, $p<0.001$), arrhythmic (3.05% vs 0.35%, $p<0.001$), heart failure (5.66% vs 0.82%, $p<0.001$) event rate than group B, especially infarct-like LGE located in free wall. In multivariate analysis, LVEF (HR, 0.93; 95% CI: 0.915-0.96, $P<0.001$), the presence of NTHA III/IV (HR, 2.29; 95% CI: 1.10-4.78, $P=0.028$) and the presence of infarct-like LGE (HR, 3.69; 95% CI: 1.70-8.00, $P=0.001$) were identified as independent prognostic risk factors of cardiovascular events.

Conclusion: Infarct-like LGE was not rare in HCM. If confirmed in further studies, presence of infarct-like LGE can be used for risk stratification in cardiovascular events of HCM.

B-1819 14:24

Sudden cardiac death (SCD) risk stratification in hypertrophic cardiomyopathy (HCM) patients by cardiac magnetic resonance imaging (CMR) with late gadolinium enhancement (LGE)

E. Merschina, N. Krylova, V.E. Sinitsyn, N. Poteskina, M. Balaeva, A. Pylev; Moscow/RU (elena_merschina@mail.ru)

Purpose: To study the relationship between the functional heart parameters of HCM patients and the extent of LGE by CMR.

Methods and Materials: EchoCG and LGE CMR at 1.5T scanner were performed in 44 patients with HCM (55.2±15.8 years old; f/m=22/22). The myocardial mass, the mass of LGE foci, the values of LVEDV, LVESV were obtained. The myocardial performance index (Tei) was calculated by EchoCG.

Results: LGE CMR has identified intramyocardial fibrosis in 34 (77.3%) patients. Total number of ventricular extrasystoles (VE) during 24-hour ECG-monitoring was correlated with the extent of myocardial fibrosis ($r=0.45$, $p=0.04$). Patients with the presence of LGE had larger LV EDV and larger RV EDV ($p=0.02$). There was no correlation between LGE presence and LVOT obstruction ($p>0.05$). A direct relationship was established between the myocardial performance index (Tei) and the presence of myocardial fibrosis: for basal interventricular septum segments $r=0.47$ ($p=0.03$), for basal lateral segments $r=0.52$ ($p=0.02$); for global LV $r=0.54$ ($p=0.03$), for RV $r=0.67$ ($p=0.046$). HCM patients with myocardial fibrosis had more pronounced dyspnea ($r=0.43$, $p=0.046$) due to myocardial dysfunction. Estimated risk of SCD by ESC calculator was associated with the presence ($r=0.35$, $p=0.02$) and severity ($r=0.48$, $p=0.017$) of LV myocardial fibrosis.

Conclusion: The presence of LV myocardial fibrosis in HCM patients according to LGE CMR was associated with the increase of the LV and RV volumes, myocardial dysfunction, the increase of VE amount and estimated risk of SCD. The global LV index $T > 0.5$ can predict LV myocardial fibrosis existence in HCM patients.

B-1820 14:32

The diagnostic performance of novel non-contrast markers in discrimination of cardiac amyloidosis and hypertrophic cardiomyopathy on cardiovascular magnetic resonance imaging

S. Huang, Z.-G. Yang, K. Shi, K. Diao, Y. Gao, Y.-K. Guo, Y. He, S. He, M.-T. Shen; Chengdu/CN (huangshan82833@163.com)

Purpose: To evaluate and compare the diagnostic accuracy of myocardial contraction fraction (MCF), ejection fraction strain ratio (EFSR) and other deformation-based parameters in differentiating cardiac amyloidosis (CA) from hypertrophic cardiomyopathy (HCM) without using contrast agents on cardiovascular magnetic resonance imaging (CMR).

Methods and Materials: We retrospectively analysed CMR scans of patients with biopsy-proven CA ($n = 45$, 59.2±1.6 years) and HCM ($n=45$, 50.5±2.1 years), both with preserved left ventricular ejection fraction (LVEF) and moderate increased LV mass. Morphological and functional parameters combined with strain and strain-derived ratios indices were analysed. MCF was calculated by dividing LV stroke volume by LV myocardial volume which was calculated as the ratio of LV mass over 1.05 (myocardial density). EFSR was

calculated by dividing LVEF by global longitudinal strain (GLS).

Results: The maximum LV mass showed no significant difference between the two groups (CA 112±5.4g vs HCM 122.5±5.0g; $p=0.16$). CA patients had preserved LVEF (56.68 ± 1.01%) but slightly lower than HCM patients (62.51 ± 0.72%) ($p<0.05$). MCF showed the best performance to discriminate CA from HCM (AUC=0.87, 95%CI [0.80-0.94]), followed by EFSR (AUC=0.86, 95%CI [0.78-0.95]) (MCF vs EFSR, $p=0.87$). Individual systolic strains including global radial strain (GRS), circumferential strain (GCS) and longitudinal strain (GLS) had smaller AUCs (GRS: 0.73, 95%CI [0.61-0.85]; GCS: 0.73, 95%CI [0.62-0.85]; GLS: 0.74, 95%CI [0.64-0.86]) than MCF (all $p<0.05$) and EFSR (all $p<0.05$).

Conclusion: MCF and EFSR, two useful indices derived from non-contrast cine images, manifest excellent diagnostic performance in differentiating CA from HCM.

B-1821 14:40

Cardiac magnetic resonance in myotonic dystrophy type 1: a contribution to risk assessment

M. Ali, C.B. Monti, L. Melazzini, B. Fossati, M. Cavalli, R. Cardani, G. Meola, F. Sardanelli, F. Secchi; Milan/IT (marco.ali90@gmail.com)

Purpose: To evaluate left ventricular extracellular volume (ECV) and strain on cardiac magnetic resonance (CMR) as potential imaging-biomarkers of subclinical cardiac pathology in myotonic dystrophy type-1 (DM1) patients.

Methods and Materials: We retrospectively analyzed CMR examinations of DM1 patients with preserved ejection fraction performed between 2014 and 2016. ECV was calculated from native and post-contrast T1-mapping, referring to normal values reported in literature. Global circumferential strain (CS) was calculated and negative non-contrast CMR scans in age- and sex-matched subjects without history of cardiac disease were used as controls.

Results: Nine patients and nine controls without significant difference for age ($p=0.931$) and sex ($p=1.000$) were analyzed. Global CS was -19.1% (interquartile range [IQR] -20.9%,-15.3% in patients and -21.7% [IQR -22.7%,-21.3%] in controls ($p=0.011$)). Patients had a median global ECV of 32.3% (IQR 28.4%,37.6%). A positive significant correlation between global ECV and CS ($p=0.733$, $p=0.025$) and a borderline significant correlation between septal ECV and septal CS ($p=0.667$, $p=0.050$) were found.

Conclusion: In DM1 patients with preserved ejection fraction, CMR allowed to detect impaired contractility, correlated with ECV expansion, likely due to subclinical fibrosis. CMR-derived CS and ECV may have a role as imaging biomarkers of myocardial involvement in DM1 patients, with potential prognostic role.

B-1822 14:48

Cardiovascular magnetic resonance (CMR) in patients with Fabry disease

E.A. Merschina, S.V. Moiseev, V.E. Sinitsyn, P.S. Pilius, A.S. Moiseev, V.V. Fomin; Moscow/RU (polishka1903@gmail.com)

Purpose: To perform an analysis of the imaging biomarkers found with CMR with late gadolinium enhancement (LGE) in patients with Fabry disease.

Methods and Materials: 61 patients (19-69 years, median 37,3: m/f - 45/16) with a confirmed diagnosis of Fabry disease who underwent CMR were included in the analysis. CMR images were obtained with a 1.5T scanner before and after gadolinium injection. The images were acquired in cardiac short-axis and in 4, 3 and 2-chamber orientations. The total mass of the myocardium was calculated including papillary muscles and trabecular layer. The indexed values of EDV, ESV, SV, and EF were obtained. Patterns of LGE were analysed.

Results: The patients were divided into 3 subgroups based on their imaging phenotypes: 1) without LV wall thickening; 2) with concentric LV wall thickening; 3) with asymmetric septal hypertrophy (ASH). Hypertrophy of the LV myocardium was detected in 35 patients (59%), 23 of 35 patients had ASH. In 15 of 35 patients (4%) with myocardial hypertrophy, intramyocardial fibrosis was identified with LGE. Most frequently the fibrosis was found in the inferolateral ($n=6$) and anterolateral segments ($n=6$). The frequency of myocardial LGE was 24% in men (11/45) and 25% in women (4/16).

Conclusion: The results of the study demonstrate that Fabry disease has a number of different phenotypic expressions which are manifested on CMR images both in extent and location of hypertrophy and pattern of myocardial LGE. Combination of radiological and genetic assessments of patients with suspected Fabry disease brings the optimal results.

B-1823 14:56

Role of cardiac magnetic resonance (CMR) imaging for early detection of myocardial involvement in patients affected by Anderson Fabry disease (AFD)

S. Coco, R. Ammendola, A. Bracci, F. Catapano, F. Cilia, G. De Rubeis, N. Galea, M. Francone, C. Catalano; Rome/IT (simona.coco@uniroma1.it)

Purpose: Cardiomyopathy is a complication of Anderson-Fabry Disease (AFD) with dramatic impact on morbidity and mortality; medical therapy is

recommended in patients with evidence of cardiac involvement. Our aim was to investigate the role of Cardiac Magnetic Resonance (CMR) in early detection of cardiac involvement in AFD at pre-hypertrophic stage.

Methods and Materials: 10 biopsiproven AFD patients with normal wall thickness at echocardiography (<11mm) underwent to CMR (1.5 T, Avanto, Siemens, Erlangen, Germany) with following sequence protocol: STIR T2w, cineMR, late enhancement and T1 mapping with MOLLI technique before and 15 minutes after injection of 0.15 mmol/Kg gadolinium (GdDOTA, Guerbet, Paris, France). Indexed LV volumes and mass, native T1 (nT1), extracellular volume fraction (ECV) and tissue tracking parameters were analysed. Results were compared with 10 healthy age and gender-matched volunteers.

Results: No significative differences were found in myocardial mass (Mass/BSA: 44,81 vs 47,72 g/m², p:0,59), ventricular volumes (EF: 58,95 vs 60,62%, p:0,62) and left ventricular myocardial strain (Global radial strain: 48,9 vs 45,7 p:0,45; global circumferential strain: 21,4 vs 19,5 p:0,41; global longitudinal strain: 20,5 vs 19,5, p:0,59) between AFD and healthy subjects. No subjects had shown edema or LGE; nT1 was significantly lower (p<0,01) in AFD patients (933 +/- 22 ms) than healthy volunteer cohort (1010 +/- 16 ms); no significative discrepancy was noted between the two groups in ECV values (23% vs 24,2%, p: 0,23).

Conclusion: nT1 value appears the only marker of early myocardial involvement in nonhypertrophic AFD patients.

B-1824 15:04

Feature tracking allows detection of diminishing wall motion disturbances in Takotsubo cardiomyopathy

R.M. Brumberg, T. Emrich, P. Wenzel, S. Benz, R. Kloeckner, M.C. Halfmann, C. Düber, K.-F. Kreitner; Mainz/DE (tilman.emrich@gmail.com)

Purpose: Wall motion disturbances in Takotsubo cardiomyopathy (TTCM) are often rapidly decreasing in days between diagnosis via ventriculography and CMR imaging. The purpose of this retrospective study was to illuminate the diagnostic performance of cardiac magnetic resonance imaging feature tracking in fading wall motion abnormalities in TTCM.

Methods and Materials: We compared cardiac magnetic resonance imaging (CMR) and ventriculography of 41 consecutive patients with TTCM. TTCM-involved regions were defined as regions with wall motion disturbances in ventriculography. With a dedicated cardiovascular software (Circle CVI®, Calgary, Canada), left and right ventricular strain values from TTCM-involved and non-involved region were analysed and recorded.

Results: In all patients, there was a mild or marked normalisation of regional wall motion between ventriculography and CMR. Nevertheless, even in the CMR presence of only mild wall motion disturbances, feature tracking parameters of the left ventricle could easily discriminate between TTCM-involved and non-involved segments (e.g. circumferential strain in TTCM-involved region: -14.0 ± 7.9 vs. TTCM-non-involved: -19.2 ± 4.4; p < 0.0001). Interestingly, right ventricular strain values did not differ between involved and non-involved segments (e.g. RV radial strain: p = 0.069).

Conclusion: CMR feature tracking is a powerful tool for detection of fading left ventricular wall motion abnormalities in TTCM. Further research in larger cohorts is needed to establish the time relation between diminution of wall motion disturbance and feature tracking parameters.

B-1825 15:12

Functional assessment and prognostic value of cardiac magnetic resonance in arrhythmogenic right ventricular cardiomyopathy

M.-T. Shen, Z. Yang, K. Diao, L. Jiang, B. Hu, S. Huang, Y. Guo; Chengdu/CN (smt1020@qq.com)

Purpose: To assess left ventricular (LV) global systolic function using feature tracking cardiovascular magnetic resonance (FT-CMR) in arrhythmogenic right ventricular cardiomyopathy (ARVC) patients and investigate if the LV systolic function abnormalities and clinical characteristics predict adverse outcome in ARVC patients.

Methods and Materials: CMR was performed in 40 ARVC patients and 32 healthy controls. Feature-tracking analysis was applied to cine CMR images on a commercial post-processing image station. LV global longitudinal strain (GLS), circumferential strain (GCS) and radial strain (GRS) were defined as the peak strain value within a cardiac cycle. The end-point was a composite of cardiac death, sustained ventricular tachycardia, ventricular fibrillation, and appropriate ICD discharge.

Results: LV GRS(35.11 ±11.30% vs 50.84 ± 12.08%), LV GCS(-15.78 ± 3.25% vs -20.18 ±1.88%), LV GLS(-12.79 ±2.70% vs -18.15 ±1.93%, p<0.001 for respectively) were lower in ARVC patients compared with healthy controls. Twenty-seven with Late Gadolinium enhancement(LGE)(67.5%), eight with myocardial fatty infiltration(20%), eleven patients occurred syncope(27.5%), nine with heart failure(22.5%) and nine had Implantable Cardioverter Defibrillator(ICD)(22.5%). Thirteen patients met the end-point over a mean follow-up of 3.6 ±1.7 years. Univariate analysis showed LV GS, clinical and imaging characteristics (concluding the presence of LGE, syncope, heart failure and ICD) correlated with adverse outcome(p<0.005). Logistic regression

analysis showed syncope and LV GCS were independent predictors of adverse outcome(p<0.05).

Conclusion: Strain analysis by FT-CMR can objectively quantify global left ventricular dysfunction in ARVC patients and can also provides important prognostic information. LV GCS and syncope were independent predictors of cardiac events in ARVC patients.

B-1826 15:20

Magnetic resonance first-pass perfusion imaging for assessment of myocardial microvascular dysfunction in pediatric patients with acute leukemia

Q. Zhao, R. Xu, Z.-G. Yang, Y.-K. Guo; Chengdu/CN (zhaoqin626@foxmail.com)

Purpose: Daunorubicin-induced cardiotoxicity remains an important concern in patients with acute leukaemia. This study aimed to clarify the segmental coronary microvascular dysfunction in paediatric leukaemia patients with daunorubicin therapy using cardiac magnetic resonance (CMR) first-pass perfusion imaging.

Methods and Materials: Thirty-six patients with leukaemia (25 in treatment group and 11 in non-treatment group) and 9 healthy volunteers (control group) underwent CMR at rest. Perfusion parameters including maximal slope (Slope_{max}), time to peak (T_{peak}) and peak signal intensity, late gadolinium enhancement (LGE), left ventricular ejection fraction (LVEF) were evaluated and compared by independent-sample t-test or ANOVA test. The spearman correlation test was used to calculate the relationships between perfusion parameters, LVEF, LGE, and cumulative dose of daunorubicin.

Results: A total of 720 myocardial segments were analyzed. Compared with non-treatment group, T_{peak} increased in basal segments (24.86±7.29 s vs. 31.27±8.18 s, p < 0.05) and mid-ventricular segments (27.70±6.62 s vs. 33.39±6.61 s, p < 0.05) in treatment group. Slope_{max}, peak signal intensity and LVEF were not shown significant difference in the three groups. LGE was identified in 12 patients with daunorubicin therapy. Cumulative dose of daunorubicin (mean 129.25±60.31 mg) was moderately associated with the degree of LGE (r = 0.36, p < 0.05).

Conclusion: The segmental myocardial microvascular dysfunction could be early identified by CMR resting first-pass myocardial perfusion, which may contribute for the prevention or timely treatment of daunorubicin-induced cardiotoxicity in paediatric patients with acute leukaemia.

Semi-automatic technique for Crohn's disease diagnosis, using a supervised machine learning algorithm

G. Lo Re, M.C. Terranova, D. Picone, S. Franchini, S. Vitabile, M. Midiri; Palermo/IT (giuseppe.lore12@gmail.com)

Purpose: Radiological diagnosis of Crohn's disease (CD) may be challenging, mimicking different non-CD ileitis, and requires gastro-intestinal expertise. Our purpose is to develop a new semi-automatic technique for CD diagnosis, using Kernel Support Vector Machine (KSVM).

Methods and Materials: Three radiologists without gastrointestinal expertise extracted a dataset, composed of 900 MR enterography studies of 900 different patients (400 affected by CD, 500 not affected), selected for KSVM training and validation. Each patient was "labelled" by 22 determined qualitative features, which are associated with CD or may help in CD diagnosis, according to worldwide literature. At the end, each study was labelled according to histological specimen results (HR). 900 MR enterography studies have been divided as follows: 4/5 (720 patients) with HR labelling were used for KSVM training, and 1/5 (180 patients) without HR labelling were used for KSVM validation. Stratified K(5)-fold cross-validation strategy was used to enhance KSVM classifier reliability to compute and reduce the average error and/or any patient selection bias across all K experiments.

Results: The KSVM results were compared with the histological specimen results: sensitivity: 92.80%; specificity: 97.00%.

Conclusion: The great advantage is that this method, compared to the traditional reporting, does not require gastro-intestinal expertise and allows an easier differential diagnosis from non-CD ileitis.

B-1828 14:08

CT texture analysis to predict response to target therapy of hepatic metastases from colorectal cancer

L. Vassallo, V. Giannini, A. Defeudis, S. Mazzetti, G. Cappello, D. Regge; *Candiolo/IT (lorenzovassallo1987@gmail.com)*

Purpose: To identify specific imaging biomarkers of hepatic metastases using CT texture analysis (CTTA), able to predict patient's response to therapy and overall survival.

Methods and Materials: We exploited the imaging dataset of HERACLES trial (NCT03225937): 23 patients with amplified HER2 mCRC were included in the study. All had received anti-HER2 treatment, and underwent CT examination every 8 weeks, until disease progression. CT scans were semi-automatically segmented to extract all liver metastases. CTTA was performed on each segmented area, computing for each lesion 34 quantitative parameters. Mono-parametric and multi-parametric analysis were assessed to identify features correlated to therapy response. We also performed a correlative survival (OS) analysis, considering subjects with good survival those with OS > 9 months.

Results: In 23 patients we found 124 metastases, 55 classified as responding and 69 as non-responding. Nine parameters reached statistical significance in mono-parametric analysis (best AUC=0.67, p=0.001), while in multivariate regression ten parameters were used in the model, achieving AUC equal to 0.82, sensitivity of 82% and specificity of 72%. For OS analysis, 12 patients were "good" and 11 "poor" survivors. In mono-parametric analysis, "cluster prominence" and "sum entropy" predicted OS with AUC equal to 0.78 and 0.83, respectively. The regression model with two variables ("cluster prominence" and "dissimilarity") reached sensitivity of 83% and specificity of 82%.

Conclusion: Our study demonstrated CTTA as a potential biomarker to predict response of hepatic metastases to target therapy, possibly saving patients predicted as non-responder from toxicity. Moreover, CTTA could give indications on patients' OS.

B-1830 14:16

Automatic visceral fat characterisation on CT scans through deep learning and CNN for the assessment of metabolic syndrome

A. Jimenez-Pastor, A. Alberich-Bayarri, F. Garcia-Castro, L. Marti-Bonmati; *Valencia/ES (anajimenez@quibim.com)*

Purpose: Metabolic syndrome is a risk factor of developing cardiovascular disease and diabetes. Visceral fat has been recognized as a predictor of metabolic risk factors. The main goal is the fully-automatic segmentation of visceral and subcutaneous fat by the concatenation of different convolutional neural networks (CNN) on Computed Tomography (CT) images.

Methods and Materials: A set of 20 CT series from obese patients with metabolic syndrome were collected. In CNN development, 80/20% images was used for training/test, respectively. The axial reconstructed images were manually classified into abdominal or non-abdominal. All these images were used to train a first 15-layer-CNN to classify abdominal CT sections of the full scan. For the fat segmentation, all the abdominal CT images were manually segmented into visceral and subcutaneous fat. A total of 1270 2D-images were used to train two new different encoder-decoder CNN for the automated fat segmentation and volumes quantification.

Results: The accuracy obtained on the first CNN for abdominal/non-abdominal images classification was 99.35%. To evaluate the performance of both encoder-decoder-CNN, the DICE coefficient over the validation dataset was calculated, obtaining 94.55% and 98.05% for visceral and subcutaneous fat respectively. Mean relative error between the handcrafted and CNN visceral/subcutaneous fat volumes was 3.01/0.94% and the mean relative error on mesenteric-to-total-fat-ratio was 2.17%.

Conclusion: Visceral and subcutaneous fat can be automatically characterized through the segmentation of both fat components by CNNs. This allows the precise measurements of the relative fat fraction and the prediction of metabolic risk factors development on patients with metabolic syndrome.

B-1831 14:24

Application of a clinical decision support system to the imaging pathway of patients with hepatocarcinoma and cholangiocarcinoma

M. Gabelloni, M. Di Nasso, C.A. D'Amore, R. Morganti, L. Faggioni, G. Masi, E. Neri; *Pisa/IT (mgabelloni@sirm.org)*

Purpose: To determine the effectiveness of the ESR iGuide clinical decision support system in reducing the rate of inappropriate diagnostic examinations and the resulting costs for the healthcare system.

Methods and Materials: Forty patients (17 affected by hepatocarcinoma and 23 by cholangiocarcinoma, respectively) were retrospectively evaluated. Using ESR iGuide, all patient data (including signs and symptoms and laboratory values) that could have justified imaging were reviewed to calculate the appropriateness score of every imaging examination performed. The agreement between the examinations suggested by ESR iGuide and those actually performed was assessed using Cohen's k coefficient.

Results: A total of 98 imaging examinations of the abdomen were performed in 40 patients from year 2013 to 2017. Out of all imaging examinations, 79.6% (78/98) were considered appropriate by ESR iGuide and 20.4% (20/98) were designated as having marginal utility or even not suggested. Out of these latter, 85% were biopsies (17/20), 5% (1/20) abdominal CT, 5% (1/20) barium contrast enemas, and 5% (1/20) colonoscopies, respectively. The agreement between the examinations suggested by ESR iGuide and those actually performed was poor in all cases (Cohen's k less than 0.2). According to the established prices in the BLINDED regional healthcare system, the total cost of the 98 imaging examinations was €14,016, of which 21.6% (€3,033) were related to imaging tests classified as inappropriate by ESR iGuide.

Conclusion: The use of ESR iGuide could cut the costs of the healthcare system by reducing the number of inappropriate abdominal diagnostic examinations and potentially improving patients' outcome.

B-1832 14:32

Automated CT abdominal imaging protocol selection using natural language processing and machine learning

P. Rogalla¹, B.E. Hoppel², K. Noro³, Y. Yamazaki³, K. Utsunomiya³, Y. Shimomura³, S. Sugiyama³; ¹Toronto, ON/CA, ²Delafield, WI/US, ³Nasushiobara/JP (patrik.rogalla@uhn.ca)

Purpose: To develop and evaluate an automatic protocolling engine based on machine learning for predicting the correct imaging protocol in abdominal CT.

Methods and Materials: Determining the optimal imaging protocol for patients undergoing abdominal CT has become a challenging and time consuming task in most Radiology Departments Under ethical approval, 110,000 historical imaging requests were extracted from a RIS database containing the executed imaging protocols and associated patient information values (eg, history, indication, primary diagnosis, age, free text comment field). 141 features were identified from the valuables, including 100 features extracted from the free text comments using Latent Dirichlet Allocation; (natural language processing). This approach summarizes words as "topics" by finding the repeating pattern of co-occurring terms in a text. Using 141 features as input, the classification model was trained by L1 Logistic Regression predicts the 12 most frequently applied protocols. A 5-fold cross validation was executed using all the imaging requests with an 80/20 split of training to testing.

Results: The natural language processing method had an average specificity and sensitivity of 96.1 % and 62.5% compared to L1 Logistic Regression, not using natural language processing with specificity and sensitivity of 96.0% and 39.1%. Evaluation when using highly recommended results increase sensitivity to 81.4% and accuracy of 88.4% when choosing protocol.

Conclusion: The use of a natural language processing models with machine learning for protocolling in abdominal CT improves the average sensitivity for picking the correct protocol making it feasible to predict the radiologist's choice correctly in most cases.

AI automatic identification of complete- and non- responders using texture analysis of rectal cancer 3T MR images performed before, during and after neoadjuvant CRT

R. Ferrari, C. Mancini Terracciano, C. Voena, M. Rengo, M. Zerunian, R. Paramatti, R. Faccini, A. Laghi; *Rome/IT (marta.zerunian@gmail.com)*

Purpose: To evaluate an Artificial Intelligence (AI) model for classification of Complete (CR) and Non Responders (NR) patients with rectal cancer treated with neoadjuvant Chemo-RadioTherapy (CRT). AI input is based on textural analysis of high resolution 3T MR images performed before, during and after CRT.

Methods and Materials: 55 consecutive patients with rectal cancer were prospectively enrolled in this study. Patients underwent 3T T2-weighted (T2w) Magnetic Resonance Imaging (MRI) before, during and after CRT; ROIs around the tumor were manually drawn. All patients underwent complete surgical resection and the specimen was used to evaluate patients' response. Two AI models were built with the most statistically significant features training a Random Forest (RF) classifier on a 28 patients (training cohort). The model performances were estimated on 27 patients (validation cohort) using a ROC curve analysis and a decision curve analysis.

Results: Textural analysis points to a lower intra-tumor heterogeneity at the pre- and during-treatment stage for CR patients with a characteristic time evolution of some of the textural features. The obtained AI model shows good discriminatory ability with a ROC AUC of 0.94 (95% CI: 0.89,0.99) in the validation cohort. The discriminatory power of the AI model built for NR discrimination has a ROC AUC of 0.85 (95% CI: 0.80,0.90). Decision curve analysis confirms clinical usefulness of the models.

Conclusion: AI models based of textural parameters of MR images of patients with rectal cancer taken before, during and after CRT, show good performances for stratification of response to therapy.

Radiomics nomogram for the preoperative prediction of lymph node metastasis in pancreatic cancer

Y. Bian; Shanghai/CN (bianyun2012@foxmail.com)

Purpose: To develop and validate a radiomics nomogram for the preoperative prediction of lymph node (LN) metastasis in pancreatic ductal adenocarcinoma (PDAC).

Methods and Materials: In this retrospective study, 213 patients with surgically resected, pathologically confirmed PDAC underwent multislice computed tomography (MSCT) within one month before surgery. All patients were divided into a training set (n=185) and a validation set (n=46); The least absolute shrinkage and selection operator (LASSO) logistic regression algorithm was used to select the radiomics features. Multivariable logistic regression analysis was used to develop the predictive model that incorporated the radiomics signature, computed tomography (CT)-reported organs or vascular status, and CT-reported LN status, and a radiomics nomogram was built. The performance of the nomogram was assessed in the training set and validated in the internal independent validation set. Finally, decision curve analysis (DCA) was performed to estimate the clinical usefulness of the nomogram.

Results: The multivariable logistic regression model included the radiomics signature, CT-reported organ or vascular invasion status, and CT-reported LN status. The individualized prediction nomogram showed good discrimination in the training set [area under the curve (AUC), 0.9206; 95% confidence interval (CI), 0.88816-0.9597] and in the validation set (AUC, 0.9125; 95% CI, 0.8311-0.9938) and good calibration. DCA demonstrated that the radiomics nomogram was clinically useful.

Conclusion: The presented radiomics nomogram that incorporates the radiomics signature, CT-reported organ or vascular invasion status, and CT-reported LN status was a noninvasive preoperative prediction tool with favourable predictive accuracy for LN metastasis in patients with PDAC.

A sparse representation radiomics method based on multi-modality ultrasound images for hepatocellular carcinoma diagnosis and PD1 prediction

W. Wang, Y. Dong, Z. Yao, Q. Zhang, D. Yang, J. Yu; Shanghai/CN (puguang61@126.com)

Purpose: Programmed cell death protein 1 (PD1) is of great importance for surveillance and treatment of hepatocellular carcinoma (HCC). An updated radiomics method based on multi-modality ultrasound image is proposed to discriminate HCC and predict PD1 index.

Methods and Materials: A total of 65 patients with operation and histopathologically proved HCC were included in the prospective study. Every patient underwent multi-modality ultrasound examination before operation, including B mode ultrasound (BMUS), shear wave elastography (SWE), and shear wave viscosity (SWV) imaging. The radiomics analysis system was built on sparse representation theory (SRT) and support vector machine (SVM) for asymmetric data. With the sparse regulation of the SRT, we try to make accurate diagnosis of HCC and prediction of PD1 before operation. The accuracy, sensitivity, specificity and area under the receiver operating characteristic curve (AUC) were calculated to evaluate performance of radiomics models.

Results: Based on radiomics methods, a total of 2560 features were extracted from multi-modality ultrasound images for each HCC lesion. Two radiomics models were built and leave-one-out cross validation (LOOCV) was used to evaluate models. The performance of each model improved as the viscosity modality was included. In LOOCV, the AUC was 0.97 for HCC discrimination (95% CI 0.93 to 0.99) and 0.97 for PD1 prediction (95% CI 0.89 to 0.98).

Conclusion: Radiomics analysis based on multi-modality ultrasound images could help to make accurate diagnosis of HCC and prediction of PD1 level before operation.

Dynamic contrast-enhanced CT diagnosis of primary liver cancers using transfer learning of pre-trained convolutional neural network: comparison with radiologists

K. Oyama, A. Yamada, E. Yoshizawa, F. Ichinohe, D. Komatsu, Y. Fujinaga; Matsumoto/JP (oyama1988@shinshu-u.ac.jp)

Purpose: To evaluate diagnostic performance of transfer learning (TL) using pre-trained convolutional neural network and 3 phasic dynamic contrast-enhanced CT (DCE-CT) in primary liver cancers.

Methods and Materials: We evaluated 215 consecutive patients with histologically proven primary liver cancers including 6 early, 58 well-differentiated, 77 moderately-differentiated, 29 poorly-differentiated hepatocellular carcinomas (HCCs), and 13 non-HCC malignant lesions containing cholangiocellular components. TL using pre-trained convolutional neural network (GoogLeNet) and preoperative 3-phasic DCE-CT images at maximum cross sectional area of lesion was performed. Diagnostic performance (DP = [number of correctly classified cases]/[total number of cases]) was compared with general radiologists (GR) and experienced abdominal radiologists (AR). Correlation between sub-categorical number of training samples and DP was statistically evaluated.

Results: Overall DP for classification of histological subtype and differentiation in primary malignant liver tumors on DCE-CT by TL, GR, and AR was 45.9%, 39.1%, and 47.9%, respectively. Sub-categorical DP for well-/moderately-differentiated HCC by TL (50.0%/59.1%) was better than that by AR (48.3%/51.4%). Sub-categorical DP for early HCC/non-HCC malignant lesions by TL (20.0%/0%) was worse than that by GR (33.3%/30.8%). Sub-categorical DP for poorly-differentiated HCC by TL was 16.7%. There is a significant correlation between Sub-categorical DP by TL and sub-categorical number of training samples ($r=0.89$, $p<0.05$).

Conclusion: TL by pre-trained convolutional neural network may aid diagnosis of primary liver cancers on DCE-CT for GR in future because its diagnostic performance was close to that by AR when sub-categorical number of training samples was large.

Chronic liver disease assessment with a machine learning method using parameters derived from ultrasound B-mode and shear wave elastography examination

P. Drazinos¹, I. Gatos², S. Yarmenitis³, I. Theotokas², A. Soultatos², E. Panteleakou², P. Zoumpoulis¹; ¹Kifissia/GR, ²Athens/GR, ³Marousi/GR (p.zoumpoulis@echomed.gr)

Purpose: Chronic Liver Disease (CLD) is one of the major causes of death and the major cause of Hepatocellular Carcinoma development. Therefore, accurate diagnosis regarding CLD progress is very important. Our aim is to build and train a machine learning model that will estimate the impact of parameters derived from an Ultrasound (US) B-Mode and Shear Wave Elastography (SWE) examination in significant fibrosis (F_≥F2) diagnosis using Liver Biopsy (LB) as 'Gold Standard'.

Methods and Materials: Our dataset consisted of 217 individuals (132 F0-F1 and 85 F2-F4). An US examination was performed on all individuals and an LB examination for individuals with fibrosis stage F1-F4. We randomly divided our dataset into training and test samples (70%-30%). For the training sample a 10-fold cross validation (CV) was performed. The SWE measurements of the Liver's Right Lobe and Left Lobe as well as the existence of Nodularity and the CLD subtype/etiology of the patient were used as inputs for the training and testing of a Neural Network (NN) classifier.

Results: The NN classifier had a 10-fold CV accuracy of 96.26% and a 95% Confidence Interval (CI) of 96.18% - 96.35%. The mean accuracy of the classifier on the test samples was 95.56% with a 95% CI of 95.46% - 95.66%. The mean Area Under Curve (AUC) for the test samples was 0.983 with a 95% CI of 0.976 - 0.991.

Conclusion: The proposed method achieved high accuracy results and could be used to assist radiologists for CLD assessment in everyday clinical practice.

Proposal of a breast phantom for dosimetry quality control procedures in digital mammography and digital breast tomosynthesis

C. Fedon¹, R. Van Engen¹, J. Binst², L. Cockmartin², D. Dance³, A. Jacobs², R. Longo⁴, K. Tri Wigati², I. Sechopoulos¹; ¹Nijmegen/NL, ²Leuven/BE, ³Guildford/UK, ⁴Trieste/IT (christian.fedon@radboudumc.nl)

Purpose: To design new quality control (QC) phantoms that properly stimulate the automatic exposure control (AEC) of current digital mammography (DM) and breast tomosynthesis (DBT) systems to prospectively determine the exposure parameters selected for patient breasts of varying characteristics.

Methods and Materials: Breast fibroglandular information (e.g. peak and mean density, and mean dense tissue area) was obtained retrospectively from a cohort of about 4000 screening DM images using commercial software (Volpara™). A 2 cm-thick phantom slab was designed and manufactured based on the acquired Volpara™ data and the state-of-art of AEC for all current systems. This *base* slab is composed of polyethylene (PE) (simulating adipose tissue) with a half-ellipsoid inset of polyoxymethylene (simulating fibroglandular tissue). Phantom thicknesses up to 8 cm were obtained by adding 2 cm-thick PE slabs to the *base* slab. The AEC response was tested on systems from several vendors, which utilize different AEC philosophies and techniques. The average glandular dose (AGD) from AEC based phantom acquisitions was compared to AGDs from patients and from the standard homogeneous PMMA phantoms (according to the EU guideline).

Results: The mean AGD of the phantom images agrees with the mean patient AGD to within one standard deviation. Results from statistical student t-test show that the new phantom has the potential to better reproduce the exposure parameters used for patients than current homogeneous PMMA phantoms (without the need for spacers).

Conclusion: The phantom seems to provide a simple and reproducible QC method to predict the patient AGD using routine clinical settings.

Device-specific reference values for modulation transfer function (MTF) quality control measurements of digital mammography detectors

K. Wigati¹, H. Bosmans¹, D.S. Soejoko², L. Cockmartin¹, A. Jacobs¹, J. Binst¹, K. Lemmens¹, N. Marshall¹; ¹Leuven/BE, ²Jakarta/ID (kristinatri.wigati@kuleuven.be)

Purpose: Presampling modulation transfer function (MTF) measurements quantify detector sharpness and are recommended in the EUREF digital mammography quality control (QC) protocol. The full potential from this measurement will only be realized when reproducibility and limiting values are known for the systems in service. This retrospective study produces average MTF data for vendors/devices and assesses MTF measurement reproducibility.

Methods and Materials: Our physics QC service routinely measures MTF in two perpendicular directions using an edge test object imaged with 2 mmAl at the tube, grid removed. MTF is calculated from linearized DICOM 'For Processing' images and averaged for the two directions, where appropriate. The 50% point of the MTF (MTF_{0.5}) and MTF at 5mm⁻¹ (MTF_{5mm-1}) were collated from seven years of QC reports of 37 digital mammography systems (6 vendors/9 models). For these parameters, difference from test to test, and difference from baseline value were calculated.

Results: MTF measurements were found to be reproducible. For example, 5 fault-free Siemens Inspiration systems (14 tests) had a mean MTF_{0.5} of 5.32±0.28mm⁻¹ (coefficient of variation (cov) of 5.3%) while MTF_{5mm-1} was 0.53±0.02 (cov of 4.7%). Average deviation of MTF_{0.5} between successive tests (with 95% confidence intervals) was 3.9% (2.6%-5.2%), while for the difference from baseline value, this result was 4.1% (2.6%-5.7%). For comparison, the permitted baseline change is ±10% in the protocol. For all other vendors, similar reproducibility and confidence intervals were found.

Conclusion: Average deviation of MTF from baseline is typically <5%, making the MTF a robust means of assessing detector sharpness.

Comparative phantom tests of digital mammograms, breast tomosynthesis and synthetic mammograms

L. Vancoillie, L. Cockmartin, N. Marshall, H. Bosmans; Leuven/BE (liesbeth.vancoillie@uzleuven.be)

Purpose: To compare digital mammography (DM), digital breast tomosynthesis (DBT) and synthetic mammograms (SM) using the 3D structured L1 phantom with calcification and mass lesion-like inserts via a human observer detectability study.

Methods and Materials: Twelve combined DM-DBT phantom images were acquired at automatic exposure controlled dose levels on the GE HC Senographe Pristina, Hologic Selenia Dimensions and Siemens Inspiration systems at respective MGD/image values for DM/DBT: 1.20mGy/1.20mGy; 1.77mGy/2.24mGy; 1.33mGy/2.61mGy. Detectability was assessed via human reading using a 4-alternative forced choice (4-AFC) method. Threshold diameter (d_r) of the different inserts was defined as the diameter for 62.5% detected fraction.

Results: Microcalcification detectability was better for DM and DBT compared to SM, with p< 0.001 for all systems. Threshold diameter increased from DM to SM by 23 μm, 17 μm and 33 μm for the GE, Hologic and Siemens, respectively. Detection of both spiculated and non-spiculated masses was significantly better in DBT mode compared to SM, while SM in turn outperformed DM. For the 3 vendors, d_r for mass-like lesions increased going from DBT to SM by 2.06 mm, 1.42 mm and 1.11 mm for the non-spiculated masses and by 1.50 mm, 0.05 mm and 1.46 mm for the spiculated masses for GE, Hologic and Siemens respectively.

Conclusion: For microcalcification detection, better scores were obtained for DM than for SM, while DBT was significantly better than SM for mass-like lesions, suggesting that SM, in its current stage of development, cannot be recommended as a stand-alone modality for any of the devices.

Image improvement factor (Q) measured for three different antiscatter grids used in mammography imaging

N. Marshall, H. Bosmans; Leuven/BE (nicholas.marshall@uzleuven.be)

Purpose: The grid image improvement factor (Q) describes the relative improvement in signal to noise ratio (SNR) for grid use compared to a non-grid technique: a well-designed grid should improve SNR, allowing dose reduction at constant SNR. The Q factor was assessed for grids in three different digital mammography systems.

Methods and Materials: Grids from GEHC Pristina (2D and 3D mode), Siemens Inspiration (2D) and Hologic Dimensions (2D) were assessed. The grid primary and total transmissions, T_p and T_t, were measured for poly(methyl methacrylate) (PMMA) thicknesses from 20mm to 70mm, using automatic exposure control factors. For T_t, the PMMA was positioned on top of the breast support and imaged with a large field of view. T_p was measured with PMMA at the x-ray tube, with a 10mm collimated beam. Q was computed as Q = T_p²/T_t.

Results: For GEHC Pristina, Q increased from 0.774 at 20mm to 1.367 at 70mm PMMA. For the same thickness range, Q ranged from 0.835 to 1.259 for Siemens Inspiration, while for Hologic Dimensions, Q varied from 0.866 to 1.333. Reproducibility error was 0.6%. At 45mm PMMA, equivalent 53mm breast thickness, Q was 1.140, 1.076 and 1.136 for GEHC Pristina, Siemens Inspiration and Hologic Dimensions, respectively.

Conclusion: The Q factors show a dose-equivalent SNR gain by 4-9% for PMMA thicknesses above 40mm, suggesting grid use is beneficial above this thickness. Benefit can reach 26-37% for the thickest breasts (70mm PMMA, 90 mm breast equivalent). Assessment is straightforward and should be part of commissioning tests.

Analysis of noise decomposition results in mammography quality control: is quantum noise the dominant noise source?

K. Wigati¹, H. Bosmans¹, D.S. Soejoko², K. Lemmens¹, J. Binst¹, A. Jacobs¹, L. Cockmartin¹, N. Marshall¹; ¹Leuven/BE, ²Jakarta/ID (kristinatri.wigati@kuleuven.be)

Purpose: The EUREF QC protocol for digital mammography describes decomposition of noise, measured in homogeneous images into electronic, quantum and structured noise terms: quantum noise must form the highest percentage of the total. This study examined reproducibility and produced typical values for different models.

Methods and Materials: Variance was measured from homogeneous response function images acquired as a function of detector air kerma (DAK). A weighted 2nd order polynomial curve fit was made to variance versus DAK, giving the three noise components. Results for 309 QC tests on Fuji Innovality, Fuji Amulet(S), GEHC Essential, IMS Giotto, Hologic Selenia/Dimensions, Philips/Sectra and Siemens Inspiration systems were analyzed to give percentage of noise at clinical DAK. Typical values were calculated and, averaged across systems of the same model.

Results: For the Innovality (detailed data available for all), the quantum noise percentage (with 95% confidence intervals) was 94.6% (93.2%-96.0%), electronic noise was 4.4% (3.1%-5.6%) and structured noise was 1.0% (0.8%-1.2%), at the clinical DAK. Quantum noise percentage was 61.3% for the Amulet(S), 82.8% for the Essential, 84.6% for the Selenia/Dimensions, 72.4% for the Giotto, 97.3% for the Philips/Sectra and 78.1% for Inspiration. Electronic noise formed the next highest percentage (range 1.0% to 37.3%), while structured noise was low (range 0.1% to 4.1%). Coefficient of variation for the quantum percentage ranged from 1.7% to 9.7%.

Conclusion: Three component noise decomposition is reproducible and quickly verifies whether quantum noise is the dominant noise source. This is a useful QC test for tracking system noise performance.

Personalised estimates of mean glandular dose and image quality investigations in cone-beam computed tomography dedicated to the breast

A. Sarno¹, G. Mettievier¹, R.M. Tucciariello², J.M. Boone³, H. Bosmans⁴, K. Bliznakova⁵, P. Russo¹; ¹Naples/IT, ²Pisa/IT, ³Sacramento, CA/US, ⁴Leuven/BE, ⁵Varna/BG (sarno@na.infn.it)

Purpose: To estimate the mean glandular dose (MGD) and imaging technology assessment in dedicated breast computed tomography (BCT) exams, by means of anthropomorphic digital breast phantoms produced from 3D clinical breast images.

Methods and Materials: We developed 200 anthropomorphic digital breast phantoms by classifying glandular, adipose and skin tissues in 3D breast images acquired at the University of California, Davis (USA), with their dedicated BCT scanner. The MGD patient-specific estimates were compared to those resulting from the adoption of the glandular/adipose homogeneous mixture and cylindrical breast geometry model. We developed a Monte Carlo code validated vs data of the AAPM TG-195. We replicated the specifications of the scanner developed at the UC Davis and input the heterogeneous breast models in the simulations. We also provided a code module for producing monoenergetic and polyenergetic breast projections of 3D digital phantoms, for investigating BCT technology.

Results: The average difference in MGD estimates by means of heterogeneous patient-specific and that for homogeneous breast models resulted ~7%. However, the homogeneous assumption led to a maximum mean glandular dose overestimation of 28% and a maximum dose underestimation of 16%, over the considered breast cohort.

Conclusion: We showed that the homogeneous breast assumption in mean glandular dose estimates in BCT leads to differences ranging between -16% and +28% when compared to patient-like heterogeneous models. We provided glandular dose distribution maps that will be a valid support for risk models. Moreover, we setup and presented a Monte Carlo software for future BCT scanner optimisations.

The effect of overestimating glandularity on mean mammographic glandular dose

M.E. Suleiman, P.C. Brennan, M.F. McEntee; Sydney/AU (moe.suleiman@sydney.edu.au)

Purpose: This work aimed to explore mammographic breast density (MBD) for women who attend BreastScreen NSW. Furthermore, this study explored the effect of MBD on mean glandular dose (MGD), proposing the use of MBD in the calculation of actual glandular dose (AGD).

Methods and Materials: Anonymised sample of mammograms (31,097) was retrieved from a central database. Patient data and examination technical parameters were exported from DICOM headers using third-party software. LIBRA software was used to estimate MBD for each mammogram. MGD was estimated using Dance et al. method, whilst AGD was calculated by replacing Dance et al.'s standard glandularities with LIBRA estimated MBDs. Linear regression analysis was used to study the correlation between MGD and AGD. Bland-Altman analysis was performed to assess their mean difference.

Results: MGD, AGD, and MBD medians were 1.53mGy, 1.62mGy and 8%, respectively. Median MBDs were lower than Dance's standard glandularities for all breast thickness (almost 50% for 20mm breast thickness). There was a strong positive correlation ($R^2 = 0.987$, $p < 0.0001$) between MGD and AGD although Bland-Altman analysis revealed small statistically significant bias of 0.087mGy between MGD and AGD ($p < 0.001$).

Conclusion: Median MBD was comparable to that previously reported for Australian women (8.1%). AGD is highly correlated to MGD, although the Dance method particularly underestimates dose at smaller compressed breast thicknesses.

B-1845 15:05

Accuracy testing of two partial breast imaging simulation platforms for applications in virtual clinical trials

L. Vancoillie¹, M. Herbst², L. Cockmartin¹, N. Marshall¹, F. Schebesch³, J. Vignero¹, H. Bosmans¹; ¹Leuven/BE, ²Forchheim/DE, ³Erlangen/DE (liesbeth.vancoillie@uzleuven.be)

Purpose: Simulation platforms lie at the heart of virtual clinical trials and must be verified for accuracy and realism. Two platforms ('A' and 'B') developed by 2 different groups were evaluated for these aspects. Both platforms employ partial simulation, whereby lesions or objects are simulated into real images.

Methods and Materials: Both platforms undertake: (1) object creation (2) generation of object template including realistic resolution and scatter (3) template insertion followed by reconstruction, but there are differences in implementation. Verification measurements were made using digital mammography and tomosynthesis scans acquired on a Siemens Inspiration system. A small high contrast 0.5mm aluminium sphere and a large area contrast 10x10x0.2mm³ aluminium foil were simulated using both platforms and compared to measurements. Parameters assessed included contrast, signal different to noise ratio (SDNR), a profile through the sphere and foil in the xy-direction and the artefact spread function (ASF). A visual comparison was also made.

Results: Contrast and SDNR for the sphere showed good agreement (<5% error), while consistent deviations of $\pm 20\%$ were seen using platform B for the foil, which was also noticeable visually. There were only small differences between all profile plots and the ASF of the Al sphere, indicating good geometric modelling for both platforms.

Conclusion: Close correspondence was demonstrated between the simulated and the real objects, both visually and quantitatively for platform A. The deviation of the foil in platform B requires further investigation. Prior to their use in virtual clinical trials, simulation platform accuracy must be verified.

Towards clinical phase-contrast breast CT at Elettra: major SNR improvement at larger propagation distances

L. Brombal¹, P. Delogu², D. Dreossi¹, B. Golosio³, P. Oliva⁴, G. Mettievier⁵, L. Rigon¹, A. Taibi⁶, R. Longo¹; ¹Trieste/IT, ²Siena/IT, ³Cagliari/IT, ⁴Sassari/IT, ⁵Naples/IT, ⁶Ferrara/IT (luca.brombal@phd.units.it)

Purpose: In-vivo phase-contrast breast CT is feasible using synchrotron radiation. Novel results towards the clinical exam based on a surgical specimen are reported, showing a major SNR improvement associated to larger propagation distances.

Methods and Materials: Effects of propagation distance on image quality metrics, i.e., SNR, contrast and spatial resolution, are quantitatively evaluated by scanning a large breast surgical specimen at 3 propagation distances (1.5, 2.7, 6.4 m). The sample is imaged at 30 keV with a CdTe single-photon-counting detector (60 μ m pixel pitch) and the flux is adjusted to provide similar doses at all distances. Images are acquired in free-space-propagation and the Paganin's phase-retrieval algorithm is applied. Experimental results are described within a rigorous theoretical framework accounting for propagation, phase-retrieval and tomographic reconstruction processes.

Results: A major (4-fold) SNR increase is observed going from the shortest to the longest propagation distance while no significant differences in contrast or spatial resolution are reported. As a result, a major visibility improvement of fibroglandular or tumoural details (e.g., spicules) is demonstrated. For all the distances experimental data are in a good agreement with theoretical predictions.

Conclusion: Moving towards larger propagation distances offers significant advantages since it greatly improves soft tissue details' visibility (i.e., SNR) at a constant radiation dose, without altering the image appearance in terms of contrast and spatial resolution. Conversely, the same image quality can be attained by reducing the radiation dose. The proposed theoretical background is a valuable tool for propagation distance optimization towards the clinical exam.

B-1847 15:21

Dose-compatible grating-based phase-contrast mammography on mastectomy specimens using a compact synchrotron source
L. Heck¹, E. Eggel¹, S. Grandt², M. Dierolf¹, D. Mayr², K.A. Hellerhoff², M.F. Reiser², F. Pfeiffer¹, J. Herzen¹; ¹Garching/DE, ²Munich/DE (lisa.heck@tum.de)

Purpose: In X-ray breast imaging, the low soft-tissue contrast of conventional attenuation-based images can be improved by phase-contrast imaging. Here, the diagnostic performance of grating-based phase-contrast mammography with a compact synchrotron source was evaluated.

Methods and Materials: In this study, grating-based multimodal mammography on mastectomy specimens at an inverse Compton compact synchrotron source was performed. This novel X-ray source offers a quasi-monochromatic X-ray beam which is tunable in its energy and is partially coherent. Grating-based phase-contrast and dark-field images as well as conventional absorption images were acquired. Here, we examined four freshly dissected breast specimens and one mammographic accreditation phantom for a quantitative analysis.

Results: We found enhanced diagnostic information in monochromatic grating-based phase-contrast images while the applied dose was lower or equal to the clinically applied dose. Microcalcifications could be identified equally well at significantly reduced dose in the monochromatic images. In a quantitative analysis performed with a mammographic accreditation phantom, the monochromatic absorption-contrast images showed better or equal contrast-to-noise ratio (CNR) compared to the clinical one even at 20% reduced dose. The monochromatic grating-based dark-field images outperformed the clinical image in case of the tumor masses even at 65% reduced dose.

Conclusion: The demonstrated improved content of diagnostic information and increased CNR at lower or equal dose indicates that compact synchrotron sources have great potential to bring benefits to clinical imaging for mammography. This is particularly advantageous with regard to the radiation exposure, since glandular breast tissue is one of the tissues most sensitive to the applied dose.

Perfusion-ventilation CT via three-material differentiation in dual-layer CT: a feasibility study
A. Sauter¹, J. Hammel¹, M. Kimm¹, D. Pfeiffer¹, F.K. Kopp¹, K. Achterhold², F. Pfeiffer², E.J. Rummeny¹, P.B. Noel¹; ¹Munich/DE, ²Garching/DE (andreas.sauter@tum.de)

Purpose: Evaluation of a simultaneous xenon-ventilation and gadolinium-perfusion dual-energy computed tomography (CT) examination in a pig-model using a tissue discriminating two-material decomposition, resulting in a three-material differentiation.

Methods and Materials: For verification, xenon and gadolinium quantification were examined in a phantom model by comparing nominal to measured concentrations. A landrace pig was examined using a dual-layer CT (DL-CT). Three scans were performed: 1) native; 2) xenon ventilation only; 3) xenon ventilation and gadolinium perfusion. An in-house-developed algorithm was used to obtain xenon- and gadolinium-density maps. Firstly, lung tissue was segmented from other tissue. Consequently, a two-material decomposition was performed for lung tissue (xenon/soft tissue) and for remaining tissue (gadolinium/soft tissue). By combining both density maps, a xenon-gadolinium density map was generated.

Results: Measurements of xenon and gadolinium concentrations showed accurate results. For xenon, a percentage difference between nominal and measured concentration of below 1.2% was shown. For gadolinium, a difference of below 1.3% for all concentrations >1mg/ml resulted. Using the in-house-developed algorithm, it was possible to differentiate xenon and gadolinium in a ventilation/perfusion scan of a pig, resulting in xenon and gadolinium density maps. By summation of both density maps, a three-material differentiation (xenon/gadolinium/soft tissue) can be performed and thus, xenon ventilation and gadolinium perfusion can be visualized in one CT scan.

Conclusion: With DL-CT, xenon and gadolinium can be quantified accurately. Via three-material differentiation, a ventilation/perfusion examination can be performed during one CT-scan, resulting in decreased radiation dose and increased accuracy compared to other previously described methods.

B-1849 14:08

Fine focal spot: a technique to improve image quality of computed tomography pulmonary angiography

K.K. Lau¹, L. Abdelganne¹, K. Buchan¹, A. Kuganesan¹, T. Lau²; ¹Melbourne/AU, ²Southport/AU (kenkplau@gmail.com)

Purpose: Faster temporal resolution (FTR) is routinely employed in CTPA to reduce motion artefacts. CT with fine focal spot (FFS) enables fine anatomical details. The latest x-ray tube design allows the use of FFS in body, but tube rotation time (rt) needs to be reduced. The aim of this retrospective study of CTPA was to compare FFS and FTR in CTPA image quality.

Methods and Materials: 50 consecutive adults with FTR CTPA (0.275 second-rt and standard focal spot) and another 50 consecutive adult patients with FFS CTPA (0.33 second-rt and FFS) were included. Two radiologists blindly, randomly and independently performed qualitative review on the clarities of PAs, lungs, aortas, hearts, ribs and livers on images from 2 groups using 5 point ranking method.

Results: 50 FFS CTPA (19 male, mean age of 62, 13% PE incidence) and 50 FTR CTPA (23 male, mean age of 65, 6.7% PE incidence) were studied. Mann-Whitney U test showed FFS was significantly better than FTR in the image qualities of pulmonary arteries, lungs, aorta, liver and ribs.

Conclusion: Despite slower CT rt, FFS still has stronger positive influence on CTPA image quality than FTR. FFS may become an important CTPA scanning tool that aid the PE detection.

B-1850 14:16

Do subtraction CT-derived iodine maps have the same impact on pulmonary embolism detection as dual-energy CT-derived maps?

D. Grob¹, E.J. Smit¹, J. Prince², J. Kist², L.J. Oostveen¹, M. Prokop¹, C. Schaefer-Prokop³, I. Sechopoulos¹, M. Brink¹; ¹Nijmegen/NL, ²Utrecht/NL, ³Amersfoort/NL (Dagmar.Grob@radboudumc.nl)

Purpose: To compare the impact on pulmonary embolism (PE) detection of adding iodine maps derived from either subtraction CT (SCT) or dual-energy CT (DECT) to CT angiography (CTA).

Methods and Materials: In this prospective study, 274 patients with suspected PE underwent CTA+DECT, and an additional pre-contrast scan to generate the SCT-based iodine map. The SCT image sets were acquired at similar but lower dose than the DECT sets. Truth was established by expert consensus using all clinical data, including six-month follow-up. An enriched 1:1 dataset of 75 randomly selected patients with and without PE were reviewed by three radiologists and six radiology residents, who scored separately the CTA alone, the CTA+SCT and the CTA+DECT for the presence of PE. The partial areas under the receiver operating characteristic curves (pAUC) for the clinically relevant specificity region were compared using multi-reader multi-case variance.

Results: The pooled sensitivities were not significantly different (95% confidence intervals for CTA: 67%-89%, SCT: 70%-91%, DECT: 72%-91%). Pooled specificity was significantly higher for SCT (100%-100%) compared to the other two techniques (CTA: 89%-97%, DECT: 89%-98%, p<0.001). The pAUCs for the average reader increased equally with the addition of either iodine map (p=0.029 SCT vs. CTA, p=0.009 DECT vs. CTA, p=0.65 DECT vs. SCT). Average reading times were equivalent while the median dose-length-products were 166 mGy-cm for SCT and 177 mGy-cm for DECT (p<0.001).

Conclusion: Iodine maps increase PE detection accuracy over CTA alone with similar reading times. SCT has the same diagnostic performance as DECT, at similar dose, without the need for dedicated hardware.

Split-bolus contrast injection protocol enhances the visualisation of the thoracic vasculature during chest CT

C. Saade; Beirut/LB (charbel.saade@aub.edu.lb)

Purpose: To investigate the visualization of mediastinal lymph nodes during thoracic CT employing a multi-phasic contrast media (CM) protocol.

Methods and Materials: IRB approved retrospective study consisting of 300 patients with known chest malignancy. Patients were allocated to one of two

CM protocols: Protocol A, consisted of dual bolus (Phase 1: 100mL CM followed by 100mL saline chaser) intravenously injected at 2.5mL/s; Protocol B employed 100mL of CM using a multi-phasic injection protocol (Phase 1 and 2: 60mL contrast and saline, followed by phase 3 and 4: 40mL contrast and saline injected at 2.5mL/s) with a fixed scan delay of 70sec for each acquisition. Attenuation profiles of the thoracic arteries and veins were calculated as well as the arterio-venous contrast ratios (AVCR). Receiver operating characteristic (ROC), visual grading characteristic (VGC) and Cohen's kappa analysis were assessed.

Results: Arterial opacification was up to 24% ($p < 0.032$) higher in protocol B than A, whereas, in the veins it was significantly lower in protocol B than A; with a maximum reduction of up to 84% ($p < 0.0001$). There was no statistical significance between the central and peripheral pulmonary arteries (> 263 HU) in each protocol. Protocol B, demonstrated significant improvement in AVCR at various anatomical sites ($p < 0.002$). Radiation dose was significantly reduced in protocol B compared to A ($p < 0.004$). Both ROC and VGC demonstrated significantly higher Az score for protocol B compared to A ($p < 0.0001$) with an increased inter-reader agreement from poor to excellent.

Conclusion: Employing a multi-phasic CM protocol significantly improves opacification of the thoracic vasculature and visualization of mediastinal lymph nodes during thoracic CT.

Lung dual-energy quantitative CT vs single-photon emission computed tomography for quantification of the perfusion

S.A. Si-Mohamed¹, C. Moreau-Triby¹, Q. Wdowik², P. Douek¹, L. Boussel¹; ¹Bron/FR, ²Lyon/FR (salim.si-mohamed@chu-lyon.fr)

Purpose: Perfusion scintigraphy is the current gold standard to assess the fractional contribution of each lobe to the total lung function. We developed a quantitative CT-derived method based on iodine density maps obtained from a dual-layer CT (DLCT) acquisition and compared it with perfusion single-photon emission computed tomography-CT.

Methods and Materials: Fifty three patients who underwent both modalities for suspected acute and chronic pulmonary embolism were retrospectively enrolled. CT angiography was performed on a DLCT (iQon, Philips, Haifa, Israel). Lung lobes were segmented semi-automatically on conventional images, using the 'COPD' module (Intellispace portal, Haifa, Israel). The lobar masks were then transposed onto the iodine density maps using in-house software, in order to compute the absolute amount of iodine in mg per lobe and the total amount in both lungs. The relative perfusion of each lobe was obtained by dividing the amount of iodine per lobe by the total amount and compared to the gold standard using linear regression and Bland-Altman analysis.

Results: Linear regression between the relative pulmonary lobar perfusion showed excellent good correlation (slope=0.88, offset=2.11 and $R^2=0.87$) for 265 lobes. Linear regression for each lobe demonstrated a R^2 at 0.85, 0.81, 0.81, 0.70, 0.87 for the left superior, inferior and right superior, middle, inferior lobes respectively. Bland Altman analysis demonstrated a bias at -0.10 and agreement limits [-6.01; 5.81].

Conclusion: Given its simplicity, we anticipate that quantitative dual-layer CT could be widely used to measure the relative lung perfusion and replace perfusion lung scintigraphy for various clinical applications.

B-1853 14:40

Influence of respiratory position on pulmonary artery contrast enhancement in dual-energy computed tomography angiography

J. Vaimel¹, M.-K. Uprus¹, N. Igumenova², Å. Roose¹, A. Samarin¹; ¹Tallinn/EE, ²Peetri/EE

Purpose: Transient interruption of contrast results in suboptimal enhancement of pulmonary arteries due to increased flow of unopacified blood from the inferior vena cava as a result of patient's deep inspiration prior to the scan. The primary purpose of this study was to determine if shallow-inspiration breath-hold allows superior pulmonary artery attenuation compared to deep-inspiration breath-hold CT angiography.

Methods and Materials: CT pulmonary angiographies were acquired in 107 patients (58 women, 49 men; age 16-91 years, mean 67 years) in shallow-inspiration breath-hold and in 115 patients (47 women, 58 men; age 26-92 years, mean 67 years) in deep-inspiration breath-hold using 64-detector row CT scanner and dual energy protocol. Bolus tracking was used for triggering the scan. Attenuation in Hounsfield units (HU) was measured in pulmonary trunk, thoracic aorta and superior vena cava on 65keV images. Scans with pulmonary trunk attenuation 250HU and higher were considered diagnostically adequate.

Results: Diagnostically adequate image quality was achieved in 82.6 % of the scans ($n=95$) in deep-inspiration breath-hold group and 93.4 % ($n=100$) of the scans in shallow-inspiration breath-hold group with a mean pulmonary trunk attenuation of 384.6 HU and 406.7 HU, respectively. In patients with inadequate pulmonary trunk attenuation a pattern consistent with transient interruption of contrast were seen in 45% of the inadequate scans ($n=9$) in

deep-inspiration group and in 25% of the inadequate scans ($n=2$) in shallow-inspiration group.

Conclusion: CT pulmonary angiography performed after shallow-inspiration breath-hold leads to higher contrast enhancement of pulmonary arteries reducing the number of diagnostically inadequate scans.

Dual-energy CT pulmonary angiography and lung perfusion imaging with ultra-low-dose contrast application

K. Hekimoglu, K. Haberal, H. Turnaoglu, G. Kahraman; Ankara/TR (korayhekim@yahoo.com.tr)

Purpose: To prospectively evaluate the quantitative and subjective quality of low-dose contrast dual-energy CT pulmonary angiography (DE-CTPA) and lung perfusion imaging (LPI) in comparison with routine pulmonary angiography (CTPA).

Methods and Materials: CTPA ($n=49$) had been done with 16-slice multidetector CT (MDCT) by 60 mL contrast media (21 gr iodine). A third-generation dual-energy MDCT system was used for DE-CTPA and LPI ($n=45$) with ultra-low contrast media (7 gr iodine). Average enhancement levels, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. A five-point scale was used to subjectively evaluate image quality and noise. Shapiro-Wilk test was used to evaluate the normality assumption for enhancement values. Variables are presented as median with 25% and 75% interquartile range (IQR). Comparison between groups was performed with Mann-Whitney U test and LPI added three groups with Kruskal-Wallis test. p values < 0.05 were considered statistically significant.

Results: Pulmonary enhancement levels of two protocols revealed no significant difference between ultra-low-dose contrast DE-CTPA protocol and routine CTPA ($p=0.18$). The SNR and the CNR ratios also revealed no statistical difference between protocols ($p=0.2$ and $p=0.18$, respectively). The five-point score was significantly better in the DE-CTPA and LPI ($p=0.007$) for image quality. There was not detected any significant difference for image quality and image noise evaluation between protocols ($p=0.3$).

Conclusion: DE-CTPA with ultra-low-contrast media allows sufficient enhancement in pulmonary arteries combined with high-quality lung perfusion images. This allows a significant reduction in iodine load while improving diagnostic confidence.

B-1855 14:56

Value of CT pulmonary angiography to predict short-term outcome in a patient with pulmonary embolism

A.M. Osman, E. H. Abdeldayem; Cairo/EG (Dr_osman80@yahoo.com)

Purpose: To evaluate the role of CT pulmonary angiography (CTPA) in the assessment of pulmonary embolism (PE) severity and the related CT cardiac changes reflecting the clinical status of the patients and predicting the outcome.

Methods and Materials: This is a prospective study of 184 patients presented with suspicious acute PE. All patients underwent CTPA followed by ECHO. Pulmonary artery obstructive index (PAOI) using Qanadli Score was calculated and cardiac changes were recorded. The patients' outcome was followed up for 30 days.

Results: Only 150 patients completed the study; 26.7 % needed ICU admission while 13.3 % died during follow-up. There was a significant relationship between the PAOI and the risk classification, right ventricular dysfunction (RVD) diagnosed by ECHO and the patients' short outcome. We found PAOI cutoff value of 45% for mortality and 35% for ICU admission and 27.5% for RVD with 60%, 75% and 90% sensitivity and 80%, 73.3% and 68.6% specificity, respectively. CT RV/LV ratio was the most sensitive parameter to predict RV dysfunction followed by pulmonary artery diameter.

Conclusion: CTPA is not only used for diagnosis but also to assess the severity of PE, the effect on the right ventricular function and subsequently the need for ICU admission and prediction of the outcome.

D-dimers, Wells' scores and CTPA for pulmonary embolism: are all diagnostics used appropriately?

C. So, P. de Souza, R. Kumar, D. Remedios; London/UK (chunwah.so@nhs.net)

Purpose: Pathways for the management of a suspected pulmonary embolism (PE) rely on pre- and post-test probability. This audit assesses adherence to established pathways, incorporating use of Wells' Score, D-dimer and CT Pulmonary Angiography (CTPA).

Methods and Materials: Wells' scores, D-dimer levels, CTPA requests and reports from 60 consecutive patients were retrospectively analysed. Clinical, laboratory and request data were correlated with the CTPA report to assess adherence to pathways and accuracy of supplied information.

Cardiac magnetic resonance feature tracking for quantifying right ventricular deformation in type 2 diabetes mellitus patients

B. Hu, Z.-G. Yang, Y.-K. Guo; Chengdu/CN (brigitteyue@foxmail.com)

Purpose: To determine the feasibility of deformation analysis in the right ventricle (RV) using cardiovascular magnetic resonance feature tracking (CMR-FT) in type 2 diabetes mellitus (T2DM) patients.

Methods and Materials: We enrolled 70 T2DM patients, including 12 with impaired right ventricular ejection fraction (RVEF \leq 45%) and 58 with preserved RVEF (RVEF > 45%), and 22 healthy controls in this prospective study. CMR was used to determine cardiac function and RV feature-tracking parameters. Binary logistic regression was used to predict RV dysfunction. ROC analysis was used to assess the diagnostic accuracy.

Results: Compared with controls, RV global longitudinal peak strain (GLPS) and circumferential peak strain (GCPS) were significantly lower in T2DM patients, without or with reduced RVEF [GLPS, -10.24 (-11.41 – -9.27)] % vs. -6.84 (-8.79 – -4.68) % vs. -7.71 (-10.15 – -4.79) %; GCPS, -4.84 (-6.05 – -3.36) % vs. -2.45 (-4.76 – 4.30) % vs. 0.59 (-3.83 – 3.42) %; all $p < 0.01$). PS in all three directions was significantly lower at basal, mid, and apical slices in T2DM patients than in controls (all $p < 0.05$), except for radial PS at the apical slice and circumferential PS at the basal slice. GCPS was an independent predictor of RV dysfunction (odds ratio: 1.265, 95% confidence interval: 1.020–1.568; $p = 0.032$), and GLPS demonstrated greater diagnostic accuracy (area under curve: 0.813) to predict RV dysfunction at a cut-off value of less than -9.54%.

Conclusion: In T2DM patients, CMR-FT could quantify RV deformation and identify subclinical RV dysfunction in those with normal RVEF; further, RV strain parameters are potential predictors for RV dysfunction.

B-1860 14:08

Magnetic resonance functional assessment of the right ventricle in the short-axis plane as obtained from cross-referenced atrioventricular plane localisation

M. de Meyere, B. Dubourg, D. Delacour, S. Bejar, P.J. Michelin, J.-N. Dacher; Rouen/FR

Purpose: Axial orientation may have been favoured over short-axis orientation (SAO) for evaluating the right ventricular function. The main reason lays in the difficulty to identify the atrioventricular junction in the short-axis plane implying lower reliability of the derived volumes. Our goal was to assess the accuracy and reproducibility of SAO-derived stroke volume measurement when using cross-referenced localisation of the atrioventricular plane at the tricuspid valve.

Methods and Materials: 41 patients referred for various acquired and congenital cardiopathies underwent CMR including SAO bSSFP slices. Additional right ventricular vertical long-axis and four-chamber views were used for semi-automatic localisation of the tricuspid plane. Right ventricle stroke volume (RV SV) was obtained three times by two observers. Two-dimensional phase contrast MRI "through plane" was performed at the level of the pulmonary trunk to measure the pulmonary stroke volume (PSV) and used as reference to assess accuracy. Intra- and inter-observer variabilities were tested using Bland-Altman analysis.

Results: There was high correlation ($r=0.94$) and no significant difference between RV SV and PSV (83 ± 20 mL vs. 81 ± 21 mL $p > 0.05$). The RV SV, as well as others functional parameters of the RV, showed good intra- (ICC: 0.95; COV: 6.2) and inter-observer reliabilities (ICC: 0.91; COV: 8.9).

Conclusion: Right ventricle stroke volume derived from SAO analysis using cross-referenced localisation of the atrioventricular plane can be routinely performed with high accuracy and reproducibility.

Results: There was 100% concordance of the supplied D-dimer result with the laboratory value confirming the absence of gaming. In 22 cases the D-dimer was not used according to guidelines, of which 9 had a low Wells' score but no D-dimer performed. In these 9 cases, the CTPA was negative. Furthermore, 13 cases had a high Wells' score with an unnecessary D-dimer. Pulmonary embolism was identified in 17% of cases in keeping with the published pickup rates for a CTPA - all of which either had a high Wells' score, high D-dimer or both, reinforcing the value of the pathway.

Conclusion: The rate of non-adherence with national pathways for PE investigation is 37%, resulting in waste of laboratory and radiological resources. A clinical decision support tool which factors in risk stratification and laboratory data may reduce waste by guiding clinicians towards the most appropriate first-line investigation, radiological or otherwise.

The effect of different monochromatic image choices on the reconstruction of CT perfusion data in one-stop spectral and perfusion CT scan

H. Wang, P. Lu, S. Yue, W. Li; Zhengzhou/CN (1508249322@qq.com)

Purpose: To assess the effect of monochromatic images with different energy levels on the reconstruction of CT perfusion data in one-stop spectral and perfusion CT scan as compared with perfusion CT scan alone.

Methods and Materials: Twenty patients with lung tumours underwent one-stop spectral and perfusion CT scan (including whole tumour perfusion CT and whole lung contrast-enhanced CT). In the study group, monochromatic images with energy level from 40 to 80 keV (group A1 to A5), 100 kVp-like images (corresponding 68keV, group B) generated from spectral CT were used to reconstruct CT perfusion images with primary perfusion data. Another ten patients with lung tumours underwent perfusion CT scan alone was taken as the control group (group C). CT perfusion parameters of the tumours including blood volume (BV), blood flow (BF), mean transit time (MTT) and permeability surface (PS) were compared by using One-way ANOVA and independent-t test.

Results: Significant differences in CT perfusion parameters except for BV were found among the study group, and the BF and MTT increased with the increase of energy level. There was no difference of all CT perfusion parameters between group B and group C. However, compared to control group, BV in group A(except for group A3), BF in group A1 to A3, MTT in group A4, A5 increased and MTT in group A1 to A2, PS in group A1, A5 decreased ($P < 0.05$).

Conclusion: 100 kVp-like energy level (corresponding 68keV) was the optimal energy level to reconstruct perfusion images in the one-stop spectral and perfusion CT scan.

B-1858 15:20

CT angiography for pulmonary embolism in the emergency department: diagnostic accuracy of 20ml high-concentration contrast medium

G. Milanesi¹, R. Cobelli¹, C. Manna¹, M. Silva¹, E. Rasciti², S. Poggesi¹, N. Sverzellati¹; ¹Parma/IT, ²Bologna/IT (gianluca.milanesi@studenti.unipr.it)

Purpose: To compare the diagnostic performance of CT pulmonary angiography (CTPA) between 20 ml and 40 ml of contrast medium (CM), in patients with suspected pulmonary embolism (PE).

Methods and Materials: CTPAs performed by 64-row multidetector scanner with 20ml (ultra-low volume: ULV) or 40 ml (low volume: LV) of high-concentration CM (Iomeprol 400 mgI/ml; iodine delivery rate 1.2 mgI/sec) were retrieved; tube potential was optimized for angiographic scan (100 kVp). Two radiologists independently scored vascular enhancement and image noise by a 5-point Likert score. Quantitative analysis was performed by densitometric parameters, including vascular contrast enhancement (CE; densitometric threshold for diagnostic CE > 250 HU), and quantitative metrics for image noise, both in central and peripheral pulmonary arteries; furthermore, the overall mean CE was calculated.

Results: 102 ULV and 74 LV were included. The qualitative score was overall sufficient by ULV, yet inferior than LV ($p < 0.001$). Qualitative image noise was comparable between ULV and LV, though the inter-observer agreement was only fair for peripheral vessels. Non-diagnostic qualitative parameters was reported in 9/102 ULV, of which 7/9 were associated with major pulmonary abnormalities. Quantitative image noise was not significantly different between ULV and LV. The mean CE was lower in ULV group ($p < 0.001$), though > 250 HU in both groups.

Conclusion: CTPA with 20 ml allows sufficient CE of the pulmonary arteries in patients with clinical suspect of PE. Decreased image quality was mostly associated with massive PE or concomitant pleuro-pulmonary abnormalities.

B-1861 14:16

Cardiac magnetic resonance imaging study of right ventricular myocardial deformation in spontaneous T2DM rhesus monkey
T. Zhu¹, C. Yushu¹, Z. Yu¹, Z. Wen¹, J. Zheng², G. Fabao¹; ¹Chengdu/CN, ²St. Louis, MO/US (965967939@qq.com)

Purpose: To assess right ventricular function in rhesus monkeys with spontaneous T2DM using cardiac magnetic resonance imaging.

Methods and Materials: Twelve male spontaneous T2DM rhesus monkeys, and age- and sex-matched nine control monkeys underwent cardiac magnetic resonance imaging scanning to evaluate biventricular function using CMR cine and CMR-tissue tracking. Glucose, insulin, triglycerides, cholesterol, lipoprotein and liver, and renal function were assessed from blood.

Results: There was no significant decrease in RV and LV ejection fraction in T2DM ($p < 0.05$). However, the absolute value of radial and circumferential global peak systolic strain, systolic strain rate and three directions global peak diastolic strain rate of the RV free wall were lower in the diabetic group ($p < 0.05$). Also, only radial and circumferential peak systolic strain and radial diastolic strain rate of LV were higher ($p < 0.05$). Our study also demonstrated that RV deformation, especially radial and circumferential, was negatively correlated with age, weight and glycated haemoglobin level ($p < 0.05$).

Conclusion: RV showed systolic and diastolic dysfunction which was consistent with that of LV in spontaneous T2DM rhesus monkeys. RV dysfunction is closely related to blood glucose level, age and weight.

B-1862 14:24

Right ventricular functional assessment with cardiac MRI by comparing volume measurements between axial and short axis orientations
D.G. Oktay, E. Peker, I. Erden; Ankara/TR (gizemoktay@gmail.com)

Purpose: Right ventricular (RV) volume and function assessment is usually performed on patients with cardiovascular diseases by using cardiac magnetic resonance imaging (CMRI). It's important to clear that which slice orientation provides better overall assessment of RV functional performance. This study is designed to evaluate right ventricular (RV) volume measurements and their reproducibility with comparing axial and short axis orientation acquisition techniques.

Methods and Materials: From December 2015 to December 2017, 40 patients who underwent CMR (1.5 T) and had axial and short axis acquisitions were retrospectively evaluated. Measurements of RV from data sets acquired in axial and short axis orientations were compared.

Results: Comparison between the axial and short axis methods, there wasn't any significant and systematic difference in the EDV, ESV and SV volumes, EF values (mean bias EDV 15.6 +/- 27.6 mL/m² difference; ESV 8.5 +/- 15.96 mL/m²; difference; SV 7.18 +/- 18.7 mL/m² difference; EF -1.63 +/- 6.5 difference). Also, there was no difference between two method in terms of intraobserver reliability in all measurements.

Conclusion: There is not any significant impact of the slice acquisition orientation on CMR assessment of RV volumes and the addition of the axial acquisitions extend the duration of CMRI; so its reproducibility were not clinically significant.

B-1863 14:32

Balloon pulmonary angioplasty (BPA) improves right ventricular dysfunction and pulmonary haemodynamics in inoperable CTEPH
A. Hasse¹, K. Tello¹, H. Gall¹, A. Breithecker¹, C.B. Wiedenroth², W. Seeger¹, E. Mayer², G.A. Krombach¹, F.C. Roller¹; ¹Giessen/DE, ²Bad Nauheim/DE (alexander.hasse@mail.de)

Purpose: To assess the effect of BPA on right ventricular (RV) dysfunction and pulmonary haemodynamics in patients with inoperable chronic thromboembolic pulmonary hypertension (CTEPH).

Methods and Materials: MRI at 1.5 Tesla and right heart catheterization were performed before and 6 months after BPA in 30 consecutive patients (mean age 63.4 ± 10.6 years; 17 female). Right ventricular function (RVEF) and feature tracking strain analysis (global longitudinal (GL), circumferential (GC) and radial (GR)) were obtained and correlated to mean pulmonary arterial pressure (mPAP) and pulmonary vascular resistance (PVR).

Results: RVEF (35.9% ± 10.8 to 48.4% ± 8.7), mPAP (42.1mmHg ± 8.0 to 33.1mmHg ± 8.0) and PVR (551.8 ± 192.3 to 377.7 ± 140.2) significantly decreased after BPA ($p < 0.0001$). Moreover, RV strain parameters significantly decreased after BPA (GL -19.9 ± 5.7 to 24.0 ± 3.5, $p < 0.001$; GC -9.4 ± 4.0 to -11.0 ± 3.5, $p < 0.022$; GR 38.2 ± 19.1 to 50.7 ± 15.0, $p = 0.001$) and GL strain revealed the best and significant correlations to RVEF (before BPA $r = -0.75$; after BPA $r = -0.54$), mPAP ($r = 0.36$; $r = 0.52$) and PVR ($r = 0.49$; $r = 0.48$).

Conclusion: BPA in patients with CTEPH leads to significant improvement of RV function and pulmonary haemodynamics. RV mechanical dysfunction is significantly improved and RV strain measures showed promising correlations to function and haemodynamics. In the course of CTEPH, strain analysis might enable new insights regarding therapy effect, therapy monitoring and prognosis.

B-1864 14:40

Application of CMR derived myocardial deformation parameters to predict restrictive physiology in repaired tetralogy of Fallot patients
X.-W. Tong¹, R. Wald², G.R. Karur², Y.-F. Cheung¹, M.-Y. Ng¹; ¹Hong Kong/HK, ²Toronto, ON/CA (xiaowan@connect.hku.hk)

Purpose: Surgically repaired tetralogy of Fallot (rTOF) patients can be subdivided into those with restrictive right ventricular (RV) physiology and those without based on main pulmonary artery (MPA) end-diastolic forward flow (EDFF). Our aim was to assess the value of cardiac magnetic resonance (CMR) feature-tracking (FT) for RV restrictive physiology pre and post pulmonary valve replacement (PVR).

Methods and Materials: 141 rTOF patients with PVR were prospectively recruited as part of the multicenter international CORRELATE study. All patients underwent pre-PVR MRI and 78 underwent post-PVR MRI with multiplanar steady-state free precession cine imaging and phase-contrast imaging at the MPA. CMR-FT was performed to calculate late-diastolic strain rate in longitudinal (late-LDSR), radial (late-RDSR) and circumferential (late-CDSR) planes using dedicated software. RV volumetric parameters, exercise performance with peak VO₂ and its predicted value were evaluated. Mann-Whitney U-test and paired t-test were performed to compare differences between restrictive and non-restrictive groups, pre/post-PVR changes.

Results: Among 141 patients, 68 (48.2%) patients showed restrictive RV prior and 3 (3.8%) post PVR. EDFF-negative group showed higher late-RDSR, late-CDSR, peak VO₂ but less regurgitation fraction (RF) (all $p < 0.05$) than EDFF-positive. After PVR, predicted peak VO₂ improved 8.6% in EDFF-negative ($p = 0.021$) but not for EDFF-positive group. Both groups showed decreased RV size and increased late-RDSR ($p < 0.05$).

Conclusion: EDFF-positive group showed decreased RV compliance, more RF and worse exercise performance. Prevalence of restrictive RV was common in rTOF and diminished after PVR. RV reverse remodelling after PVR with improvement in RV compliance, but only non-restrictive patients showed improved exercise.

B-1865 14:48

Evaluation of ascending aorta flow pattern in patients with repaired TOF using 4D flow CMR
S. Lee, Y.J. Kim; Seoul/KR (sjlee37@yuhs.ac)

Purpose: To evaluate characteristics of the ascending aorta flow patterns with 4D-flow MRI and to determine possible predictors of aortic dilatation late after tetralogy of Fallot (TOF) repair.

Methods and Materials: Total 66 subjects underwent 4D-flow MRI (44 with repaired TOF patients and 11 volunteers). Data analysis included aortic diameters, velocity, wall shear stress (WSS), flow jet angle (FJA) and flow displacement (FD) at the level of sinotubular junction (STJ) and mid-ascending aorta(AA). Differences in the parameters between patients group and volunteers were analysed. Relationship between aortic dimension and flow parameters in patients group was also analysed.

Results: In the repaired TOF group (M:F=25:19, mean age=25.5), aortic dimensions at sinus of valsalva (SOV), STJ and AA were significantly increased compared with the volunteer group (M:F=10:1, mean age=36.00) ($P = 0.002$, $P < 0.001$, $P = 0.013$). Among the flow parameters at STJ and AA, maximal velocity (V_{max}), mean velocity (V_{mean}), maximal WSS (WSS_{max}), mean WSS (WSS_{mean}), mean WSS at axial direction ($WSS_{ax,mean}$), mean WSS at circular direction ($WSS_{cir,mean}$) were significantly decreased ($P = 0.002$, $P < 0.001$, $P < 0.001$, $P = 0.003$, $P < 0.001$, $P = 0.023$) and FJA was significant increased ($P < 0.001$) in the level of STJ. And V_{max} , V_{mean} , and $WSS_{cir,mean}$ were significantly decreased ($P = 0.003$, $P < 0.001$, $P = 0.016$) and FJA was significantly increased ($P = 0.003$) in the level of AA. In regression test, V_{mean} and WSS parameters ($P = 0.0019$, $P = 0.0147$ for WSS_{max} , $P = 0.0020$ for WSS_{mean} , $P = 0.0300$ for $WSS_{ax,mean}$, $P = 0.0016$ for $WSS_{cir,mean}$) were significantly correlated to STJ diameter. V_{mean} , WSS_{mean} and $WSS_{cir,mean}$ ($P < 0.0001$, $P = 0.0244$, $P = 0.0035$) were significantly correlated to AA diameter.

Conclusion: In repaired TOF patients, WSS is decreased at ascending aorta and it was correlated with ascending aorta dilatation, especially in proximal portion.

B-1866 14:56

Measurement of wall shear stress and pressure gradients using 4D-flow-MRI in patients with Fontan circulation
A. Curta, A. Lehner, S. Ulrich, R. Dalla-Pozza, M. Fischer, N. Haas, H. Kramer; Munich/DE (adrian.curta@med.uni-muenchen.de)

Purpose: To assess feasibility of indirect measurements of wall shear stress (WSS) and pressure gradients (PG) using 4D-phase-contrast-flow(4D-flow)-MRI in the work-up of patients with a univentricular system and Fontan circulation.

Methods and Materials: 4D-flow-MRI was acquired in 9 patients (13.9±4.2 years old) with a Fontan circulation. Velocity encoding was set at 100 cm/s with a spatial resolution of 2.2x1.8x1.8mm and a temporal resolution of 10

frames/cardiac cycle. Vessel geometry was measured in contrast enhanced MR-angiography using 3D multiplanar reconstructions. Flow was visualized using path lines; WSS and PG were visualised using time-resolved colour-coded maps. Data was processed offline using a commercially available software.

Results: The PG from the Fontan tunnel (FT) to the right pulmonary artery (RPA) was lower than from the FT to the left pulmonary artery (LPA) (-0.7 ± 1.6 mmHg vs. -1.2 ± 1.4 mmHg). Average WSS was lower in the RPA than in the LPA (0.19 ± 0.08 Pa vs. 0.23 ± 0.11 Pa). There was a significant negative correlation of the angle of the RPA anastomosis to the average WSS of the RPA ($P=0.76$; $p=0.03$) and of the angle of the sum of the angles of the LPA and RPA anastomosis to the average WSS of the LPA ($P=0.937$; $p=0.001$) and RPA ($P=0.760$; $p=0.029$).

Conclusion: Indirect measurements of WSS and PG using 4D-flow-MRI were feasible. These measurements could aid in further optimizing surgical methods in order to improve flow from the FT to the pulmonary arteries to prevent complications such as protein-losing enteropathy and intrapulmonary shunts.

Pulmonary insufficiency: extending the advantage of pulmonary regurgitation volume versus pulmonary regurgitation fraction to a congenital heart disease mixed population

M. Petrimi¹, F. Secchi², C.B. Monti², M. Ali², P.M. Cannao², E. Michieletti¹, F. Sardaneli²; ¹Piacenza/IT, ²Milan/IT

Purpose: To compare the use of pulmonary regurgitation volume (PRV) and pulmonary regurgitation fraction (PRF) in the assessment of patients with pulmonary regurgitation (PR) undergoing cardiac magnetic resonance (CMR).

Methods and Materials: 179 patients with PR who had undergone CMR were retrospectively evaluated. Their right ventricular diastolic (EDVI) and systolic (ESVI) volume indexes, stroke volume and ejection fraction were obtained from cine CMR sequences, while PRV and PRF were obtained by phase contrast sequences. Patients were divided into subgroups, according to their underlying pathology, and to PR severity. Correlations between PRV or PRF and RV parameters were studied through Spearman's ρ both in the main group and subgroups. Afterwards, follow-up examinations were studied when present, and correlations between PRV or PRF from the first CMR examination and volume data from the second were analysed.

Results: Tetralogy of Fallot was the main setting of PR (98/179). Overall, EDVI had a stronger correlation to PRV ($\rho=0.592$, $p<0.001$) than PRF ($\rho=0.522$, $p<0.001$), and ESVI had a stronger correlation to PRV ($\rho=0.454$, $p<0.001$) and PRF ($\rho=0.406$, $p<0.001$). Regarding subgroup analysis, in moderate or severe PR patients, EDVI had a significantly ($p=0.043$) stronger correlation to PRV ($\rho=0.499$, $p<0.001$) than PRF ($\rho=0.317$, $p<0.001$). Follow-up EDVI had a significant correlation to PRV ($\rho=0.450$, $p=0.031$), while not with PRF.

Conclusion: Especially when assessing moderate to severe PR, PRV may be a better indicator of right ventricular dysfunction than PRF. Moreover, PRV may be a predictor of worsening RV dilation.

B-1868 15:12

Free breathing real-time cardiac MRI in children with congenital heart disease: comparison of right ventricular function with standard breath-hold imaging

C. Treutlein, M. Zeilinger, R. Heiß, W. Wuest, O. Rompel; Erlangen/DE (christoph.treutlein@uk-erlangen.de)

Purpose: Right ventricular (RV) functional parameters in children with congenital heart disease acquired in free-breathing (FB) and single-breath-hold (SB) full cardiac cycle real-time compressed sensing (CS) cine CMR compared with standard retrospective segmented multi-breath-hold cine CMR.

Methods and Materials: 23 patients with biventricular congenital heart disease underwent standard segmented breath-hold cine, single-breath-hold and free-breathing CS real-time cine CMR with inline motion correction to obtain a stack of continuous axial images of the right ventricle. Functional parameters and scan time were compared. Two radiologists independently performed qualitative analysis of image quality (rated on a 5-point scale; 1 = nondiagnostic up to 5 = excellent) and quantitative analysis of right ventricular volume measurements.

Results: All functional parameters correlated significantly (all $p<0.01$). Image quality score was slightly lower in SB and FB than in standard BH (4.1 ± 0.8 and 4.2 ± 0.8 vs. 5.5 ± 0.6). Differences in functional results of the right ventricle based on Bland-Altman analysis were less than 5% (95% CI, -8.7 to 7.2). Scan time was 20s (± 22) and 14s (± 10) vs. 209s (± 89). Overall inter-rater variability ranged from -9.0 to 8.1%.

Conclusion: Free-breathing and single-breath-hold real-time compressed sensing cine CMR in children with congenital heart disease could evaluate RV volume with excellent accuracy and delivers diagnostic image quality in a shorter examination time than standard segmented BH examination. It may replace multi-breath-hold standard cine CMR.

B-1869 15:20

Regional right ventricular deformation in hypertrophic cardiomyopathy: assessed with cardiovascular magnetic resonance tissue tracking

X. Li, Y. Zhigang, Y. Guo, Y. He, S. He, K. Shi, C. Xia, Z. Li; Chengdu/CN (lixiang5861@163.com)

Purpose: To evaluate the regional right ventricular (RV) systolic function in patients with hypertrophic cardiomyopathy (HCM) using cardiovascular magnetic resonance-3D tissue tracking.

Methods and Materials: Seventy-one HCM patients classified as late gadolinium enhancement (LGE) present or absent groups and 15 healthy controls were enrolled. The short-axis and four-chamber long-axis cine imaging as well as LGE imaging were performed. The ejection fraction of right ventricular (RVEF), global and regional (basal, mid, and apical) RV tracking strain variables were measured.

Results: In the HCM group, 44 patients presented with LGE and 27 without LGE. The RVEF were not comparable among all patients and controls ($P=0.58$), but global peak longitudinal strain (PLS) in HCM patients with LGE were significantly lower than those without LGE ($-5.64 \pm 12.93\%$ vs. $-10.68 \pm 5.53\%$, $P<0.05$). Furthermore, the apical and mid regional of RV-PLS were significantly lower in HCM patients with LGE compared with those without LGE and controls (apical PLS: $-6.59 \pm 14.53\%$ vs. $-10.38 \pm 7.61\%$ vs. $-12.43 \pm 6.69\%$, $P<0.05$; mid PLS: $-0.13 \pm 23.11\%$ versus $-9.72 \pm 7.72\%$ versus $-10.28 \pm 5.36\%$, $P<0.05$). The basal RV longitudinal strain in HCM patients with LGE were significantly lower than without LGE ($-6.58 \pm 20.11\%$ vs. $-10.30 \pm 6.28\%$, $P<0.05$).

Conclusion: In HCM, the decreased regional RV myocardial strain occurred before the RVEF reduced, which suggests that regional RV systolic function for HCM is impaired in subclinical state. Moreover, myocardial deformation of RV was more severe with the presence of LV LGE.

Significance of multidetector computed tomography in the assessment of achalasia subtypes and detection of pulmonary complications

S. Jovanovic, A. Djuric Stefanovic, A. Simic, O. Skrobic, D. Masulovic; Belgrade/RS (dr.sanja.jovanovic@gmail.com)

Purpose: To evaluate the multidetector computed tomography (MDCT) findings in patients who have achalasia, to assess its role in differentiating three different subtypes, detecting lung involvement and extra-oesophageal thoracic complications.

Methods and Materials: Clinical retrospective study included 51 patients with manometrically confirmed achalasia who underwent chest X-ray and MDCT in preoperative diagnostic workup. Oesophageal wall thickness and morphology, luminal dilatation, lung changes and extra-oesophageal manifestations were analysed on MDCT. Wilcoxon, Kruskal-Wallis and Mann-Whitney test were used for assessing the differences among the achalasia subtypes.

Results: Fourteen (27.5%) patients had achalasia subtype 1, 21 (60.8%) had subtype 2 while 6 (11.8%) had subtype 3. Oesophageal wall thickness of the oesophageal body (EB) and distal oesophageal segment (DES) as well as nodular/lobulated appearance of DES were significantly more often found in subtype 3 ($p=0.024$, $p<0.001$, $p=0.009$, respectively). Oesophageal dilatation gradually decreased from subtype 1 to 3 ($p=0.006$). Chest X-ray revealed lung changes in 9 (17%) and MDCT in 21 (41%) patients ($p=0.001$), most frequently in subtype 1, with predominance of ground-glass opacities. Tracheal/carinal compression was detected in 27 (52.9%) and left atrial compression in 17 (33.3%) patients.

Conclusion: MDCT is a useful tool in detection of lung and extra-oesophageal thoracic complications in patients with achalasia, and a valuable additional imaging modality in differentiation of achalasia subtypes.

B-1872 14:08

Value of MRI with static and dynamic sequences in the study nature extension of the tight stenosis of the oesophagus-gastric junction

G. De Franco¹, S. Bruni¹, G. D'Alesio², S. Bux¹, A. Ambrosi³, A. Vaccaro¹, V. Grimaldi¹, M. Fracella¹; ¹Bari/IT, ²Triggiano/IT, ³Valenzano/IT (dotgiuliofranco@yahoo.it)

Purpose: Evaluation of the efficacy of MRI with static and dynamic sequences in the diagnostic procedure for the evaluation of the extension and nature of the tight stenosis of the gastric-oesophageal junction.

Methods and Materials: From August 2016 to February 2018, 112 patients with tight stenosis of the gastric-oesophageal junction were assessed by gastroscopy. After distension of the stomach by 700-900 cc of water and intravenous administration of hypotonic drug (1fl of n-methyl scopolamine) MRI of the oesophagus and stomach was performed with 1.5 T high-field magnet and phased-array surface coils. The protocol provided the execution of morphological sequences (true fisp / HASTE), cine -RM, DWI and VIBE with intravenous contrast medium.

Results: The MRI examination allowed to identify in all cases the thickening of the oesophagus-gastric junction. The identification of the parietal signal, the enhancement and the DWI signal of the wall allowed to correctly characterize: 60 fibrotic stenosis (53%), 24 acalasic stenosis (22%) and 16 neoplastic stenosis (14%). In the remaining 12 cases (10% of the total) the examination was not conclusive due to the poor collaboration/claustrophobic crisis of the patients (8 cases) or to associated comorbidities (4 cases).

Conclusion: The MRI of the oesophagus and the stomach has the possibility to discriminate with high accuracy the extension and nature of the tight gastric-oesophageal stenosis with very high diagnostic efficacy and allowing patients a subsequent adequate and appropriate therapeutic approach.

B-1873 14:16

Accuracy of 3.0 T MRI in the preoperative T staging of patients with potentially resectable oesophageal cancer, with histopathological correlation

Y. Lu¹, J. Qu¹, Z. Wang¹, X. Yan²; ¹Zhengzhou/CN, ²Shanghai/CN (15249675779@163.com)

Purpose: To explore the value of 3.0 T MRI using multiple sequences (T2-TSE-BLADE, contrast-enhanced star-VIBE, delayed star-VIBE, and combination of the three sequences) in evaluating the preoperative T staging for potentially resectable oesophageal cancer (EC) with pathologic confirmation.

Methods and Materials: Patients with endoscopically biopsy-proven EC and T1/T2/T3/T4a staging by CT who were imaged on a 3.0 T scanner were prospectively enrolled. The MRI protocol included T2-TSE-BLADE, contrast-enhanced star-VIBE, and delayed star-VIBE. Readers assigned a T stage on MRI, and post-operative pathologic confirmation was considered the gold standard. Inter-reader agreement was also calculated. The diagnostic accuracy of T staging on T2-TSE-BLADE, contrast enhanced star-VIBE, delayed star-VIBE, and the combination of the three sequences were analysed and compared to post-operative pathologic T staging.

Results: The study included 158 patients. Inter-reader agreements of T staging were excellent for T2-TSE-BLADE (Kappa=0.818, $P<0.0001$), contrast-enhanced star-VIBE (Kappa=0.807, $P<0.0001$), delayed star-VIBE (Kappa=0.817, $P<0.0001$) and the combination of the three sequences (Kappa=0.935, $P<0.0001$). Diagnostic accuracies of delayed star-VIBE for T1/T2 staging were 95.57% and 97.47% for reader 1 and reader 2, respectively. For T3/T4 staging, diagnostic accuracy of T2-TSE-BLADE and contrast enhanced star-VIBE ranged between 88.61% and 97.47% for reader 1 and reader 2, respectively. Diagnostic accuracy of the combination of the three sequences was higher than individual sequences for both readers.

Conclusion: 3.0T MRI using the 3 combined sequences showed higher diagnostic accuracy in T staging of patients with potentially resectable EC compared to individual sequence.

B-1874 14:24

Is the perfusion-metabolic tumour phenotype related to tumour volume and nodal stage in primary oesophageal tumours undergoing DCE-MRI and ¹⁸F-FDG PET/CT?

S.J. Withey, K. Owczarczyk, C. Yip, M.M. Siddique, A. Green, J. Bell, G. Cook, V.J. Goh; London/UK (samuel.withey@nhs.net)

Purpose: Locoregional stage remains a relatively poor outcome discriminator in primary oesophageal cancer undergoing curative treatment. We aimed to assess the relationship between tumour perfusion, metabolism & volume with nodal stage.

Methods and Materials: Following ethical approval and informed consent, DCE-MRI and ¹⁸F-FDG PET/CT were performed at staging in 24 patients (18 male; mean age 64 ± 10 years; 21 adenocarcinoma, 3 squamous cell carcinoma) with primary oesophageal cancer, planned for surgery ± neoadjuvant therapy. DCE-MRI transfer constant (K^{trans}), ¹⁸F-FDG PET/CT maximum standardised uptake value (SUV_{max}) and FDG-avid mean tumour volume (MTV) were calculated. Spearman rank correlation assessed the relationship between K^{trans} , SUV_{max} and MTV. K^{trans} , SUV_{max} and MTV were compared in clinically and pathologically node positive patients (cN and pN respectively) using Wilcoxon rank test. Significance was at 5%.

Results: No correlation was observed between K^{trans} , SUV_{max} or MTV (Spearman 0.1 and 0.01 respectively). No statistically significant difference between K^{trans} , SUV_{max} or MTV in cN+ versus cN- or pN+ versus pN- patients. When stratifying patients by MTV (<median versus ≥median), in patients with lower metabolic tumour volume, baseline K^{trans} was significantly higher in node negative patients (cN and pN, $p=0.02$ and $p=0.04$ respectively). This trend was not observed in patients with high metabolic volume cancers. In patients with lower MTV, baseline K^{trans} was inversely correlated with number of pathologically involved lymph nodes (Spearman -0.65, $p=0.01$).

Conclusion: Low DCE-MRI K^{trans} appears predictive of nodal involvement in lower MTV cancers.

B-1875 14:32

Combination of quantitative ¹⁸F-FDG PET parameters and contrast-enhanced CT in locoregional restaging and prognostication of survival in patients with oesophageal cancer

D. Tamandl, B. Fueger, A. Haug, A. Ba-Ssalamah; Vienna/AT (dietmar.tamandl@meduniwien.ac.at)

Purpose: To assess whether the combination of contrast-enhanced CT (CE-CT) and quantitative ¹⁸F-FDG PET parameters can improve locoregional restaging in oesophageal cancer (EC) after neoadjuvant therapy.

Methods and Materials: Eighty-eight consecutive patients with locally advanced EC, who underwent oesophagectomy after neoadjuvant chemotherapy or chemoradiotherapy were included in this retrospective study. The diagnostic accuracy of CE-CT, visual ¹⁸F-FDG PET/CT (vPET/CT) and quantitative PET parameters were assessed for local staging. Histopathology was used as the reference standard. The prognostic value on survival was assessed using Cox regression analysis.

Results: T,N staging: sensitivity, positive predictive value (PPV) and accuracy was 78.8%, 70.2%, 59.0% (CE-CT) and 81.1%, 81.1%, 68.2% (vPET/CT) for T staging as well as 59.5%, 75.9%, 50.0% (CE-CT) and 70.2%, 93.7%, and 67.0% (vPET/CT) for N staging, respectively. Tumour length (TL) and metabolic tumour volume (MTV) correlated with advancing T stages ($p=0.002$ and 0.038). CE-CT had the best sensitivity to differentiate between T3/4 and T0-2 stages (AUC 0.86, $p<0.001$), while MTV had the highest sensitivity to detect complete response (T0 vs. 1-4, AUC 0.77, $p=0.002$). The combination of CE-CT and MTV had an even superior accuracy to predict complete response (AUC 0.82, $p<0.001$). The imaging AJCC stage provided a better prognostication of RFS, CSS and OS than either T stage, N stage derived from CE-CT or vPET/CT, or quantitative PET parameters alone.

Conclusion: Combining both CE-CT and quantitative PET parameters allows for robust prediction of restaging, recurrence and survival in EC.

B-1876 14:40

Correlation between dual-energy CT and perfusion CT parameters in patients with gastric carcinoma

Y. Chai; Zhengzhou/CN (chaiyarcy@163.com)

Purpose: To develop a dual-energy enhanced CT protocol using time attenuation curves from previously acquired perfusion CT data and to evaluate the relationship between iodine enhancement value at dual-energy CT and perfusion parameters in gastric carcinoma patients.

Methods and Materials: The retrospective part included the development of a dual-energy enhanced CT protocol to evaluate peak arterial and venous enhancement on the basis of time-attenuation curves from previously acquired perfusion CT data in 40 patients. The prospective part consisted of an intraindividual comparison of dual-energy CT and perfusion CT data in another 40 patients with gastric carcinoma. Iodine value and normalized iodine value in arterial and venous phase from dual-energy CT and perfusion parameters (arterial flow, AF) from perfusion CT were compared. Pearson R and linear correlation coefficients were calculated.

Results: The strongest intraindividual correlations in gastric carcinoma were found between iodine value in AP with AF ($r=0.73$, $P=0.001$). Moderate correlations were found between normalized iodine value in AP with AF ($r=0.52$, $P=0.021$) and between normalized iodine value in VP with AF ($r=0.57$, $P=0.013$). No further significant correlations were found. The volume CT dose index (10.3 mGy) and dose-length product (214.0 m Gy·cm) of dual-energy CT were lower than those of the arterial phase of perfusion CT (29.8m Gy and 654.9 m Gy·cm, respectively).

Conclusion: A enhanced dual-energy CT protocol acquired from perfusion CT data sets in patients with gastric carcinoma could show good correlation between iodine value from dual-energy CT with perfusion parameters.

B-1877 14:48

Clinical value of radiomics nomogram in preoperative prediction of lymph node metastasis of gastric adenocarcinoma

R. Wang, J. Li, J. Gao; Zhengzhou/CN (wr807115125@163.com)

Purpose: To develop and validate the spectral CT-based radiomics in predicting preoperatively the lymph node metastasis (LNM) of gastric adenocarcinoma.

Methods and Materials: A total of 196 gastric adenocarcinoma patients confirmed by pathology and underwent preoperative spectral CT scanning were retrospectively enrolled (98 in the training set and 98 in the test set). The clinical information of these patients were recorded, and the CT values, iodine concentration (IC) values and normalized iodine concentration (nIC) values of primary lesions and lymph nodes in dual-phases were measured and calculated in the postprocessing workstation. 273 radiomics features were extracted from the dual-phases CT images in different energy level (40, 65 and 100KeV) to build a radiomics signature. Univariate and multivariable logistic regression analysis were performed to screen predictive indicators for LNM in gastric adenocarcinoma. A radiomics nomogram incorporating significant indicators was developed in the training set, and its performance was measured using the receiver operating characteristics (ROC) curves and was compared with DeLong test.

Results: The radiomics nomogram, which incorporated the CT-reported LN status, IC values in portal venous phases of primary lesions and two radiomics signatures (RSa40, RSp65) distinguished LNM with an area under curve (AUC) of 0.822 (95% CI, 0.739-0.906) in the training set. It yielded an AUC of 0.819 (95% CI, 0.732-0.906) and an accuracy of 0.735 (95% CI, 0.636-0.819) in the test set. There were no significant differences in AUC between two sets ($p=0.9533$).

Conclusion: The radiomics nomogram provides individualized preoperative prediction of LNM in gastric adenocarcinoma patients.

Imaging of mini/one anastomosis gastric bypass abdominal complications

G. Scavone¹, D.C. Caltabiano¹, M.V. Raciti², M.C. Calciagno¹, G. Caltabiano¹, F. Gulino¹, A. Giarrizzo¹, L. Piazza¹, A. Scavone¹; ¹Catania/IT, ²Pavia/IT (mc.calciagno@gmail.com)

Purpose: Mini/One Anastomosis Gastric Bypass(MGB/OAGB) is a restrictive and malabsorptive bariatric surgical procedure; it consists of a gastric tubulization carried out along the small curvature of the stomach that is sutured to a long jejunal loop. The purpose of this retrospective study is to investigate outcome and abdominal complications evaluated by radiological techniques and to assess the role of multidetector computer tomography(MDCT) and radiographic upper gastrointestinal(UGI).

Methods and Materials: Since January 2005, 953 patients (female 684-71.7%, male 269-28.3%; mean 42 years old, range 18-70) underwent videolaparoscopic MGB/OAGB in our center and were evaluated with UGI series in 3th day after procedure. In clinical suspect of gastric leakage (abdominal pain, tachycardia/tachypnea, chest pain, fever and leukocytosis) and hemorrhage(hypotension, tachycardia, cold sweating, hematemesis/melena) in stable patients, MDCT with intravenous and oral contrast media administration was performed.

Results: MDCT detected two types of abdominal complications: early (within one month after procedure) and late (from second month to 10 years after procedure). We found 13 early complications (6 endoluminal/intra-abdominal bleedings, 4 gastric pouch leaks, 1 anastomotic dehiscence, 1 anastomotic stenosis, 1 abdominal abscess) and 16 late complications (11 Weight Regain: 7 for dilatation of gastric pouch, 4 for gastro-gastric fistula, 3 excessive weight loss for malabsorption syndrome, 1 intestinal occlusion due to adherence and 1 peri-anastomotic abscess). Only 2(6.8%) complications were detected using UGI.

Conclusion: In presence of a reasonable clinical suspect, MDCT with oral and intravenous contrast media administration is a robust technique for diagnosis of complications, useful for surgical, interventional radiological or conservative treatment planning.

B-1879 15:04

Structured CT reporting improves accuracy in diagnosing internal herniation after laparoscopic Roux-en-Y gastric bypass

J.C. Ederveen¹, S.W. Nienhuijs², J. Nederend²; ¹Maastricht/NL, ²Eindhoven/NL (jeannette.ederveen@mumc.nl)

Purpose: To confirm that structured reporting of CT scans using ten signs in clinical practice leads to a better accuracy in diagnosing internal herniation (IH), compared to non-structured reporting.

Methods and Materials: A cohort was used of patients who had undergone laparoscopic gastric bypass surgery between January 1, 2011 and January 1, 2018. CT scans between June 1, 2017 and October 1, 2018 were prospectively included and structured reports were made using ten signs: (1) swirl sign, (2) small-bowel obstruction, (3) clustered loops, (4) mushroom sign, (5) hurricane eye sign, (6) small bowel behind superior mesenteric artery, (7) right-sided anastomosis, (8) enlarged nodes, (9) venous congestion, and (10) mesenteric oedema. Furthermore, an overall impression of IH likelihood was given using a 5-point Likert scale. CT scans performed between January 1, 2011 and January 1, 2017, without structured reporting, were used for comparison. Accuracy was calculated using two-way contingency tables. Reoperation and three-month follow-up were used as reference.

Results: A total of 472 CT scans were performed in the study period, 292 in 2011-2016 without structured reporting and 180 in 2017-2018. Of these, 164 (91.1%) were reported using structured reporting. Sensitivity was 79.5% (95%-CI: 67.6-91.5%) and 86.2% (95%-CI: 73.7-98.8%), respectively ($p=0.467$); specificity was 87.6% (95%-CI: 83.5-91.7%) and 95.6% (95%-CI: 92.1-99.0%), respectively ($p=0.011$); positive predictive value was 53.0% (95%-CI: 41.0-65.1%) and 80.6% (95%-CI: 66.7-94.6%), respectively ($p=0.009$); negative predictive value was 96.1% (95%-CI: 93.5-98.6%) and 97.0% (95%-CI: 94.1-99.9%), respectively ($p=0.644$); and accuracy was 86.4% (95%-CI: 81.8-90.0%) and 93.9% (95%-CI: 88.8-96.9%), respectively ($p=0.014$).

Conclusion: Structured reporting for the diagnosis of internal herniation after bariatric surgery improves accuracy and can be implemented in clinical practice with good result.

Can routine postoperative CT scan provide reliable leakage risk stratification after laparoscopic sleeve gastrectomy (LSG)?

D. Palumbo, G. Guazzarotti, C. Martinenghi, R. Nicoletti, A. Del Maschio, F. De Cobelli; Milan/IT (palumbo.diego@hsr.it)

Purpose: Our aim was to assess the role of routine postoperative CT scan in the early identification of factors representing potential substrates of leakage after LSG.

Methods and Materials: We enrolled 208 LSG patients (139F, 69M; 43±12.1 years; 43.5±6.5kg/m²) who underwent contrast enhanced CT scan within 72 hours from surgery between September 2015 and September 2018. Imaging post processing included measurement of the distance between the first staple firing and pylorus (StP). We also evaluated the presence of perigastric haematoma and of any twisting of the stomach remnant.

Results: 9 patients suffered from gastric leak (4.3%). The mean StP was significantly lower in patients who developed gastric leak (24.2±11.9 mm vs. 40.3±16.4 mm; $p=0.005$). ROC analysis identified as best threshold for StP 29.9 mm, below which patients demonstrate a higher rate of gastric leakage (AUC: 0.83; Se: 81.8%; Sp: 75.4%). 9 patients (4.3%) suffered from perigastric haematoma; they were more likely to develop gastric leakage after LSG (33.3%; $p=0.005$). 16 patients developed twist of stomach remnant (7.7%); we identified two patterns of twist: type A (10 patients, 4.8%), if the twist involves the proximal third of the gastric remnant; type B (6 patients, 2.9%), if it involves its middle and distal part. 5 out of 6 type B patients suffered from gastric leak, while no gastric leak was found in type A group, thus suggesting that type B twisting of the gastric remnant significantly increases the probability of gastric leak after LSG ($p=0.004$). By means of a step wise multivariate analysis we identified this CT sign as the strongest risk factor for leakage after LSG ($p=0.005$).

Conclusion: Routine postoperative CT scan has a promising role in the risk stratification of patients who underwent LSG.

Evaluation of visuospatial memory performance in temporal lobe epilepsy: a retrospective fMRI study

V. [Schmidbauer](#), O. Fösslleitner, K.-H. Nening, G. Kaspran, M. Schwarz, G. Geisl, C. Baumgartner, D. Prayer, S. Bonelli; *Vienna/AT* (victor.schmidbauer@meduniwien.ac.at)

Purpose: Impairment of cognitive functions is often observed in temporal lobe epilepsy (TLE). Adapted versions of the Roland's Hometown Walking (RHTW) task offer a possibility to examine visuo-spatial memory performance non-invasively by functional MRI (fMRI). The aim of this study was to test whether by means of an adapted form of the RHTW paradigm laterality of visuo-spatial memory function can be identified.

Methods and Materials: Between 01/2013 and 09/2017, 32 patients with the diagnosis of medically intractable TLE were examined on the same 3 Tesla MRI scanner using an adapted form of the RHTW fMRI task as part of the pre-surgical work-up. EEG revealed a right-sided seizure onset in 9/32 and a left-sided origin in 23/32. Imaging data were analyzed using spm12. Significance levels were set at $p < 0.05$ family-wise error (FWE) corrected and $p < 0.001$ uncorrected. Special attention was paid to mesio-temporal regions.

Results: Left TLE patients showed significant activations in both, right mesio-temporal structures (right posterior parahippocampal gyrus: FWE-corrected $p = 0.007/z\text{-score} = 5.17$) and left mesio-temporal structures (left posterior parahippocampal gyrus: FWE-corrected $p = 0.026/z\text{-score} = 4.86$). Right TLE patients showed significant activations only in left mesio-temporal structures (left hippocampus: uncorrected $p \leq 0.001/z\text{-score} = 3.37$). No significant activations were observed in right mesio-temporal structures, most likely due to the underlying disease.

Conclusion: Using an adapted version of the RHTW fMRI task it was possible to lateralize visuo-spatial memory function in patients with left and right TLE.

B-1882 14:08

Disturbed hippocampal integration into the functional language network in patients with temporal lobe epilepsy

K.-H. Nening, V. [Schmidbauer](#), O. Fösslleitner, D. Prayer, C. Baumgartner, E. Patariaia, G. Langs, S. Bonelli, G. Kaspran; *Vienna/AT*

Purpose: Temporal lobe epilepsy (TLE) in the language dominant hemisphere may impair language function. We used functional magnetic resonance imaging (fMRI) to study the language network and its hippocampal integration in patients with left and right TLE.

Methods and Materials: Analysis was based on fMRI data (3T MRI, verb-generation task) of a homogeneous group of 32 patients with TLE due to unilateral hippocampal-sclerosis (HS) (17 left) and 14 healthy controls. We analyzed differences in task activation and alterations in the whole-brain language connectome. We quantified the hippocampal integration into the language network with seed-based connectivity analysis, evaluated the hippocampal involvement in the altered language connectome, and more specifically, we analyzed the functional dissociation along the anterior-posterior axis of both hippocampi.

Results: While no significant differences in task activation were found, widespread alterations of the language connectome were observed in left TLE. The diseased hippocampus, and in left TLE also the right hippocampus, showed significantly impaired connectivity. While the right hippocampus showed primarily impaired connectivity to regions associated with the task-negative default mode network, the left hippocampus showed disturbed connectivity to frontal task-positive language regions. Additionally, analysis of the functional dissociation revealed a reduced connectivity for more anterior parts of the diseased hippocampus, particularly in left TLE for hippocampal connections to inferior frontal language regions.

Conclusion: Our analysis revealed widespread disruptions of fronto-temporal language networks and impairment of fronto-hippocampal connectivity only in patients with left TLE. This emphasizes the critical role of the integration of the left hippocampus during language tasks.

B-1883 14:16

Study of correlation between hippocampal perfusion and volume in patients with temporal lobe epilepsy for epileptic lateralisation

Y. [Zhang](#), H. You, Y. Lv, W. Dou, B. Hou, F. Feng; *Beijing/CN* (1556222529@qq.com)

Purpose: To analyse the asymmetry of hippocampal perfusion and volume quantitatively for epileptic lateralization based on the application of MRI arterial spin labelling (ASL) in cerebral blood flow (CBF) and MR automated volumetry and to assess the relationship between perfusion and volume atrophy.

Methods and Materials: Fifty-two patients (28 (53.8%) women; mean age 27.9 ± 9.64 years) with temple lobe epilepsy were recruited retrospectively. Regions of interests (ROIs) were provided in hippocampal head, body and tail for average hippocampal CBF ratio measurements (CBF ratio = CBF (non-epileptogenic hippocampi)/CBF (epileptogenic hippocampi)). The hippocampal volume was automatically segmented and measured using AccuBrain®. The radios for hippocampal volume were also calculated (volume ratio = volume (non-epileptogenic hippocampi)/volume (epileptogenic hippocampi)). The logistic regression model examined the utility of perfusion and volume asymmetry in lateralizing seizure onset determined by video-EEG. The Spearman correlation was used to evaluate the relationship between perfusion and volume asymmetry.

Results: 45 (86.5%) and 44 (84.6%) patients showed average hippocampal CBF ratios and hippocampal volume ratios were bigger than 1, respectively. Logistic regression analysis showed that the hippocampal perfusion and volume asymmetry was the strong predictor of epileptic laterality (hippocampal perfusion asymmetry $\beta = 3.455$, $P < 0.001$; hippocampal volume asymmetry $\beta = 3.620$, $P < 0.001$). There was significant correlation between hippocampal perfusion and volume asymmetry ($r = 0.33$, $P = 0.017$).

Conclusion: The hippocampal perfusion and volume asymmetry were highly correlated and both were significant predictors of epileptic lateralization in TLE patients.

B-1884 14:24

DTI-MRI findings in synthetic cannabinoid users

F.D. Gokharman, S. [Aydin](#), S.C. Paltun, E. Fatihoglu, S. Yalcin Sahiner, P.N. Kosar, H.K. Karli Oguz; *Ankara/TR* (sonaydin89@hotmail.com)

Purpose: Synthetic cannabinoids (SC) are major agonists of cannabinoid receptors. There are so many different SC types based on their chemical structure, some widely known subtypes Spice, Bonzai, K2, Aroma or Kronik. These SC subtypes have become increasingly popular especially among young adults and adolescents in Europe. In the literature there is some conventional MRI findings are defined for SC abusers, such as restricted diffusion and increased T2/FLAIR signal in the corpus callosum and cerebellar peduncles. In this study, we aimed to analyse microstructural alterations in the white matter of the brains in SC users as demonstrated by diffusion tensor imaging (DTI).

Methods and Materials: Approval of ethical committee was obtained. Diffusion imaging data were acquired in 41 non-collinear directions to create diffusion tensor images of 22 patients (F/M: 0/22, Age range: 18-41 years, mean age: 22.7 ± 4.8 years) who have used SCs for at least six months and more than one times in a day. We have compared the FA values with a sex and age matched, healthy control group.

Results: We have detected no abnormal conventional MRI findings. Patients had been using SCs for a mean of 13 months (min-max: 5-37 months), a mean of 4 times in a day (min-max: 1-12). We showed that FA values acquired from left temporal lobe (inferior longitudinal fasciculus) (216.2 ± 58.9 vs 263 ± 27.4 ; $p = 0.002$), and right hippocampus (224.5 ± 61.5 vs 255 ± 24.3 ; $p = 0.040$) are lower than control group.

Conclusion: DTI can show micro structural white matter changes occurring in SC users, before conventional MRI sequences.

B-1885 14:32

Validating the efficacy of multiple high-resolution MRI sequences with 18 FDG-PET co-registration in detecting epileptogenic lesion

T. [Krishna Moorthy](#)¹, K. Rahmat², L.K.S. Lim¹, N. Ramli¹; ¹*Petaling Jaya/MY*, ²*Kuala Lumpur/MY* (thulakm@gmail.com)

Purpose: To identify the more superior magnetic resonance imaging (MRI) sequences to co-register with 18-fluorodeoxyglucose-positron emission tomography (PET) scan in order to obtain the best possible images to detect epileptogenic lesion and to guide a second look interpretation of the MRI studies.

Methods and Materials: Twenty-eight patients with non-lesional intractable epilepsy were included prospectively. Preliminary assessment was carried out following the standard protocol of our epilepsy unit. For each subject, the attenuation corrected PET images and four MRI sequences (FSPGR, FSPGR BRAVO, T2 FLAIR and FLAIR CUBE) were each co-registered in turn, using Statistical Parametric Mapping (SPM) 12 software implemented in MATLAB R2015b. Two neuro-radiologists were assigned to interpret, compare and

detect areas of hypometabolism in the fused images. Finally, a second look MRI interpretation was done to determine the presence of MRI morphometric abnormality in the detected hypometabolic region.

Results: Comparison between two co-registered high resolution T1WI sequences using Wilcoxon signed-ranks test, which indicated that the FSPGR BRAVO-PET images was rated more favourable than the FSPGR-PET $z=-4.5$, $p<0.001$. Similar test was done for T2WI sequences, where FLAIR CUBE-PET images was rated more favorable than T2FLAIR-PET, $z=-5.0$, $p<0.001$. Second look guided MRI showed 53.6% change in diagnosis from non-lesional to possible-lesional study.

Conclusion: FSPGR BRAVO(T1WI) and FLAIR CUBE(T2WI) are the more superior T1WI and T2WI MRI sequences respectively that can be utilized in PET co-registration process in order to detect epileptogenic lesion. PET-MRI co-registration is a useful imaging variant in guiding second look MRI to detect morphometric abnormalities.

B-1886 14:40

Evaluation of MRI findings in Hippocampal sclerosis with special reference to T2 relaxometry

V. Inampudi¹, S. Nimmalapudi², A. Prakash³, ¹Vijayawada/IN, ²Kolar/IN, ³Bengaluru/IN (vineel.inampudi@gmail.com)

Purpose: 1. To evaluate MR detectable changes of hippocampal sclerosis in patients presenting with seizure. 2. To determine the T2 relaxation time in bilateral hippocampus in control and study population.

Methods and Materials: We conducted a prospective analysis of 120 cases presenting with hippocampal sclerosis referred to the Department of Radiodiagnosis during November 2014 to May 2018. A Control group of 120 healthy subjects are evaluated for normal hippocampal T2 relaxation time. Patients were evaluated with Siemens Magnetom Avanto 1.5T whole body MR system with epilepsy protocol.

Results: A total of 120 patients with hippocampal sclerosis are included in our study, which included 64 male patients and 56 female patients. Second decade individuals are most commonly effected. Hippocampal atrophy was the most common change associated with mesial temporal sclerosis seen in 86% cases followed by FLAIR hyperintensity in 80% of cases. 100 cases had unilateral hippocampus involvement and 20 patient had bilateral hippocampus involvement. The mean T2 relaxation time in normal hippocampi was 104.15ms and a value more than three standard deviation of 110ms was set as normal cut off value. In right diseased hippocampus T2 relaxation value was 120.57 ms and left hippocampus was 119.4 ms.

Conclusion: MRI with specific epilepsy protocol is the investigation of choice for Mesial Temporal Sclerosis. T2 relaxometry allows quantification of hippocampal signal intensity allowing detection of even subtle changes. In bilateral disease, T2 relaxometry can indicate the side of severity which helps to determine the side to be operated.

Metabolic changes after severe TBI: ¹H MRS study

P. Menshchikov, A. Ivantsova, A. Manzhurtsev, M. Ublinskiy, I. Melnikov, T. Akhadov, N. Semenova; Moscow/RU (peeterem@gmail.com)

Purpose: Previous ¹H MRS studies reported significant decrease of major neuronal marker (N-acetyl aspartate (NAA)) concentration. The possible reasons for NAA reduction are not still completely known. Disruption of the NAA synthesis from aspartate Asp may result in its decrease. Thus, the main idea of this study is the investigation of dynamic changes in NAA, Asp and glutamate Glu concentrations using ¹H MRS.

Methods and Materials: We studied 2 patients groups: eight children (mean age - 14±2 years) with acute sTBI (23±4 hours after trauma) and seven patients with chronic sTBI (3 months after trauma). Control group consisted of 11 healthy children (mean age - 15±1 years) without history of any TBI. ^{Asp}MEGA PRESS (Menshchikov et al. 2018) was acquired from voxels (25×25×30 mm) located in the frontal lobe (predominantly grey matter).

Results: NAA and Asp concentrations are reduced in both the patient groups (acute sTBI - on 65% and 61%, chronic sTBI - on 65% and 61%). Glu is significantly reduced only in acute sTBI; however, a significant decrease in the Asp/Glu ratio was found in patients with chronic sTBI.

Conclusion: Since stoichiometric Asp-Glu ratio is maintained by the exchange of glutamate with mitochondrial aspartate, significant reduction of [Asp]/[Glu] may indicate a disruption in the normal functioning of the malate-aspartate shuttle in chronic sTBI. Reduced Glu and Asp concentrations in acute sTBI are associated with excitotoxicity. This research was supported by RFBR 17-04-01149.

Cortical atrophy and cerebral hypoperfusion in anti-N-methyl-D-aspartate receptor encephalitis: relationship to cognitive impairment and disease severity

Y. Li, Y. Xiang, C. Zeng, J. Wang, Y. Han, Q. Luo, Y. Zheng; Chongqing/CN (lymzhang70@aliyun.com)

Purpose: To investigate cortical morphology and cerebral perfusion changes in anti-N-methyl-D-aspartate receptor (NMDAR) encephalitis and analyze their correlations with cognitive impairment and disease severity.

Methods and Materials: For this prospective study between October 2012 and July 2017, 38 patients with anti-NMDAR encephalitis and 26 age- and sex-matched healthy controls underwent 3-tesla MRI with FreeSurfer image analysis to explore the cortical morphology changes and pseudo-continuous arterial spin labelling (pc-ASL) sequence to quantify cortical perfusion alterations. Meanwhile, comprehensive neuropsychological tests in participants were performed, and correlation, mediation and receiver operator characteristic (ROC) analyses were conducted to assess their relationships with cognition and disease severity (the modified Rankin scale, mRS).

Results: Reduced cortical volumes, thickness and perfusion ($P<.01$) were clearly indicated in patients. The bilateral hippocampus and right thalamus were more different in the subcortical areas. Correlation analysis demonstrated the significant relationship between cortical atrophy and perfusion in the left fusiform cortex ($r=0.434$, $P=.044$). Regional cortical atrophy and hypoperfusion were associated with cognitive deficits and clinical outcome ($P<.05$). Mediation analysis found the total cortical volume mediated the effect of epilepsies on disease severity (mRS) and in turn led to worse cognitive abilities (MoCA). ROC analysis revealed regional cortical atrophy, especially in the hippocampus, and decreased cortical perfusion discriminated significantly between the two groups ($P<.05$).

Conclusion: Cortical atrophy and cerebral hypoperfusion in anti-NMDAR encephalitis were discovered in our study and were closely related to cognitive deficits and disease severity. Moreover, they may have opposite predictive effects on clinical outcomes.

B-1889 15:04

Predictive value of two-tensor unscented Kalman filter tractography in the reconstruction of the arcuate fasciculus in patients with gliomas involving eloquent language areas

J. Yan, J. Cheng, J. Geng; Zhengzhou/CN (ayyj1986124@126.com)

Purpose: To preliminarily investigate the post-operative changes of arcuate fasciculus (AF) in glioma patients detected by two-tensor unscented Kalman filter tractography (UKFT) from the perspective of the usefulness as a reference for post-operative recovery of language functions.

Methods and Materials: Nine right-handed patients with gliomas involving eloquent language areas successfully post-operative follow-up were enrolled, and all underwent MRI protocols including 3D-T1, T2-FLAIR and DTI. UKFT was applied to reconstruct the long, anterior and posterior segment of bilateral AF. The relative ratio of AF (RRAF) was calculated according to the formula: $RRAF = (\text{volume of left AF}_{\text{Postop}}/\text{volume of right AF}_{\text{Postop}})/(\text{volume of left AF}_{\text{Preop}}/\text{volume of right AF}_{\text{Preop}})$. Language assessment was conducted using the aphasia battery of Chinese. The changes in language functions were analysed according to the formula: subtraction score = (score in language function_{Postop}) - (score in language function_{Preop}).

Results: Post-operative RRAF of the long segment of the left AF was positively correlated with the subtraction score in AQ ($r=0.777$, $P=0.014$), comprehension ($r=0.711$, $P=0.032$) and repetition ($r_s=0.740$, $P=0.023$); Post-operative RRAF of the posterior segment of the left AF was positively correlated with the subtraction score in comprehension ($r_s=0.850$, $P=0.007$) and repetition ($r_s=0.747$, $P=0.033$).

Conclusion: UKFT can preliminarily show that increasing volume of the long segment of the left AF may be a predictor of a well restoration of post-operative language function. The restoration of post-operative long and posterior segment of the left AF may be helpful for improving language comprehending and repeating ability of patients.

B-1890 15:12

Feasibility of evaluating the genetic mutation status of grade II and III gliomas by diffusion-weighted imaging

Y. Zhang, S. Liu, H. You, Y. Wang, B. Hou, Y. Lv, F. Feng; Beijing/CN (1556222529@qq.com)

Purpose: To explore the feasibility and value of distinguishing and predicting genetic status (e.g. IDH1, MGMT, and TERT mutation status) in WHO grade II and III gliomas by diffusion-weighted MRI.

Methods and Materials: Sixty-eight patients with pathologically confirmed WHO grade II and III gliomas, IDH1 and MGMT, TERT mutation status (MUT/WT) were included retrospectively in this study. In all patients, normalised apparent diffusion coefficient (ADC) was estimated within T2 hyperintense lesions. Mann-Whitney U test was used to evaluate differences

between genetic mutation status of grade II and III gliomas. Receiver operating characteristic (ROC) analysis was performed to assess normalised ADC in the diagnostic performance. A logistic regression model examined the utility of threshold ADC in predicting genetic mutation status.

Results: Normalised ADC showed significant differences between IDH1 mutation status in grade II and III gliomas ($P=0.0002$). There were no statistical differences presented in MGMT and TERT mutation status (MGMT: $P=0.03545$, TERT: $P=0.0632$). In ROC analysis, the AUC of normalised ADC for IDH1 mutation status was 0.7584 (95%CI: 0.6361-0.8806). The sensitivity and specificity were 70.37% and 85.37%, respectively, when the cutoff value of normalised ADC was set as 1.59. Logistic regression analysis showed that normalised ADC could be identified as the strong independent parameter in the differentiation of IDH1 mutation status ($\beta=2.629$, $P<0.001$) in grade II and III gliomas.

Conclusion: DWI could be the potential tool for differentiating different IDH1 mutation statuses. MGMT and TERT mutation status of II and III gliomas have little influence on MR diffusion parameter.

B-1891 15:20

The dorsolateral prefrontal cortex mediates the recruitment of auditory cortex in cross-modal plasticity and higher order cognitive functions in sensorineural hearing loss

Y. Luan, G.-J. Teng; Nanjing/CN (luan0610@hotmail.com)

Purpose: The recruitment of auditory cortex in the non-auditory sensory and higher order cognitive processing was demonstrated following hearing deprivation. The dorsolateral prefrontal cortex (dlPFC), with dense anatomical connections with auditory pathway, is involved in the multi-sensory integration, auditory regulation and various cognitive functions. We aimed to verify the mediation role of the dlPFC in the cross-modal reorganization and cognitive participation of auditory cortex in the long-term sensorineural hearing loss (SNHL) by combing the functional and structural measurements.

Methods and Materials: 35 long-term bilateral SNHL patients and 35 well-matched controls were recruited for assessment of structural imaging, resting-state functional magnetic resonance imaging, diffusion tensor imaging and neuropsychological test.

Results: No difference of grey matter volume in dlPFC was found. The functional connectivity (FC) between dlPFC and auditory cortex, cuneus, fusiform, lingual gyrus and calcarine sulcus was increased in the SNHL patients. The FC in the auditory cortex was associated with the symbol digit modality test (SDMT) scores, which reflect the attention, processing speed and visual memory. Hearing-related FC with dlPFC was found particularly in visual areas. Tract-based spatial statistics (TBSS) analysis revealed decreased FA values mainly in inferior fronto-occipital fasciculus (IFOF), which showed negative correlations with dlPFC FC in auditory cortex in SNHL.

Conclusion: Higher functional coupling between dlPFC with auditory and visual areas, accompanied by decreased FA along the fasciculus connecting frontal cortex with temporal and occipital areas, might mediate the cross-modal plasticity via a top-down regulation and facilitate the involvement of auditory cortex into higher order cognitive processing following SNHL.

Why guidelines are important: inter observer variability in assessing MRI signs of endometriosis between reader following ESUR guidelines vs. reader using prior domain knowledge

S. Rajan, R. Rajan, M. Murugavel, M. Barnwal, S. Gupta, V. Venugopal, V. Mahajan; New Delhi/IN (drsriramrajan@gmail.com)

Purpose: To assess the interobserver variability in identifying the MRI signs of endometriosis as described by European society of urogenital radiology.

Methods and Materials: This retrospective study included 77 randomly selected cases of endometriosis diagnosed on MRI. The cases were pulled from PACS, anonymized and assigned to two radiologists with 16 years and 11 years of experience in body imaging. The radiologists identified the presence or absence of following signs in each case: Retroflexion of uterus, torus uterinus involvement, Uterosacral ligament thickening, tethering of rectum, ovaries adherent to uterus, posterior position of ovaries, cluster of haemorrhagic cysts in ovaries, thickened round ligament, uterus and ovaries posterior to inter-ischial line, T2 Shading, restricted diffusion, hematosalpinx,

vaginal vault pulled-up, bladder involvement and superficial peritoneal implants. Radiologist 1 followed the definitions of the ESUR guidelines whereas Radiologist 2 assigned the labels based on prior domain knowledge. Interobserver variability was assessed (Fleiss bounds) via the Krippendorff's alpha coefficient corrected for chance.

Results: The interobserver variability ranged from 'fair to good' (Fleiss bounds, 0.41-0.75) in 9 labels (retroflexion, ovaries adherent to uterus, posterior position of ovaries, haemorrhagic cluster cyst in ovaries, T2-shading, hematosalpinx, pulling up of vaginal vault, bladder involvement, superficial peritoneal implants). Five labels (torus uterinus involvement, uterosacral ligament thickening, tethering of rectum, thickened round ligament, uterus and ovaries posterior to inter-ischial line, restricted diffusion) were deemed 'poor' (<0.40)

Conclusion: We identified the MRI signs of endometriosis having high inter-observer variability. There is scope for improvement in the agreement if the guidelines are followed universally.

B-1893 14:08

Multi-parametric magnetic resonance relaxometry as an assessment of dysmenorrhea severity in patients with adenomyosis

C. Lin, Y. He, Y. Qi, X. Wang, H. Zhou, H. Xue, Z. Jin; Beijing/CN (linchengyu@pumch.cn)

Purpose: To determine whether dysmenorrhea described as visual analogue scale (VAS) in patients with adenomyosis can be estimated by magnetic resonance (MR) relaxometry.

Methods and Materials: This prospective study was approved by institutional review board and ethical committee. Written informed consents were obtained. From Nov 2017 to June 2018, 60 patients suspected of adenomyosis were continuously enrolled. Pelvic MR examinations including T1, T2 and T2* relaxometry were performed on 3T Ingenia CX (Philips Healthcare, the Netherlands) during peri-ovulatory period. No visible adenomyosis lesions were found in 22 patients, and 38 patients were finally enrolled. VAS of dysmenorrhea were collected. T1, T2, and T2* relaxation times of lesions were measured blindly by two radiologists via Intellispace Portal (version 10.1.0.64190, Philips Healthcare, the Netherlands) on slices showing maximum lesion area. Intraclass correlation coefficient (ICC) was used to evaluate interobserver reproducibility. Spearman rank correlation coefficients were calculated to demonstrate the relationship between relaxation times and VAS, and a p value <0.05 was considered statistically significant.

Results: ICC ranged from 0.857 to 0.988. A moderate, negative correlation was found between T2* relaxation time of lesions and VAS ($r=-0.5444$, $p=0.0006$). Weak correlations were found regarding T1 and T2 relaxation times but they are not statistically significant ($r=-0.8563$, $p=0.6195$, and $r=-0.1129$, $p=0.4999$, respectively).

Conclusion: T2* relaxation time of lesions in peri-ovulatory period can quantitatively assess dysmenorrhea severity in patients with adenomyosis.

Diagnostic algorithm to differentiate benign atypical leiomyomas from malignant uterine sarcomas using MR imaging

C. Abdel Wahab¹, A.-S. Jannot¹, P.A. Bonaffini², M.-A. Lefrere Belda¹, A.-S. Bats¹, I. Thomassin-Naggara¹, A. Bellucci², C. Reinhold³, L. Fournier¹; ¹Paris/FR, ²Monza, QC/CA, ³Issy Les Moulineaux/FR, ⁴McGill, QC/CA (aw.cendos@gmail.com)

Purpose: To build a diagnostic algorithm to differentiate malignant uterine sarcomas from benign leiomyomas with atypical presentation on MRI.

Methods and Materials: An IRB-approved case-control study included 156 women (51 sarcomas and 105 atypical leiomyomas) with an atypical uterine mass on MRI underwent before surgery or with MRI follow-up > 1 year. A diagnostic algorithm was developed for the prediction of malignancy. Clinical and MRI data were collected and compared with pathological findings. Two independent populations (N=43 and 59) were used for validation, one with a reader with no previous knowledge of the algorithm to evaluate its generalizability.

Results: Predictive imaging criteria for malignancy included enlarged lymph node or peritoneal implants (OR = 21), high signal on DWI > the endometrium (OR = ∞), ADC ≤ 0.905 × 10⁻³ mm²/s (OR = 178). Conversely, the presence of a portion, even partial, with low T2 signal had a VPN of 100% ($p<0.0001$). The accuracy of the algorithm for differentiating benign atypical leiomyomas from sarcomas was 96.8% in the training set, and 95% and 95% in the two validation populations. The algorithm, however, should not be applied to extensively haemorrhagic masses.

Conclusion: Beyond the previously known clinical and morphologic criteria, adding a DWI sequence with ADC on MRI better differentiates malignant sarcomas from atypical leiomyomas, to guide optimal therapeutic management. We developed an interpretation model usable in routine practice for myometrial tumours on MRI including T2 and T1 signal, DWI signal and ADC value.

B-1895 14:24

Differentiation of uterine sarcomas from benign atypical leiomyomas: diagnostic value of quantitative parameters based on diffusion-weighted imaging

E. Kim, S. Rha, M.H. Choi, M. Choi, J.-I. Choi; *Seoul/KR*
(doorihyun6@gmail.com)

Purpose: To investigate the diagnostic value of quantitative parameters based on diffusion-weighted imaging (DWI) for differentiation between uterine sarcoma (US) and benign atypical leiomyoma (ALM).

Methods and Materials: This retrospective study include 80 women (ALM=56, US=24) imaged with pelvic MRI with DWI prior to surgery. Two readers independently evaluated each lesion for qualitative features as well as quantitative parameters including the mean ADC_{mass}, the ADC ratio [ADC_{mass}/ADC_{muscle}], the relative contrast ratio (RCR) [SI_{mass} on b₁₀₀₀/SI_{muscle} on b₁₀₀₀], and the contrast-to-noise ratio (CNR) [(SI_{mass} on b₁₀₀₀-SI_{muscle} on b₁₀₀₀)/SD_{muscle} on b₁₀₀₀]. The diagnostic performance of the calculated parameters in discriminating US and ALM was compared using receiver operating characteristic (ROC) analysis.

Results: The area under the ROC curve (AUC) for the mean ADC_{mass} was most superior (0.818 [95% confidence interval (CI) (0.716-0.896)] with sensitivity (SN) and specificity (SP) of 83% and 77%), followed by the RCR (0.811 [95% CI (0.708-0.890)] with SN and SP of 79% and 78%), the CNR (0.742 [95% CI (0.632-0.833)] with SN and SP of 75% and 75%), and the ADC ratio (0.729 [95% CI (0.618-0.822)] with SN and SP of 50% and 91%). All four parameters showed statistically significance for discrimination between US and ALM (p≤0.006).

Conclusion: The clinical application of quantitative parameters based on DWI and ADC map is helpful for distinguishing US from ALM preoperatively.

B-1896 14:32

Correlation between zonal oblique multislice intravoxel incoherent motion and dynamic contrast enhanced magnetic resonance imaging parameters in endometrial cancer

C. Lin, Y. He, Y. Qi, X. Wang, H. Zhou, H. Xue, Z. Jin; *Beijing/CN*
(linchengyu@pumch.cn)

Purpose: To investigate the correlation between parameters of Zonal Oblique Multislice (ZOOM) Intravoxel Incoherent Motion (IVIM) and Dynamic Contrast Enhanced Magnetic Resonance Imaging (DCE-MRI) in patients with endometrial cancer.

Methods and Materials: Institutional review board approval and informed consents were obtained. Between December 2017 and September 2018, 36 patients pathologically confirmed of endometrial cancer were included in this prospective study. Pelvic examinations were performed in a 3.0 T MR scanner (Ingenia CX, Philips Healthcare, the Netherlands), including ZOOM IVIM with 8 b values and DCE-MRI with 3 different flip angles (5° and 15° initially; and 8° sequentially afterwards). IVIM parameters (D, diffusion coefficient; Dstar, pseudo-diffusion coefficient; and f, perfusion fraction) and DCE-MRI parameters (time to peak; wash in rate; wash out rate; Ktrans, transfer constant between blood plasma and extravascular extracellular space; and Kep, transfer rate between extravascular extracellular space and blood plasma) were blindly measured by two radiologists via Intellispace Portal (version 10.1.0.64190, Philips Healthcare, the Netherlands). Spearman correlation was performed and a p value <0.05 was considered statistically significant.

Results: Interobserver measurement reproducibility was good to excellent. A moderate correlation was found between f and wash out rate (r=0.500, p=0.0019). Mild correlations were found between D and Ktrans (r=0.329, p=0.0498), D and Kep (r=0.411, p=0.025), f and time to peak (r=-0.358, p=0.0319), f*Dstar and wash in rate (r=0.345, p=0.0423), and f*Dstar and wash out rate (r=0.377, p=0.0255).

Conclusion: ZOOM IVIM perfusion-related parameters demonstrated moderate-to-mild correlation with DCE-MRI quantitative parameters in endometrial cancer.

B-1897 14:40

Multi-parametric MR imaging for prediction of response to gonadotropin releasing hormone analogue in patients with adenomyosis: a preliminary study

C. Lin, Y. He, Y. Qi, X. Wang, H. Zhou, H. Xue, Z. JIN; *Beijing/CN*
(linchengyu@pumch.cn)

Purpose: To evaluate the feasibility of multi-parametric MR imaging in predicting the therapeutic response to gonadotropin releasing hormone analogue (GnRHa) in patients with adenomyosis.

Methods and Materials: 12 patients suspected of adenomyosis were continuously involved in multi-parametric pelvic MR examinations between October 2017 and May 2018. Intravoxel Incoherent Motion (IVIM) with 8 b values and Amide Proton Transfer (APT) imaging were performed on 3T Ingenia CX (Philips Healthcare, the Netherlands) during peri-ovulatory period.

Visual analogue scale (VAS) of dysmenorrhea and menstrual blood volume (MBV), were collected before GnRHa injection and 3 months after. APT values and IVIM parameters (D, diffusion coefficient; Dstar, pseudo-diffusion coefficient; f, perfusion fraction) of adenomyosis lesions were blindly measured by two radiologists and compared between patients with different therapeutic responses. Receiver operating characteristic (ROC) analysis was performed.

Results: Among 12 patients, 6 patients achieved complete response (CR, VAS=0 and normal MBV), while 6 patients with partial response (PR, otherwise). APT values in lesions were higher in patients with PR than those with CR (2.387% vs. 1.668%, p=0.01300), and Dstar values were found lower (22.69 mm²s⁻¹ vs. 84.47 mm²s⁻¹, p=0.0087). AUC of APT and Dstar for differentiating PR from CR was 0.9167 (p=0.0163) and 0.9444 (p=0.0104), respectively. The feasible threshold values was estimated as 2.035% and 52.92 mm²s⁻¹, with sensitivity of 83.33% and specificity of 100%, respectively.

Conclusion: Parameters acquired from multi-parametric MR imaging, especially APT and Dstar values showed potentials in predicting GnRHa therapeutic response in patients with adenomyosis.

B-1898 14:48

Conservative treatment in patients with cervical cancer on FIGO stage IB1-IIA1 >2cm: the role of MRI in a pilot study: preliminary results

B. Gui, L. Russo, F. Cambi, F. Petta, S. Persiani, R. De Vincenzo, R. Manfredi; *Rome/IT* (lucarusso.md@gmail.com)

Purpose: To evaluate the role of Magnetic Resonance (MRI) in the detection of staging and evaluation of response to "fertility-sparing" treatment in patients with early stage cervical cancer (FIGO stage IB1-IIA1 >2cm).

Methods and Materials: In this prospective study, 11 patients with early-stage cervical cancer (FIGO stage IB1-IIA1 >2cm) and negative pelvic lymphadenectomy, who want to preserve their fertility, have been enrolled. Patients performed colposcopy, MRI, transvaginal sonography and PET-CT at staging moment and during the follow-up. All patients enrolled underwent neoadjuvant chemotherapy (nCT), with platinum and taxanes, and instrumental evaluation. In case of clinical complete response to treatment (CR) to nCT, patients underwent conization. Follow-up MRI exam has been performed at 6 and 18 months, including conventional and diffusion-weighted sequences.

Results: Patients' mean age was 30 years old (range 23-36 years old). MRI correctly identified tumor FIGO stage and classified treatment response in all 11 patients. 9 out of 11 patients had CR to nCT, 1 patient had no response to nCT, 1 patient developed disease progression after nCT. Between the 9 patients with CR to nCT, 1 patient decide to abandon the protocol to undergo radical hysterectomy, 7 patients completed study protocol without disease recurrence (1 of them completed a pregnancy) and 1 patient developed liver metastasis recurrence 6 months after conization, but she is still alive at 57 months of follow-up.

Conclusion: In patients with early-stage cervical cancer who undergo fertility-sparing treatment, MRI exam is very helpful to assess response to nCT and during follow-up after conization.

B-1899 14:56

Quantitative MR texture analysis to distinguish leiomyosarcoma from benign leiomyoma with high signal intensity on T2-weighted imaging

T. Yaqi, A. Tasaki, T. Hirata, M. Yamazaki, N. Yoshimura, H. Aoyama; *Niigata/JP*

Purpose: To distinguish leiomyosarcoma (LMS) from benign leiomyoma (LM) with high signal intensity (SI) on T2-weighted imaging (T2WI) using quantitative MR texture analysis.

Methods and Materials: We retrospectively studied 39 patients with uterine smooth muscle tumours with high SI on T2WI, which were surgically resected and pathologically diagnosed as LM or LMS, between October 2009 and November 2012. From pathological analysis, 33 were diagnosed with LM, and six with LMS. Each tumour was manually segmented and assessed on axial or sagittal MR images on T2WI and on apparent diffusion coefficient (ADC) map using ImageJ (a software program for quantitative analysis). Quantitative MR texture parameters analysed in each lesion included T2WI skewness, T2WI kurtosis, T2WI entropy, T2WI uniformity, ADC mean, ADC variance, ADC skewness, ADC kurtosis, ADC entropy, ADC uniformity and percentile ADC values. The differences between LMs and LMSs were statistically evaluated by Mann-Whitney U test, logistic regression analysis and receiver operating characteristic curves.

Results: In the univariate analysis, significant differences between LMs and LMSs were observed in ADC variance, ADC entropy and ADC uniformity (P < 0.05, respectively). Compared with the LMs, the LMSs exhibited larger ADC variance and ADC entropy, but smaller ADC uniformity on the histogram. The multivariate analysis revealed that the independent differentiator was ADC entropy (P < 0.05) with moderate accuracy (area under the curve, 0.838). The best cutoff value for ADC entropy was 9.901 (sensitivity: 64%, specificity: 100%).

Conclusion: ADC entropy can help accurately distinguish LMSs from LMs with high SI on T2WI.

B-1900 15:04

Imaging of potential donors for uterus transplantation, with emphasis on the uterine arteries

J. Båth, P. Dahm-Kähler, N. Kvarnström, A. Thilander Klang, M. Brännström, H. Leonhardt; *Gothenburg/SE (john.bath@vgregion.se)*

Purpose: To explore the optimal imaging evaluation algorithm regarding potential donors for uterus transplantation and assessing the uterine arteries.

Methods and Materials: In this prospective study, 10 women aged 45-62 willing to donate their uteri underwent MR imaging of the pelvis, including contrast-enhanced MR angiography (MRA), contrast-enhanced CT angiography (CTA), and digital subtraction angiography (DSA). Details of the uterine arteries were compared between the three different angiographic modalities.

Results: MRA was not able to adequately identify 7 out of 20 arteries. One of these arteries was questionable on CT and judged to be generally thin, but DSA finally visualized it as proximally divided in two small-calibre branches and the woman was accepted for surgery. Another MRA absent artery was identified as adequate on both CTA and DSA. There was no significant difference of average arterial lumen diameter measured by MRA, CTA and DSA. Three women were excluded from surgery because of significantly stenosed uterine arteries bilaterally. There were no method-related complications found.

Conclusion: Given the capacity of MRI to describe details of uterine anatomy and pathology it is valuable to start with this modality. If fully visualized from the origin into the uterus wall by MRA with a diameter of at least 1.5 mm, there is no need to move on with other angiographic methods. If not, CTA should be performed for better details of the uterine arteries. In a few cases, there may be a need for further investigation by the more invasive modality of DSA.

B-1901 15:12

Diffusion tensor imaging parameters of endometrial carcinoma can predict local tumour behavior: a feasibility study

A. Ghosh, T. Singh, V. Singla, R. Bagga, R. Srinivasan; *Chandigarh/IN (tulikardx@yahoo.com)*

Purpose: We evaluated diffusion tensor parameters of endometrial tumours and their correlation with myoinvasion and tumour-grade; demonstrating the feasibility of predicting myoinvasion and tumour grade, demonstrating the feasibility of predicting them, using quantitative diffusion tensor imaging.

Methods and Materials: This prospective study included 26 consecutive patients with endometrial carcinoma. Patients underwent DCE-MRI and DTI with 12 diffusion sensitising directions in the sagittal plane on a 1.5 tesla scanner. Fractional Anisotropy, mean, radial and axial diffusivity and eigen values 1&2 were recorded from freehand ROIs-drawn on the endometrial tumour by two radiologists separately.

Results: Multivariate analysis was done which showed that the mean and minimum values of mean-diffusivity, fractional anisotropy, axial-diffusivity and eigenvalue2 correlated significantly with myoinvasion. The minimum axial diffusivity of the tumour had an AUC of 0.87(0.68 to 0.97) and 0.708 (0.50 to 0.87) in predicting superficial and deep myoinvasion. Similarly FA sum obtained an AUC of 0.81 (0.61 to 0.94) in predicting type 1 versus type 2 endometrial tumours.

Conclusion: Diffusion Tensor Imaging parameters can be used to characterise endometrial tumours and predict local myoinvasion, thus demonstrating the utility of physiological diffusion imaging in tumour staging and characterisation.

B-1902 15:20

Shear wave elastography of the endometrium: a simple tool to improve diagnostic accuracy of endometrial carcinoma from other benign endometrial diseases

S. Mah, A. Vijayanathan, K. Rahmat, R. Muridan, Y. Abdul Aziz, C.H. Yeong; *Kuala Lumpur/MY (stephen_mah7@hotmail.com)*

Purpose: The incidence of endometrial cancer (EC) is increasing globally and in Malaysia, it rose from 3300/100,000 in 2003 to 4100/100,000 in 2007. We evaluated the diagnostic value of endovaginal shear wave elastography (SWE) of the endometrium in patients with abnormal uterine bleeding (AUB) in order to reduce the incidence of unnecessary invasive endometrial biopsy.

Methods and Materials: 43 subjects were enrolled, where shear wave elastography ultrasound were performed. There were 24 healthy controls and 19 patients who presented with AUB, where histopathology results were available. SWE average values were elaborated as E_{max} and E_{mean} where, "E" represents the longitudinal elasticity of a material. These values were described in kilopascal (kPa) unit. Analysis was performed for the SWE values and endometrial thickness (ET).

Results: The mean age of patients were 58.9 years. Highly significant correlation between the SWE values and ET was present in AUB patients ($r_s=0.771$, $p<0.001$). Significant difference of ET and SWE values were demonstrated between the control and AUB patients ($p<0.05$). Amongst the AUB patients, there was also significant difference of SWE values between the

malignant and non-malignant diseases, where $p=0.01$. The SWE cut-off value of ≤ 82.5 kPa (E_{mean}) and ≤ 103.7 kPa (E_{max}) resulted in 100% sensitivity, 86.8% specificity and 88.4% accuracy.

Conclusion: Endometrial SWE serves as a clinically applicable diagnostic tool in women with AUB. With cut-off values of E_{mean} 82.5 kPa and/or E_{max} 103.7 kPa, EC were excluded from other non-malignant endometrial diseases. This will aid in triaging patients for invasive biopsy procedures.

How to overcome barriers for breast MRI screening?

Moderator:

L. Umutlu; Essen/DE

Showing MRI efficacy vs mammography

J. Barkhausen; Lübeck/DE

More than 30 years ago, MRI emerged as a new technique in clinical breast imaging and over the last three decades numerous clinical studies have shown excellent results for the detection and characterization of breast lesions. However, despite this tremendous gain in knowledge, breast MRI still has its share of controversies, including appropriate indications for screening and appropriate indications for preoperative breast MRI. In this lecture the results of the most recent clinical trials comparing MRI and x-ray mammography will be presented in a comprehensive manner, and the impact of these studies on daily clinical routine will be discussed. Additionally, there are possible new indications for breast MRI, bearing in mind that breast cancer subsumes different diseases with varying histologic subtypes, clinical presentations, and treatment responses. Therefore, several studies aim to investigate the associations between MR imaging features and breast cancer subtypes as well as treatment responses. The recent efforts to characterize cancer subtypes and to support individualized tumor treatment based on quantitative imaging parameters are a unique feature of multiparametric breast MRI, and offer important advantages over mammography and ultrasound.

Learning Objectives:

1. To gain knowledge on the results of the most recent trials comparing MRI and mammography.
2. To discuss the impact of the results on the management of breast lesions.
3. To learn about future developments and applications.

3D automated breast ultrasound: accuracy and diagnostic potentials

M.J.C.M. Rutten; 's-Hertogenbosch/NL

Automated 3D breast ultrasound (US) is a new technique, which scans the breast automatically and almost entirely. Data sets can be stored and are available for 3D cross-correlating review. This technique may eliminate the subjectivity of conventional 2D ultrasound, and disconnects the acquisition and assessment of US data. It facilitates the possibility of double reading, review of follow-up studies and the application of computer-aided detection. Issues to be discussed are: - Implementation of automated 3D breast ultrasound in the clinical radiological setting - Technique of reading and interpretation of 3D US data sets - Standardization of assessment and reproducibility (e.g., CAD and reading software) - Diagnostic yield, sensitivity and specificity and factors

influencing these, such as limitations, artefacts and pitfalls.

Learning Objectives:

1. To learn how to implement 3D breast US in daily practice.
2. To become familiar with the technique and assessment software.
3. To understand the accuracy and limitations of 3D breast ultrasound.
4. To become familiar with potential future developments.

Advanced elastography in breast cancer detection

M. Vancu; Craiova/RO

The 3D reconstruction of the breast has opened up a new era in breast ultrasound. This new technique has improved the quality of ultrasound images to such an extent that sonography is now a major mode of detection for breast cancer. The ACUSON S2000 ABVS overcomes the inherent limitations of the breast ultrasound investigation: a small field of view and poor reproducibility. The advantages of the ACUSON S2000 ABVS include standardization with the possibility of second-look and follow-up studies, reproducibility and operator independence. Coronal slices of the breast allow quick identification of areas with impaired architecture. The tools perform measurements more accurately, an attribute critical for follow-up studies such as in cases of chemotherapy. Cancer tissue is stiffer than normal breast tissue. The idea of using this stiffness information for diagnosis evolved into a new diagnostic imaging method for detecting tissue elasticity. Ultrasound elastography is an excellent technique for characterizing breast lesions as benign or malignant. There are two types of elastography: strain elastography, which allows for a qualitative assessment of the lesion, and shear wave elastography, which can be measured as a velocity, with a quantitative value of the stiffness. We have used elastography on over 3000 diagnostic breast ultrasound cases over several years and it has been a "virtual biopsy". The technique has been extremely helpful in increasing confidence in breast evaluation.

What you need to know when using contrast media in breast imaging

E.M. Fallenberg; Munich/DE

Since nearly 100 years contrast agents are used in imaging. The big leap for contrast use in breast imaging was the introduction of breast MRI in the 80s. Contrast enhanced breast MRI is the most sensitive technique for detection of breast cancer today. Digital full-field mammography introduced roughly 20 years ago also paved the way for contrast enhanced mammography. In contrast to MRI, where gadolinium based contrast agents (GBCA's) are applied, contrast enhanced mammography uses iodine containing agents. Even if contrast agents are generally judged as safe, some specialties for both of them have to be considered to prevent side effects or damage to the patient. This talk will focus on the history of contrast enhanced breast imaging and point out advantages and disadvantages of the different types of contrast agents. Recent data will address risks and concerns regarding Gd presence of GBCA's in the brain. To conclude you will learn which patient history information and laboratory is required to securely apply different contrast agents and how to manage of the most common side effects.

Learning Objectives:

1. To give an overview of the advantages and disadvantages of the different available contrast agents.
2. To enable audience to prepare patients adequately for contrast administration and handle possible side-effects.

Clinical utility of contrast enhanced dual energy mammography

L.J. Pina Insausti; Pamplona/ES

Titanium Contrast Enhanced Mammography (TiCEM) is a development of digital mammography. By using dual energy (conventional low energy mammography plus high energy mammography) after the administration of a bolus of intravenous iodinated contrast medium, a morpho-functional image of the breast is acquired. This technique joins the high spatial resolution of conventional digital mammography and the functional information based on neoangiogenesis. The unique titanium filter enables consecutive TiCEM studies without tube overheating. The indications of this technique for the clinical use include: Problem -solving technique after inconclusive mammography, preoperative assessment of breast cancer, follow-up of scars after conservative treatment, follow-up of intermediate risk patients (borderline histological lesions, such as lobular carcinoma in situ, atypical ductal or lobular hyperplasia, as well as positive family history of breast cancer). In fact, the majority of indications are those of MRI, including the contraindications for MRI (pacemakers, claustrophobic patients...). According to our clinical experience with 200 cases, TiCEM significantly increases the accuracy and sensitivity of mammography, with no loss of specificity. Unfortunately, some false negative results can be obtained in DCIS and some false positive results in papilloma and some fibroadenomas. TiCEM is contraindicated for patients allergic to iodine, for patients with renal insufficiency and for pregnant women.

Learning Objectives:

1. To become familiar with Titanium Contrast Enhanced Mammography (TiCEM).
2. To learn the main indications for this technique.
3. To learn the main limitations of TiCEM.

Non-invasive phenotyping of breast cancer with novel MR biomarkers

P.A.T. [Baltzer](#); Vienna/AT

Breast imaging aims to identify breast cancer. Suspicious lesions detected by imaging nowadays undergo image-guided biopsies to secure a final diagnosis. One aim of imaging is to provide a maximum sensitivity while maintaining the highest possible specificity. False positive imaging findings undergo unnecessary biopsies and follow-up examinations and thus cause a substantial economical and medical burden. In addition, the debate on overdiagnosis is still ongoing. MRI as a method providing a multitude of image contrasts including multiple (semi-)quantitative parameters allows an accurate characterization of tissue properties. These data can not only be used to distinguish between benign and malignant findings but further to characterise therapeutically and diagnostically relevant subtypes of breast disease. The subject can be referred to as non-invasive imaging-based phenotyping of breast disease. The talk will provide an evidence-based overview on the clinical relevance and current possibilities of imaging-based phenotyping applied to the breast. In addition, future developments including PET-MRI will be discussed.

What should the future of breast cancer screening with digital breast tomosynthesis look like?

Moderator:

I. Sechopoulos; Nijmegen/NL

Introduction

I. [Sechopoulos](#); Nijmegen/NL

The superiority of digital breast tomosynthesis (DBT) over digital mammography (DM) for cancer detection in screening has been proven in several population-based prospective screening trials. However, most of these results have been achieved with considerably longer reading times than with DM. In some cases, higher radiation doses have also been used. Is this acceptable? What are the most important features and characteristics on our wish list for the ideal breast cancer screening program with DBT in the future? In this symposium, the latest results of clinical trials will be presented, analyzed in terms of effectiveness when considering population screening, and the remaining knowledge gaps identified. We will discuss whether we should just copy the standard approach with DM for screening with DBT or whether we should go in new directions. Finally, we will review the challenges faced in the widespread implementation of DBT for population screening.

View of future screening programmes: conclusion from the Malmö Breast Tomosynthesis Screening trial - a concept for breast screening

S. [Zackrisson](#); Malmö/SE

According to some of the important principles of screening established by WHO in 1968, a screening test should be fast, safe, efficient and acceptable for the target population. Screening with 2D mammography fulfills many of these prerequisites, but how will digital breast tomosynthesis, DBT, fit in? The organization and workflow in mammography screening is long-standing and well-established in many countries, and changes may have a great impact on these issues. This talk will focus on the facts about digital breast tomosynthesis regarding screening performance, effectiveness and possible measures to reduce reading time. When planning the Malmö Breast Tomosynthesis Screening Trial we took the principles of screening into consideration and used 1-view DBT and reduced compression. Furthermore, artificial intelligence in combination with the radiologist opens up possibilities for further future improvements.

Comparison of two-dimensional and three-dimensional mammography performance in breast cancer screening

D. [Pavic](#); Charleston, SC/US

Aim: The study compares breast cancer screening performance using Full Field Digital Mammography images (2D) and three-dimensional Digital Breast Tomosynthesis (DBT) images, in MLO projection only (3DMLO) and as a complete DBT exam in MLO and CC projections (3D). Introduction: Radiation dose at 3D screening can be reduced by omitting separate 2D acquisition and abandoning CC projection in DBT, if 3DMLO could demonstrate comparable diagnostic performance. Material and methods: Women age 40 and older who had screening exams using Siemens a DBT unit in the period from Aug 1, 2016 to Sep 30, 2017 were included. 21 biopsy-proven cancer patients with 24 cancers were identified. Based on age and Breast Imaging Reporting and Data System (BI-RADS) density assessment (DS) they were matched with 24 biopsy-proven benign patients and 25 patients who were negative or benign on screening. Age, race and DS were collected. Lesion location, type and size, axillary lymph nodes status and pathological diagnosis were also collected for biopsy patients. Screening exams of those 70 patients, consisting of 2D and 3D mammography images, were included in the image set. Three fellowship-trained breast radiologists and two breast imaging fellows were the readers. We will compare the diagnostic performance of 3DMLO, 3D and 2D readings, separately for each reader and for all readers, by looking at recall rate, cancer detection rate, positive predictive value and area under curve (AUC).

CAD for breast cancer screening: first experiences with a CAD integration for screen-reading of 3D mammograms and with 3D CAD for tomo-reading

S.H. [Heywang-Köbrunner](#); Munich/DE

So far, CAD has not routinely been applicable for screen-reading in organized screening programs, mostly due to excessively false positive rates (of 1 to 1/3 hit per mammogram). Tomosynthesis, which is considered the most promising method for breast cancer screening, is associated with a 10-20-fold increase in the number of images. Insufficient data exists concerning the capability of maintaining the reader's concentration with this work load, so the need for CAD-support increases. Also, new artificial intelligence (AI) algorithms promise improved sensitivity and specificity. We present a software solution that allows integration of an AI-CAD system with the screen reading software. Mammograms are automatically assigned a degree of suspicion (1-10), based on a large number of screening mammograms. Filtering cases with high suspicion (9 or 10), either a selective third reading may be considered, or a second reader might decide to spend more time on these cases or read them first. Due to the high sensitivity for microcalcifications, less reading time can be used for cases rated 1-4. In a different study using AI-CAD for tomosynthesis an excellent sensitivity of 90-92% combined with a very low false positive rate of 9-15% was achieved in a demanding case series of 400 proven cases. These results indicate important progress compared to prior CAD systems on 2D mammograms.

Learning Objectives:

1. Prior limitations of CAD.
2. Possibilities for integrating a CAD system for screen reading.
3. Progress achieved by CAD-3D reading.

The future role of synthetic mammograms: is it more than a 2D image?

C. [Van Ongeval](#); Leuven/BE

A synthetic mammography (SM) is a two-dimensional image, reconstructed from digital breast tomosynthesis (DBT) data. Simulation studies (work of Michlielsen et al.) using insertion of simulated microcalcifications and mass lesions in raw data of tomosynthesis showed an impact of reconstruction algorithm on the lesion detection fraction. The algorithm of SM impacts on the presentation of line structures and high density structures like microcalcifications, resulting in increased conspicuity of lesions in the SM. In the Oslo trial (Per Skaane et al.) SM was included into the screening protocol and in this study it was concluded that improvement of the reconstruction algorithm had an impact on the lesion detection. Further work on the reconstruction algorithm of SM can improve the presentation of suspicious lesions with careful attention to the creation of false positive lesions: how far is this CAD related enhancement allowed in clinical practice? Physical-technical evaluation of the quality of SM is ongoing and will be complicated by the complex structure of the applied processing algorithms.

Personalised breast cancer screening and the role of breast density

M. [Broeders](#); Nijmegen/NL

Breast screening programs today generally offer a mammographic examination every two years to women in a specified age range. Ongoing research is exploring the added value of personalized risk-based screening, i.e. screening strategies tailored to a woman's individual risk of breast cancer. A vital prerequisite for personalized risk-based screening is a comprehensive breast

cancer risk prediction model. The next step is to develop screening regimens for women at varying levels of risk, which may be addressed in several ways: changing starting and stopping ages, changing screening intervals, as well as offering further imaging techniques in addition to digital mammography. Using modeling techniques, the harm-benefit ratios and cost-effectiveness can then be estimated to find the optimal screening strategies. In parallel, it is essential to understand the acceptability of personalized approaches, especially for women at low risk, and the challenges in communication and implementation. Breast density is an important factor in this research area because it can contribute to risk prediction, but will also play a role in finding the optimal screening strategy. Automated measures of breast density on digital mammography are being updated rapidly, which will facilitate getting this data for all women in the target population. However, the fact that DBT may replace digital mammography in the near future raises the following questions: how does DBT perform across breast density categories? What is the relationship between automated breast density measures on DBT and breast cancer risk? What is the role of additional imaging modalities when DBT is the screening test?

Learning Objectives:

1. To understand the components of a personalized breast cancer screening program.
2. To explore the role of automated breast density estimates in personalized breast cancer screening with tomosynthesis.

Pretherapeutic diagnostics of tumour extent (part 1)

E. Wenkel; Erlangen/DE

In pretherapeutic diagnostics to determine the extent of spread of a breast cancer (TNM staging), the interaction of the various breast imaging modalities (comprehensive mammo diagnostics) plays a particularly important role. Various clinics are working on modern staging concepts, combining current guidelines with new imaging procedures. In this symposium, two experts will each discuss pretherapeutic TNM staging diagnostics cases from their clinical routine. The audience will be actively involved in the coordination processes and is invited to participate in the discussion.

Roadmap for artificial intelligence in radiology: recognition, reconstruction, reasoning

B. Van Ginneken; Nijmegen/NL

Artificial Intelligence, in the form of deep learning, is extremely successful in automated recognition of abnormalities, in segmentation and in quantification. I will illustrate this with some recent results. Increasingly, deep neural networks are used to generate new images. They can be used for reconstruction, for denoising extremely low dose scan, for creating novel images, and for mapping images from one modality to another, for example CT to MR. The next frontier is to go beyond mappings from input data to output data and design systems that can reason based on variable inputs.

Deep learning reconstruction: the next step in CT image quality

M. Prokop; Nijmegen/NL

I will present the first clinical results of Deep Learning Reconstruction (DLR) algorithm for CT (both 320-row CT and UHR-CT), featuring a deep learning neural network that can differentiate and remove noise from signal, creating extraordinary high quality images.

MRI and advanced algorithms like computed MRI from research to clinical practice

L. Saba; Cagliari/IT

Computed MRI finally has become more practical in a clinical setting. Clinical imaging therefore may very well profit from these advanced imaging techniques. Where in the past these tools were mostly used in research it can also provide flexibility and reduction in examination time in daily practice. It also offers the possibility to offline reconstruct conventional sequences with different contrast settings and it allows to obtain quantitative values that may be used for follow up or for tissue characterization.

Multiparametric approach for diffuse liver disease with ultrasound

V. Vilgrain; Clichy/FR

Diffuse liver disease poses a major challenge to the global healthcare system. Quantitative techniques in ultrasound have recently been developed for follow-up and for therapy monitoring. Nowadays, the measurement of shear wave propagation speed is already being used to assess liver elasticity in clinical routine. In this talk we will discuss novel techniques such as the quantitative imaging of the attenuation of the longitudinal ultrasound waves (ATI), as well as the quantitative imaging of shear wave dispersion (SWD) to assess tissue parameters related to steatosis and to the viscosity of liver tissue, and present early clinical experience.

**Samsung innovations for patient safety:
CEUS and paediatric DR imaging**

Moderator:

V. Cantisani; Rome/IT

CEUS: from guidelines to clinical practice

V. Cantisani; Rome/IT

To date CEUS EFSUMB guidelines reporting on hepatic and non-hepatic applications have been published with an additional recent statement on EFSUMB CEUS use in pediatric applications and one on liver which is ongoing provided by WFUMB. Those guidelines updated the previous ones and had the purpose to inform recommended and tailored clinical practice rather than to report on research projects. Thus, they provide a kaleidoscope of current findings, formulated by a group of experts and are primarily based on surveys of the published peer-reviewed literature. In general, CEUS is most useful where an abnormality can be displayed on B-mode ultrasound (US), and the better the quality of the B-mode imaging, the better the quality of the CEUS images, although sometimes especially in liver metastasis detection they may reveal what was not previously observed at Baseline Ultrasound. Therefore, CEUS is frequently used as an extension of conventional US (B-mode and color Doppler). Contrast studies should always be interpreted in the context of the overall clinical picture, other imaging and laboratory tests. Overall, UCAs are mainly used as vascular agents following intravenous injection and they highlight the macro- and microvascular systems. However, they can also be instilled into body cavities, both normal and pathological. According to indications and recommendations in the present lecture daily practice cases will be presented in order to enhance the benefit of CEUS application over baseline Ultrasound or even CT and MRI. Tips and tricks to tailor the examination will be provided as well.

Balancing the risks and benefits in radiology - contrast and x-rays and paediatric blunt abdominal trauma: safety and dose reduction

M. Sellars; London/UK

CT - enhanced ultrasound (CEUS) is a cost effective, safe alternative to computed tomography (CT) when imaging children who have sustained blunt abdominal injuries. CT still remains the gold standard for assessment of abdominal and pelvic injuries however, depending on the mechanism of injury and the severity of solid organ injury these patients are often exposed to repeated examinations involving ionising radiation and intravenous iodinated contrast agents. The use of CEUS in the follow up of severe blunt abdominal injuries in the paediatric population has evolved in the past 10 years and more recently in our institution has also proved beneficial as a first line imaging technique in children who have sustained minor blunt abdominal injuries. Although current data has shown that ultrasound contrast agents are safe for use in the adult population, few studies have evaluated safety in children. Clinicians therefore have to be prepared for the possibility of both anaphylactoid and severe anaphylactic reactions as would be the case when administering any intravenous contrast agent.

Clinical trial to evaluate the dose reduction in paediatric radiography

S. Oh; Seoul/KR

Objectives: To prove that an upgraded image post-processing engine (IPE) in S-station, exclusively installed in Samsung Digital Diagnostic X-ray system, provides achievable dose reduction at a certain lower dose than the predicate device (old IPE) used in pediatric patients. Methods: Validation study of a noise simulation tool and clinical image evaluations on clinical images and low dose images rendered by the validated noise simulation tool was done, respectively. Results: Both quantitative and qualitative analysis results strongly suggested that simulated low dose images by a noise simulation tool showed almost the same image quality as corresponding real dose images. The dose step difference were shown to have statistical significance. Conclusions: The performance of the new IPE suggests achievable dose reduction rates up to 45% relative to the predicate IPE for pediatric populations.

Precision ultrasound for an increasingly XXL population using image fusion, CEUS and improved ultrasound penetration

A. Nilsson; Uppsala/SE

As an increasingly large proportion of our patient population can be classified as obese, finding, characterizing and potentially treating focal lesions is routinely becoming more difficult. Diagnostic tools, such as high quality contrast enhanced ultrasound and multi-modality fusion, in conjunction with improved ultrasound penetration, can help us personalize ultrasound to meet this challenge.

CEUS diagnostic imaging in the paediatric population

M. Stenzel; Jena/DE

An overview of current best practice of ultrasound in infants and children referencing adult patients where appropriate. Sonography is the imaging modality of choice in paediatrics because it provides a cross-sectional depiction of anatomical structures with high spatial and temporal resolution and is relatively robust handling restless and active patients. No other method can provide comparable diagnostic information. Indications for paediatric sonography include: screening, diagnosis and follow up exams. Contrast enhanced ultrasound can be used to enhance diagnostic possibilities. The two main indications for contrast enhanced ultrasound in children are the assessment of vesicoureteral reflux disease and the characterization of focal lesions, particularly in the liver.

New horizons in breast ultrasound

M. Daniaux; Innsbruck/AT

In conjunction with the superb spatial resolution of high frequency B-mode ultrasound and highly sensitive colour Doppler, advanced applications like Strain and Shear Wave Elastography provide clinicians with the tools necessary to deliver precision medicine. Strain Elastography can be used to classify a lesion according to specific recognized patterns. Shear Wave Elastography allows for the quantification of tissue stiffness by providing a velocity map which allows comparison of the shear wave velocities at multiple points. Using these three imaging modes (B-mode, Colour and Elastography) improves diagnostic confidence and may reduce the costs associated with unnecessary biopsies and improve the patient experience.

Arthro-cone beam computed tomography for the detection of osteoarthritis

S. Boudabbous; Geneva/CH

Introduction: XR remain the gold standard for establishing an imaging-based diagnosis of osteoarthritis. However, the criteria of Kellgren and Lawrence classification (KLC) are delayed and lack of sensitivity and specificity. CBCT is an emerging modality in extremity's imaging allowing low dose radiation with diagnostic quality images.

Materials and Methods: 32 arthro-CBCT requested for osteoarthritis assessment, preceded by XR were performed. All Arthro-CBCT were reconstructed with Modeled Based Iterative Reconstruction and were analysed by 2 independent-blinded MSK radiologists for the overall quality (3-point Likert scale). Contrast, bone density and minimal joint space width (JSW) were evaluated. The stage of Kellgren and Lawrence was compared between ArthroCBCT and XR as well as sclerosis and erosions using 3-point Likert scale. P value was calculated using the Wilcoxon test. Finally, radiation dose was estimated and compared between the two modalities.

Results: The image quality was excellent in all cases of arthro-CBCT with excellent inter observer concordance ($\kappa=1$). The mean of density was 1966,328,812 and 330 respectively for the contrast, the trabecular bone, the subchondral cortex and for the cartilage. An under classification of osteoarthritis was noticed with XR regarding the JSW ($p=0.02$), the detection of osteophytes (<0.0001) and the KLC ($P<0.0001$). The dose for arthro-CBCT and XR were estimated at 4.9 and 0.05 mSv.

Conclusion: Arthro-CBCT may be a new way to assess osteoarthritis due to its high image quality and low radiation dose.

Articular surfaces of the tibiotalar joint from different medical imaging technologies: for morphological models and custom-made prostheses

A. Leardini; Bologna/IT

Total ankle replacement still suffers of failures and patient dissatisfaction, likely accounted for to the poor design and the limited number of sizes. To match better patient-specific joint anatomy, custom-made prostheses are being introduced, possibly to reduce the mismatching. Additive manufacturing, i.e. 3D printing, and biomechanical modelling and designing nowadays make this possible. For this purpose, however, reliable medical-imaging analyses are mandatory, to achieve accurate patient-specific models of the joint to be replaced, and in case of the contralateral as a reference. The aim of this study was to investigate the quality of customized morphological models of the ankle on different medical imaging technologies. A cadaver shank-foot specimen instrumented with multi-modal markers was plastered. Scans were taken in a CT standard, Dual-Energy (DE) and Cone-Beam (CB) technologies, as well as on 1.5 and 3.0 T MRI. Relevant DICOM files were used to create CAD models for the tibia and talus bones, the cartilages and the beads. Also to create bone-cartilage models, these models were registered based on the fiducial markers or 3D shape matching. Distance map analysis calculated the inter-model differences. Large distances by corresponding models were observed using surfaces derived from standard CT and 1.5 T MRI. More uniform distance maps of cartilage and bone models were obtained respectively by 3.0 T MRI and CBCT, which resulted also in best bone-cartilage models. In personalized joint replacements, these findings support the definition of subject-specific morphological models for better custom-made prostheses.

Clinical and weight-bearing indication for CBCT of the extremities

M. Boesen; Copenhagen/DK

CBCT offers the opportunity to study the bony changes in a variety of clinical and research indications of the musculoskeletal system such as 3D isotropic high resolution bone imaging of trauma to the extremities, 3D isotropic high resolution bone imaging of rheumatic diseases (Osteoarthritis, Rheumatoid Arthritis, Psoriasis Arthritis, Gout and Pseudo Gout (CPPD/HADD) with a low radiation dose. Weight-bearing CBCT can also provide important information regarding mechanical changes in knee and foot in 3D between supine and weight-bearing conditions. The lecture will summarize the potential for application of CBCT in the above mentioned conditions and show preliminary results regarding weight-bearing imaging of the patellofemoral joint and ankle.

Extremity CT: the basics and the promise

J. Yorkston; Rochester, NY/US

Recent years have seen the introduction of a number of specialized x-ray systems optimized for imaging specific anatomical regions. In particular, volumetric imaging systems designed to acquire dental, ENT and extremity images based on Cone Beam CT technology are now commercially available. This submission will review the technical aspects of these new systems with a focus on their unique capabilities. The presentation will also describe the ongoing work to improve the image quality of the Carestream Onsite system with a view to enabling various quantitative CT capabilities. Model based iterative reconstruction coupled with advanced scatter correction algorithms have resulted in a significant improvement in HU accuracy. Continuing development of semi and fully automated measurement tools hold the promise of providing the clinician with a full array of accurate 3D measurements in the foot, knee and hand in an efficient, reproducible manner that should enhance clinical decision making once fully implemented. The talk will review a number of these forthcoming capabilities. Additionally the potential for advances in patient specific instrumentation to improve surgical efficiency and patient outcomes will be discussed in the context of 3D printing of patient specific surgical implants and surgical guides. Ongoing work associated with image analysis of the high quality 3D reconstructions to detect, classify and monitor early onset OA and RA will also be highlighted.

How MRI with AIR™ Technology brings comfort, speed and quality (SY 3)

Martini I., Polici M., Zerunian M., Landolfi F., Panzuto F., Rinzivillo M., Annibale B., Laghi A., Iannicelli E.

CT-texture analysis of liver metastases in PNETs vs NPNETs: correlation with histopathological findings (SS 616a), B-0525

Martini K., Caviezel C., Schneiter D., Milanese G., Schmitt-Opitz I., Weder W., Frauenfelder T.

Dynamic magnetic resonance imaging as an outcome predictor for lung-volume reduction surgery in patients with severe emphysema (SS 604), B-0577

Martinoli C.

Spine and peripheral nerve imaging: Keynote lecture (SS 1910b), K-41

Mascherbauer J.

Cardiac imaging in structural heart disease: B. Defining the optimal time to treat valvular heart disease: role of MR (RC 1503), A-0878

Masselli G.

Emergency radiology II: B. Non-traumatic urinary tract emergencies (E³ 521), A-0203

Masselli G.

Imaging in pregnancy: Chairperson's introduction (RC 1307), A-0808

Massmann A., Lepper P.M., Fries P., Wilkens H., Buecker A., Huasen B.

Vacuum-assisted aspiration thrombectomy for treatment of acute massive pulmonary embolism (SS 1009), B-0961

Massmann A., Frenzel F., Fries P., Kubale R., Shayesteh-Kheslat R., Buecker A.

Prospective single-centre registry of endovascular aortic repair (EVAR) using ultra-low profile aortic endograft (SS 1009), B-0963

Mastio M., Duarte A., Raya J., Jazrawi L., Bencardino J.T.

Can pre-operative MR imaging findings predict early failure following anterior cruciate ligament reconstruction? (SS 1810), B-1510

Mastio M.T., Duarte Vallejo A., Raya J., Jazrawi L., Bencardino J.T.

Rupture of the anterolateral ligament in complete acute traumatic anterior cruciate ligament tear: new insights into acute pivot shift trauma to the knee (SS 1810), B-1508

Matos J., Mussetto I., Paparo F., Perugin Bernardi S., De Cesari M., Cevasco L., Cenderello G., Bacigalupo L., Rollandi G.A.

Prospective comparison of transient elastography (1D-TE), shear wave elastography (2D-SWE) and magnetic resonance elastography (MRE) for assessment of liver fibrosis in HCV patients (SS 1801a), B-1528

Matzek W.K.

US and vascular disease: a perfect match: C. Ultrasound as guidance for vascular interventions (RC 1315), A-0754

Maurea S., Ginocchio M.I., Verde F., Romeo V., Mainenti P.P., Petretta M., Sarno L., Martinelli P., Brunetti A.

Comparison of diagnostic accuracy between clinical risk factors and MRI to predict placental adhesion disorders in patients with placenta previa (SS 1507), B-1385

Maurer M.H., de Bucourt M., Berghöfer A., Huppertz A., Rosenkrantz A.B., Streitparth F., Heverhagen J.T., Meyl T.

Subspecialisation in radiology: effects on the diagnostic spectrum of radiologists and report turnaround time in a Swiss university hospital (SS 1405), B-1184

Maurer M.H., Lachenmayer A., Beldi G., Candinas D., Heverhagen J.T., Kim-Fuchs C.

Percutaneous stereotactic CT-based microwave ablation for neuroendocrine liver metastasis (SS 1709), B-1434

Maurer M.H., Banz-Wüthrich V., Beldi G., Kim-Fuchs C., Candinas D., Tinguely P., Heverhagen J.T., Lachenmayer A.

Stereotactic image-guided microwave ablation of hepatocellular carcinoma (SS 1709), B-1438

Maurer M.H., Lachenmayer A., Banz-Wüthrich V., Weber S., Candinas D., Heverhagen J.T., Tinguely P.

Stereotactic image-guided microwave ablation for malignant liver tumours: can computer-assistance broaden treatment eligibility? (SS 1709), B-1442

May M.S., Prael I., Heiß R., Kopp M., Uder M., Wuest W.

Late phase lung perfusion by dual energy CT: image quality and clinical findings compared to arterial perfusion (MY 4), B-0426

Mayerhöfer M.E.

Which whole-body exam should I choose?: Keynote lecture (SS 1716), K-33

Mayrhofer M.T.

Will the General Data Protection Regulation (GDPR) hamper the secondary use of clinical imaging data for research?: Can I reuse, share or give open access to existing imaging data for research? (ESR/BBMRI-ERIC), A-0631

Mazzaro A., Gatti F.L., Bettini R., Mandruzzato N., Contro A., Mansueto G.

Transjugular portal vein stenting: an original approach for palliative treatment of portal vein stenosis/occlusion in neoplastic patients (SS 109), B-0009

Mazzaro A., Zamboni G., Figuera A., Campagnola A., Mansueto G.

CT texture analysis for detection of tumour recurrence in patients resected for pancreatic adenocarcinoma (SS 1401a), B-1103

Mazzilli A., Loria A., Castriconi R., Lusa Agüero T., Calandrino R., del Vecchio A.

A radiation dose index monitoring (RDIM) systems comparison for CT procedures (SS 1413), B-1194

McCarthy L.L., Brenner C., Sammon J., Spence L.D., O'Connor J.

The applicability of the Greulich and Pyle atlas to a modern Irish population (SS 1012), B-1056

McAnulla S.J., Knapp K.M., Ball S.

Understanding diagnostic student radiographer attrition in the UK (SS 1914a), B-1698

McDermott G.M., Hayball M., Ganeshan B., Riaz Z., Scarsbrook A.

Automated CT texture analysis of lung cancer FDG PET-CT data using a novel software tool: preliminary results (SS 204), B-0150

McDermott G.M., Brown P., Scarsbrook A.

Evaluation of pre-treatment FDG PET-CT-based imaging parameters and textural features as prognostic indicators in non-small cell lung carcinoma (SS 704), B-0771

McGinty G.

Clinical audit: how to deal with the legal and professional requirements: Peer review as key for quality improvement: the US experience (PI 2), A-0588

Automatic pulmonary nodule detection in low-dose CT scans using convolutional neural networks based on maximum intensity projection (SS 1905a), B-1756

Zholdybay Z., Akhmetova G., Akhmetova G., Panina A., Ainakulova A.

Lung cancer screening with low dose computed tomography: the republic of Kazakhstan experience (SS 1016), B-1026

Zhong J., Arunsingh M., Brown P., Dyker K., Prestwich R., Currie S., Vaidyanathan S., Scarsbrook A.

Prediction of patient outcome in head and neck squamous carcinoma following chemo(radiation): comparison of 4 different FDG PET-CT response assessment interpretative criteria (SS 706), B-0666

Zhong J., Brown P., Nelstrop H.L., Prestwich R., McDermott G.M., Currie S., Vaidyanathan S., Scarsbrook A.

Performance of FDG PET-based textural features for prediction of loco-regional recurrence in advanced larynx and hypopharynx squamous cell carcinoma (SS 706), B-0667

Zhou F., Wang Y., Schoepf U.J., Tesche C., Xu L., Hou Y., Yan J., Zhang J.Y., Zhang L.J.

Diagnostic performance of fractional flow reserve derived from coronary computed tomography angiography in myocardial bridging: a comparison with invasive fractional flow reserve (SS 703), B-0785

Zhou J., Dan H., Cheng G.

Feasibility study of whole breast texture analysis for predicting tumour response to neoadjuvant chemotherapy (SS 1402b), B-1171

Zhou W., Chai M., Wong W., Yap P., Lai Y., Lee T., Leung S., Lee J., Ng M.

Prognostic value of myocardial perfusion reserve index in patients with coronary microvascular disease: a multi-centre study (SS 1403), B-1220

Zhou X., Xiao B., Hu H., Tang J.

The development of a novel manganese dioxide-based nanoparticles and real-time monitoring of its anticancer effect by MRI (MY 5), B-0472

Zhu B., Jiang T., Peng P., Li M.

Can dual-energy CT replace perfusion CT for the diagnosis of the solid pulmonary nodules? (SS 204), B-0151

Zhu L., Denecke T., Asbach P., Hamm B., Xue H., Jin Z.

Relapse of type 1 autoimmune pancreatitis after steroid therapy: imaging findings and risk factors (SS 501), B-0450

Zhu L., Sun Z., Jin Z., Qian T., Nickel D., Makowski M., Asbach P., Hamm B., Xue H.

T1 mapping of autoimmune pancreatitis as a quantitative outcome biomarker (MY 17), B-1475

Zhu T., Yushu C., Yu Z., Wen Z., Zheng J., Fabao G.

Cardiac magnetic resonance imaging study of right ventricular myocardial deformation in spontaneous T2DM rhesus monkey (SS 1903b), B-1861

Zhu Y., Chen Y., Guan W.

The experimental study of prostate cancer imaging using PSMA targeting ultrasound/MRI dual modality nanobubbles (SS 606), B-0511

Zhu Z., Zhao X., Zhou C.

Wide-detector axial scan on revolution CT for combining application of ASIR-V and ASIR on unenhanced abdominal CT in vivo: the image quality and radiation dose evaluation (SS 407), B-0445

Authors' Index

Zhu Z., Zhao X., Zhou C.

Perfusion MRI prediction of progression-free survival in patients with hepatocellular carcinoma treated with TACE (MY 8), B-0832

Zhuravlev K.N., Sinitsyn V.E., Shpektor A.V.

Coronary calcium screening with non-gated standard and low-dose chest CT in comparison with ECG-gated calcium scoring CT (SS 1503), B-1314

Zimny A.

Inflammatory and infectious CNS pathology: B. Infectious encephalitis (RC 1211), A-0677

Zini C., Notaro D., Sadotti G., Bellini M.

Percutaneous intervertebral disc coagulation therapy (PDCT) by plasma light: a new method for the treatment of lumbar and cervical disc herniation (SS 1809), B-1575

Zins M.

Visceral arteries: B. Acute and chronic mesenteric ischaemia (RC 115), A-0022

Zins M.

Tumour response assessment in abdominal imaging: C. Pancreatic adenocarcinoma (RC 301), A-0109

Zins M.

How to face the tsunami of pancreatic intraductal papillary mucinous neoplasia (IPMN): Chairperson's introduction (SA 5), A-0236

Zins M.

How to face the tsunami of pancreatic intraductal papillary mucinous neoplasia (IPMN): Panel discussion: Management of IPMN: what is the Achilles heel of our current concept? (SA 5), A-0240

Zins M.

Solid pancreatic neoplasms: Diagnosis (E⁹ 24D), A-0852

Zolda P.

Growing radiography research: Turning your research idea into reality: opportunities for European funding (EFRS WS), A-0864

Zorzenon I., Ukmar M., Gennari A., Zdjelar A., Bottaro L., Sartori A., Dinoto A., Cova M.A.

Evaluation of signal intensity in dentate nucleus and globus pallidus after repeated administrations of gadolinium in multiple sclerosis patients (SS 611), B-0536

Zubler V.

Inflammatory and infectious diseases of the spine: how to differentiate from degeneration: A. Spondyloarthritis: a diagnostic chameleon (RC 910), A-0541

Zugni F., Funicelli L., Bertani E., Bellomi M.

Lymphadenectomy of small intestine neuroendocrine neoplasias (si-NEN): testing the most recent preoperative classification with contrast-enhanced computed tomography (CT) (SS 1401b), B-1281

Zur G., Lesman-Segev O., Schlesinger I., Eran A., Kahn I.

Structural integrity impact of focused ultrasound thalamotomy and correlation to behavioural outcomes for tremor disorders (SS 1811a), B-1557

Zwierko B., Dura M., Zuchowski P., Jeka S.

Applying the low-dose protocol in high resolution computed tomography examination in patients with rheumatoid arthritis (SS 1604), B-1408
