Imaging of benign liver lesions: still difficult?

A-0001 08:30

Chairperson's introduction

P. Ricci; Rome/IT (paolo.ricci@uniroma1.it)

Focal liver lesions are routinely encountered by clinical radiologists and represent a wide spectrum of pathology. Majority of these lesions are likely to be benign in nature, especially in the absence of chronic liver disease or primary cancer. A radiologist must be aware of common and uncommon imaging features of benign lesions across the various imaging modalities. Benign focal liver lesions can originate from all kinds of liver cells: hepatocytes, mesenchymal and cholangiocellular line. Their features at imaging may sometimes pose difficulties in differential diagnosis with malignant primary and secondary lesions. In particular, the use of MDCT and MRI with extracellular and hepatobiliary contrast agents may non-invasively help in correct interpretation and definition of hepatocellular or mesenchymal and inflammatory nature, allowing to choose the best treatment option. The correct differential diagnosis is based on the knowledge of the main diagnostic features. There are some malignant lesions which may mimic benign liver conditions. The most challenging lesions should be cystic lesions, hemangiomas, focal nodular hyperplasia and adenoma, whose features are not always so clear and unequivocal.

Session Objectives:

1. To understand the role of different imaging techniques in the characterisation of focal liver lesions.
2. To be aware of malignant lesions which may mimic benign liver conditions.
3. To underline current guidelines for the characterisation of equivocal liver lesions.

A-0002 08:35

A. Hepatic cysts: always simple?

I. Santiago; Lisbon/PT (ines_agp_santiago@hotmail.com)

The differential diagnosis of cystic liver lesions is as broad as their clinical significance, which ranges from benign to malignant and/or potentially lethal conditions. These lesions include foregut and ductal plate malformations, infectious conditions, primary and secondary neoplasms and traumatic/isotrogenic fluid collections. The number of lesions, morphology, fluid content characteristics, presence/absence of septae and/or solid components are the key imaging features for the diagnostic approach, and different imaging modalities pose different advantages and disadvantages for their characterisation. Given imaging characteristics may overlap between distinct conditions, patient history and laboratory data should be integrated to allow a more definitive diagnosis.

Learning Objectives:

1. To learn about different types of cystic lesions in the liver, including giant biliary hamartomas or foregut cysts.
2. To understand the diagnostic approach to differentiate simple and complex cysts/cystic lesions.
3. To appreciate advantages and limitations of imaging for differentiating simple cysts from other cystic lesions.

A-0003 08:58

B. Liver haemangiomas and mimickers

F. Caseiro Alves; Coimbra/PT (caseiroalves@gmail.com)

Haemangiomas are common focal liver lesions, generally detected in the workup of asymptomatic patients and do not require further workup, follow-up, or treatment. From the morphologic point of view, they can be classified as small (capillary) or large, with cavernous vascular spaces that may be prone to show thrombosis, calcifications and hyalinisation. The polymorphic imaging appearance of haemangiomas depends on their histological features and flow pattern. The widespread use of cross-sectional imaging has allowed a better characterisation of this benign vascular tumour, and for this lecture, illustrative cases will be displayed especially using CT and multiparametric MRI including hepato-biliary contrast agents. Haemangiomas imaging findings may range from the commonly known aspects especially after extra-cellular Gd-chelates administration to atypical patterns where its recognition and positive diagnosis may not be so straightforward. The scope of the present lecture to present and discuss the patterns of those vascular liver lesions, describing normal findings, pitfalls, potential differentials, confounders and complications.

Learning Objectives:

1. To learn about typical imaging findings of liver haemangioma.
2. To understand the atypical imaging findings of liver haemangiomas.
3. To appreciate the role of multiparametric and liver-specific contrast MRI in differentiation between haemangiomas and malignant lesions mimicking haemangiomas.

A-0004 09:21

C. FNH or adenoma?

A. Ba-Ssalamah; Vienna/AT (ahmed.ba-ssalamah@meduniwien.ac.at)

FNH and hepatocellular adenoma (HCA) is liver lesions of hepatocellular origin. Whereas FNH commonly occurs, HCA is very rare. Distinguishing FNH from HCA is of great importance clinically, as FNH is considered a benign lesion and needs no further management. In contrast, HCA, according to its subtype, can be considered a borderline tumour due to the risk of haemorrhage, growth, and even malignant transformation, and therefore requires individualised management. The genotype/phenotype classification of HCA is an evolving issue, and there is now a recent HCA molecular classification by which to stratify patients according to the risk of complications. On imaging, HCA is no longer a distinct entity, and imaging features reflect the tumour subtypes. Contrast-enhanced MRI is much more accurate because of its ability to visualise the textural composition of the HCA. However, even after the administration of MRI hepatobiliary contrast agents, a small proportion of HCA subtypes still show either inhomogeneous uptake or inhomogeneous washout in the hepatobiliary phase (HBP); making them difficult to differentiate from FNH on the basis of imaging presentation alone. This may pose a diagnostic dilemma as both FNH and HCA tend to occur in women of child-bearing age. Clinical presentation and risk factors, male gender, patient age, the presence of storage disease, obesity, metabolic or inflammatory syndrome, hepatitis, alcohol abuse and tumour over five cms, as well as significant growth have been identified as factors associated with an HCA-subtype of higher malignant potential. In difficult cases, histology remains the gold standard.

Learning Objectives:

1. To learn the imaging features associated with FNH and adenoma on contrast-enhanced CT and MRI.
2. To understand how the imaging characteristics are related to the underlying pathological findings.
3. To appreciate the optimal use of liver-specific contrast media for distinguishing between FNH and adenoma, and current classification and pathological characteristics and its impact on the management.

Contemporary breast imaging

A-0005 08:30

Chairperson's introduction (Part 1)

E. Metsala; Helsinki/FI (eija.metsala@metropoli.fi)

This session covers many very up to date issues related to breast imaging. The final aim of breast imaging is to find breast cancer. For that, we need optimal screening policies and protocols for finding breast cancer from various types of breast. What is good for most women, might not be optimal for all of us. However, we want to produce optimal diagnostic services for all types of women. In addition to breast ultrasound, tomosynthesis and breast MRI seem to be the most used imaging modalities for finding breast cancer at the moment. It is important to discuss the options we may have for screening purposes. However, there is no use for excellent technical and diagnostic devices and processes in case the client/patient does not show up for examinations. To ensure that we must carefully pay attention to the information we deliver about breast cancer and breast examinations, patient guidance and make the imaging and diagnostic process as patient-centred as possible. To achieve this, we need interprofessional co-operation between various health care professionals: radiologists, radiographers, physicists, biomedical laboratory scientists and pathologists to mention a few.

Postgraduate Educational Programme

Session Objectives:

1. To discuss the relevance and application of tomosynthesis in breast imaging.
2. To understand the indications and use of breast MRI in pre-menopausal women.
3. To appreciate the current debate regarding the appropriateness of breast screening programmes.

A-0006 08:33

Chairperson's introduction (Part 2)

G. Ivanac; Zagreb/HR (gordana.augustan@gmail.com)

Tomosynthesis is a relatively new modality in digital mammography that increases conspicuity if lesions that are hidden by superposition of breast parenchyma. Also, MRI is established diagnostic modality for numerous indications: for high-risk screening, detection of residual lesions or recurrence after surgery, for the detection of breast cancer when axillary lymph nodes are positive and mammography and ultrasound negative, and for monitoring of neoadjuvant treatment, and in some cases for preoperative evaluation of the extent of cancer. Breast cancer screening is a matter of many controversies, in the light of overdiagnosis and overtreatment, but it is generally accepted that biannual mammographic screening should be offered to healthy women of the age group of 50-69. Supplemental screening with ultrasound and tomosynthesis is indicated in many cases of dense breasts, and a special regimen should be applied to women with a high risk of acquiring breast cancer.

Session Objectives:

1. To discuss the relevance and application of tomosynthesis in breast imaging.
2. To understand the indications and use of breast MRI in pre-menopausal women.
3. To appreciate the current debate regarding the appropriateness of breast screening programmes.

A-0007 08:35

A. Tomosynthesis

H. Yule; Cardiff/UK

The aim of the presentation is to provide a basic introduction to digital breast tomosynthesis (DBT) and the principles that underpin this technique. An overview in general of the current evidence to support the use of DBT in clinical practice. A discussion of the impact of DBT in terms of mammographic practice to include technique and positioning.

Learning Objectives:

1. To review the technology underpinning tomosynthesis.
2. To understand the current evidence base for use of tomosynthesis.
3. To appreciate results from the UK TOMMY trial and others.

A-0008 08:58

B. Breast imaging in young females: the role of MRI

M.M. Ribeiro; Lisbon/PT (margarida.ribeiro@estel.ipl.pt)

Nowadays, Magnetic Resonance Imaging (MRI) is used routinely to provide anatomic details and contrast while, allows the evaluation of the functionality of the organ, the quantification of the lesions and histological information. Although breast cancer in young women is relatively uncommon, affecting about 4-6% of women under the age of 40 and less than 4% are diagnosed under the age of 35, there has been an increase in the number of breast cancers diagnosed in the premenopausal women. The first indication to Breast MRI from EUSOBI is the screening of women at high risk of breast cancer; however, diagnosing breast cancer in women under 40 years old is more difficult as their breast tissue is, generally, denser. There have been significant advances in technical developments and clinical applications with the goal to improve image acquisition, early cancer diagnosis, treatment monitoring, the prognostic indication and predictive biomarkers. The discussion is centred on the new acquisition techniques to improve cancer detection specificity in premenopausal women and the comparatively to mammography and ultrasound. The limitations of the technique and, in the other hand, the technology improvements like technical developments on advanced quantitative MRI, the breast MRI in clinical trials, the fast techniques, updates on DWI, perfusion, novel contrasts, spectroscopy and the impact of artificial intelligence on breast MRI research and clinic, will be addressed. We cannot forget the strategies to increase the early prevention, regarding the appliance of best practices around the world and incorporating the psychosocial concerns of the disease.

Learning Objectives:

1. To understand current sensitivity of MRI when imaging the breast.
2. To discuss the varying sensitivities of mammography and ultrasound according to age.
3. To appreciate the potential use of abbreviated MRI sequences.

A-0009 09:21

C. Breast screening programmes: current evidence

S. Hofvind; Oslo/NO

"no abstract submitted"

Learning Objectives:

1. To identify advantages and disadvantages of breast screening regarding false positives.
2. To appreciate current debate both for and against organised screening programmes.
3. To consider alternatives to breast screening.

Mobile devices in radiology

A-0010 08:30

Chairperson's introduction

O. Ratib; Geneva/CH

Mobile devices such as tablets and high-resolution smartphones are becoming widely available providing convenient mobile solutions for physicians and healthcare providers to access imaging data. This is particularly attractive in medicine where "nomad" physicians who need to be able to access relevant patient data and images anywhere-anytime in their daily practice where they are rarely a single location. While they may not always be adequate for routine diagnostic tasks, they provide a convenient mobile solution for on-call and remote consultations. There are different types of software architecture that can be implemented for such tasks. Two major different design are: (1) online web-based applications where the device serves as a "thin-client" to display images rendered and manipulated on a remote computer and (2) local applications that reside on the mobile device and can run independently after images have been downloaded on the device. The first solution requires the user to be constantly connected to the network, while the second solution can continue to function after disconnecting from the network. Most vendors are starting to provide web access to their imaging solutions that can be accessed from mobile devices. Web access can, however, be slow and dependent on reliable access to wireless network.

Session Objectives:

1. To give an overview of tools available on mobile devices for education and exam reporting.
2. To underline the impact of mobile devices in routine clinical activity.
3. To learn about the legislative backbone and potential drawbacks of mobile technology.

A-0011 08:35

A. Security and confidentiality aspects of mobile computing

E.R. Ranschaert; Tilburg/NL (ranschaert@telenet.be)

Medical specialists and radiologists are using mobile devices to share and exchange medical information and images with other healthcare professionals. Usually, they need advice regarding a diagnosis or treatment, sometimes in an acute setting. Mobile devices with viewing apps and messaging services such as WhatsApp are frequently used for such purpose. Transmission of patient data by viewing apps or messaging services, however, does have several risks and limitations, mostly related to the security and privacy of patients, but also from an ethical and legal point of view. Some questions need to be answered: is this type of communication accurate for diagnosis, is it secure and legally allowed? What regulations or guidelines are available and what legislation is applicable? What secure options are available? In this scientific focus session these issues will be discussed in more depth.

Learning Objectives:

1. To provide an overview of technical solutions for patients' image and data mobility.
2. To provide a risk assessment analysis (data loss, privacy, etc.) of mobile technology.
3. To give an overview of European legislation in relation to patient image and data mobility.

Author Disclosure:

A-0012 08:58

B. Added value of mobile devices in education

E. Kotter; Freiburg/DE (elmar.kotter@uniklinik-freiburg.de)

E-learning has been used in radiology for more than 30 years. The lecture will give an introduction to and an overview of e-learning systems for radiology with emphasis on e-learning on mobile devices. Advantages and limitations of mobile e-learning will be discussed. An outlook to the future development of e-learning will be given.

Learning Objectives:

1. To give an overview of tools available for e-learning.
2. To explore the potential impact of e-learning in the daily radiological practice.
3. To explore future developments and limits of e-learning.

Author Disclosure:

E. Kotter: Advisory Board; Agfa.

A-0013 09:21

C. Recommendations for reporting on mobile devices

N.H. Strickland; London/UK

"no abstract submitted"

Learning Objectives:

1. To give an overview of available DICOM viewers and software for reporting imaging studies.
2. To discuss technical requirements of mobile devices for use in imaging interpretation.
3. To provide insight on future developments of imaging viewing technology.

09:44

Panel discussion: Can mobile technology supplement stationary technology in radiology?

Discussion will address main controversies of the use of mobile technology in a clinical environment such as image quality, data mobility, safety and legal issues, etc.

08:30 - 10:00

Room N

EuroSafe Imaging Session

EU 1

Cardiovascular effects after radiotherapy for breast cancer: the European MEDIRAD Project

A-0014 08:30

Chairpersons' introduction (part 1)

A. Crijs; Groningen/NL (a.p.g.crijs@umcg.nl)

Radiation-induced major cardiac events (MCEs) are becoming increasingly relevant for breast cancer (BC) patients, affecting the quality of life and increasing morbidity and mortality. Information regarding the relationship between radiation dose to cardiac substructures and MCEs and their early subclinical precursor cardiovascular effects is needed to develop preventive strategies for radiation-induced MCEs. In this session, current knowledge of dose-effect relationships will be discussed as well as which important information is still lacking. The European MEDIRAD project comprises a multicenter retrospective cohort study aiming at the development and external validation of prediction models for MCEs. In addition, a prospective multicenter study for identification of early subclinical cardiovascular effects with three different cardiac imaging modalities; echocardiography, cardiac MRI and cardiac CT is ongoing. We will present how the European MEDIRAD project provides the data needed for the development of individualised preventive strategies for radiation-induced MCEs. Finally, the technical issues of cardiac CT and MRI in detecting early subclinical morphological and/or functional cardiovascular effects will be discussed.

Session Objectives:

1. To learn about major cardiovascular events after radiotherapy for breast cancer.
2. To understand the importance of assessing their relationship with radiation dose to cardiac substructures.
3. To appreciate the potential of imaging biomarkers for their early detection and their role in prevention strategies.

Author Disclosure:

A. Crijs: Research/Grant Support; supported by the European Community's Horizon 2020 Programme.

A-0015 08:33

Chairpersons' introduction (part 2)

G. Frija; Paris/FR (guy.frija@aphp.fr)

MEDIRAD (Implications of Medical Low Dose Radiation Exposure) is a multidisciplinary, cross-cutting project funded under the Euratom research and training programme 2014-2018 under grant agreement No. 662287. The four-year MEDIRAD project kicked off in June 2017 and is led by the European Institute for Biomedical Imaging Research (EIBIR). The consortium brings together a wide range of expertise, with 33 partners from 14 European countries, and involves research groups that focus on radiology, nuclear medicine, radiotherapy, dosimetry, epidemiology, biology, bioinformatics, modelling, radiation protection, and public health. MEDIRAD has three major operational objectives. Improving organ dose estimation and registration; evaluating and understanding the mechanisms of the effects of medical radiation exposure, focusing on two outcomes of public health relevance (cardiovascular effects of radiotherapy in breast cancer treatment and cancer risk following CT scanning of children and adolescents); and, developing science-based policy recommendations for the effective protection of patients, workers, and the general public. This session will focus on cardiovascular effects after radiotherapy for breast cancer and introduce the Early-Heart Study developed under work package 4 of the MEDIRAD project.

Session Objectives:

1. To learn about major cardiovascular events after radiotherapy for breast cancer.
2. To understand the importance of assessing their relationship with radiation dose to cardiac substructures.
3. To appreciate the potential of imaging biomarkers for their early detection and their role in prevention strategies.

A-0016 08:36

Overview of dose-effect relationships and their use in strategies for prevention of cardiovascular effects after radiotherapy for breast cancer

A. Crijs; Groningen/NL (a.p.g.crijs@umcg.nl)

Breast cancer (BC) radiotherapy leads to incidental cardiac irradiation, resulting in an increased risk of various major cardiac events (MCEs). The risk of a MCEs increases linearly by 7.4% per Gray of the mean heart dose. Recent studies have shown that MCEs may already appear within 5-10 years of radiotherapy. Due to an increased incidence of BC in Europe and a continuously improving survival rate, the prevalence of BC survivors at risk of MCEs is also growing. Information regarding the relationship between radiation dose to cardiac substructures and MCEs is scarce. Knowledge about early subclinical cardiovascular effects (ESCEs) induced by radiotherapy that eventually develop into MCEs is also largely lacking. We need this information to optimise radiation dose distributions as a primary preventive strategy. In addition, we need tools to identify BC patients -already treated with radiotherapy- who have a high risk of future treatment-related MCEs. These patients may benefit from secondary preventive strategies. Finally, information on potential targets for developing strategies to prevent or delay progression into clinically apparent is not currently available. The European MEDIRAD Project; Modern imaging techniques such as echocardiography, cardiac MRI and cardiac CT can be used to identify morphological and functional ESCEs, considered risk factors for developing MCEs. This information will provide better insight into the biological mechanisms of radiation-induced MCE and may provide potential targets for secondary prevention. In addition, by relating imaging-derived ESCEs and/or MCEs to local radiation dose, prediction models can be developed to optimise radiation planning techniques.

Learning Objectives:

1. To learn about the increased risk of various major cardiac events after incidental exposure of the heart during breast radiotherapy.
2. To understand that multivariable prediction models are needed describing the relationship between radiation dose to cardiac substructures and (early) cardiovascular effects.
3. To appreciate the role of modern cardiac imaging techniques in providing detailed information regarding early cardiovascular effects after radiotherapy.

Author Disclosure:

A. Crijs: Research/Grant Support; supported by the European Community's Horizon 2020 Programme.

08:52

Discussion

A-0017 08:57

Optimisation of multivariable prediction models for major cardiac events after radiotherapy for breast cancer

D.S. Spoor; Groningen/NL (d.s.spoor@umcg.nl)

The relationship between radiation dose to the heart in breast cancer radiotherapy (RT) and various major cardiac events (MCEs) can be described with normal tissue complication probability (NTCP) models. Previous studies showed the predictive value of the mean heart dose (MHD) for the risk of acute

coronary events (ACE). Recent studies suggest that the dose delivered to cardiac substructures, like the left ventricle, might be better predictors of MCEs. Furthermore, preliminary results of ongoing work suggest that radiation dose to coronary arteries, particularly the left anterior descending artery, may have superior predictive value. More accurate risk estimations for MCEs requires improved NTCP-models, which requires large retrospective cohort studies with sufficient length of follow-up to capture sufficient numbers of cardiac events. MEDIRAD-BRACE is an international multicenter retrospective cohort study. The study will include 7000 female breast cancer patients treated with primary surgery and postoperative RT treated from 2005 to 2014 and who were aged 40-75 years at a time of RT start. A test cohort of 5000 patients will be used to develop NTCP-models for MCEs, which will be validated using a validation cohort consisting of 2000 patients. The primary endpoint of the study is an ACE after completion of treatment, and secondary endpoint comprises other MCEs. The resulting models can be used to identify patients at increased risk for MCE, which allows for the development of primary and secondary preventive measures. Moreover, NTCP-models may be further improved by incorporating imaging-derived subclinical cardiac effects that precede MCE. This is studied in MEDIRAD-EARLY HEART.

Learning Objectives:

1. To appreciate how the MEDIRAD-BRACE study will provide optimised multivariable prediction models for major cardiac events.
2. To learn that optimal prevention of radiation-induced major cardiac events requires early detection/imaging biomarkers.

09:13

Discussion

A-0018 09:18

The MEDIRAD Early-Heart study

S. [Jacob](mailto:jacob@irsn.fr); Fontenay aux Roses/FR (sophie.jacob@irsn.fr)

Radiotherapy (RT) plays a major role in breast cancer (BC) treatment. However, BC RT can lead to incidental irradiation of the heart, resulting in cardiac complications with an increased risk of various heart diseases arising many years after RT. Long before the onset of clinically significant late cardiac complications, subclinical cardiac changes may occur over months or years after RT that can be detected using anatomical and functional cardiac imaging. Therefore, detecting early signs of cardiotoxicity and determining the relationship between radiation dose to specific cardiac structures and subclinical cardiac changes is crucial for primary/secondary prevention. In the frame of the MEDIRAD European project, the EARLY-HEART study was launched in 2017. This five European centres prospective cohort study will include approximately 250 unilateral BC women aged 40-75 years treated with RT without chemotherapy and followed for two years. Baseline (before RT) and follow-up data (6 and 24 months after RT) include cardiac imaging measurements: myocardial deformation is evaluated with myocardial strain imaging (2D-speckle-tracking echocardiography); cardiac magnetic resonance imaging is performed to detect subtle changes in cardiac function and structure; cardiac computed tomography is performed to evaluate coronary artery lesions. Radiation exposure to cardiac structures based on 3D-dosimetry is precisely evaluated for all patients. Dose-response relationship will allow modelling radiation-induced occurrence and evolution of subclinical cardiac lesions to develop early cardiotoxicity prediction models. Based on emerging research in advanced imaging modalities, this study will allow enhanced detection and prediction of early radiotherapy-induced cardiotoxicity and patients' care.

Learning Objectives:

1. To appreciate that there is already some information from cardiac imaging studies regarding early cardiovascular effects after breast cancer radiotherapy.
2. To learn how the MEDIRAD Early-Heart study will provide information regarding imaging biomarkers of early cardiovascular effects after radiotherapy for breast cancer.
3. To understand that cardiac imaging can provide clues for underlying mechanisms of radiation-induced major cardiac events.

09:34

Discussion

A-0019 09:39

Imaging biomarkers of cardiovascular effects of incidental cardiac radiation

E. [Mousseaux](mailto:mousseaux@egp.ap-hop-paris.fr); Paris/FR (elie.mousseaux@egp.ap-hop-paris.fr)

Since Radiotherapy (RT) has been linked to cardiac diseases, detection of early signs of radiotherapy-induced cardiotoxicity (RTIC) is crucial and challenging for prevention. To identify and validate cardiac imaging biomarkers of RTIC arising within two years after breast cancer RT. CT and MRI will be done at baseline, and at RT+6 months (MRI), and RT+24 months (CT+MRI) during follow-up. By using MRI, in association to conventional ventricular function analysis of both ventricles, myocardial strain (deformation) will be quantified by studying cavity contours length changes ($\Delta l/l^{\circ}$) during the cardiac

cycle in each of four cardiac chambers. In addition, after myocardial T1 estimation of the left ventricle before and after gadolinium injection, derived indices of intra- and extra-cellular lesions will be calculated since RT is likely to modify components of these two compartments (cell destruction, inflammation and/or appearance of interstitial fibrosis). Cardiac CT will also be performed to evaluate coronary artery, valves and pericardium lesions by estimating local and global calcium score with a non-enhanced acquisition, and by subjectively analysed all these structures with enhanced acquisitions before and after RT. All analysis will be done in a core lab without knowledge of any possible clinical events that may occur and of information regarding the site of a tumour and RT procedures. Based on emerging results in CT and MRI to analyse sensitive biomarkers of cardiac lesions, hypotheses of the study are that early signs of RTIC could be detected to predict irreversible cardiotoxicity better and to improve patients' care.

Learning Objectives:

1. To appreciate how radiation-induced coronary artery lesions can be studied by cardiac CT.
2. To understand how MRI can be used to evaluate myocardial tissues abnormalities induced by incidental cardiac radiation, including morphology, function and tissue abnormalities.

09:55

Discussion

08:30 - 10:00

Room O

Vascular

RC 115

Visceral arteries

A-0020 08:30

Chairperson's introduction

J.A. [Reekers](mailto:Reekers@amsterdam.nl); Amsterdam/NL

The visceral vessels are the superior and inferior mesenteric artery, coeliac trunk, hepatic artery and splenic artery and the renal arteries. There is a wide variety of pathology including both stenotic disease and dilating vessel disease. There is also a wide variety of interventional treatment options to treat these problems.

Session Objectives:

1. To learn about incidence and aetiology of visceral arteries diseases.
2. To become familiar with clinical symptoms and evaluation in visceral arteries diseases.
3. To indicate the role of radiology in diagnosis and treatment of the visceral arteries.

A-0021 08:35

A. Diagnosis of vascular compression syndromes

B.E. [Cil](mailto:cil@kuh.ku.edu.tr); Istanbul/TR (bcil@kuh.ku.edu.tr)

Vascular compression syndromes are clinical entities caused by the entrapment of veins or arteries between rigid or semirigid anatomic structures or compression of hollow viscera by vascular structures. Although they occur infrequently (less than 1% of the general population are affected), they may cause significant disease, including median arcuate ligament syndrome, May-Thurner syndrome, nutcracker syndrome, superior mesenteric artery syndrome, and ureteropelvic junction obstruction. These syndromes are usually seen in otherwise healthy young patients, among whom underdiagnosis is common. Most occurrences of vascular compression are associated with an underlying anatomic abnormality. The diagnosis must be based on both clinical and radiologic findings. Digital subtraction angiography, venography or Doppler ultrasonography can provide hemodynamic information in cases of vascular compression. However, computed tomographic angiography and magnetic resonance angiography are particularly useful in that it allows comprehensive, fast evaluation of the anatomy and resultant morphologic changes. Symptomatic patients may require treatment, which is generally surgical due to the need for the relief of external compression. However, endovascular techniques are also increasingly being used to treat venous compressions.

Learning Objectives:

1. To become familiar with abdominal arterial and venous compression syndromes.
2. To learn about functional imaging techniques in assessment of vascular compression syndromes.
3. To become familiar with the typical imaging findings in abdominal compression syndromes and their clinical relevance.

Postgraduate Educational Programme

A-0022 08:58

B. Acute and chronic mesenteric ischaemia

M. [Zins](mailto:mzins@hpsj.fr); Paris/FR (mzins@hpsj.fr)

Acute mesenteric ischemia (AMI) corresponds to the inadequate blood supply to the gastrointestinal tract resulting in an ischemic and inflammatory injury that may progress to necrosis of the bowel wall. Prognosis is poor with a mortality rate superior to 95 % without treatment, dropping to around 70% when surgical treatment is performed. Contrast-enhanced computed tomography (CT) has become the cornerstone of the diagnosis by showing features of vascular disorder (occlusion and/or low blood flow) and features of intestinal ischemic injury. Imaging-based patient management is required, and multimodal and multidisciplinary management should be introduced. The treatment involves gastroenterologists, vascular and digestive surgeons, cardiologists, intensivists, and diagnostic and interventional radiologists. This lecture will give an overview of pathophysiology, diagnosis, and treatment of Acute and Chronic Mesenteric Ischemia. The goal is to improve the understanding and management of this life-threatening condition.

Learning Objectives:

1. To become familiar with occlusive and non-occlusive, mesenteric ischaemia.
2. To understand the differences between acute and chronic ischaemia.
3. To learn about the importance of fast and correct diagnosis in acute mesenteric ischaemia.

A-0023 09:21

C. Endovascular treatment of mesenteric ischaemia

R. [Morgan](mailto:robert.morgan@stgeorges.nhs.uk); London/UK (robert.morgan@stgeorges.nhs.uk)

Mesenteric ischaemia is divided into acute and chronic mesenteric ischaemia. The main imaging modalities of mesenteric ischaemia are CT angiography and duplex ultrasound. Acute mesenteric ischaemia (AMI) is an abdominal emergency and is usually due to acute thrombotic or embolic occlusion of one or more of the arteries supplying the gastrointestinal tract. In practice, this is often the superior mesenteric artery (SMA). In some patients, acute mesenteric ischaemia is caused by acute mesenteric venous thrombosis, although such cases are unusual. Standard therapy is by surgical thrombectomy, embolectomy or bypass. In cases where there are no signs of irreversible intestinal ischaemia, patients may be suitable for endovascular treatment, either transcatheter thrombolysis or thrombectomy. Chronic mesenteric ischaemia (CMI) causes postprandial abdominal pain, "food-fear" and weight loss. CMI is usually due to severe stenosis or occlusion of two or three of the coeliac trunk, SMA or inferior mesenteric artery. Endovascular treatment is the primary first method used to treat CMI. Stenting is usually performed in preference to angioplasty. There are insufficient data to decide which endovascular method is best and there are no data on the use of drug-eluting technology.

Learning Objectives:

1. To review indications for endovascular treatment of mesenteric ischaemia.
2. To become familiar with the technical possibilities of endovascular repair of visceral arteries.
3. To learn about risks and complications of endovascular treatment of mesenteric ischaemia.

09:44

Panel discussion: Radiologists as the best case managers in acute and chronic mesenteric ischaemia

How to implement MRI neuro advanced techniques at home

Moderator:

P.C. Maly Sundgren; Lund/SE

A-0024 08:30

A. Practical approach to cerebral perfusion techniques

H.R. [Jäger](mailto:jager@london.uk); London/UK

"no abstract submitted"

Learning Objectives:

1. To learn about the essentials in MRI perfusion techniques.
2. To understand how to interpret the data in brain perfusion MRI.
3. To know the limitations in perfusion MRI studies.

A-0025 09:00

B. How to read susceptibility-weighted imaging (SWI)

S. [Haller](mailto:haller@me.com); Carouge/CH (sven.haller@me.com)

Susceptibility weighted imaging (SWI) is increasingly used in clinical routine and is useful notably for the detection of hemosiderin (in a variety of hemorrhagic conditions) as well as iron deposition (in a variety of neurodegenerative diseases). The first part will discuss the essential technical aspects of SWI, and how imaging parameters will influence imaging contrast and consequently image analysis and results. The second part will assess imaging, interpretation and implications and notably the differential diagnosis of cerebral microbleeds, which occur in a variety of conditions including arterial hypertension, cerebral amyloid angiopathy (CAA), CADASIL (Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy), trauma (hemorrhagic diffuse axonal injury DAI) and brain irradiation. The third part will discuss imaging of the nigrosome 1 of the substantia nigra, also known as swallowtail sign, as an imaging marker of Parkinson Disease and Dementia with Lewy bodies. The final fourth part will discuss applications of SWI in a variety of vascular and neurodegenerative disorders including NBAI (neurodegeneration with brain iron accumulation), ASL (amyotrophic lateral sclerosis), clot imaging in acute stroke, and iron deposition during ageing.

Learning Objectives:

1. To be familiar with the practical basics of MRI SWI sequences.
2. To learn what information we can get from the SWI sequence.
3. To understand the importance of applying the SWI technique in individual patients.

A-0026 09:30

C. How to read diffusion tensor imaging (DTI)

R. [Gasparotti](mailto:gasparotti@med.unibs.it); Brescia/IT (gasparotti@med.unibs.it)

Diffusion Tensor Imaging provides in vivo visualisation of white matter tracts by voxel x voxel mapping of the anisotropy and local direction of fibres. Conventional MR imaging is limited to detecting macroscopic brain changes, while DTI quantifies diffusion characteristics within microscopic nerve fibre bundles and is thought to represent axon density, diameter, and continuity, myelin and interstitial water content. Due to recent advances in the technical design of sequences a DTI study of the brain with 64 directions and 1.8 mm voxel size can be obtained in 5 minutes with a 3T MR unit. Therefore DTI can be easily included in routine clinical MR protocols. There are no standardised approaches in DTI pre and postprocessing despite the availability of proprietary software and several freely distributed software packages providing good quality tractography of the brain white matter bundles. The easiest implementation of DTI in clinical practice is based on deterministic tractography, which provides an acceptable reproducibility in the identification and quantitative analysis of the brain white matter bundles through a rather standardised approach. Common clinical applications of DTI in single subjects are represented by brain neoplasms, neurodegenerative disorders and traumatic brain injuries. DTI-based tractography is widely used for presurgical planning and is a powerful tool in the evaluation of major WM fibre bundles; it has also a positive impact on neurosurgical resection, disease prognosis, and preservation of brain function.

Learning Objectives:

1. To learn the principals of DTI imaging in neuroradiology.
2. To appreciate the practical value of DTI in different neurological disorders.
3. To be familiar with pitfalls of DWI and DTI imaging - common language with neurosurgeons.

08:30 - 10:00

Special Focus Session

SF 1

Screening with imaging: a new era?

A-0027 08:30

Chairperson's introduction

A. [Devaraj](mailto:devaraj@london.uk); London/UK

This session will review common aspects of screening for lung cancer, colorectal cancer and breast cancer: namely the evidence for the particular screening programme, the additional challenges of implementing screening in the real world compared to a research setting, and future developments in each area. Common areas of debate such as overdiagnosis will also be addressed.

Postgraduate Educational Programme

Session Objectives:

1. To understand how screening is currently implemented in Europe.
2. To understand the challenges familiar to all screening programmes when aiming to continually enhance quality and minimise harms.
3. To understand the emerging technologies in screening of lung, breast and colorectal cancer.

A-0028 08:35

Screening of lung cancer with low dose CT

M. [Prokopp](#); Nijmegen/NL

"no abstract submitted"

Learning Objectives:

1. To understand the current situation with lung cancer screening in Europe.
2. To understand the challenges of implementing a new screening programme for lung cancer.
3. To discuss areas for quality assurance and standardisation in lung cancer screening.

A-0029 08:58

Screening of colorectal cancer with CT colonography

A. [Laghi](#); Latina/IT (andrea.laghi@uniroma1.it)

Colo-rectal cancer (CRC) is currently the second leading cause of cancer-related deaths in males and females. However, it could be easily prevented because of the favourable natural history. Radiologists can now fully support CRC screening, thanks to the availability of Computed Tomography Colonography (CTC). Three randomised clinical trials, investigating the performances of CTC in asymptomatic average-risk individuals, demonstrated good CTC patient acceptance, lower than FOBT, but higher than FS and CC, and good CTC adenoma detection rate, slightly lower than CC, but much higher than FS and FOBT. CTC in the setting of CRC screening has different roles, depending if an organised CRC screening program is available or not. If it is not available, CTC might be used as an opportunistic screening test together with FOBT/ FIT, FS and CC. In this case, individuals should be informed about the benefits and possible drawbacks of CTC in comparison with other tests. In many European countries, where established screening programs based on FOBT/FIT are available, CTC can be used as a back-up for an incomplete CC, performed after a positive FOBT/FIT. Alternatively, CTC might be offered as an alternative test in those patients (they are not few) tested positive at FOBT/FIT, but who refuse CC. The next goal would be to introduce CTC as a population screening test, replacing FOBT/FIT. However, the demonstration of higher cost-effectiveness compared with the available screening test is still missing and the major barrier preventing the endorsement by policymakers.

Learning Objectives:

1. To understand the rationale for a colorectal cancer screening programme.
2. To be updated about current experiences on screening CT colonography.
3. To learn about advantages and limitations of CT colonography in comparison with other colorectal cancer screening tests.

A-0030 09:21

Screening of breast cancer with abbreviated MRI

C.K. [Kuhl](#); Aachen/DE (ckuhl@ukaachen.de)

Early diagnosis improves the survival of women with breast cancer. Mammographic screening improves early diagnosis of breast cancer. And yet, there appears to be room for improvement. Major shortcomings of mammographic screening are overdiagnosis of prognostically unimportant cancer, as well as underdiagnosis of cancers that are indeed relevant. Failure to detect biologically relevant breast cancer with mammographic screening is driven by host-related factors, i.e. breast tissue density, but also tumour-related factors: Biologically relevant cancers may exhibit imaging features that renders them indistinguishable from normal or benign breast tissue on mammography. These cancers will then progress to become the advanced-stage interval cancers observed in women undergoing mammographic screening. Since breast cancer continues to represent a major cause of cancer death in women, the search for improved breast cancer screening method continues. Abbreviated breast MRI has been proposed for this purpose because it will greatly reduce the cost associated with this method, due to a greatly reduced magnet time (down to 3 minutes), but especially also due to a greatly abridged image interpretation time, i.e. radiologist reading time. This lecture will review the current evidence and presents the EA1141 trial designed to investigate the utility of abbreviated breast MRI for screening average-risk women with dense breast tissue.

Learning Objectives:

1. To list the cancer detection rates of radiographic, ultrasound and MR imaging for screening of breast cancer.
2. To describe the respective diagnostic accuracies published for breast MRI with abbreviated vs full diagnostic protocols.
3. To list rates and causes of over- and underdiagnosis of breast cancer in current breast cancer screening programmes.

Musculoskeletal: bones and soft tissues

Moderator:

A.H. Karantanas; Iraklion/GR

A-0031 08:30

Bone marrow diseases

K. [Verstraete](#); Ghent/BE

Bone marrow consists of trabecular bone, a stroma of connective tissue, hematopoietic cells (red marrow) and fat (yellow marrow). Distribution of red and yellow marrow is age-dependent, with gradual conversion of red to yellow marrow in the limbs during childhood, and patchy heterogeneity in the spine in the elderly patient. There are many causes of reconversion from yellow to red bone marrow, like smoking, long distance running, obesity, anaemia, erythropoietin, etc. Depletion may occur in aplastic anaemia and after radiation therapy. Gelatinous transformation is seen in anorexia nervosa, cachexia, HIV and after successful therapy in multiple myeloma. Bone infarction and avascular necrosis are well-delineated areas of dead bone marrow. The value of different imaging techniques, including plain radiography, (dual-energy)-CT, bone scintigraphy, PET and the most sensitive technique, MRI (conventional T1, T2, fat suppression techniques, in-phase, out-phase and diffusion imaging), will be explained. The imaging characteristics of many diseases will be reviewed (diffuse bone marrow replacement in hematologic diseases, multiple myeloma, metastases; treatment-related changes of bone marrow, primary bone tumors, and multiple causes of bone marrow edema, like bone contusion, stress fracture, insufficiency fracture, Modic changes, spondylodiscitis, osteomyelitis, abscess, arthritis and specific bone tumors).

Learning Objectives:

1. To describe the typical features of normal bone marrow.
2. To determine origin of bone marrow changes.
3. To present the imaging characteristics of a bone marrow disease of the different types.

A-0032 09:00

Soft tissue tumours

V.N. [Cassar-Pullicino](#); Oswestry/UK (Victor.Pullicino@nhs.net)

All imaging modalities can play a role in the diagnosis and management of soft tissue tumours and pseudotumours with a variable contributory performance to both sensitivity and specificity. MRI steals the show with an unparalleled role in soft tissue assessment ranging from detection, localisation, characterisation, identifying multiple lesions, other syndrome stigmata, the probability of benignity/malignancy, local staging and recurrence identification. Sonography does have a supporting role especially in the initial assessment of the likelihood of cystic/benign/abnormal malignant Colour Doppler flow patterns. This presentation aims to provide a distillation of the knowledge regarding soft tissue tumour imaging which can be applied in practice using a stepwise analytical approach. Despite an overwhelming spectrum of potential histological diagnosis, the radiologist needs to remember that eight benign and six malignant lesions account for 80% of all soft tissue tumours.

Learning Objectives:

1. To determine the origin of a soft tissue tumour (e.g. fat, neural, vascular, etc.).
2. To present current imaging techniques for evaluation of soft tissue tumours.
3. To discuss the imaging findings which are important for the diagnosis of soft tissue tumours.

A-0033 09:30

Bone tumours

J.L. Bloem; Leiden/NL (j.l.bloem@lumc.nl)

Bone sarcomas are rare (0.2% of all neoplasms, annual incidence in Europe is 0.8 per 100,000 population), in contrast to benign bone tumours and the so-called tumour-like lesions. The incidence of these benign entities is relatively high, but not known exactly as these are often asymptomatic. The WHO (version 2013) classified benign and malignant bone tumours in 13 main categories; chondrogenic, osteogenic, fibrogenic, fibrohistiocytic, hematopoietic, osteoclastic giant cell rich, notochordal, vascular, myogenic, lipogenic, undefined neoplastic nature and miscellaneous tumours. Each category is further subdivided into 1-14 tumour types. Imaging plays an important role in diagnosis, monitoring therapy, staging, and detecting recurrent disease. Diagnosis is mainly based on conventional radiography using morphologic appearance in combination with location, and age. Advanced imaging techniques are used for local staging (MR), detection of metastases (chest CT), monitoring therapy (MR, ultra-sound, PET-CT), detecting recurrence (MR, ultra-sound, PET-CT). Typical imaging features based on the WHO classification system will be presented with a focus on conventional radiography, common tumours, and relevance.

Learning Objectives:

1. To review the classification of bone tumours.
2. To present current imaging techniques for evaluation of bone tumours.
3. To describe the typical features of common bone tumours.

New Horizons Session

NH 1

The role of imaging in the era of liquid biopsy

A-0034 08:30

Chairperson's introduction

D. Regge; Turin/IT (daniele.regge@ircc.it)

Tumours shed DNA fragments in the bloodstream when undergoing apoptosis. Technology is now available that allows genotyping of circulating tumour DNA (ctDNA) to detect somatic alterations found in tumours by sampling blood, a test commonly described as a liquid biopsy. This technique has shown promise in the detection of cancer in its early stages, in the identification of cancer recurrence following surgery and to monitor antineoplastic treatment longitudinally. Detecting the evolving polyclonal mechanisms of drug resistance hints at what personalised treatment could look like in the future. If liquid biopsy proves up to expectations, the role of imaging in the assessment of cancer will have to be revised. This session will explore the potential impact of liquid biopsy on diagnostic imaging from the perspective of the molecular biologist and of the imaging doctor with the aim of drawing-up a shared view.

Session Objectives:

1. To learn about the role of liquid biopsy in cancer detection and tumour surveillance.
2. To become familiar with advances of imaging in cancer detection and characterisation.
3. To understand the revised role of imaging in monitoring of cancer therapy.
4. To explore how combining molecular and imaging metrics could improve clinical decision in cancer patients.

A-0035 08:35

Liquid biopsy in perspective: colorectal cancer as a model system

A. Bardelli; Turin/IT (alberto.bardelli@ircc.it)

When metastatic colorectal cancers are challenged with targeted agents almost invariably a subset of cells insensitive to the drug emerges. As a result, in most instances, targeted therapies are only transiently effective in patients. Strategies to prevent or overcome resistance are therefore essential to design the next generation of clinical trials. How can we overcome the near-certainty of disease recurrence following treatment with targeted agents? To address this question a deeper understanding of the evolutive nature of cancer cells is necessary. We used colorectal cancer (CRC) as a model system to test the hypothesis that by understanding tumour's evolution the emergence of drug resistance can be controlled. We find that clonal dynamics can be monitored in real time in the blood of patients, and liquid biopsies can be used to intercept the emergence of resistant clones before relapses are clinically manifest. We discovered that a multistep clonal evolution process driven by progressive

increases in drug fitness underlies the development of resistance in cells and patient avatars. To have long-term efficacy, the use of targeted therapies must take into account the continuous evolution of cancer cells, that is to say, therapies must adapt to tumour evolution. One possibility is to anticipate the changes the tumours will make. For example, we propose to use liquid biopsies to know early the mechanisms of resistance to EGFR blockade in individual patients, and devised further rounds of therapy accordingly.

Learning Objectives:

1. To explain the principles of liquid biopsy.
2. To review the role of liquid biopsy as a diagnostic tool for early diagnosis.
3. To learn about the role of liquid biopsy as a predictor of cancer recurrence.
4. To explore how liquid biopsy could complement imaging, from a molecular biologist's perspective.

A-0036 08:53

New imaging tools for cancer detection and characterisation

H.-P. Schlemmer; Heidelberg/DE (h.schlemmer@dkfz.de)

Prognostic and predictive imaging biomarkers are essential for personalised oncology, regarding both, research as well as clinical practice. With the backing of computer assistance, an increased amount and complexity of multiparametric and multimodal imaging data enable to precisely detect cancer including its origin, local infiltration pattern and distant spreading, to gain important functional/biological information about its individual aggressiveness and to monitor or even predict morphologic and functional tumour changes during therapy. Sophisticated image postprocessing tools serve to extract information in a quantitative, objective and reproducible way. Recent research on radiomics, deep learning and artificial intelligence even envisage gaining information, which is otherwise inaccessible to conventional visual image analyses by radiologists. But the potential of imaging is inevitably limited for intrinsic reasons, why in many clinical situations microscopic/molecular tissue analyses are still imperative. The collection and molecular analysis of circulating tumour cells, extracellular vesicles and/or cell-free nucleic acids from fluids, especially blood, is currently object of intensive research. It is even hoped that in certain cases non-invasive/ minimal-invasive, the so-called liquid biopsy may replace tissue biopsy. The integration of imaging with liquid biopsy accordingly opens the door to new diagnostic opportunities. Personalised oncology may significantly benefit from the integration of spatial/functional information from imaging and molecular information from a liquid biopsy. But various scientific and methodological issues have still to be addressed before this concept will become a valuable tool for clinical practice.

Learning Objectives:

1. To review the modern approach to early diagnosis with imaging.
2. To become familiar with the new imaging biomarkers for tumour characterisation.
3. To envisage how liquid biopsy and imaging could complement each other in cancer diagnostics.

A-0037 09:11

Is there still a role for imaging surveillance? And when?

V.J. Goh; London/UK (vicky.goh@kcl.ac.uk)

Cancer surveillance aims to detect disease recurrence at an early enough stage for further definitive treatment to be a success. Accurate quantification of disease burden & comprehensive localisation of disease sites is required to improve patient stratification for further therapy - definitive or otherwise. This ensures that progression-free survival is improved particularly for patients undergoing definitive therapy. Imaging may be utilised either as the primary surveillance tool or to localise disease sites once other techniques have detected recurrence. A liquid biopsy is a highly sensitive test, and one of the challenges for imaging is to be able to localise small burden disease if further treatment is an option. Ultimately, the choice of imaging modality and strategy for active surveillance has to balance sensitivity with cost-effectiveness. This lecture will explore current surveillance protocols for common cancers and the future role of imaging in the era of liquid biopsy.

Learning Objectives:

1. To explain the rationale of cancer surveillance.
2. To review current cancer surveillance imaging strategies.
3. To become familiar with new imaging tools for surveillance of patients with cancer.
4. To explore how liquid biopsy and imaging could improve detection of minimal residual disease.

Postgraduate Educational Programme

A-0038 09:29

Combining molecular and imaging metrics in cancer (radiogenomics)
K. [Pinker-Domenig](mailto:pinkerdk@mskcc.org); Vienna/AT (pinkerdk@mskcc.org)

With the genomic revolution in the early 1990s, medical research has been driven to study the basis of human disease on a genomic level and to devise precise cancer therapies tailored to the specific genetic makeup of a tumour. To match novel therapeutic concepts conceived in the era of precision medicine, diagnostic tests must be equally sufficient, multilayered and complex to identify the relevant genetic alterations that render cancers susceptible to treatment. With significant advances in training and medical imaging techniques, image analysis and the development of high-throughput methods to extract and correlate multiple imaging parameters with genomic data, a new direction in medical research has emerged. This novel approach has been termed radiogenomics. Radiogenomics aims to correlate imaging characteristics (i.e., the imaging phenotype) from different imaging modalities with gene expression patterns, gene mutations, and other genome-related characteristics and is designed to facilitate a deeper understanding of tumour biology and capture the intrinsic tumour heterogeneity. Ultimately, the goal of radiogenomics is to develop imaging biomarkers for an outcome that incorporate both phenotypic and genotypic metrics. Due to the non-invasive nature of medical imaging and its ubiquitous use in clinical practice, the field of radiogenomics is rapidly evolving, and initial results are encouraging. In this article, we will briefly discuss the background and then summarise the current role and the potential of radiogenomics in oncology.

Learning Objectives:

1. To explain the basic principles of radiogenomics.
2. To summarise the current clinical applications of radiogenomics.
3. To explore how radiogenomics could guide clinical decisions in the future.

Ultrasound simulation models in training and education: where are we going?

A-0039/A-0040 08:30

Chairpersons' introduction

D.A. [Clevert](mailto:Dirk.Clevert@med.uni-muenchen.de); Munich/DE (Dirk.Clevert@med.uni-muenchen.de),
P.S. [Sidhu](mailto:paulsidhu@btinternet.com); London/UK (paulsidhu@btinternet.com)

This session deals with the ever advancing practice of using simulators for education and training of ultrasound practitioners. Many new developments of technology related to the machines and simulators make this an attractive proposal. Experts in the field will detail experience and discuss the future directions. New simulators will be presented, and data will be discussed.

Session Objectives:

1. To learn about which technical procedures are proposed in a simulation-based curriculum in radiology.
2. To learn about advantages and disadvantages of the different types of ultrasound simulators available.
3. To learn about the possibility of using virtual reality and gamification for training.
4. To learn about the experience from different parts of Europe in using ultrasound simulation training.

Needs assessment of simulations-based training in radiology
L. [Nayahangan](mailto:leizl.joy.nayahangan@regionh.dk); Copenhagen/DK (leizl.joy.nayahangan@regionh.dk)

Radiology is rapidly evolving with the advent of sophisticated, state-of-the-art imaging modalities. The implementation of these advanced technologies requires the need for alternative training methods such as simulation to supplement the traditional apprenticeship approach. Simulation-based education has been adapted in radiology to provide trainees with the opportunities to practice different technical and diagnostic skills, including interpretative and non-interpretative skills. Many simulation-based training programs exist; however, they are most often developed based on the availability of simulation equipment, local interests or other practical considerations. The development of training programs should follow a systematic approach by starting with a general needs assessment to ensure that these are aligned with current trainee needs. The needs assessment follows a structured three-round Delphi method to identify technical procedures that are suitable for simulation-based training. This iterative approach involves a panel of key opinion leaders to gather information and achieve consensus regarding procedures for simulation training. Round 1 is a brainstorming phase to gather procedures that a newly qualified radiologist should be able to perform. Round 2 is rating the procedures using a needs assessment formula to explore frequency, the number of doctors, impact on patients and feasibility for simulation-based training. Round 3 involves the elimination and final prioritisation of the procedures. The needs assessment process using the Delphi method identifies and prioritises a list of technical procedures for simulation-based training. This list provides an important foundation for the planning and development of simulation-based training programs in Radiology.

Learning Objectives:

1. To learn about how to perform a needs assessment using the Delphi method.
2. To learn about how a needs assessment identified and prioritised technical procedures to be included in a simulation-based curriculum.
3. To learn about how the list of procedures may be used as guide for development of training programmes.

A-0042 09:00

Review of the available market of ultrasound simulators

M. [Bachmann Nielsen](mailto:mbn@dadlnet.dk); Copenhagen/DK (mbn@dadlnet.dk)

A number of simulators are available for training abdominal ultrasound examinations. A screen with limited number of knobs aims to resemble a clinical ultrasound machine. Most simulators will use a dummy torso and a look-a-like transducer and others will use a joystick or a mouse. To train the coordination of the probe positioning and the screen a simple cartoonish sonogram may suffice. The presentation will aim to present a number of simulators available as per February 2019 including simple simulators, high-end simulators comprised of 3D patient examinations, virtual reality simulators and simulators aimed for biopsy training. Each simulator will have its strengths and weaknesses. It is not clear which simulator to use for specific needs.

Learning Objectives:

1. To learn about different types of simulators on the market.
2. To learn about which are suitable for beginners or advanced levels, and which can be used for training in interventional ultrasound.
3. To learn about advantages and disadvantages of different types of ultrasound simulators.

A-0043 09:20

Gamification and virtual reality in medical simulation

L. [Konge](mailto:lars.konge@regionh.dk); Copenhagen/DK (lars.konge@regionh.dk)

The old "see-one, do-one, teach-one" approach to medical education is outdated. Simulation-based training provides evidence for better efficacy, less stress, better patient outcomes, and improved return-on-investment. The question is no longer if we should use simulators to train our future doctors but how. There is a huge implementation gap regarding simulation in medical education. Despite the solid evidence, simulation is still severely under-utilised as a teaching modality, and initial training on patients are still very common. Virtual reality simulators and gamification allow new trainees to measure their own progress and compete against peers - this is highly motivating and could be a driver for implementation.

Learning Objectives:

1. To learn about gamification as a tool in medical education.
2. To learn about virtual reality in medical education.
3. To learn which possible ways virtual reality and gamification could be implemented in ultrasound.

09:40

Panel discussion: Will there be an option to include these technics in our daily work and how could we improve the outcome?

E³ 121

Emergency radiology I

A-0044 08:30

A. Acute aortic syndrome

H. Alkadhi; Zurich/CH (hatem.alkadhi@usz.ch)

Computed tomography (CT) angiography represents the major imaging modality for the diagnosis of acute aortic syndromes. This lecture will review the various underlying diseases of the acute aortic syndrome, demonstrate typical imaging features enabling the diagnosis and discuss management options depending on the type, extent, and location of the disease. Clinical examples will be shown in this presentation.

Learning Objectives:

1. To understand the different types of acute aortic syndrome.
2. To learn about imaging findings and management options.

A-0045 09:15

B. Abdominal trauma

R. Basilio; Chieti/IT (rbasilio@unich.it)

Abdominal traumas can be classified into two categories: penetrating and blunt traumas. Abdominal injuries are more often observed in the setting of polytrauma: in fact, they are present in about 10% of patients admitted to level 1 trauma. However, only 11% of patients with abdominal trauma require laparotomy when a correct imaging-guide approach is performed. In fact, because the management of trauma patients mainly depends on the mechanism and severity of the trauma, it is crucial to choose the correct imaging modality and/or technique when evaluating a trauma patient on the basis of these two parameters. For example, an ultrasound examination, possibly integrated by contrast-enhanced ultrasonography, may be adequate to image a minor blunt abdominal trauma. This modality, however, is not appropriate when evaluating a severe blunt or penetrating abdominal trauma or even a polytrauma patient with a minor mechanism of injury. Multidetector CT is actually the modality of choice for evaluating severe trauma patients, accompanied by an appropriate CT protocol to image these patients so as to avoid missed injuries and to correctly detect abdominal solid organ injuries, mesenteric and intestinal injuries and abdominal vascular traumatic lesions. Moreover, due to the fact that during the past decades there has been a major change from operative to increasingly conservative management of abdominal traumatic injuries, even in patients with higher grades of injuries or those with older age, imaging features together with hemodynamic considerations play an essential role in the treatment choice: surgery, conservative management, endovascular treatment.

Learning Objectives:

1. To identify the signs of trauma.
2. To provide an indication of their clinical significance.

Patient-specific dosimetry

A-0046 08:30

Chairperson's introduction

E. Samara; Sion/CH (elina.samara@hopitalvs.ch)

The use of ionising radiation in medical imaging offers substantial benefits for the diagnosis and treatment of numerous medical conditions in children and adults. However, exposure to ionising radiation may be associated with harmful risks. Justification and optimisation as principles of radiation protection make radiation dosimetry fundamental. Physicians need to know the levels of exposure, and hence the risks from imaging examinations that they have to justify and operators of X-ray cases such as examinations of children and pregnant patients or screening examinations require specific organ dose estimations. Moreover, to prevent tissue reactions patient skin dose needs to be estimated during radiological interventional procedures. Patient characteristics, such as age, sex and size, should be taken into consideration

for specific patient dose assessments. Each modality (radiography, fluoroscopy, mammography, computed tomography, etc.) has its specificities and demands different methods to calculate the dose. Modern imaging modalities usually display conventional dosimetry metrics, such as dose-area product, incident air-kerma or computed tomography dose index that do not represent individual patient dose. Thus, numerous sophisticated concepts and methods have been proposed to estimate patient radiation dose that includes either physical measurements with dosimeters and anthropomorphic phantoms or computational measurements using Monte Carlo simulations. All these methods progressively allow to more accurate estimations of individual patient doses.

Session Objectives:

1. To understand the needs for personalised dosimetry.
2. To learn about existing and new methodologies used for patient dosimetry.
3. To understand the challenges for the implementation of patient-specific dosimetry.

A-0047 08:35

A. Breast imaging dosimetry

I. Sechopoulos; Nijmegen/NL (ioannis.sechopoulos@radboudumc.nl)

Mammographic dosimetry is a subject of intense interest due to the use of this imaging modality for population-based screening. However, established breast dosimetry methods do not result in patient-specific dose estimates. Rather, our current methods provide estimates of dose to a model breast, even if the actual technique used for a specific acquisition is taken into account. New insights into breast anatomy have provided us, for the first time, with estimates of how current dose predictions can differ from actual patient-specific doses. During this talk, the current method and model for breast dosimetry in mammography and digital breast tomosynthesis will be reviewed, and its capabilities and limitations discussed. How patient-specific breast dosimetry could be achieved and the current progress towards this goal will be presented, and what its potential applications could be will be discussed.

Learning Objectives:

1. To understand the current method to estimate organ dose in mammography and its limitations.
2. To understand breast dosimetry in emerging modalities.
3. To learn about upcoming approaches in breast dosimetry.

Author Disclosure:

I. Sechopoulos: Advisory Board; Fischer Imaging. Research/Grant Support; Siemens Healthcare, Canon Medical Systems. Speaker; Siemens Healthcare.

A-0048 08:58

B. Patient dosimetry in CT and CBCT

S. Edyvean; London/UK (sue.edyvean@phe.gov.uk)

Conventional CT is a complex imaging device which can utilise narrow or wide beams, helical scanning, varying tube current, varying kV, and operating with various and dynamic collimations - all of which can affect patient dose. Cone beam CT (or flat panel CT) uses different technology, referring to cross-sectional imaging with digital x-ray systems used in dental, digital radiography or radiotherapy. Many of the challenges are similar for both conventional CT and cone-beam CT; however, there has been substantially more research, and literature available, for the former. The dose distribution for both can be complex, due to the geometry of irradiation. When considering patient-specific dosimetry, the technology, exposure settings, and the patient, all need to be considered. As with other modalities, the scope to directly measure doses using physical dosimeters is limited. Therefore, doses need to be estimated using regular-shaped, or anthropomorphic, phantoms, or calculated using mathematical modelling techniques. The appropriate application, and the limitations, of standard dose indices (such as the computed tomography dose index, the size-specific dose index, the cone beam dose index), together with their associated methodologies and phantoms, will be addressed. Monte Carlo calculations from a modelled scanner and patient characteristics give more precise organ dose information, and there are a number of applied software packages developed to utilise these data. The advantages and limitations of these will be discussed.

Learning Objectives:

1. To understand what is estimated.
2. To learn how to measure it.

A-0049 09:21

C. Patient dose in fluoroscopy and interventional

A. Trianni; Udine/IT (annalisa.trianni@asuuiud.sanita.fvg.it)

Biological effects induced by exposure to radiation made evident the need for accurate dosimetry from the early days of X-ray use in medicine. Later the scientific interest turned also to the estimation of risks of radiation-induced cancer and genetic effects. Various dosimetric quantities have been used in diagnostic radiology and sometimes confusion is caused because the same name is used for different quantities. The question arises: what is patient dose and what is not? It's common practice to indicate the dose received by a

patient in radiology using the dosimetric indexes defined for the different imaging modalities. However, dosimetric indexes are a useful tool for practices optimisation and comparison, but certainly, they don't describe patient dose. To accurately estimate patient dose there is the need to collect a lot of information concerning patient characteristics and irradiation events in order to obtain organ or tissue dose. Nowadays, thanks to the digital technology used in medical imaging, various ways of collecting these data are available. The information is communicated using specific standards (i.e. DICOM), such as the non-image information object definitions. These objects are carrying information about equipment output and other dose-related information which allow the user to provide a more accurate estimate of patient dose. This talk will review the basic concepts of patient dosimetry as well as the existing DICOM objects and IHE profiles used to monitor patient exposure, highlighting the pros and cons and introducing to future developments.

Learning Objectives:

1. To review the fundamental patient dosimetry quantities.
2. To learn about calculation of patient dose for interventional procedures.
3. To learn about real time patient dose monitoring strategies.

Multidisciplinary Session

MS 1

Lung cancer team

A-0050 08:30

Chairperson's introduction

A.R. [Larici](#); *Rome/IT (annarita.larici@unicatt.it)*

Lung cancer is the leading cause of cancer-related mortality worldwide. Non-small cell lung cancer (NSCLC), the most common subtype, has an overall 5-year survival rate of 16%, which has not improved significantly for several decades. The poor prognosis could be attributed to the diagnosis of lung cancer at an advanced stage and the lack of a cure. Radiological imaging plays a crucial role in the diagnostic workup of lung cancer, from the early identification to the accurate staging. The new staging TNM system introduced relevant changes in order to better reflect different patient prognosis, even though with some limitations. It is mandatory when lung cancer is suspected, to obtain a tissue diagnosis to ascertain the tumour type. Imaging modalities represent effective tools to guide further investigative procedures for tissue sampling and, therefore, to adequately guide patient management and treatment planning. In the past decade, the therapeutic arsenal for NSCLCs has diversified significantly, with the emergence of targeted therapies and, more recently, immunotherapies. Personalised treatment has grown with the integration of predictive biomarkers, giving the potential to identify patients who may experience the lowest toxicity and/or derive the greatest benefit from these new treatments based on individual tumour profile. Lung cancer treatment planning is a complex process that involves multiple specialities. In the past two decades, multidisciplinary care has emerged as the standard of care in lung cancer management. This session will be focused on discussing the main aspects of lung cancer diagnosis and management.

Session Objectives:

1. To understand how to carry out an accurate diagnosis of lung cancer.
2. To learn about the actual therapeutic approach to lung cancer in the era of "personalised treatment".
3. To appreciate how a multidisciplinary team can make the difference in effectively managing lung cancer.

A-0051 08:35

Imaging and staging

M. [Silva](#); *Parma/IT (mariosilvamed@gmail.com)*

Lung cancer (LC) staging is mandatory to formulate effective treatment strategies and optimise patient outcomes. The staging has traditionally relied on the TNM system, for which the International Association for the Study of Lung Cancer (IASLC), which is now in his eighth edition (TNM-8). The TNM-8 is based on detailed analysis of a new large international database of lung cancer cases assembled by the IASLC. Fundamental cornerstones of TNM-8 include the modifications to the T classification on the basis of 1-cm increments in tumour size, the grouping of lung cancers that result in partial or complete lung atelectasis or pneumonitis, and grouping of tumours with involvement of a main bronchus irrespective of the distance from the carina. Furthermore, reassignment of diaphragmatic invasion was included in terms of T classification, whilst the mediastinal pleural invasion was removed from the T classification, and the M classification was divided into different descriptors on the basis of the number and site of extrathoracic metastases. In response to

these revisions, established stage groups have been modified, and others have been created. In addition, recommendations for classifying patterns of disease that result in multiple sites of pulmonary involvement, including multiple primary lung cancers, lung cancers with separate tumour nodules, multiple ground-glass/lepidic lesions, and consolidation, as well as recommendations for lesion measurement, are addressed. Understanding the key revisions introduced in TNM-8 allows radiologists to accurately stage patients with lung cancer and optimise therapy.

Learning Objectives:

1. To learn how to optimise the diagnostic algorithm of lung cancer.
2. To understand the evolving meaning of TNM classification.
3. To become familiar with key imaging criteria to manage lung cancer.

A-0052 08:53

Role of the pathologist: making the most of the sample

G. [Rossi](#); *Ravenna/IT (giurossi68@gmail.com)*

The advent of effective targeted therapies in lung cancer has significantly changed the standard of care and contemporarily stressed the need for even more tumour tissue finalised at predictive biomarker determinations. Lung cancer presentation, patients characteristics, tumor location and stage profoundly impact on the better approach to maximize the amount of neoplastic material using conventional invasive methods, while liquid biopsy does represent a new source of tumour cells, particularly helpful in monitoring disease progression and in the comprehension of the mechanisms of drug resistance when using specific inhibitors in oncogenic driven malignancies. Actually, radiologists and bronchoscopists are both involved in the correct choice to sample lung cancer, but no universally perfect procedures do exist. The significant increase of adenocarcinoma histology, representing about 60% of all lung malignancies, led to a huge number of peripheral tumours with more frequent mediastinal lymph node involvement. Then, computed-tomography (CT)-guided and transbronchial (with/without endobronchial ultrasound guidance, EBUS) fine-needle aspiration (FNA) are the most common adopted techniques, equally allowing a fair-to-optimal tumour specimen. First line treatment initially requires a precise histological definition of lung cancer. Indeed, about 30% of non-small-cell carcinoma (NSCLC) are poorly-differentiated requiring immunostains with TTF-1 (quite specific for adenocarcinoma) and p40 (indicating squamous cell differentiation). Advanced/metastatic adenocarcinoma, squamous cell carcinoma arising in non-smokers and NSCLC not otherwise specified require a prompt determination of EGFR mutations, ALK and ROS1 rearrangements and PD-L1 expression, whereas conventional squamous cell carcinoma needs only PD-L1 investigation.

Learning Objectives:

1. To learn about the best way to obtain tumour tissue using different approaches.
2. To optimise tumour tissue management increasing the diagnostic yield in histologic subtyping and predictive molecular determinations.
3. To understand the correct information to relate to the oncologist as the first line of treatment.

A-0053 09:11

Role of the oncologist: personalising the treatment

S. [Novello](#), M.L. Reale; *Orbassano/IT (silvia.novello@unito.it)*

Lung cancer treatment has become a paradigmatic example of personalised medicine. Therapeutic management takes into consideration histology, molecular pathology, staging, patients' characteristics. The identification of oncogenic driver alterations (EGFR activating mutations, ALK/ROS1 translocations) allowed the development of targeted therapies based on molecular profiling, enriching the previous 'histology-directed treatment' paradigm. These drugs, counteracting the deregulated pathways, improved outcomes substantially, quality of life and toxicity in molecular selected populations and represent today the standard of care in the oncogene-addicted advanced disease. Nevertheless, acquired resistance arises. Newer agents, overcoming cancer escape, showed remarkable outcomes. Unfortunately, the best sequence of the available treatments, in most cases, is not defined. The landscape is evolving, and other oncogenes are emerging as potential targets implementing personalised medicine algorithms. In the case of non-oncogene addiction and permissive comorbidities, immunotherapy demonstrated successful results in different settings. PDL-1 is the current biomarker to identify patients who may benefit from frontline immune checkpoint inhibitors. However, because of its high variability and dynamic expression, complementary predictive factors are exploring to maximise patients' selection. In this scenario, tissue availability, after histologic definition, is necessary; non-invasive methods are emerging to overcome the potential limits of biopsies or aspirates. Lung cancer is an increasingly complex and heterogeneous disease. Understanding how to best sequence and combine therapies could represent another important step in treatment personalisation. Cooperation and multidisciplinary approaches are the keys for the shared vision of a precision medicine aimed to offer the best treatment to every single lung cancer patient.

Joint Session of the ESR and EIBALL

ESR/EIBALL

Imaging biomarkers and their combinations in the era of artificial intelligence

A-0056 08:30

Chairpersons' introduction (part 1)O. Clément; Paris/FR (olivier.clement@aphp.fr)

Imaging biomarkers have raised a major interest over the last ten years by a radiologist to quantify and monitor diseases. The rapid spread of artificial intelligence in our discipline might trigger a new era where complex information will be more easily integrated. This session focuses on techniques, examples, opportunities and pitfalls in the use of AI for biomarkers development.

Session Objectives:

1. To introduce the potential of AI to accelerate the introduction of imaging biomarkers.
2. To introduce the challenges of managing biomarkers with AI systems.
3. To introduce the speakers.

Author Disclosure:**O. Clément:** Advisory Board; Bayer. Speaker; Bracco, Guerbet.

A-0057 08:33

Chairpersons' introduction (part 2)

N.M. deSouza; Sutton/UK

This session will focus on the use of artificial intelligence for selecting and managing imaging biomarkers. Clarification around the use of terms such as 'artificial intelligence' and 'biomarkers' will be discussed. The strengths and limitations of the technologies used will be considered. The development of researcher-driven science and technology networks through the EU COST (Co-operation in Science and Technology) action initiative will be showcased using renal biomarkers as an exemplar. Finally, the selection of combinations of biomarkers from hybrid imaging technologies using AI will be addressed.

Session Objectives:

1. To introduce the potential of AI to accelerate the introduction of imaging biomarkers.
2. To introduce the challenges of managing biomarkers with AI systems.
3. To introduce the speakers.

Author Disclosure:**N.M. deSouza:** Grant Recipient; Cancer Research UK, EU Framework 7.

A-0058 08:35

Building and discovering biomarkers with AIB. Rance; Paris/FR (bastien.rance@aphp.fr)

In recent years, Deep Neural Networks (DNN) have achieved unprecedented performances in many domains, especially with the analysis of images. Major results have been announced for several applications, including skin lesions, pneumonia, pathology and so forth. Several algorithms have even been approved by regulatory agencies, e.g. for the diagnosis of diabetic retinopathy in specific circumstances. It now makes no doubt that artificial intelligence algorithms will be part of the medical experts' toolboxes. In this presentation, we will explore the basic principles behind artificial intelligence and neural networks: supervised and unsupervised algorithms, neurons, activation functions, and the overall architectures of networks. We will discuss more specific classes of DNN used today for the exploration of images, namely the convolutional network and the autoencoder-denoiser, and how they can be used to identify new biomarkers. We will emphasise the crucial role played by expert annotations on images, and explore how experts annotations are used to build models. Finally, we will discuss the implications of the use of deep neural networks in medicine and radiology, and briefly explore new risks (for example adversarial attacks) linked with the use of such technologies.

Learning Objectives:

1. To learn about available supervised vs unsupervised machine learning techniques.
2. To learn about deep-learning methods to discover biomarkers.
3. To understand the strength, but also limits and pitfalls, of machine learning methods.

Learning Objectives:

1. To learn about the meaning of personalised treatment and the evolution of lung cancer therapies in the last 10 years.
2. To understand the role of the newer targeted therapies.
3. To become familiar with the needs of the oncologist to optimise lung cancer treatment.

Author Disclosure:**S. Novello:** Speaker; Bureau for Roche, Boehringer Ingelheim, Eli Lilly, Astra Zeneca, MSD, BMS, Takeda.

A-0054 09:29

What the surgeon needs to knowU. Pastorino; Milan/IT (ugo.pastorino@istitutotumori.mi.it)

The optimal management of non-small cell lung cancer (NSCLC) requires multidisciplinary collaboration. The incidence of stage I and II NSCLC is likely to increase with the ageing population and the introduction of lung cancer screening for high-risk individuals. The surgical approach is to be tailored upon each individual case, and options are lobectomy, sublobar resections (SLR), sleeve resections, and minimally invasive techniques such as video-assisted thoracic surgery (VATS) and robot-assisted thoracic surgery (RATS). Furthermore, radiation therapy (especially stereotactic body radiation therapy - SBRT), is a valid alternative in compromised patients who are high-risk candidates for surgery. Minimally invasive techniques are suitable for a subset of patients who can be selected on the basis of a pre-surgical investigation by imaging and bronchoscopic sampling by ultrasonography. Stage III NSCLC is also treated surgically with curative purpose when specific conditions are fulfilled. A variable combination with neoadjuvant chemotherapy in specific cases is discussed by the lung cancer team before surgical resection, to improve long-term outcome. The synergistic collaboration of the lung cancer team is based on diagnostic cornerstones, which are demanded by the surgeon for the optimal planning of lung cancer resection (either minimally invasive or enlarged) with or without pre-surgical neo-adjuvant therapy, or for the definition of those subjects at high risk for surgical procedures (alternative treatment such as SBRT).

Learning Objectives:

1. To learn about the advances in the surgical approach for lung cancer treatment.
2. To understand how the clinical staging may affect surgical results in lung cancer.
3. To become familiar with the needs of the surgeon to define the appropriate surgical approach.

A-0055 09:47

Multidisciplinary case presentation and discussionA.R. Larici; Rome/IT (annarita.larici@unicatt.it)

Lung cancer management and treatment planning are complex processes involving multiple specialities. In the past two decades, multidisciplinary care has emerged as the standard of care for lung cancer patients. Multidisciplinary care facilitates discussions between the different specialists involved in the diagnostic process to ensure that the site with the highest chance of obtaining tissue from is targeted first, thereby minimising the risk to the patient of recurrent procedures. There is evidence that access to the most accurate staging investigations is improved by multidisciplinary care, helping to limit unnecessary surgery which does not appear to occur at the expense of patient undertreatment. The impact of multidisciplinary care on measures of quality lung cancer treatment includes staging accuracy, access to diagnostic investigations, improvements in clinical decision making, better utilisation of radiotherapy and palliative care services, and improved quality of life for patients. Multidisciplinary care reduces variation in care, overcomes barriers to treatment, promotes standardised treatment through adherence to guidelines, and allows the audit of clinical services and for these reasons is more likely to provide quality care for lung cancer patients. This presentation is a case-based review demonstrating the added role of the multidisciplinary discussion on lung cancer patient management.

A-0059 09:00

COST action initiatives as a platform for image biomarker selection

A. Caroli; Ranica/IT (acaroli@marionegri.it)

COST actions are EU-funded, open, and growing pan-European networking tools aimed at building, bridging and expanding interdisciplinary research communities. A successful example is the COST action PARENCHYMA (Magnetic Resonance Imaging Biomarkers for Chronic Kidney Disease - www.renalMRI.org), which coordinates the research of leading European groups working on renal MRI. The rising prevalence of Chronic Kidney Disease (CKD) poses a major public health challenge, and an alarming number of negative clinical trials on CKD progression point out the urgent need for better biomarkers to identify patients that are at risk of progression or are likely to respond to candidate therapeutics. MRI biomarkers have shown a high potential to help fill this gap, as they are non-invasive and sensitive to CKD pathophysiology. Based on this rationale, PARENCHYMA is trying to unlock renal MRI biomarker potential by improving their standardisation and availability, and by generating strong multicentre clinical evidence of biological validity and clinical utility. As different imaging biomarkers provide complementary information on pathophysiology, they need to be combined to reach the highest sensitivity. Artificial intelligence could help to identify best disease-specific combinations.

Learning Objectives:

1. To learn about how COST actions work and the outputs generated.
2. To appreciate examples of a successful COST action for selecting imaging biomarkers.
3. To understand difficulties in selecting biomarkers for specific indications.

A-0060 09:25

Role of AI in the introduction of imaging biomarkers: accelerator or obstacle?

J.C. Waterton; Manchester/UK (John.Waterton@manchester.ac.uk)

According to the FDA/NIH BEST resource, a biomarker is a "defined characteristic that is measured as an indicator of normal biological processes, pathogenic processes, or responses to exposure or intervention, including therapeutic interventions; ... radiographic characteristics are types of biomarkers". Imaging biomarkers include scores from scoring systems, such as objective tumour response; extensive variables, such as LVEF; and intensive variables, such as the CT Hounsfield Unit. Biomarkers are essential for evidence-based medicine, for regulatory approvals, and for prescribing information. However biomarkers must be reproducible over time and space: the measured imaging biomarker value must not drift when measured in a different clinic, or when better scanners are introduced. Radiologic examinations often provide imaging biomarkers which guide patient care. However much of the information in single images, or from multi-modal imaging examinations, is not captured in currently available imaging biomarkers. In the hands of an expert radiologist, this additional information further improves patient care: AI offers the hope of creating new biomarkers by quantifying this additional information. AI-derived imaging biomarkers are, however, not exempt from the need to follow established scientific and regulatory validation pathways and roadmaps. They should show which aspect of the underlying pathology is captured by the new biomarker and must demonstrate reproducibility over time and space (including strategies to maintain validity with future scanners yet to be designed). Otherwise, AI-derived imaging biomarkers will not translate and will remain academic curiosities.

Learning Objectives:

1. To learn how AI can improve imaging biomarkers from multiple imaging modalities.
2. To appreciate the challenges "big data" pose to regulators, whether from imaging biomarkers or from the more conventional biospecimen (genomic, proteomic) biomarkers.
3. To understand how best to utilise AI for imaging biomarkers and to avoid the pitfalls.

Interventional radiology (IR) in children: what a non-interventional radiologist needs to know

Moderator:

E. Alexopoulou; Athens/GR

A-0061 08:30

A. Common IR procedures in children: state-of-the-art

A. Barnacle; London/UK (Alex.Barnacle@gosh.nhs.uk)

Interventional radiology (IR) procedures are a vital part of paediatric care for most complex diseases, providing reliable intravenous access and feeding tube support during intensive therapy such as chemotherapy and delivering innovative minimally-invasive therapies for other conditions to avoid surgery and often save lives. Central venous access in children can be technically challenging but is quicker and less invasive than open surgical techniques, and there is evidence to suggest that the central veins are preserved for longer, which is key in children with chronic disease. Angiography in children is usually straightforward, with just a few important technical points to remember in small children. Looking beyond central venous access, paediatric IR delivers therapies such as sclerotherapy for vascular malformations, percutaneous nephrolithotomy (PCNL) for renal stone extraction, oesophageal dilatations to manage oesophageal strictures and biopsy to safely and accurately stage childhood tumours. As with all of IR, the key to safe and successful practice is an understanding of the different pathology processes in children and the underlying decision making processes involved in delivering best practice.

Learning Objectives:

1. To learn about the most common causes for image-guided intervention in children.
2. To understand how the practical and technical approach to intervention in a child differs from that in adults.
3. To appreciate tips, tricks and pitfalls in paediatric intervention procedures.

A-0062 09:00

B. Vascular malformations: diagnosis and interventions

M. Beeres; Frankfurt a. Main/DE (beeres@gmx.net)

Diagnosis and treatment of vascular malformations in children is a combination of different diagnostic tools adapted to the given clinical setting. It always has to be an interdisciplinary team approach mostly based in dedicated centres to first find the correct diagnosis and then decide whether or not treatment is necessary. From the clinical background, most vascular malformations don't need invasive treatment because they do not cause any symptoms. However, the clinical decision has to be based on a reliable diagnosis, and different imaging pathways have to be considered. Imaging is predominantly performed by Ultrasound and MRI. Valuable information is added by clinical examination and history as well as sometimes histopathologic specimens. Different MRI examination approaches exist that help to find the correct diagnosis in the end. In imaging, it is important to distinguish between high-flow lesions e.g. arteriovenous malformations (AVM) or low-flow lesions e.g. venous malformations. Ultrasound and MRI can help to look beyond the focal vascular malformation because other body-regions might be affected as well. The correct diagnostic workup will help to define the right clinical pathway in a multidisciplinary team discussion. The treatment decision should then include non-interventional procedures such as physiotherapy or compression hosiery as well as interventional procedures such as sclerotherapy, embolization and surgery. It is essential to talk to and support the children and their parents, so they understand the different pathways and options. When all this comes together, they can decide well-informed leading to a hopefully satisfied patient in the end.

Learning Objectives:

1. To learn about the classification of paediatric vascular malformations.
2. To understand the diagnostic work-up and the indications for percutaneous treatment of paediatric vascular malformations.
3. To appreciate the treatment options for different vascular malformations.

A-0063 09:30

C. Osteoid osteoma: diagnosis and treatment

D. [Filippiadis](mailto:dfilippiadis@yahoo.gr); Athens/GR (dfilippiadis@yahoo.gr)

Osteoid osteoma is a benign inflammatory bone tumour encompassing 2-3% of all bone tumours and 10% of benign bone tumours; it is most common in males < 25 years of age with patients typically complaining of pain that worsens at night and is promptly relieved by salicylates. A tumour was first reported by Jaffe in 1953; osteoid osteoma is composed of the nidus which is bone at various maturity stages surrounded by highly vascular connective tissue stroma. Depending on the location and axial imaging findings, osteoid osteoma can be classified into subperiosteal, intracortical, endosteal or intramedullary and intra-articular with the latter being the least common type and refers to lesions located within or near a joint. The application of radiofrequency ablation (RFA) was introduced in clinical practice by Rosenthal in 1992 performing a percutaneous approach for the treatment of osteoid osteoma. Nowadays thermal ablation of osteoid osteoma constitutes a first-line therapy. Numerous studies upon all ablation techniques, others with lesser and others with higher numbers of patients report high pain reduction rates (up to 96%) and low recurrence rates (~7% at two years). Comparing percutaneous ablation to the traditional surgical techniques for osteoid osteoma (wide excision removing a bone block, marginal resection of the entire nidus, curettage or high-speed burr techniques) favours a percutaneous approach in terms of minimum trauma, minimum functional restriction and significantly lower cost.

Learning Objectives:

1. To learn how to diagnose, and how to treat, osteoid osteomas.
2. To understand the techniques for percutaneous treatment of osteoid osteoma: preparations, procedure and follow-up.
3. To appreciate advantages and potential complications in percutaneous treatment of osteoid osteoma in children.

Imaging tumour response to immunotherapy

A-0064 08:30

Chairperson's introduction

O.L. [Sedlaczek](mailto:sedlaczek@web.de); Heidelberg/DE (sedlaczek@web.de)

Cancer Immunotherapies include a broad variety of interactions between applied substances and the immune system to treat cancer. Passive mechanisms include the delivery of compounds that may use the immune system. The more recently extensively used drugs lead to an active priming of the immune system via disinhibition of immune checkpoints either at the level of the lymphnode (CTLA 4 - interaction) or at/near the malignancy itself (PD(L) - 1 - interaction). Checkpoint-inhibitors are a breakthrough in the treatment of a variety of human malignancies including lung, renal, bladder cancer, and of course melanoma. They led to significant improvements in response and survival rates. However, the disinhibition of mechanisms normally protecting from autoimmunity and prolonged immunoreactions can lead to both unusual tumour response patterns and atypical toxicities. Concerning the response patterns the continued application of an immune treatment after the first observation of a classical RECIST - progression (pseudoprogression) is the common difference in all the response criteria specifically suggested to be used in immunotherapies (irRC, irRECIST, iRECIST). Although there are data for several substances and entities showing a beneficial effect of an ongoing treatment with checkpoint inhibitors even beyond a confirmed progression, there is a relevant role for imaging in the early prediction of treatment success particularly due the enormous cost of the treatments and the relevant toxicities associated.

Session Objectives:

1. To discuss the mechanism of action of immunotherapies.
2. To understand immunotherapy response and immune-related adverse events.
3. To become familiar with immune related response criteria (irRC), immune-related RECIST (irRECIST) and immune RECIST (iRECIST).
4. To discuss future directions for advanced imaging of immunotherapy.

A-0065 08:35

A. Imaging the immune system in cancer

C. [Dromain](mailto:Clarisse.Dromain@chuv.ch); Lausanne/CH (Clarisse.Dromain@chuv.ch)

A wide range of cancer immunotherapy approaches has been developed including non-specific immune-stimulant such as cytokines (Interferon, IL2), cancer vaccines (peptide or dendritic-cell-based vaccines), adoptive T-cell therapy (TILs, CAR, TRC) and immune checkpoint inhibitors (anti-CTLA-4, anti PD1 and anti PDL1). The most commonly used are the immune checkpoint inhibitors (ICIs). Their mechanism of action signifies a true shift in oncology where instead of targeting the tumour cells, ICIs target the immune system to break the cancer tolerance and stimulate the anti-tumour immune response. These new drugs have, since 2011, received marketing authorisation for melanoma, lung, bladder, renal, and head and neck cancer with remarkable and long-lasting treatment response. The novel mechanism of action of these drugs, with immune and T-cell activation, lead to unusual patterns of response with presence pseudo-progression more pronounced and more frequent than previously described responses. Pseudo-progression that has been described in about 3-10% of patients treated using ICIs corresponds to increase of tumour burden and/or appearance of new lesions due to infiltration of a tumour by activated T-cells before the disease responds to treatment. To overcome the limitation of RECIST criteria to assess this specific changes in tumour burden, new criteria so-called irRC and then irRECIST were proposed. The major modification involved the inclusion of the measurements of new target lesions into disease assessments and the need for a 4-week CT re-assessment to confirm progression. More recently (2017) a consensus guideline iRECIST was developed by the RECIST working group.

Learning Objectives:

1. To discuss the concept of immunotherapy treatment in cancer.
2. To review what the radiologist needs to know when assessing immunotherapy treatment.
3. To understand the challenges of assessing immunotherapy response using imaging.

A-0066 08:53

B. Monitoring immune response with CT

F. [Gentili](mailto:francescogentili@gmail.com); Siena/IT (francescogentili@gmail.com)

Computed tomography (CT) is the most widely available imaging technique for evaluating tumour response to chemotherapy. In the last years' cancer immunotherapy is changing response evaluation criteria to treatment since new patterns of treatment response have been observed employing immunomodulating agents; such therapies indeed can be associated with a significantly delayed decrease in tumour size, and new or enlarging lesions observed soon after completion of treatment may not indicate disease progression. For this reason, in this scenario, the traditional response criteria, such as WHO and RECIST 1.1, cannot be applied and therefore, during these years, several response criteria (irRC, irRECIST, iRECIST and imRECIST) were proposed and applied in clinical trials on immunotherapy. Moreover, changes of intratumoral vascularisation, objectively assessed by Perfusion-CT and Dual-energy CT, may reflect the effects of treatment and therefore be incorporated in response criteria. Finally, CT radiomics is a promising method, applied to conventional images, that seems to be able to detect subtle differences in CT values which cannot be recognised by human eyes, providing quantitative data on tumour microenvironment by analysing the distribution and relationship of pixel intensities.

Learning Objectives:

1. To discuss different types of immunotherapies and to review their mode of action as imaged with CT.
2. To understand the limitations of RECIST and become aware of immune response criteria.
3. To discuss the limitations of CT for assessment of immunotherapies.

A-0067 09:11

C. Monitoring immune response with PET

C.C. [Cyran](mailto:clemens.cyran@med.uni-muenchen.de); Munich/DE (clemens.cyran@med.uni-muenchen.de)

In recent years a range of novel immunomodulatory cancer therapeutics were introduced into clinical use aiming to boost anti-tumour immune response in cancer patients. Among these immunotherapies, neutralising antibodies targeting the immune checkpoints T-lymphocyte-associated protein 4 (CTLA-4) and programmed cell death protein 1 (PD-1) have shown effectiveness in the treatment of different tumour entities. Unlike cytotoxic radio- and chemotherapy, which directly interferes with tumour cell growth and survival, immunotherapies target the tumour indirectly stimulating the physiological anti-tumour immune response. Established methods of assessing cytotoxic tumour therapies (e.g. RECIST) have demonstrated limitations for monitoring the early therapeutic effects of immunotherapy. This has led to the development of immune-specific related response criteria (e.g. irRC, irRECIST, iRECIST) that allow continued treatment beyond progression defined by RECIST, however with also limited applicability. The complementary acquisition of functional and molecular information using PET in line with hybrid imaging techniques may

allow for a higher diagnostic accuracy in monitoring immunotherapy and the timely differentiation of responders from non-responders. The applicability of 18F-FDG PET for monitoring treatment with immune checkpoint inhibitors has been questioned because the infiltration of the tumour by immune cells may cause a transient increase in metabolic activity. Dedicated tracers for immune PET mostly aim to visualise the presence and abundance of various subsets of immune cells with different targets including PD-L1, PD-1, CTLA-4, CD3 and IFN γ . Dedicated immune PET with specific tracers may provide valuable in vivo insights into the pathophysiology of tumours under immunotherapy and new opportunities to evaluate antitumor immune response.

Learning Objectives:

1. To discuss the framework for the use of FDG PET/CT for immunotherapy assessment.
2. To become familiar with the best response criteria for assessment of immunotherapy using PET/CT.
3. To discuss the limitations of PET/CT for assessing of immunotherapies.

A-0068 09:29

D. Monitoring immune response with MRI

D.-M. Koh; Sutton/UK (dowmukoh@icr.ac.uk)

Drugs that modulate the body immune responses are increasingly used to treat cancers, either alone in combination, such as in malignant melanoma, non-small cell lung cancer, hepatocellular carcinomas. In patients receiving immunotherapies, CT is still the most widely used imaging technique to assess the treatment response of tumours and to identify drug-related side-effects. However, anatomical MR imaging is also effective in evaluating tumour regression by size measurement criteria (e.g. iRECIST). Like CT, an increase in tumour size may be observed on MRI in pseudo-progression, which can confound response assessment. Nonetheless, the superior soft tissue contrast of MRI helps to depict subtle disease (e.g. intracranial) and specific complications (e.g. hypophysitis) that are difficult to visualise on CT. There is great interest in applying quantitative MR imaging, including whole-body MRI techniques, to study functional changes in tumour cellularity (using diffusion-weighted MRI), vascularity (using contrast-enhanced MRI) and macromolecules (magnetisation transfer). These are areas of on-going research, including the use of texture analysis and radiomics analysis. Whole body MRI can provide information about inter-tumoural heterogeneity, thus allowing insights into tumour evolution and differential response to treatment. Active research in molecular probes is being undertaken to develop PET imaging tracers that can identify and predict treatment response, which can be explored alongside multi-parametric MRI measurements on an MRI/PET hybrid system as imaging biomarkers.

Learning Objectives:

1. To learn the advantages and limitations of MRI for assessment of immunotherapies.
2. To describe the potential role of whole-body MRI and quantitative MRI techniques for patient follow-up.
3. To consider the potential of integrated PET/MRI for the assessment of immunotherapies.

Early detection of ovarian cancer

A-0069 08:30

Chairperson's introduction

R. Forstner; Salzburg/AT (r.forstner@salk.at)

Ovarian cancer is still among the deadliest of cancers in females. Its prognosis depends on different factors including histologic subtype, stage at diagnosis, tumour burden after cytoreductive surgery and sensitivity to chemotherapy. However, it is early stage and detection of precursor lesions of ovarian cancer that are of utmost prognostic impact. New insights in biology and genetics in ovarian cancer hold promise in earlier detection and are pivotal in personalised treatment. Blood biomarkers and/or imaging have been widely used in screening programs of ovarian cancer. Currently, a screening test is widely recommended in patients at risk, e.g. in familial history, BRCA1 and 2 mutation carriers or HPCN families, which are estimated to account for approximately 5-15% of ovarian cancers. Imaging using US and MRI plays a central role in identifying early ovarian cancer and precursors of invasive cancer, e.g.

cystadenomas or Borderline tumours. The "O RADS" working group has developed a lexicon for both US and MRI. Such standardised terminology will allow an unequivocal and generally applicable description of ovarian masses. It will also provide an essential tool for risk stratification of ovarian lesions.

A-0070/A-0071 08:36

A. Current guidance on screening and familial ovarian cancer

A.G. Rockall; London/UK (a.rockall@imperial.ac.uk)

A. George; London/UK (angela.george@rmh.nhs.uk)

Germline BRCA1/2 (gBRCA) mutations underlie 15-20% of epithelial ovarian cancer diagnoses and are associated with biologically distinct tumours. Those with a gBRCA mutation typically have a younger age of diagnosis, higher rates of visceral and nodal metastases and an improved prognosis compared to those with gBRCA wildtype tumours. Mutation carriers also have increased rates of synchronous/metachronous tumours, particularly breast and pancreatic cancers. As ovarian cancer is typically diagnosed at a late stage, with poor long-term survival, there has been interest in screening, to try and improve outcomes. A number of screening studies have investigated the role of transvaginal ultrasound +/- CA-125 testing in both those with a family history of ovarian cancer; and those at population risk. To date, no improvement in overall survival has been observed with screening, although studies assessing relative CA-125 levels are ongoing. The methods and results of the largest screening trials will be presented with a discussion of findings.

Learning Objectives:

1. To be aware of the implications of results of recent screening trials.
2. To be aware of BRCA gene testing and treatment implications.
3. To know the guidance on screening high risk groups.

B. ORADS: ultrasound and International Ovarian Tumor Analysis (IOTA) group models

R.F. Andreotti; Nashville, TN/US (rochelle.f.andreotti@vanderbilt.edu)

"O-RADS" is an acronym for an Ovarian-Adnexal Imaging-Reporting-Data System which is being developed by an international committee that is sponsored by the American College of Radiology (ACR) and will function as a quality assurance tool for the standardised ultrasound (US) and magnetic resonance imaging (MRI) description of ovarian/adnexal pathology. The O-RADS Committee has published a lexicon for describing US imaging characteristics of ovarian/adnexal masses. The terminology has been applied to a risk stratification classification for consistent follow up and management in clinical practice. The use of these internationally agreed upon standardised descriptors should result in consistent interpretations and decrease or eliminate ambiguity in reports resulting in a higher probability of accuracy in assigning the risk of malignancy and, subsequently, optimal patient management. The US lexicon is based upon supporting evidence for the performance of terms with regards to classification of the mass as benign or malignant and common usage of terms. A large part of the lexicon is based upon terms in use by the International Ovarian Tumor Analysis Group (IOTA). These terms demonstrate consistency regarding performance in the evaluation of malignancy risk and have been supplemented with other modifying, non-IOTA descriptors. Risk categories were developed using the most predictive descriptors in the lexicon that, in combination, include all possible lesions. The risk table is based on statistics collected by IOTA/ADNEX models. Cases that illustrate the O-RADS-US Lexicon and Risk Stratification System will be discussed.

Learning Objectives:

1. To understand a new lexicon for ovarian/adnexal mass evaluation on ultrasound.
2. To understand the use of the lexicon in the development of a risk stratification and management system.
3. To apply O-RADS-US to case management.

A-0073 09:32

C. ORADS: MRI

I. Thomassin-Naggar; Paris/FR (isabelle.thomassin@tnn.aphp.fr)

The O-RADS classification has been developed by the American College of Radiology in collaboration with ESR members. This classification helps the radiologist to evaluate the risk of malignancy of an adnexal mass and was built as a five categories steps. O-RADS needs the analysis of morphological and functional criteria including DCE MR images and DWI. This lecture will present the new lexicon.

Learning Objectives:

1. To understand a new lexicon for ovarian/adnexal mass evaluation on MRI.
2. To understand the use of the lexicon in the development of a risk stratification and management system.
3. To apply O-RADS-MRI to case management.

Functional imaging in head and neck oncology

A-0074 08:30

Chairperson's introduction

F. Bidault; Villejuif/FR (francois.bidault@gustaveroussy.fr)

Squamous cell carcinoma of the head and neck is one of the most common cancers worldwide. Advanced tumours are associated with high morbidity and mortality rate. Risk factors are tobacco, alcohol, wood dust (professional disease), and viral infections (EBV, HPV). A multidisciplinary team approach is required to undertake effective personalised care planning. Decision process requires understanding patient's wish, conducting a physical examination, making imaging examination, panendoscopy, tumour biopsy with a pathological result, checking the patient's suitability for surgery. Imaging is the extension of physical examination and definitely is of tremendous importance for decision making. Speakers of this master session are leading experts in the field of imaging for locoregional tumour assessment with M.G. Mack, from Munich, incidence and prognosis of synchronous cancer or distant metastases from head and neck tumours with A.D. King, from Hong Kong, and question of the need for functional imaging to detect distant metastases with R. Maroldi, from Brescia.

Session Objectives:

1. To discuss the role of functional imaging in tumour staging.
2. To learn about the presentation and prognosis of head and neck cancer patients.
3. To understand the clinical impact of imaging findings.

A-0075 08:35

A. Functional imaging for locoregional tumour assessment

M.G. Mack; Munich/DE (m.mack@radiologie-muenchen.de)

Head and neck cancer is one of the most common cancers worldwide. MRI based diffusion and perfusion techniques enable the non-invasive assessment of tumour biology and physiology and add additional information to standard structural MRI scans. Head and neck squamous cell carcinoma may cause a decreased apparent diffusion coefficient (ADC) on diffusion-weighted magnetic resonance imaging (DW MRI) and an increased standardised uptake value (SUV) on fluorodeoxyglucose (FDG) positron emission tomography (PET/CT). These techniques can improve the initial staging and can help to monitor treatment response. In addition, these techniques can improve patient selection for therapeutic strategies and provide evidence for a change of therapy regime. This presentation summarizes recent literature and provides an overview of the various studies in which diffusion or perfusion-based MRI studies are applied to head and neck cancer and will provide an overview of commonly used acquisition protocols and postprocessing methods, followed by advanced data analysis, imaging findings regarding tumour characterization and differentiation, tumour risk stratification and staging, monitoring and prediction of treatment response. Limitations will be highlighted followed by a conclusion with recommendations for the future.

Learning Objectives:

1. To learn about functional imaging (perfusion, DWI, PET) in head and neck cancer patients.
2. To understand the value of functional imaging for tumour assessment.
3. To discuss nodal assessment in head and neck cancer.

A-0076 08:58

B. Incidence and prognosis of synchronous cancer or distant metastases from head and neck tumours

A.D. King; Hong Kong/CN

Second primary tumours Head & neck cancer has one of the highest associations with second primary tumours (SPT). SCC is associated with smoking and high alcohol intake, and so patients are also at risk of SPTs in other sites of the head & neck, lung and oesophagus. Less commonly SPTs arise in the colon, pancreas and bladder. SPTs are usually metachronous with synchronous tumours being diagnosed in only ~ 4% of patients. SPTs are a leading cause of death in patients with early-stage SCC, but SPTs detected early are potentially curable. Distant metastases With advances in locoregional control distant metastases (DM) now are emerging as a major determinant of survival. Therefore, a more active approach is being taken to detect and

manage distant site disease, including the use of a new generation of immunotherapy agents. The incidence, risk factors, sites, prognosis, and management of DM vary with histology and will be discussed in three main groups comprising carcinomas of the aerodigestive tract, thyroid and salivary glands. Most DM manifest after initial treatment, the most common sites being lung or bone, followed by the liver. Prognosis tends to be poor with most patients succumbing to disease within a year. However, the prognosis is dependent on many factors which include histology, site and number of DM. Notably, some patients survive, and there is a subgroup of patients with oligometastases who have a potentially curable disease.

Learning Objectives:

1. To become familiar with the incidence of the synchronous tumours in the head and neck population.
2. To become familiar with the incidence of the distant metastases in the patients with newly diagnosed head and neck cancer.
3. To understand the consequences in a prognosis.

A-0077 09:21

C. Is functional imaging necessary to detect distant metastases in head and neck cancers?

R. Maroldi; Brescia/IT (roberto.maroldi@unibs.it)

Head and neck squamous cell carcinoma (HNSCC) is a predominantly locoregional disease. The reported incidence of distant metastasis (DM) varies in a wide range, between 3% and 50%, reflecting heterogeneity in population characteristics disease stages included, timing of diagnosis of DM, etc. DM factors do not only influence prognosis, but it is a major determinant of the choice of treatment. Patients with known DM can possibly be spared the toxicities of aggressive and often unnecessary locoregional therapy. Fdg-PET-CT is the most used imaging techniques for detecting DM in HNSCC. Because the sensitivity for lesions with size less than 10mm is poor, the negative predictive value is considered insufficient for a low-volume disease. In fact, if the follow-up window increases from 12 to 30 months, the sensitivity of Fdg-PET-CT decreases from 83-97% to 60-82%, probably because of metastases too small for the technique. False positive findings are an additional troublesome factor, as the imply increased costs and delay of treatment. Therefore, Fdg-PET-CT has a diagnostic yield low in early-stage disease. The highest clinical value is obtained in the pretreatment evaluation of advanced-stage (III/IV) and recurrent HNSCC. A new oncologic perspective has been recently explored: the concept of treating oligometastases (metastasectomy or stereotactic body radiotherapy). If the locoregional disease is controlled/resected, and the distant sites ablated, a prolonged disease-free interval and possible cure may be achieved. In addition to Fdg-PET-CT, a growing body of evidence has been published in the recent literature, supporting Whole-Body MRAs screening for DM.

Learning Objectives:

1. To review the advanced imaging for detection of distant metastases of head and neck cancer.
2. To understand the advantages and disadvantages of functional imaging modalities for M staging.
3. To discuss when to image for distant metastases.

A-0086 10:30

Acute aortic syndrome

T. Jargiello; Lublin/PL (tojarg@interia.pl)

Acute aortic syndrome (AAS) describes symptoms relevant to severe chest or back pain caused by several aortic pathologies which can be potentially life-threatening. The most common aetiology comprises the majority of AAS is aortic dissection. Other causes of AAS with similar presentation include intramural haematoma, penetrating aortic ulcer (atherosclerotic), aneurysm formation (rupture, enlargement) and traumatic transection (pseudoaneurysm). Imaging plays a vital role in diagnosing AAS. The role of the plain chest radiograph is nowadays historic. Echocardiography (plain or transoesophageal) is an effective portable tool but does not visualise the whole thoracic aorta. It may only suggest a certain AAS aetiology. Contrast-enhanced

CT is now considered as the diagnostic method of choice. It provides an accurate aortic assessment as well as a detailed evaluation of other thoracic structures. CT permits 3D reconstructions, essential for intervention planning and it is widely available. Its sensitivity for aortic disorders reaches 100%. MRI is another imaging modality to diagnose AAS. Although it provides greater anatomical detail than CT, it is seriously limited. The limitation involves procedure time, lesser availability, and the expense.

Learning Objectives:

1. To become familiar with the most common aetiologies of acute aortic diseases.
2. To present current imaging techniques for evaluation of acute aortic diseases.
3. To demonstrate the most important imaging findings.

A-0087 11:00

Pulmonary embolism

C. Loewe; Vienna/AT (christian.loewe@meduniwien.ac.at)

Pulmonary embolism (PE) represent a daily clinical challenge at the emergency department: out of the patients admitted to an emergency room because of the very unspecific clinical symptom of chest pain and/or dyspnea, the early identification of patients with a high clinical likelihood for PE is a difficult task. The D-Dimer test is very sensitive but unspecific for pulmonary embolism, and by using this test without clinical assessment, a high number of patients will be diagnosed as "false positives". On the other hand, PE is potentially life-threatening; and early and safe diagnosis of this relevant disease is important to improve patient's outcome. CT angiography of the pulmonary arteries has been established as the first method of choice to accurately detect PE with a high PPV and NPV. This presentation will provide an overview of the diagnostic challenges in the chest pain unit and will explain the need for accurate clinical assessment to select the right patient for the appropriate diagnostic test. Furthermore, the risks due to overdiagnosis or false-positive diagnosis will be exemplified. In the second part, this presentation will focus on the radiological view on this picture by explaining an optimised imaging technique and possible pitfalls and problems. Challenging situations in the daily clinical practice will be discussed by addressing the role of imaging in suspected PE in pregnancy and the oncologic patients. Finally, typical findings in acute and chronic pulmonary embolism will be reviewed.

Learning Objectives:

1. To review the most common pathologies leading to pulmonary embolism.
2. To present current imaging techniques for evaluation of pulmonary embolism.
3. To become familiar with the typical findings in acute and chronic pulmonary embolism.

A-0088 11:30

Acute coronary syndrome

R.M.M. Hinzpeter; Zurich/CH (Ricarda.Hinzpeter@usz.ch)

Normal anatomic conditions of the coronary artery tree consist of two main coronary arteries, a left coronary artery and a right coronary artery arising from the coronary sinuses in the proximal ascending aorta immediately distal of the aortic valve. The right coronary artery descends in the right atrioventricular groove to the inferior surface of the heart, continuing as the posterior descending artery representing a right dominant circulation. After a short common stem, the left coronary artery bifurcates into the left anterior descending, coursing in the anterior interventricular groove and the left circumflex artery coursing in the left atrioventricular groove. After the initial workup of an acute coronary syndrome in the emergency department, including laboratory values and ECG changes, coronary CT angiography (CCTA) as a non-invasive examination plays an important role besides invasive techniques. Especially in patients with low to intermediate risk CCTA is a quick and reliable method for ruling out coronary artery disease with a very high negative predictive value in the absence of coronary artery calcifications. Besides the detection of significant coronary artery stenosis, the presence, amount and composition of non-calcified plaques and the degree of coronary remodelling is substantial. In addition, information about structural changes of the myocardium and myocardial perfusion can be obtained by CCTA.

Learning Objectives:

1. To become familiar with segmental coronary anatomy.
2. To present different techniques for assessment of acute coronary syndrome.
3. To become familiar with the typical findings of acute coronary syndrome.

E³ 221

Musculoskeletal radiology: inflammation

A-0089 10:30

A. Inflammatory and infections in the soft tissues

S. Martin; Palma de Mallorca/ES (silvia.m.martin@gmail.com)

The diagnosis of infections is based on the presence of clinical symptoms like erythema, swelling and pain. Also, the diagnosis is based on the presence of clinical signs such as fever, tachycardia and shock and laboratory test such as leukocytosis and C protein reactive. However, the clinical symptoms and signs of infection may not be specific, especially in the early stages of the disease. In these cases, imaging tests play a fundamental role in the early diagnosis of infections and the differential diagnosis. The most important radiological findings for inflammatory and infections soft tissue are: 1/ Intramuscular fluid collections. 2/ Soft tissue air. 3/ Fascial fluid collections and 4/Muscle oedema. Potential causes of these radiological findings are diverse, including, infectious, autoimmune, inflammatory, neoplastic, neurologic, traumatic and iatrogenic conditions. Some of these conditions require prompt medical or surgical management, whereas others do not benefit from medical intervention. Necrotising fasciitis is a rare, life-threatening soft-tissue infection and a medical and surgical emergency that radiologist must know. The presence of gas within the necrotised fascia is characteristic, but may be lacking. The main finding is thickening of the deep fascia due to fluid accumulation and reactive hyperemia. All these findings may be seen in other different conditions. The ability to accurately diagnose these conditions is therefore necessary. Clues to the correct diagnosis and whether a biopsy is necessary or appropriate are often present on the images techniques, especially when they are correlated with clinical features.

Learning Objectives:

1. To learn the key signs for differential diagnosis.
2. To learn about imaging findings and management options.

A-0090 11:15

B. Arthropathies

U. Aydingoz; Ankara/TR (uaydingo@hacettepe.edu.tr)

Arthropathies are one of the most common health problems and the leading cause of disability in adults. Imaging plays an essential role in their diagnosis and follow-up. Plain films remain the first line imaging tool in the diagnosis and management of arthropathies, whereas MR imaging is essential to ascertain the presence of active inflammation and disruption of intra- and periarticular structures. This interactive presentation focuses on radiological features of common (and several less common) arthropathies and how they help in narrowing the differential diagnostic considerations.

Learning Objectives:

1. To explain the key points in the differential diagnosis of common arthropathies.
2. To describe the imaging findings of common arthropathies as they relate to pathophysiology.

Early detection of prostate cancer

A-0091 10:30

Chairperson's introduction

G.M. Villeirs; Ghent/BE

Prostate cancer is traditionally diagnosed on the basis of the combination of elevated PSA, abnormal digital rectal examination and transrectal biopsy. New biomarkers, including imaging, are currently challenging this gold standard diagnostic test. They are equally useful in the choice between immediate versus deferred treatment. Both aspects will be covered in detail during this session.

A-0092 10:36

A. Screening for prostate cancer: where are we now? (part 1)

A. [George](#); London/UK (angela.george@rmh.nhs.uk)

Screening for prostate cancer with prostate-specific antigen (PSA) has been widely investigated. Several large screening studies, e.g. prostate, lung, colorectal and ovarian (PLCO), European randomised study of screening for prostate cancer (ERSPC) and cluster randomised trial of PSA testing (CAP), have shown PSA screening may lead to increased prostate cancer diagnoses, and at best may result in a small benefit in disease-specific mortality over 10 years but does not improve overall mortality. These benefits need to be considered against possible harms of PSA screening, including complications from a biopsy and subsequent treatments and the risk of overdiagnosis and treatment. Recent studies suggest incorporating MRI in the investigation of those with positive PSA test reduces the false positive rate and unnecessary biopsies and also increases the accuracy of biopsies in those with clinically significant cancer. Trials screening for prostate cancer with MRI is being proposed. Incorporating the patient's genetic mutation status into risk algorithms may allow development of targeted screening programs for early cancer detection and treatment, and may improve survival. Those with germline mutations such as BRCA2 have an increased risk from the age of 40yrs, and often more aggressive disease. There is also ongoing work stratifying prostate cancer risk at a population level with the use of single nucleotide polymorphism (SNP) panels. This use of targeted PSA and MRI screening in men with DNA repair mutations, adverse SNP profile and Afro-Caribbean ethnicity may result in improved outcomes and management algorithms based on biological disease behaviour.

Learning Objectives:

1. To be aware of important prostate cancer genetics and familial cancer.
2. To learn about the difference in low risk vs high risk genetic groups.
3. To be aware of the use of imaging and other biomarkers.

S. [Punwani](#); London/UK

"no abstract submitted"

Learning Objectives:

1. To understand the role of mpMRI in tumour detection.
2. To be aware of texture features of prostate cancer.
3. To learn how texture analysis differentiate benign from malignancy prostate lesions.

A-0095 11:32

C. Active surveillance: best practice

J.J. [Fütterer](#); Nijmegen/NL (jurgen.futterer@radboudumc.nl)

In order to avoid unnecessary radical treatment, active surveillance (AS) is becoming a viable treatment alternative in low-risk prostate cancer. Because most low-risk prostate tumours have an indolent course and the slow growth rate allows ample time during follow-up to detect tumours that begin more aggressive while remaining in a window of definitive curability. Patients are carefully observed every three or four months for changes in PSA, digital rectal examination or changes upon performed transrectal ultrasound (TRUS) guided biopsy. MR imaging is an appealing imaging technique to select and to surveil patients who choose for active surveillance. The addition of prostate MR imaging to the biopsy strategy or, in select patients, using MR imaging as a substitute for a repeat biopsy improves prostate cancer detection.

Learning Objectives:

1. To be familiar with case selection for active surveillance.
2. To know the frequency of imaging.
3. To understand when treatment will be commenced.

Acute pancreatitis

Moderator:

R. Manfredi; Rome/IT

A-0096 12:30

Atlanta Classification of acute pancreatitis

T. [Bollen](#); Nijmegen/NL (tlbollen@hotmail.com)

The 2012 Revised Atlanta Classification (RAC) distinguishes between clinical severity of acute pancreatitis (AP) based on clinical parameters and morphologic severity based on CT parameters. The RAC defines three grades of clinical severity with increasing morbidity and mortality rates: Mild AP: defined as the absence of systemic or local complications. Moderately severe AP: defined as the presence of transient organ failure, deteriorating pre-existing co-morbid disease and/or presence of local complications requiring prolonged stay or intervention. Severe AP: defined as persistent organ failure (>48 h). Morphologically, interstitial and necrotising pancreatitis are discriminated, depending on the absence or presence of tissue necrosis, respectively. In general, patients with interstitial pancreatitis have clinically mild disease, and conversely, most patients with necrotising pancreatitis will sustain clinically severe AP. CT findings, however, are not absolutely predictive of outcome for an individual patient. Approximately 5% of patients with minimal changes on CT will have significant complications with mortality of around 1-3%. An even larger number of patients, up to 30%, will have a relatively benign clinical course despite the presence of pancreatic necrosis. Therefore, ultimate severity of disease is based on clinical parameters, primarily organ failure. CT is regarded as the frontline imaging technique for full evaluation of AP severity, especially in those who are predicted severe by clinical assessment. Follow-up studies are dictated by clinical findings that include sudden-onset or increase of abdominal pain and organ failure, signs of sepsis or other clinical signs of local complications or when invasive treatment is contemplated.

Learning Objectives:

1. To understand grading of acute pancreatitis: Atlanta Classification.
2. To learn about the clinical impact of Atlanta Classification.
3. To understand the follow up of acute pancreatitis.

A-0097 13:00

Role of imaging

C. [Triantopoulou](#); Athens/GR (ctriantopoulou@gmail.com)

Imaging is frequently recommended in patients with acute pancreatitis (AP) to confirm the clinical diagnosis, ascertain the cause, grade the extent and severity of the disease, evaluate severe complications and indicate interventional procedures. The revised 2012 Atlanta criteria for classification of the severity of AP are widely accepted. The challenge for imaging remains to recognise patients suffering from severe or moderately severe AP. But, a direct correlation between clinical severity and morphology may not exist. Imaging is of utmost importance in the 2nd phase of the disease evolution (usually >2 weeks after onset) where AP resolves or evolves secondary to the presence of necrosis and infection, thus morphologic criteria are needed as defined by imaging techniques. It is important to evaluate the extent of necrosis (intrapancreatic, extrapancreatic or both) and also to define if this is sterile or infected. Contrast-enhanced CT is the best technique; however the staging of

severity and detection of complications depend on the timing of CT scanning. In the first 24-48 hours, the CT findings of necrosis may be equivocal. In severe AP, unless the patient is critically ill and in need of emergency intervention, the initial CT scan should ideally be obtained at least 72 hours following symptoms onset. As 50% of AP cases are gallstone-related, transabdominal ultrasound is the most common initial radiologic investigation of choice. MRI can better differentiate complex fluid collections from mature pseudocysts and hemorrhagic collections, while MRCP is the best technique to identify pancreatic duct disconnection.

Learning Objectives:

1. To learn about diagnosis of acute pancreatitis.
2. To understand how to apply Atlanta Classification to imaging.
3. To learn about new trends in diagnosis of acute pancreatitis.

Infection: bone and soft tissue

J.L. Bloem; Leiden/NL (j.l.bloem@lumc.nl)

In this lecture, we'll focus on imaging osteomyelitis of the appendicular and axial skeleton, and their differential diagnosis using radiographs, US, and especially MRI and PET-CT. Understanding the interaction between invading organisms and intact or compromised host response is essential in the interpretation of imaging features. Major routes of infection include hematogenous or contiguous routes occurring in respectively pediatric-geriatric, or immunocompromised and diabetic, or post-procedure infections. Location in the metaphysis and vertebral body are hallmarks of hematogenous spread. Location in bones close to skin defects, pressure points, and soft tissue infection are hallmarks of contiguous spread, especially in diabetic foot, intensive care patients, and following surgical or image guided procedures. Knowledge of age and the comorbidity-related relationship between vasculature on one-hand and growth plates and discs, on the other hand, is essential in the diagnosis of infection. Also, imaging features of host response depend on the pressure within anatomical compartments. The most relevant differential diagnostic issues including posttraumatic sequelae, degenerative disease, Charcot foot and spine, sterile inflammatory disease (CRMO, SAPHO), tumours, and also the differentiation between mild and life-threatening infection like necrotising fasciitis will be discussed. The impact of imaging on clinical outcome as it depends on treatment options, cost-effectiveness, predictive values of various imaging studies relative to clinical and laboratory tests, is addressed.

Learning Objectives:

1. To become familiar with pathophysiology of infectious diseases pertinent to imaging features.
2. To understand imaging features of infectious diseases and their differential diagnosis.
3. To appreciate the clinical perspective of imaging infectious diseases.

Tumour response assessment in abdominal imaging

Moderator:

S.M. Ertürk; Istanbul/TR

A-0107 14:00

A. Colorectal liver metastases

S.K. Venkatesh; Rochester, MN/US (venkatesh.sudhakar@mayo.edu)

Colorectal liver metastases (CRLM) occur in nearly half of the patients with colorectal cancer. Neoadjuvant chemotherapy (NAC) is the treatment of choice. Surgical resection and locoregional control have evolved as treatment options in the patients with single or oligometastatic disease and in those who show excellent response to NAC. The number, location and response of CRLM

are critical in determining their surgical resection. Assessment of treatment response of CRLM to NAC and locoregional treatment is therefore very important to provide guidance for their management. Standard methods of assessment (RECIST) use size (one-dimensional, bi-dimensional, volume) and a reduction in the size is considered a response. However there are pitfalls to these methods and they will be highlighted during the presentation. Variable responses of CRLM and to different chemotherapy regimens add another dimension to complexity of assessment of the response. The most important information is a viable or a residual tumour which tumour size alone cannot predict but can be assessed with additional information from dynamic contrast-enhanced MRI (DCE-MRI), diffusion-weighted imaging (DWI), positron emission tomography (PET). NAC and some locoregional treatment also cause liver toxicity including sinusoidal obstruction syndrome (SOS), chemotherapy-associated steatohepatitis (CASH) or simple fatty change that can influence the assessment of response. In this presentation, an overview of response of CRLM to treatment will be presented and this will be followed by review of different methods for response assessment including their limitations and advantages.

Learning Objectives:

1. To learn about different methods to assess the tumour response in the colorectal metastases.
2. To understand usefulness and limitation of techniques and the role of different contrast media.
3. To appreciate the variable response pattern of colorectal liver metastases.

A-0108 14:30

B. Rectal carcinoma

M.J. Lahaye; Amsterdam/NL (MJ.Lahaye@gmail.com)

MRI is the modality of choice for restaging rectal cancer. The high soft-tissue contrast of MRI can accurately assess the extramural tumour spread and relation to surrounding structures after chemoradiation. This lecture will have a practical approach to determining the role of MRI in the restaging of rectal cancer. The relevant anatomy, MRI techniques, the rationale for neoadjuvant treatment, and post-chemoradiation therapy imaging (including detection of patients with a complete response) will be discussed with special attention to how to apply recent advances in knowledge to daily clinical practice.

Learning Objectives:

1. To learn about the rationale for neoadjuvant treatment in rectal cancer and the impact on subsequent surgery.
2. To understand why imaging is needed to assess the response to neoadjuvant therapy, what to look for when judging response and where the challenges lie.
3. To appreciate when surgery can be deferred or avoided and how to best follow-up on these patients.

A-0109 15:00

C. Pancreatic adenocarcinoma

M. Zins; Paris/FR (mzins@hpsj.fr)

Pancreatic ductal adenocarcinoma (PDA) remains among the most challenging malignancies to treat. At diagnosis, the tumour often already extends beyond the confines of the pancreas, spreading to an extent such that primary surgery with curative intent is very rarely feasible. Considerable momentum is now being given to a treatment strategy involving neoadjuvant chemotherapy or chemoradiotherapy in patients with nonmetastatic PDA. The main advantage of this strategy is a better selection of patients likely to benefit from curative-intent surgery via the achievement of negative resection margins. Patients with a rapidly progressive disease are identified and spared ineffective surgery with its attendant morbidity. Neoadjuvant therapy can convert tumours classified as locally advanced by initial imaging studies to resectable tumours. However, the imaging study evaluation of the response to neoadjuvant therapy is extremely complex. Thus, the diagnostic performance of imaging studies is not sufficient to ensure the accurate selection of patients in whom negative-margin resection is likely to be achieved. More specifically, standard criteria for predicting vascular invasion, based on the amount of tumour-vessel contact, are not valid after neoadjuvant therapy.

Learning Objectives:

1. To understand the rationale for neoadjuvant treatment in pancreatic adenocarcinoma.
2. To learn the limitations of CT in assessing treatment response.
3. To learn how to accurately select patients for curative-intent surgery after neoadjuvant therapy.

Hybrid imaging: the best of both worlds

Moderators:

N.N.

K. Riklund; Umea/SE

Session Objectives:

1. To review the principles of hybrid medical imaging.
2. To understand the indications, limitations and comparative merits of hybrid medical imaging across a wide range of cardiac, vascular and oncological conditions.
3. To appreciate the need for optimisation and dose management within hybrid imaging.

A-0110 14:00

A. PET/CT

M. [Zeilinger](mailto:markus.zeilinger@thwn.ac.at); Wiener Neustadt/AT (markus.zeilinger@thwn.ac.at)

The establishment of highly sensitive molecular imaging techniques, in combination with the synthesis of novel radiolabelled bioactive molecules for the visualisation and quantification of numerous specific (patho)physiological processes and biochemical targets, merged the fields of molecular imaging and personalised medicine. In this context, PET belongs the most sensitive imaging modality with an excellent molecular sensitivity, capable of providing high temporal resolution for kinetic analysis of biochemical phenomena and molecular processes. The combination of a dedicated PET with a CT modality, as a morphological imaging technique, has the potential to provide essential, comprehensive information and to increase the scope of application for modern molecular imaging.

Learning Objectives:

1. To review the technology underpinning PET/CT.
2. To understand important staff and patient safety issues.
3. To discuss the current and potential clinical applications of PET/CT and optimal imaging protocols.

A-0111 14:30

B. Clinical impact of hybrid interventional imaging

S. [Robinson](mailto:sharon.robison@mtf.nhs.uk); Manchester/UK (sharon.robison@mtf.nhs.uk)

With many interventions no longer only open surgery but a combination of open and endovascular or purely endovascular, a hybrid endovascular theatre is recommended. Hybrid theatres combine access for safe open surgery with the ability to perform high quality rotational fluoroscopic imaging. As lead Interventional Radiographer at a busy tertiary vascular referral centre, the author has knowledge and experience in the implementation and use of the Hybrid theatre setting and will discuss the benefits of patient care and advanced imaging techniques provided by Hybrid imaging.

Learning Objectives:

1. To review clinical indications for hybrid interventional procedures.
2. To understand the radiographer's role in patient care and management in the hybrid suite.
3. To discuss image acquisition and processing techniques required for hybrid examinations.

A-0112 15:00

C. Optimisation/dose management in the hybrid interventional suite

D. [Maccagni](mailto:maccagni.davide@gmail.com); Milan/IT (maccagni.davide@gmail.com)

The hybrid room is a high-complexity operating room, fully equipped for minimally invasive procedures and provided with imaging techniques such as fluoroscopy/angiography, ultrasound, computed tomography, or magnetic resonance imaging. In this environment, the radiographer works with a team of health professionals including cardiologists, cardiac surgeons, vascular surgeons, urologists, anesthesiologists, sonographers, radiologists, engineers and nurses, sharing the knowledge and skills necessary to assist these specific hybrid procedures. Managing radiation exposure in the hybrid room is of utmost importance. The risk related to radiation exposure is represented by tissue reactions, (e.g., skin burns), and stochastic effects, where the risk of an outcome is proportional to the dose received, (e.g., cancer). This issue can affect patients but can also have harmful consequences for the operators that are present in the room, during the entire procedure. Nowadays, with the possibility offered by technology in a hybrid room, there are different options for dose optimisation. Modern fluoroscopy machines reduce the dose delivered while maintaining high-level image quality and some tools have been introduced to limit operators' x-ray exposure. This has indeed allowed an improvement in terms of safety, but it should not be forgotten that the

continuous application of the basic rules of radiological protection remains of fundamental importance. The proper application of radiological protection is one of the most prominent responsibilities of the radiographer's duty. A proper application of radiation protection, with continuous and updated training, can minimise the radiation issues, increasing the procedure safety, without compromising the effectiveness of the procedures.

Learning Objectives:

1. To review current options for optimisation in the hybrid interventional suite.
2. To understand the radiographer's role in optimisation and dose management in the hybrid suite.
3. To discuss occupational radiation protection issues in the hybrid suite.

Mediastinal

M. [Occhipinti](mailto:mariaelena.occhipinti@gmail.com); Florence/IT (mariaelena.occhipinti@gmail.com)

Several pathological conditions can arise from such a complex anatomical structure as the mediastinum, including large airways, large and small vessels, lymph nodes, adipose tissue, nerves, oesophagus, heart, and pericardium. The wide spectrum of mediastinal diseases makes their differential diagnosis very challenging at times. To simplify the clinical approach to the mediastinal lesions many classifications of the mediastinum based either on either chest radiography or CT have been proposed. Knowledge of the most appropriate technique to use in each clinical context as well as knowledge of specific imaging signs and features are needed to narrow the spectrum of differential diagnosis and to address most questions arisen when a mediastinal mass is either seen or suspected at chest radiography. Old and new classifications will be compared and their value discussed as well as signs useful in localising and characterising mediastinal lesions will be examined.

Learning Objectives:

1. To review the mediastinal anatomy according to old and new classifications.
2. To recap signs useful in localising and characterising mediastinal lesions.
3. To know how to choose the most appropriate imaging modality to explore the mediastinum according to the diagnostic question.

Lungs

C.M. [Schafer-Prokop](mailto:Schafer-Prokop@Amersfoort.nl); Amersfoort/NL

"no abstract submitted"

Learning Objectives:

1. To know how to interpret mediastinal lines and contours in chest radiography.
2. To get familiar with "signs" in chest radiography helpful for diagnosis.
3. To know the normal appearance of lung parenchyma on CT and to use the anatomy of the secondary lobule for analysis of chest diseases.

A-0124 15:00

Vasculature

M. [Francone](mailto:marco.francone@uniroma1.it); Rome/IT (marco.francone@uniroma1.it)

Present lecture aims to review the normal anatomy of chest vasculature including caval venous system, great vessels and coronary arteries. Common and less common variants and anomalies will also be displayed and classified, analysing strength and weakness of different imaging methods. Some of these anomalies are found in children having impact, but they are more commonly discovered later in adulthood. Many of these anomalies are asymptomatic or 'leave alone' lesions, but some of these anomalies are symptomatic and need to be treated. Not only cardiovascular imaging dedicated physicians but all general radiologist we have to be familiar with normal vascular anatomy as well as common and less common anomalies.

Learning Objectives:

1. To learn peculiarities of coronary arteries anatomy with specific referral to its implications on myocardial physiology.
2. To review anatomic features of pulmonary arteries and thoracic aorta.
3. To examine patterns and variants of the venous drainage of both the pulmonary and caval system.

Artificial intelligence (AI): driven by radiologists

A-0125 14:00

Chairperson's introduction

E. [Kotter](mailto:elmar.kotter@uniklinik-freiburg.de); Freiburg/DE

The development of Artificial Intelligence in Radiology has been surpassing expectations over the last years. Radiologists have both great expectations and many questions regarding the introduction of these disrupting technologies in clinical routine. Many questions are raised concerning the integration of AI in the clinical workflow, and continuous clinical validation of results. Additionally, the future role of the radiologist is questioned, and there are many discussions on the ethics of AI applications in clinical routine. This session will address these questions with the support of internationally renowned speakers.

Session Objectives:

1. To learn what can be expected from AI in radiology and to know the limitations of the technology.
2. To learn how AI technology can be integrated in the radiology workflow.
3. To learn how to make radiology knowledge available for AI training.
4. To learn how the introduction of AI in radiology will change the doctor-patient and radiologist-clinician relationship.

Author Disclosure:

E. [Kotter](mailto:elmar.kotter@uniklinik-freiburg.de): Advisory Board; Agfa.

A-0126 14:05

The impact of AI technologies in patient care: advantages and limitations

E.L. [Siegel](mailto:esiegel@umaryland.edu); Baltimore, MD/US

In their recent editorial in Academic Radiology, Cohan and Davenport refer to radiologist "burnout" and having reached a "tipping point". They suggest that despite improvements in PACS and EMR's, "Radiologists are still being told to work faster as the screws continue to tighten; more images, greater case volume, increasing complexity and less time to do the work". Radiologists are increasingly asked to perform quantitative analysis on complex dynamic studies such as prostate and breast MRI, analyse multi-parametric imaging from MRI, PET, CT, and to follow new guidelines for lung cancer and other screening studies. Deep learning represents a fundamentally different approach to the development of algorithms for image acquisition, quantitative analysis, and interpretation based on learning by example from large image sets. It offers numerous advantages over more "traditional" Computer Aided Design approaches including decreased time, and less specialised medical imaging expertise required for development as well as the potential for continuous and personalised refinement of algorithms. In fact, Deep Learning may actually have its greatest initial success in solving non-image related challenges such as image quality, workflow efficiency, improved communication and patient safety. This technology, however, is also fraught with limitations including the requirement for large amounts of annotated data, regulatory, medicolegal, and relative brittleness with regard to lack of generalizability from a few to a multitude of different scanners. Overall, despite the challenges, Deep Learning will undoubtedly have a major impact in the next several years on positively resetting radiology's current "tipping point".

Learning Objectives:

1. To know the challenges of knowledge management in radiology.
2. To know the advantages of machine learning technologies compared to traditional approaches.
3. To know the technical limitations of machine learning.

A-0127 14:28

How to integrate AI technology in radiology today

W.J. [Niessen](mailto:w.niessen@erasmusmc.nl); Rotterdam/NL

The combination of big data and artificial intelligence are dramatically increasing the possibilities for prevention, cure and care, and are changing the landscape of the healthcare system. Biomedical imaging data will play a central role in this revolution. In this presentation, I will show examples of possible large benefits of big data analytics of imaging, genetic and clinical data in dementia and oncology. Both conventional machine learning techniques, such as radiomics for tumour characterisation, and deep learning techniques that directly learn from the imaging data will be addressed. Also, the concept of deep imaging, full integration of medical imaging and machine learning, will be discussed. Finally, I will address the challenges of how to successfully integrate these technologies into the daily clinical workflow.

Learning Objectives:

1. To know the challenge: multitude of AI engines to be integrated in one workflow.
2. To learn how to collect and annotate radiology data for machine learning.
3. To learn how to organise radiologist's workflow when using AI.
4. To learn to manage radiology data to be used for machine learning.

Author Disclosure:

W.J. [Niessen](mailto:w.niessen@erasmusmc.nl): Consultant; I am Scientific Lead at Quantib BV. Shareholder; I am shareholder of Quantib BV.

A-0130 14:06

A. WB MRI for staging and treatment planning in ovarian cancer

V. [Vandecaveye](mailto:vincent.vandecaveye@uzleuven.be); Leuven/BE

By their ability to evaluate distant nodal or visceral metastatic disease spread, computed tomography (CT), Fluorodeoxyglucose positron emission tomography/CT (FDG-PET/CT) and magnetic resonance imaging (MRI) have an increasingly important role in the management of gynaecological cancers. MRI has established its clinical importance by its superior contrast resolution and ability to extract morphological and functional information, beneficial for tumour detection, characterisation, staging and response assessment. The single most important prognostic factor in ovarian cancer is complete tumour resection at debulking surgery. In patients suspected for ovarian cancer, imaging workup has a major role in depicting metastases in order to assess resectability. CT tends to underestimate peritoneal disease extent; a problem that is not adequately solved by FDG-PET/CT. Recent technological progress has enabled time efficient whole-body MRI (WB-MRI) integrating diffusion-weighted imaging (DWI); the latter allows for the depiction of millimetric tumour deposits. In recent studies, WB-MRI/DWI has shown greater accuracy for a comprehensive presurgical depiction of peritoneal metastases over CT or FDG-PET/CT, while WB-MRI/DWI has shown similar accuracy to FDG-PET/CT for depicting distant metastases and lymphadenopathies. Important for surgical planning, MRI has shown better sensitivity over conventional imaging for detecting involvement of surgically critical tumour sites including mesenteric root infiltration small bowel and colon carcinomatosis and unresectable distant metastases. This presentation will discuss sequence optimisation, DWI anatomy, physiological signal and artefacts, the appearance of tumoral lesions in relation to their size and correlation of WB-MRI/DWI findings to surgical criteria that determine complete resection.

Postgraduate Educational Programme

Learning Objectives:

1. To learn the MRI technique for imaging the peritoneum in advanced ovarian cancer.
2. To learn the appearances of WB-MRI in metastatic ovarian cancer.
3. To be aware of the pitfalls to interpretation.

A-0131 14:34

B. PET/CT and PET/MRI in cervix and endometrial cancer: current status

L. [Umutlu](#); Essen/DE

"no abstract submitted"

Learning Objectives:

1. To learn the indications for use of hybrid imaging in cervix and endometrial cancer.
2. To know the strengths and weaknesses of the technique.
3. To be familiar with the role of hybrid imaging in patient prognosis.

A-0132 15:02

C. Advanced imaging techniques in metastatic gynaecological cancer

E. [Sala](#); Cambridge/UK (es220@cam.ac.uk)

Tumour heterogeneity in metastatic gynaecological cancer and especially advanced ovarian cancer has been reported at the histological and genetic levels and found to be associated with adverse clinical outcomes. Classic tumour evaluation using standard CT or MRI techniques does not account for the intra- or inter-tumoural heterogeneity in advanced ovarian cancer with peritoneal carcinomatosis. As such, computational approaches in assessing tumour heterogeneity have been proposed using radiomics and radiogenomics to capitalise the whole tumour heterogeneity as opposed to single biopsy sampling. As part of radiomics, texture analysis which includes the extraction of multiple data from the images has been proposed recently to evaluate advanced ovarian tumour heterogeneity. The preliminary data suggests that it can unravel tumour heterogeneity and predict response to treatment both conventional and immunotherapy.

Learning Objectives:

1. To learn about the concept and technique of texture analysis.
2. To be familiar with the key associations of biology and texture features.
3. To be familiar with the potential added value of texture analysis in image interpretation.

14:00 - 15:30

E³ - ECR Academies: Functional Imaging for Disease Management: Research to Medical Practice

E³ 320

Functional imaging of the brain

A-0133 14:00

Chairperson's introduction

T.A. [Yousry](#); London/UK (t.yousry@ucl.ac.uk)

Functional imaging has come a long way from being a demanding research tool to becoming an integral part of clinical MRI protocols essential for the decision-making process and therefore management of various CNS diseases. In this exciting session, we will explore the spectrum of its use from research to clinical practice in 3 distinct diseases: stroke, brain tumours, and small vessel diseases.

A-0134 14:06

A. Stroke

T. [Tourdias](#); Bordeaux/FR

Brain imaging is an emergency when an acute stroke is clinically suspected. Such acute imaging is crucial (i) to establish the diagnosis of an ischemic or hemorrhagic stroke while ruling out stroke mimics, (ii) to provide etiological and prognosis clues and mainly (iii) to guide the acute therapeutic strategies. Either computer tomography (CT) or magnetic resonance imaging (MRI) can be used depending on their availability. The protocol is typically multimodal including for CT: non-contrast acquisition, angio-CT of head and neck vessels and brain perfusion CT; and for MRI: FLAIR, diffusion, T2*, angio-MR of head and neck vessels and brain perfusion MR. In ischemic stroke, the functional information provided by diffusion and/or perfusion can now be used to select the appropriate candidates for mechanical recanalisation within an extended time window (up to 24h after stroke onset) based on the concept of penumbra.

Learning Objectives:

1. To be aware of relevant functional studies in the emergency room.
2. To learn about the most useful functional parameter to be quantified.
3. To learn about the impact of functional data for patient management.

A-0135 14:34

B. Brain tumours

A. [Majos](#); Lodz/PL (agata.majos@umed.lodz.pl)

There are quite many advanced MR imaging techniques which are currently available in the majority of MRI centres and can be used in daily routine. They offer different kinds of functional data resulting from their physical basis which can be helpful in differentiation between brain tumours and other pathological items as well as in the determination of tumour types and grades. They are also the source of vital information for clinicians to provide the most effective and safe ways of treatment. The essentials of main functional methods will be introduced including diffusion and perfusion techniques, functional MRI and just a touch of susceptibility weighted imaging. The selection of technics will be discussed, and some diagnostic algorithms will be proposed. The examples of clinical cases will be presented to illustrate the validity of multiparametric imaging in practice. Lastly, future perspectives will be mentioned, e.g. - randomised and use of machine learning developments.

Learning Objectives:

1. To learn about how functional data may help in characterising brain tumours.
2. To understand significance of quantitative data patient management.
3. To become familiar with limitations and pitfalls of functional technics.

A-0136 15:02

C. Cerebral small vessel diseases

M.A. [Van Buchem](#); Leiden/NL

"no abstract submitted"

Learning Objectives:

1. To know about main imaging criteria for characterisation of diseases.
2. To learn about the role of functional techniques for grading diseases.
3. To understand how functional imaging allows following diseases process.

ESR Audit and Standards Session

ESR Audit

Audit across Europe: directive and perspective

A-0137 16:00

Chairperson's introduction

D.C. [Howlett](#); Eastbourne/UK (david.howlett@nhs.net)

This session on clinical audit aims to further promote knowledge and understanding of clinical audit and its application in the departmental radiology setting. Topics include radiographic and industry perspectives, giving insight and guidance on local implementation of clinical audit programmes. An important update on inspection is also provided. The ESR Guide to Clinical Audit, Esperanto, is designed to support radiology departments in developing audit programmes, with an emphasis on compulsory, regulatory, radiation protection type audit and a brief update on the latest version of this guide will be provided.

Session Objectives:

1. To understand the principles of clinical audit.
2. To update on the Esperanto audit project.
3. To evaluate individual experience on implementation of a clinical audit programme.

A-0138 16:10

Clinical audit and inspection: HERCA update

S. [Ebdon-Jackson](#); Didcot/UK (steve.ebdon-jackson@phe.gov.uk)

Carrying out clinical audits in accordance with national procedures is a requirement of the Basic Safety Standards Directive (BSSD) 2013/59/Euratom Article 58(e). The Heads of the European Radiation protection Competent Authorities (HERCA) intends to publish a position paper on the differences between inspection and audit and the expectations of radiation protection competent authorities regarding the requirements. The contents of this paper will be discussed.

Learning Objectives:

1. To understand the differences between inspection and clinical audit.
2. To update on Heads of the European Radiological Protection Competent Authorities (HERCA) and departmental inspection.

Postgraduate Educational Programme

A-0139 16:20

Implementing a clinical audit programme: the Finland experience

T. [Autti](#); Helsinki/FI (taina.autti@hus.fi)

The purpose of clinical audits is to improve the quality and outcome of patient care by reviewing imaging practices against agreed standards for good medical practices and evidence-based medicine. The national advisory committee for the clinical audit (NACA) was founded to support this goal in 2004. The members of the NACA are clinical experts independent of the auditing organisations and public officers from radiation and nuclear safety authority (STUK) in Finland and the ministry of social affairs and health. So far NACA has given 14 recommendations for the clinical implementation of the clinical audit process. These recommendations will be presented and discussed in this presentation. In a clinical audit, the auditors should be independent of the audited organisations. Their role is to produce an independent assessment and report the findings and recommendations to the audited unit. The interval of clinical audits for Finnish medical units using radiation has been five years. Thus, we have experience of three completed audit rounds. Interestingly, the largest number of auditor recommendations were given in the second audit round. Based on our experience, the coordinating and advisory role of the NACA has turned out to be highly important in ensuring good quality of the clinical audit process. In addition, the recommendations of NACA help to harmonise the clinical audit process. Finally, consistent guidelines for auditors given by the recommendations seem to be necessary to produce comparable audit results.

Learning Objectives:

1. To learn about Finnish clinical audit rounds performed between 2002 and 2016.
2. To introduce the recommendations issued by the Finnish advisory committee for clinical audit and evaluate the effectiveness of these recommendations.
3. To evaluate the future of clinical audits in Finland.

A-0140 16:40

Implementing a clinical audit programme: the radiographic perspective

M.-L. [Ryan](#); Dublin/IE (marie-louise.ryan@ucd.ie)

Clinical audit is arguably the most important part of a quality programme. It allows the radiology team to measure performance against specified standards- local, national and international. This session will help the audience understand something that is often feared in clinical practice and make clinical audit something that is useable, practical and achievable. This session will bring the audience through suggested clinical audits in their department and show real life examples- namely patient identification, workflow optimisation and radiation dose optimisation and justification. The presenter will show examples of where real-life audits have fed into quality improvement in the radiology department around patient and staff safety, financial savings and optimising processes. Different challenges and how to overcome them will be discussed including staff involvement, time management and creating a culture of quality improvement.

Learning Objectives:

1. To learn how important clinical audit is in day-to-day practice.
2. To appreciate the opportunities and challenges of clinical audit in practice.
3. To understand the impact on quality improvement of clinical audit in a radiographer department, using real life examples.

A-0141 17:00

Quality improvement and change management: audit in industry

S. [Lee](#); Guildford/UK (steven.lee_1@philips.com)

A clinical audit might be likened to the process of 'continuous improvement' of quality in the industry. The later focusing on improving competitive performance by raising the quality (for customers) and reducing the cost of products and services. While the former focuses on improving the quality of patient care by ensuring clinical practice is delivered in line with defined standards. Both face the challenges of engaging people, developing supportive cultures and of using systematic methods for sustaining the improvement process. While the industry has been deploying quality improvement approaches for many decades, the practice of clinical audit in many healthcare organisations is by comparison relatively immature. The talk considers the evolution of different industrial management 'paradigms' concerned with quality improvement from the middle of the last century. The growing emphasis on the 'people dimension' of quality improvement is highlighted, as is the significance of using an agreed and systematic process (e.g. PDSA: Plan, Do, Study, Act) for effecting quality improvement. The central importance of quality improvement for achieving competitiveness in an industrial setting is described, as are the major 'trends' deployed in realising such improvement. Potential areas of symbiosis between clinical audit and management paradigms (e.g. Lean, Six Sigma etc.) are explored, particularly Lean principles, people change management and alignment of structured quality improvement processes.

Working to align the intrinsic motivation of staff with the practice of audit and quality improvement, by highlighting the benefits offered to patients (and internal customers) is emphasised as the key to securing staff engagement.

Learning Objectives:

1. To learn about the genesis of audit.
2. To appreciate the importance of audit in industry.
3. To understand the importance of clinical audit in successful management.

Everything you need to know about 3D post-processing

A-0142 16:00

Chairperson's introduction

E. [Sorantin](#); Graz/AT (erich.sorantin@medunigraz.at)

Progress in imaging technology equipment enables to scan patients in high geometrical and temporal resolution as well as in multidimensional space (e.g. 4D). The amount of resulting data cannot be read any more in 2D as done in the last millennium. Furthermore advances in computational power enables to use sophisticated processing algorithms in real time. Thus reading in 2D, as done in the previous millennium, will be gradually replaced by volumetric reading as well as extracting diagnostic information from parametric images. Moreover, for personalised medicine Radiology has to deliver more detailed information, especially to measure tumour volumes or characterise contrast uptake on perfusion imaging. In order to get familiar with those now really emerging techniques, three well-known speakers will cover essential subtopics and provide a roadmap of how to migrate from reading style in the last millennium to current millennium.

Session Objectives:

1. To learn about the state-of-the-art information regarding 3D post-processing.
2. To understand how 3D post-processing can most optimally be used in daily clinical practice.
3. To appreciate how automated 3D post-processing and quantification will lead to increased use of 3D visualisations for diagnostics and therapy planning, over 2D viewing.

A. 3D post-processing in 2019

A. [Alberich-Bayarri](#); Valencia/ES (alberich_ang@gva.es)

There is a need for the incorporation of advanced tools to assist the specialist in the study evaluation. Automated segmentation of structures based on convolutional neural networks (CNN) has already been established as a powerful tool to detect organs and regions within the body. However, there is a computational limit when working with 3D CNN. Current technology allows for the automated detection of the organs' location and identification of most of the tissue using bounding boxes. These applications may be used today in clinics for the automated assessment of tissue properties. These zero-click algorithms can run seamlessly in the back-end between image acquisition and radiological reporting, with no humans involved, and will provide a paradigm shift in 3D post-processing for radiologists, having the results of the 3D assessment already generated in their PACS even before starting a review of the study. The results of these algorithms though must be verified to provide expected results by a quality check process before getting integrated with the electronic health records.

Learning Objectives:

1. To learn about recent advances in 3D post-processing techniques.
2. To understand how these techniques can now be used in clinical practice.
3. To learn new tips and tricks to use in your daily practice.

B. Making better use of your 3D package: tips and tricks

P.M.A. [van Ooijen](mailto:p.m.a.van.ooijen@umcg.nl); Groningen/NL (p.m.a.van.ooijen@umcg.nl)

Advanced visualisation, simulation and planning software is increasingly used in clinical practice providing a shift from 2D to 3D visualisation, processing and interpretation. With this ongoing trend, the radiological profession should not only focus on the diagnosis to be made but also on the utilisation of our imaging data in patient simulation, planning, and treatment. Current functionality moves in this direction with providing extensive possibilities for support of surgical interventions and treatment planning in 3D including the advent of Virtual and Augmented Reality. With this 3D is also moving into the operating theatre. Although these new possibilities are interesting and exciting one should be very aware of the pitfalls that come with 3D visualisation and processing of data. This not only includes the technical but also the procedural pitfalls where image acquisition optimal for diagnosis is not always optimised for the intended use by the referring physician. To adequately use the new techniques and to provide optimal support from radiology to the referring physicians, training is required, and dedicated staff should be involved in this process.

Learning Objectives:

1. To learn about the functionality of state-of-the-art 3D packages.
2. To understand the pitfalls in use of 3D post-processing.
3. To appreciate the need for training in 3D post-processing techniques.

A-0145 16:51

C. Interpretation of 3D processing results: from image to volume reading

T. [Frauenfelder](mailto:thomas.frauenfelder@usz.ch); Zurich/CH (thomas.frauenfelder@usz.ch)

The widespread introduction of multidetector computed tomography has revolutionised the field of computed tomography (CT). This revolution can be attributed to three primary properties of MDCT: its ability to produce a vast quantity of volumetric data in a reduced amount of time, the high resolution, and the ability to create isotropic voxel data and, consequently, reliable multiplanar and three-dimensional reconstructions. Specialised 3D reconstruction techniques permit the visualisation of anatomical details, which would be difficult to evaluate using axial reconstructions alone. The architecture of the IT systems has undergone dramatic changes. From thick-client systems to thin-client systems and continue to cloud-based architectures. The current trend is to merge the routine diagnostic console and 3D-reconstruction workstation. Whereas there was only a single post-processing station for a whole department, a variety of functions are now available at every single workstation. Although many of us believe that the use of 3D-reconstructions greatly increases total exam evaluation time, there are reports show how using 3D reconstruction techniques for examining volumetric data are effective and improve the speed of interpretation, recognition, and description of specific clinical conditions. But this lean "infrastructure" has not only advantages. Whereas in the old days the radiologist could decide by himself about the systems, radiology is now embedded in a hospital-wide network asking for standards. This may enable the use of new software. Nevertheless, AI and other features ask for a rapid adaptation of IT-software and increase the need for storage.

Learning Objectives:

1. To learn about different developments in creating 3D anatomical and functional models for diagnostic and therapy planning purposes.
2. To understand the pros and cons of such technologies.
3. To appreciate that automated 3D image analysis will lead to new ways in which diagnosis and therapy planning will be performed.

A-0146 16:00

A. In myocarditis

M. [Francone](mailto:marco.francone@uniroma1.it); Rome/IT (marco.francone@uniroma1.it)

Natural history of acute and chronic myocarditis is often unpredictable being independent on the clinical onset of disease and even poorly correlated with more traditional clinical predictors like end-diastolic volume or ejection fraction.

In most cases, patients typically improve within weeks to months, but an unfavourable clinical evolution may be observed in a minority of individuals consisting with the development of chronic ventricular dysfunction progressing leading to transplantation or death in 25% of cases. CMR has emerged as a central prognostic indicator in inflammatory cardiomyopathies, mainly because of its ability to detect tissue fibrosis in vivo. This has been demonstrated with a growing and consistent scientific evidence, derived from late enhancement imaging and, more recently from native T1 mapping and ECV. Present lecture will aim to illustrate CMR capabilities as a prognostic indicator in acute and chronic myocarditis, providing an overview of the most important published studies and ongoing clinical trials. Particular emphasis will be given to the importance of T1 and T2 mapping techniques, being a new standard of reference for CMR diagnosis and the patient's prognostic stratification.

Learning Objectives:

1. To learn about the correlation between clinical presentation and imaging findings.
2. To understand the current state-of-art MRI methods for the evaluation of patients with suspected myocarditis.
3. To learn how MRI could be used to inform prognosis and management decisions in myocarditis.

Author Disclosure:

B. In non-ischaemic cardiomyopathy

B.K. [Velthuis](mailto:b.k.velthuis@umcutrecht.nl); Utrecht/NL (b.k.velthuis@umcutrecht.nl)

Imaging has established a diagnostic and prognostic value for non-ischaemic cardiomyopathies (CMPs). Early recognition of non-ischaemic CMPs is important for timely management and risk stratification. Cardiac MRI (CMR) provides both the most multiparametric information of all imaging modalities as well as different powerful imaging biomarkers for diagnosis and risk stratification. CMR should help differentiate early CMP from normal variation to prevent over-diagnosis and unnecessary anxiety. Ventricular volumes and function, as well as biventricular involvement, are important for all cardiomyopathies. Atrial size and function are underused but easily obtainable with CMR. Late gadolinium enhancement (LGE) can range from a specific hinge-point (insertion) fibrosis in all types of cardiomyopathies to more specific or diffuse LGE. Location, extent and biventricular involvement of LGE are important diagnostic and prognostic factors that are underutilised in current clinical risk stratification calculators. Promising tools are T1 mapping and feature tracking (FT-CMR). T1 mapping without (native) and with contrast - to calculate the extracellular volume (ECV) - are easily obtainable and have additional value to ventricular volume, function and LGE. Feature tracking (FT-CMR) is a post-processing technique performed on the standard cine imaging and is used to assess global and regional myocardial function. It is comparable to echocardiographic strain analysis and has potential as a new CMR biomarker. The presentation will provide information how to recognise early and typical manifestations of arrhythmogenic (ACM), hypertrophic (HCM) and dilating (DCM) cardiomyopathies on CMR, as well as signs that indicate a risk of progression or adverse prognosis.

Learning Objectives:

1. To recognise typical and early signs of ARVC, HCM and dilated cardiomyopathy that indicate progression and prognosis.
2. To understand what findings should be reported.
3. To appreciate the role of MRI in early diagnosis and prognosis assessment in these cardiomyopathies.

A-0148 17:00

C. In coronary artery disease

M. [Kantarci](mailto:akkanrad@hotmail.com); Erzurum/TR (akkanrad@hotmail.com)

In most patients with coronary artery disease, the decision to perform revascularisation procedures should be based not only on coronary anatomy but also on the functional severity of the lesion. If such a lesion can be clearly demonstrated by myocardial ischemia, exercise, or pharmacological stress testing, revascularisation is appropriate when medical therapy cannot control symptoms. Noninvasive tests, however, are inadequate in some patients. The technology estimates the reference standard fractional flow reserve (FFR) measurement in catheter angiography to determine lesion-specific ischemia. Myocardial FFR is a new index of functional severity of coronary stenosis calculated from pressure measurements during coronary arteriography. In 2015, FDA approved a computational flow dynamics (CFD) method for the diagnosis of hemodynamically significant coronary artery disease by noninvasive coronary CT angiography. FFR is the reference standard in catheter angiography to determine if the lesion is causing ischemia. The clinical significance of moderate coronary artery stenosis may be difficult to determine. $FFR = \text{Distal Pressure} / \text{Proximal Pressure}$. If Causes 0.8 ischemia or > 0.8 if it does not cause ischaemia The understanding of the functional

evaluation of coronary arteries is explosive in the last five years and will be increasingly encountered in clinical practice. However, calculation of FFR from pressure measurements is limited to small vessel disease, diffuse coronary artery disease and left ventricular hypertrophy. A precise understanding of FFR by the radiologist is important in terms of causing new discoveries for new or improved diagnostic tools related to the pathophysiology of vascular diseases.

Learning Objectives:

1. To appreciate the role of anatomic assessment of the coronary arteries versus functional imaging in different patient groups.
2. To learn to report on anatomic and functional imaging in patients with suspected coronary artery diseases.
3. To appreciate the role of non-invasive imaging in prognosis assessment.

The high-risk patient enigma

Moderator:

F. Kilburn-Toppin; Cambridge/UK

A-0149 16:00

A. Lesions with an elevated risk for breast cancer

G. Forrai; Budapest/HU (forrai.gabor@t-online.hu)

The histological, clinical presentation, together with the mammography and US appearance of the high-risk lesions would be demonstrated. They have very different probability figures for developing cancer. This would be detailed for each type of lesion. The concept and the global problem of the management of these lesions will be explained, together with the conflict of over/under diagnosis/treatment.

Learning Objectives:

1. To learn about different types of high-risk lesions.
2. To become familiar with the risk of developing cancer.
3. To appreciate the different imaging modalities for diagnosis.

A-0150 16:30

B. Value of breast MRI. Rate of underestimation and impact on treatment decision: is breast MRI increasing the number of high-risk lesions?

R.M. Mann; Nijmegen/NL (r.mann@rad.umcn.nl)

The evaluation of high-risk lesions on biopsy with MRI is commonly performed. One of the major ideas is to ascertain that there is not more disease present than seen with other techniques. As many high-risk lesions are, in fact, accidental findings on needle biopsy, the absence of enhancement within the breast reduces the likelihood of more extensive disease. Nevertheless, the underestimation rate with MRI is dependent on the type of high-risk lesion initially found and is still substantial for lesions like atypical ductal hyperplasia and lobular neoplasia. Moreover, several high-risk lesions may, in fact, enhance strongly in breast MRI, but are not upgraded at subsequent pathological assessment. In this lecture, MRI features of common and less common high-risk lesions will be discussed. In general, MRI cannot preclude the need for extensive tissue sampling, but it may be used for guiding of the biopsy and may obviate complete surgical excision.

Learning Objectives:

1. To learn about the evidence on MRI for evaluating high-risk lesions.
2. To become familiar with various imaging appearances of high-risk lesions.
3. To appreciate the added value for diagnosis and treatment decision.

A-0151 17:00

C. Can surgery be avoided?

S.J. Vinnicombe; Dundee/UK (s.vinnicombe@dundee.ac.uk)

Within the UK National Health Service Breast Screening Programme (NHSBSP), a median of 7% of screen-detected lesions subjected to needle core biopsy are categorised as B3, of uncertain malignant potential. These lesions comprise a diverse group of pathological entities, with or without epithelial atypia, mostly manifest as mammographic microcalcification. B3 lesions tend to be heterogeneous (such that the area sampled by needle core biopsy may not be representative) and are associated with a variable rate of upgrade to malignancy, either in-situ or invasive, at surgical excision biopsy, which has been the treatment of choice until recently. However, the approach to B3 lesions is changing. With increasing concerns about overdiagnosis (and

subsequent overtreatment) in breast screening and the widespread availability of large bore needle biopsy devices, minimally invasive modes of treatment are increasingly used for these lesions. Various techniques are available, including large bore vacuum-assisted devices and devices which remove the lesion in its entirety with a single pass. These approaches to management of B3 lesions are cost-effective and well tolerated, but oncological safety must be the key consideration. In this respect the literature is challenging to synthesise, since there is wide variability in the rates of surgical excision in differing series, introducing a source of bias. Nonetheless, many countries are gradually adopting minimally invasive approaches, and indeed, the UK NHS Breast Screening programme now recommends that no more than 25% of B3 lesions should undergo surgical excision. These developments will be discussed during this presentation.

Learning Objectives:

1. To learn about the different image guided minimally-invasive modalities to excise high-risk lesions.
2. To become familiar with the risk of avoiding surgery.
3. To appreciate the standard protocols in different countries.

My three top tips in neuroimaging (not only for neuroradiologists)

A-0152 16:00

Chairperson's introduction

M. Stajgis; Poznan/PL (stajgis@gmail.com)

I do hope that this new format of education will gain a lot of interest among radiologists. Nine hot topics in neuroradiology were deliberately chosen to be presented as short 8 minutes mini-lectures. All presenters will focus on fundamental knowledge of different pathological entities. The role of different diagnostic imaging methods and techniques as well as typical imaging findings will be overviewed. Every lecture will end with '3 top tips' based on lecturer's practical experience.

Session Objectives:

1. To highlight the importance of 'key point' knowledge of the pathological entities listed below.
2. To be familiar with most common and typical imaging features in these conditions.
3. To present crucial tips and tricks that allow you to make confident diagnoses.

A-0153 16:05

MRI T2 brain white lesions

A. Krainik; Grenoble/FR (akrainik@chu-grenoble.fr)

T2 hyperintensities are a very common finding on brain MRI, especially in elderly. Indeed, white matter hyperintensities (WMH) might be detected in up to 50% in healthy subjects before 50yo. Beside non-specific WMH of the centrum semiovale and the brainstem suggesting microangiopathy, numerous diseases harbour brain T2 hyperintensities. To further discuss their aetiology and improve MR protocol, three tips are given on their location, their appearance on other weighted images, and patient's history.

Learning Objectives:

1. To be able to identify physiological T2 white matter hyperintensities.
2. To be aware of age-related most common T2 white matter lesions.
3. To give practical clues in quick differentiation of T2 white matter lesions based on their location and appearance.

A-0154 16:13

Multiple sclerosis

K. Katulska; Poznan/PL (katarzyna_katulska@op.pl)

Multiple sclerosis (MS) is an inflammatory demyelinating disease of the central nervous system that is characterised by inflammation, demyelination and degenerative changes. The clinical use of Magnetic Resonance Imaging (MRI) in patients with MS has advanced markedly over the past few years. The benefits of the 2010 McDonald MRI criteria included the focus on lesion location; the presence of gadolinium-enhancing and gadolinium-non-enhancing lesions allows very early diagnosis in some patients who undergo a single MRI examination at any time after symptom onset. Be presented the basic symptoms differentiating demyelinating changes from other hyperintensive

lesions in T2 images dependent in the brain and spinal cord. To assure how to be confident with the correct diagnosis of MS lesions present.

Learning Objectives:

1. To give a short overview of McDonald criteria in multiple sclerosis.
2. To present the typical findings in cerebral and spinal cord multiple sclerosis.
3. To assure you how confident one can feel with correct diagnosis of the multiple sclerosis lesions presence.

A-0155 16:21

Acute disseminated encephalomyelitis (ADEM)

A. [Rovira-Cañellas](#); *Barcelona/ES (alex.rovira@idi.gencat.cat)*

Acute disseminated encephalomyelitis (ADEM) is a severe, immune-mediated inflammatory-demyelinating disorder of the central nervous system that predominantly affects the white matter of the brain and spinal cord characterised clinically by new-onset polyfocal neurologic symptoms including encephalopathy, coupled with neuroimaging evidence of multifocal white matter inflammatory-demyelinating lesions. The disorder is mainly a condition of the pediatric age group, but on rare occasions, adults and elderly patients can also be affected. In the absence of specific biologic markers, the diagnosis of ADEM is based on clinical and radiologic features. This presentation includes special consideration of the value of neuroimaging in the diagnoses of ADEM and the distinction with and other immune-mediated inflammatory demyelinating diseases, in particular, multiple sclerosis.

Learning Objectives:

1. To describe the basics of ADEM entity.
2. To be familiar with morphology, distribution and other characteristic radiographic features in patients with ADEM.
3. To highlight my point of view in the most correct diagnosis of ADEM.

A-0156 16:29

Encephalitis

H.R. [Jäger](#); *London/UK*

"no abstract submitted"

Learning Objectives:

1. To be aware of different etiology of encephalitis.
2. To learn the typical imaging picture of brain structural abnormalities in patients with encephalitis.
3. To present my tips in evaluation of encephalitis-suspected brain lesions.

A-0157 16:37

Meningitis

M.M. [Thurnher](#); *Vienna/AT (majda.thurnher@meduniwien.ac.at)*

Imaging findings in meningitis are unspecific. Computed tomography (CT) is the initial method to exclude other pathologies. Magnetic resonance imaging (MRI) findings include several indirect features suggesting meningeal pathology. Most important MR techniques to detect meningitis are FLAIR with and without gadolinium, diffusion-weighted MR imaging (DWI), postcontrast-T1WI. This lecture will teach you how to interpret MR imaging findings on different MR techniques to make a correct diagnosis of meningitis.

Learning Objectives:

1. To be familiar with different causes of meningitis.
2. To describe the most common MRI findings in acute and chronic meningitis.
3. To present my advice: 'does thickened and enhancing dura always mean meningitis?'

A-0158 16:45

Transient ischemic attack

J. [Hodel](#); *Créteil/FR*

TIA represents a major public health issue. It is crucial to identify the cause of TIA to avoid an acute stroke. The radiologist plays an important role in the management of patients with TIA. Indeed, the objective of imaging is to detect parenchymal and/or vascular abnormalities that can explain the transient clinical symptoms. Such abnormalities are frequently subtle, and the imaging protocol can be thus optimised to further improve the diagnostic performance. MRI or CT can be used, with the advantage for MRI of better visualisation of parenchymal lesions. Imaging of the supra-aortic trunks is an important step of the diagnostic work-up. Using MRI, optimised diffusion, perfusion (including arterial spin labelling) and post-contrast 3D TSE sequences can be also very useful.

Learning Objectives:

1. To understand the importance of imaging in patients with transient ischemic attack (TIA).
2. To highlight the most important imaging features.
3. To present my tips in evaluation of patients with TIA.

A-0159 16:53

Venous sinus thrombosis

P. [Vilela](#); *Almada/PT (ferrovilela@sapo.pt)*

Intracranial venous sinus thrombosis is an important cause of stroke, especially in young patients and children, and only imaging can make the diagnosis. Imaging is essential to establish the venous thrombosis diagnosis but also to evaluate and monitor associated brain lesions. Obtaining orthogonal imaging planes improves the venous thrombosis diagnosis accuracy. CT multiplanar reconstructions (MPR) views improve the CT accuracy for depicting venous thrombosis, especially cortical venous thrombosis. On MRI, the use of T2*WI and T1WI on two orthogonal planes, such as axial and coronal, are highly accurate to depict vessel thrombosis. An important pitfall is that a low T2 signal inside of a venous structure does not exclude thrombosis since a subacute thrombus is hypointense on T2WI (and isointense on T1WI) due to the presence of deoxyhaemoglobin. Computed Tomography Venogram (CTV) or Contrast-Enhanced Magnetic Resonance Venogram (CE-MRV) prove the presence of venous thrombosis by exhibiting complete or partial filling defects inside the dural sinus and/or veins. Venous thrombosis is well-known clinical and imaging mimicker with different forms of presentation. It is extremely important to think on venous thrombosis in the differential diagnosis of a brain lesion, since in a significant number of cases is not suspected by the clinician, and choose the correct imaging protocol.

Learning Objectives:

1. To be familiar with basics of pathology in cortical venous and venous sinus thrombosis.
2. To learn the most common radiologic presentation in venous sinus thrombosis.
3. To provide the hints how to avoid the confusion with sinus thrombosis mimics.

A-0160 17:01

Hydrocephalus

A. [Ramos](#); *Madrid/ES (ramosana3@yahoo.es)*

Imaging plays a central role in the diagnosis of hydrocephalus, CT is the first imaging test in emergency patients, but MRI is the first-line imaging modality. Hydrocephalus can be divided into communicating and non-communicating and obstructive and non-obstructive, depending if there is an obstruction in the ventricular system or the subarachnoid space. Communicating hydrocephalus can be further subdivided in: a) cases with no obstruction to CSF absorption, normal pressure hydrocephalus (NPH) is the most important cause in this category. b) cases with obstruction to CSF absorption due to damage to arachnoid granulations, as occurs in subarachnoid haemorrhage and meningitis. Non-communicating hydrocephalus implies a mechanical problem affecting the passage of CSF through the ventricular system (masses or stenosis in the ventricular system). MRI is useful in detecting the cause and location of the obstruction, imaging protocol should always include sagittal high-resolution T2WI, and especially rewarding are balanced steady-state gradient echo sequences that appear as highly T2 weighted sequences without fluid artefact. When an inflammatory aetiology is suspected, imaging with contrast agent administration is necessary. However, the diagnosis of NPH is difficult because of commonly associated diseases, such as Alzheimer's disease and microangiopathy. With MRI we try to predict which patients are going to respond to a ventricular shunt and include the following parameters: ventriculomegaly with frontal and temporal horns of the lateral ventricles most affected, dilated sylvian fissures, tight high convexity, acute callosal angle, and focal sulcal dilation.

Learning Objectives:

1. To gain a short knowledge of different types of hydrocephalus.
2. To learn how to differentiate normal pressure and obstructive hydrocephalus.
3. To present my 'hot points' in evaluation of patient with hydrocephalus.

A-0161 17:09

Microbleeds

L. [van den Hauwe](#); *Antwerp (Edegem)/BE (lucvdhauwe@mac.com)*

Cerebral microbleeds (CMBs) are detected with increasing frequency since MRI has become more widely available over the last decade. Especially with the introduction of high magnetic field strength (3T) and newer dedicated MR imaging sequences such as susceptibility weighted imaging (SWI), CMBs are increasingly recognized. CMBs are detected on SWI as small hypointense foci with a maximum size of 5-10 mm. They represent focal accumulations of hemosiderin-containing macrophages with paramagnetic properties causing signal loss due to susceptibility effects. CMBs may be observed as an incidental finding in the normal aging population, as well as in various disorders such as Alzheimer dementia, cerebral amyloid angiopathy, stroke, and trauma. Rare causes include endocarditis, cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL), and radiation therapy. Small (so-called type IV) cavernous malformations may be indistinguishable from CMBs. Not every black dot on SWI constitutes a CMB;

phase information obtained with SWI allows to discriminate CMBs from calcifications. Clinical information and previous medical history of the patient, spatial distribution of the lesions (superficial or lobar versus deep, supratentorial versus infratentorial), morphology, and associated imaging findings such as convexity subarachnoid hemorrhage, cortical superficial siderosis, prior lobar intracerebral hemorrhage, white matter abnormalities, are important clues to obtain the correct diagnosis.

Learning Objectives:

1. To understand the impact of presence and number of cerebral microbleeds.
2. To learn the distribution of cerebral microbleeds in different pathological conditions.
3. To give you advice how not to overdetect cerebral microbleeds and how to differentiate them from their mimics.

Small bowel

S.A. Taylor; London/UK (csytaylor@yahoo.co.uk)

Cross-sectional imaging is increasingly replacing fluoroscopic techniques for imaging the small bowel, but both still have a role. It is crucial to recognise the normal appearances of the bowel on all imaging modalities to diagnose abnormality and recognise normal variants. This talk will review the embryological development of the small bowel of importance to radiologists. The aetiology of common congenital malformations such as malrotations and Meckel's diverticulum will be outlined. The appearance of the normal small bowel on the various imaging modalities will be reviewed, along with pitfalls in interpretation.

Learning Objectives:

1. To appreciate the embryological development of the small bowel.
2. To learn about the anatomy of the small bowel relevant to radiological imaging.
3. To understand the pitfalls of the normal small bowel appearance during imaging interpretation.

Author Disclosure:

S.A. Taylor: Consultant; Robarts.

A-0163 16:30

Anorectal

S. Gourtsoyianni; Athens/GR

"no abstract submitted"

Learning Objectives:

1. To review the normal anatomy of the anorectum.
2. To learn how well depicted the different anatomical landmarks of the anorectum are with different available imaging methods.
3. To discuss the clinical scenarios for which it is necessary to be aware of the anatomy of the anorectum.

A-0164 17:00

Peritoneum and mesentery

P.K. Prassopoulos; Thessaloniki/GR (pprasopo@med.duth.gr)

Peritoneal anatomy plays a key role in the dissemination process of intraabdominal inflammatory fluid collections or malignant diseases. The peritoneum, a serous membrane, is reflected over abdominal organs to form a series of folds known as ligaments, mesenteries and omenta. They may act as conduits or barriers in the spread of intra- or extra-peritoneal diseases and they influence the peritoneal fluid circulation- responsible for malignant intraperitoneal seeding - along with bowel peristalsis, gravity and hydrostatic pressure gradients. Although not directly visible on imaging, the twelve major peritoneal ligaments and mesenteries can be identified by their typical position, organ relationships, fatty composition and anatomic landmarks provided by their constituent vessels. Peritoneal folds involved by oedema, inflammation or neoplastic infiltration alter their composition, become thickened, and they are

directly recognised on imaging. Multiplanar CT reconstructions and specific MRI sequences are useful in demonstrating ligaments and mesenteries. Peritoneal reflections subdivide the peritoneal cavity into multiple compartments and recesses that are visualised when distended by the fluid. These subdivisions provide the anatomic basis for localisation of ascites, abscesses, seeded metastases and traumatic effusions. Familiarity with the normal anatomy is essential in the clinical radiologic analysis and differential diagnosis of peritoneal and mesenteric pathology.

Learning Objectives:

1. To review the radiologic anatomy of peritoneal ligaments, mesenteries and omenta on cross-sectional imaging.
2. To describe the most clinically important peritoneal compartments and fluid collections.
3. To discuss the key role of anatomy in the dissemination of malignancies, or the restriction of inflammatory processes in the abdomen.

Imaging of 'foreign bodies'

A-0165 16:00

Chairperson's introduction

U. Linsenmaier; Munich/DE (Ulrich.Linsenmaier@helios-kliniken.de)

This integrated refresher course (iRC) will provide a thorough overview on the role of diagnostic imaging in the assessment of (I) implanted surgical and orthopaedic devices, (II) diagnosis of sharp foreign bodies as well as (III) the role of interventional radiology in the management of foreign bodies. The speakers will explain the current role of CR, CT and US in the assessment and diagnosis of implanted devices as well as ingested foreign bodies. The correct assessment of surgical and orthopaedic devices is a daily routine in many radiological institutions. The speaker will explain the appearance of established and newly introduced materials and discuss their proper positioning as well as early signs of postoperative complications. Many foreign bodies pass through the gastrointestinal tract without problems. However sharp foreign bodies may cause perforation, haemorrhage or bowel obstruction and can be complicated by abscess formation and septicemia. The speaker will discuss characteristics of commonly ingested foreign bodies as well as signs of early complications. Interventional treatment for foreign bodies is relatively rare in many radiological institutions. It comprises not only endovascular removal techniques but also techniques the treatment of complications resulting from inserted or ingested foreign bodies.

Session Objectives:

1. To become familiar with commonly used surgical and orthopaedic devices and materials.
2. To learn their proper positioning and early signs of postoperative complications.
3. To understand the imaging pathway in management of ingested foreign bodies.

A-0166 16:05

A. Surgical and orthopaedic devices: are they really properly positioned?

E. Dick; London/UK (elizabeth.dick@imperial.nhs.uk)

This session will address the common surgical and orthopaedic devices that we encounter in everyday Radiology practice. What do the clinicians consider to be the optimal placement of each device? How can we assess if positioning is suboptimal? What kind of language should we use to describe devices? It will cover lines and tubes, how to evaluate if an endotracheal tube, chest and abdominal drains are correctly placed, including assessing the position of ETT beyond vocal cords, satisfactory inflation of ETT balloon Surgical packing used in damage control surgery. How to evaluate the post-operative trauma/emergency abdomen when radiopaque and non-radiopaque packing is present. Neurosurgical devices: cervical and thoracolumbar spinal fixation: principles of stabilisation, how to evaluate if correctly positioned, what language to use, complications including malplacement and neurovascular injury. Orthopaedic devices: Rib and Pelvic fixation devices: how to assess stability, considerations of neurovascular compromise.

Learning Objectives:

1. To become familiar with different types of commonly used surgical, neurosurgical and orthopaedic devices in clinical practice.
2. To understand how to evaluate their proper positioning.
3. To be familiar with imaging signs of incorrect implementation of neurosurgical and orthopaedic devices.

A-0167 16:30

B. Did I swallow that? US and CT of sharp foreign bodies penetrating stomach and bowel

J.B.C.M. Puylaert; *The Hague/NL (dr.jbcm.puylaert@wxs.nl)*

If a sharp foreign body gets stuck in the oesophagus, the patient usually will notice its presence and will seek medical help rapidly. However, when it reaches stomach or bowel and penetrates the wall there, the ensuing symptoms are atypical and treacherous and serious delay may ensue. Perforating foreign bodies in stomach and bowel are increasingly recognised by the use of US and spiral CT with multiplanar reconstructions, and may be of help in guiding minimal invasive treatment. The most frequently encountered penetrating sharp foreign bodies are chicken bones, fish bones and wooden sticks as toothpicks. Most patients do not recall having swallowed such an object. Over two-thirds has a history of a previous operation with kinking of bowel loops caused by adhesions, which inhibit the foreign body to "take the corner". Once a sharp object penetrates the wall of the stomach or bowel, omentum and mesentery will try to wall-off the ensuing perforation. Often an abscess develops in the peritoneal cavity, in the liver or the abdominal wall. Eventually, significant migration of the object may be the result. If the sharp foreign body is beyond the reach of the endoscope, patients usually undergo laparotomy for removal of the foreign body and drainage of the abscess. US and CT are important in the diagnosis and the minimal invasive treatment of sharp foreign bodies.

Learning Objectives:

1. To be familiar with characteristics of commonly ingested foreign bodies.
2. To understand which imaging modalities are best suited for detection of foreign bodies in different clinical scenarios.
3. To recognise the first signs of early complications resulting from ingested foreign bodies.

A-0168 16:55

C. The role of interventional radiology in the management of foreign bodies and following complications

H. Leonhardt; *Gothenburg/SE (henrik.leonhardt@vgregion.se)*

The main purpose of the presentation is to give the audience an insight into how the interventional radiologist can contribute to the management of foreign bodies. Some minimally invasive methods and tools to remove foreign bodies will be presented. Strategies for high-risk situations of heavy bleeding after removal of the item by the use of occlusion balloon technique in a multidisciplinary approach within an integrated angiographic - operating room (hybrid OR) will be discussed.

Learning Objectives:

1. To recognise the role of interventional radiology in the treatment of complications resulting from the presence of foreign bodies.
2. To learn when to call the interventional radiologist.
3. To learn about techniques of removal of foreign bodies with an endovascular approach.

17:20

Panel discussion: Common language with clinicians: how to report 'foreign bodies' presence and indicate the optimal management

16:00 - 17:30

ESR Ultrasound Subcommittee Session

US 1

How to perform ultrasound image fusion

Moderator:

P.S. Sidhu; London/UK

A-0169 16:00

Liver

E.M. Jung; *Regensburg/DE (ernst-michael.jung@ukr.de)*

Ultrasound image Fusion means a combination of real-time imaging of ultrasound B-Mode or colour-coded Doppler sonography (CCDS), Power Doppler (PD) or contrast-enhanced ultrasound (CEUS) with computed tomography (CT) or magnetic resonance tomography (MRI). These techniques of image fusion are integrated into high-end ultrasound machines and need the experienced examiners. Beginning with the imaging registration step by step would be shown for a successful imaging fusion. For interventional procedures fusion could be combined with volume navigation with GPS markers. This technique could be used for difficult punctures, biopsies, drainages or also interventional procedures of ablation therapies like radiofrequency ablation (RFA) or irreversible electroporation (IRE). The results from literature would be discussed about interventional procedures using US fusion techniques. For better detection and characterisation of tumours fusion could be used by a

combination of CEUS with contrast-enhanced CT or MRI. Fusion could be used for differentiation of benign from malignant lesions, for detection and characterisation of microvascular changes, and for the planning of interventional procedures. Actually, fusion by CEUS with CT or MRI could be used to realise interventional procedures like operative procedures, intra-arterial chemoembolization (TACE) or radionuclide application (SIRT) in cases of hepatocellular carcinomas or diffuse malignant tumour lesions. There are more and more reports about post-interventional control and follow up after interventional procedures like RFA, TACE or surgery. But also for the follow up after chemotherapies fusion could be used.

Learning Objectives:

1. To learn about the advanced liver imaging fusion technique.
2. To learn how to optimise scanning protocols by using the image fusion tool.
3. To learn about common benign and malignant lesions and differential diagnosis by using image fusion.
4. To understand how to use fusion imaging of US, CT and MRI for treatment of liver tumour.

A-0170 16:20

Kidney

J. Rübenthaler; *Munich/DE*

Ultrasound is a widely accepted imaging technique for the diagnosis and monitoring of cystic renal lesions. The widely used Bosniak classification (I-IV) categorises renal cystic lesions in five distinctive groups by the help of ultrasound and CT image criteria. In unclear cases, Contrast-enhanced ultrasound (CEUS) and MRI/CT-ultrasound image fusion are able to detect and characterise difficult pathologies. In contrast to CT or MRI, ultrasound image fusion is a real-time imaging technique that can be used in combination with other cross-sectional imaging techniques. This talk explains the latest possibilities of image fusion with CEUS to detect and characterise unclear renal pathologies.

Learning Objectives:

1. To understand the imaging features of kidney lesions.
2. To become familiar with unclear cystic lesions by using the Bosniak classification.
3. To learn about the differential diagnoses of complex cystic renal masses and compare the modalities by using the image fusion tool.
4. To understand the potential pitfalls in image fusion.

A-0171 16:40

Prostate

D.A. Clevert; *Munich/DE (Dirk.Clevert@med.uni-muenchen.de)*

Prostate cancer (PCa) is one of the most common malignancies in men. The diagnostic standard to confirm prostate cancer is the transrectal ultrasound-guided biopsy. During that procedure 10-12 biopsy cores are taken. However, the standard transrectal biopsy of the prostate is associated with the underdetection of clinically significant prostate cancer and therefore needs to be improved. In the last years, MRI fusion based targeted biopsy gained importance as a consequence. Several studies already confirmed that MRI guided biopsy of the prostate improves the accuracy in detecting and localising clinical significant cancer.

Learning Objectives:

1. To explain the PIRADS system in prostate imaging.
2. To become familiar with the technical requirements for performing image fusion of the prostate.
3. To understand how to detect and biopsy guided suspicious MR-lesions using the ultrasound image fusion technique.
4. To understand the potential pitfalls and discuss the evidence for the use of these technologies in routine clinical practice.

Minimise the risk of infection transmission and effective decontamination protocols in the setting of ultrasound fusion

C. Nyhsen; *Strasbourg/FR (nyhsenc@doctors.org.uk)*

Ultrasound is generally considered one of the safest diagnostic modalities available. Causing significant harm to imaged patients by performing ultrasound is neither anticipated by professionals nor patients. However, risks of infection transmission through ultrasound have been highlighted, and public awareness is increasing. A previous survey by the ESR ultrasound working group showed a wide range of decontamination protocols throughout Europe. This led to the publication of best practice recommendations on decontamination of equipment as well as the choice of US gel and transducer covers. Ultrasound fusion is a well-established technique for diagnostic but also interventional procedures, necessitating the use of extra equipment, which may be installed as needed in different settings. Strict hygiene protocols are

Postgraduate Educational Programme

essential to ensure that transmission of pathogens is avoided and patient safety is ensured at all times.

Learning Objectives:

1. To understand the contamination risks in the setting of ultrasound fusion.
2. To learn how cross infection may occur, in particular when fusion is used for invasive procedures.
3. To appreciate the different steps of an effective decontamination, including fusion equipment.

17:20

Bone, joint and soft tissue infection

Moderator:

V. Njagulj; Novi Sad/RS

A-0178 16:00

A. Osteomyelitis

K. Verstraete; Ghent/BE

Osteomyelitis (OM) is an infection of the bone and can present clinically in an acute, subacute or chronic form. Acute OM affects mostly children, just like subacute OM which predominantly presents as a Brodie's abscess. Chronic OM is more prevalent in adults (vascular insufficiency, diabetes mellitus). Routes of contamination are hematogenous (predominantly in children), spread from a contiguous source (cutaneous, dental), or direct implantation (bites, open fractures, postoperative). One to 2 weeks after onset, when >50 % of trabecular bone is destroyed, radiography can detect OM as ill-defined radiolucencies; later findings include extensive osteolysis, periosteal reaction, sequestra, involucrum, sinus (cloaca) through the cortex, and permeative bone destruction, which may resemble a malignant bone tumour. Bone scintigraphy is highly sensitive for OM, and within 48 hours a focus of increased activity in the affected bone can be seen. Specificity is low, however, as tumours, trauma, and neuropathic osteoarthropathy can result in hot spots. CT has a limited role in acute OM but is useful to evaluate complex findings in chronic OM (e.g. sequestra). MRI is the modality of choice to detect acute OM in an early stage: it is highly sensitive and specific demonstrating bone marrow oedema, periosteal reaction, soft-tissue oedema, abscess formation and sequestra. Gadolinium administration demonstrates enhancement of granulation tissue in the abscess wall, along with sinus tracts and around sequestra. Special manifestations are Garré's sclerosing OM, tuberculous OM, diabetic foot (may resemble neuropathic osteoarthropathy), spondylodiscitis, CRMO (chronic recurrent multifocal OM) and SAPHO.

Learning Objectives:

1. To explain the pathophysiology and disease spectrum of osteomyelitis.
2. To describe the imaging criteria for diagnosis of acute and chronic osteomyelitis in children and adults.

A-0179 16:30

B. Septic arthritis

M. Zanetti; Zurich/CH (marco.zanetti@hirslanden.ch)

Septic arthritis is often a clinical diagnosis based on physical examination and prompt arthrocentesis. Sampling at arthrocentesis can usually be achieved with needle aspiration imaging-guided, such as fluoroscopy, ultrasound, MRI, or CT. Plain radiography and ultrasound have been suggested to be the preferred initial imaging method. If further imaging is required, MRI is the most accurate technique. FDG-PET is also used less commonly. Staphylococcus aureus infection is most commonly seen in acute bacterial arthritis in adults and children older than two years. Most septic joints develop hematogenously. Rarely, acute septic arthritis may also occur as a result of joint aspiration or local corticosteroid joint injection. In addition, bacterial arthritis may arise secondary to trauma even without an obvious break in the skin. Bacterial arthritis, in association with arthroplasties, is commonly seen in our areas. In infants, small capillaries cross the epiphyseal growth plate and permit extension of infection into the epiphysis and joint space. In children older than one year, osteomyelitis infection presumably starts in the metaphyseal sinusoidal veins and is usually contained by the growth plate. The joint is spared unless the metaphysis is intracapsular. In adults, the growth plate has resorbed, and the infection may again extend to the joint spaces. Based on these considerations the basic imaging criteria for the diagnosis of septic arthritis in adults will be shown.

Learning Objectives:

1. To explain the pathophysiology and disease spectrum of septic arthritis.
2. To describe the imaging criteria for diagnosis of septic arthritis in children and adults.

A-0180 17:00

C. Pyomyositis and other soft tissue infections

D.J. Wilson; Oxford/UK (davidwilson.stlukes@btconnect.com)

Soft tissue infection can range from a minor wound infection through cellulitis to pyomyositis and necrotising fasciitis. At one end of the spectrum, the treatment may be limited to anti-sepsis and oral antibiotics whilst at the other many months of intravenous antibiotics, and radical surgery may be necessary. Severe infection may be rapidly fatal. Imaging plays a crucial role in the detection of the extent of infection, the detection of abscesses and the planning of surgical procedures. It is also very useful in determining response to therapy. Ultrasound and MRI are the principal techniques. The strength of ultrasound has its rapid availability and discrimination of free fluid from oedematous solid tissue. It is also critically helpful in detecting foreign material which could be a source and irritant causing persisting infection. MRI gives us a better overview showing bone involvement and the extent of tissue damage. There is a role for both techniques and their often complementary. The first lesson is to recognise the risk of infection especially for patients who are immunosuppressed or diabetic. Imaging may be used to guide aspiration of cavities and biopsy of tissue to identify organisms. On rare occasions the primary treatment of abscesses may be via sump drainage catheter is placed using ultrasound guidance. Normally these patients are treated with surgery to include excision of necrotic tissue, but there are occasions when patients are unfit for anaesthetic, and ultrasound-guided techniques assist.

Learning Objectives:

1. To explain the pathophysiology and disease spectrum of pyomyositis and other soft-tissue infections.
2. To describe the imaging criteria for diagnosis of pyomyositis and other soft-tissue infections.

Physics in Medical Imaging

RC 413

Striking the balance: image quality assessment in radiological optimisation

A-0181 16:00

Chairperson's introduction: The big picture, can we be objective about image quality?

N. Marshall; Leuven/BE (nicholas.marshall@kuleuven.be)

Current generations of medical imaging devices come with a great deal of flexibility "designed-in", where for example, the number, energy and the temporal rate of the X-ray photons used to generate the images can be varied. Where applicable, reconstruction algorithms add further flexibility. The medical physicist is faced with the challenge of ensuring the optimal setup of imaging systems for the tasks relevant to the local clinical site. This optimisation cannot be performed without a relevant definition of image quality, and this session covers methods of assessing imaging quality in projection radiography, interventional radiology and CT. At the equipment level, we can use Fourier transforms to make technical, physics-based assessments of x-ray component performance such as the sharpness and noise. These parameters are reproducible and relatively quick to implement, but are not task-weighted and come with potential limitations in terms of task description and validity in anatomical backgrounds. An alternative, classic approach is to assess image quality using the Receiver Operating Curve (ROC) or related methods, giving a task-based figure of merit (FOM) for use in optimisation. These methods require observers, either human or algorithmic and a dataset of tasks/cases, which can be time-consuming to assemble but deliver a quantitative measurement of image quality for the imaging system and task in question. This session surveys the available methods for image quality evaluation in radiological imaging and how they are applied, thus allowing an informed choice for optimisation studies.

Session Objectives:

1. To appreciate the reasons why image quality is important in radiological optimisation.
2. To understand the main methods of image quality assessment and optimisation.
3. To learn how image quality assessment is applied in clinical practice.

A-0182 16:05

A. Between a ROC(k) and a hard place: classical and pragmatic methods of determining clinical image quality

O.J. O'Connor; [Cork/IE \(oj.oconnor@ucc.ie\)](mailto:cork/ie (oj.oconnor@ucc.ie))

Image quality assessment is an important yet challenging aspect of radiation protection and integral to the ALARA principle. Radiological image quality may pertain to the fidelity of the radiological image relative to the imaged subject, the information that may be gained from the image and the radiation cost required. Assessment methods may, therefore, measure physical or subjective/psychophysical parameters. Physical parameters include spatial resolution, signal to noise ratio and contrast to noise ratio. Spatial resolution is a measure of how close two anatomical can be in an image and still be distinguished in space. Signal to noise ratio is the mean Hounsfield Unit value within a region of interest divided by the standard deviation. Contrast to noise ratio reflects the ability to distinguish differences in intensity and radiation dose. Subjective assessment remains vital as X-ray images are visual representations of clinical information and human judgement is required. Parameters such as lesion detection can be quantified using receiver operating characteristic curves, which relate observer findings to the image contents and which reduce bias by compensating of varying reader confidence. The area under the curve serves as a figure of merit of image quality and can be used to compare systems or assess new techniques. This method is more suited to clinical trials, however, and in practice, subjective assessment of image quality entails observers reviewing anatomy on appropriate clinical images in 'normal' patients. Ultimately we aim to standardise imaging performance to provide image quality tailored to clinical indications.

Learning Objectives:

1. To learn about traditional and practical methods of determining image quality.
2. To understand how the methods are applied to projection radiography, interventional radiology and CT.
3. To identify limitations of current techniques.

A-0183 16:28

B. Bridging the gap between physical and clinical image quality

E. Samei; [Durham, NC/US \(samei@duke.edu\)](mailto:Durham, NC/US (samei@duke.edu))

Clinical image quality is the cornerstone of imaging optimisation, as images are as good as the value that they offer clinically. Over years various have been developed and used to measure image quality in terms of first-order physics-based metrics of contrast, resolution, and noise. While foundational, these attributes fall short of fully capturing the quality of images for clinical tasks. The first-order metrics need to be extended to second- and third-order metrology of task transfer function (TTF), noise power spectrum (NPS), detectability and estimability indices, and noise heterogeneity. Recent work has shown that these metrics can offer better reflections of clinical quality and integrate them in the optimisation process. This presentation offers a description of the traditional and new CT image quality metrology, outlines the new methods of their assessment, and highlights their utility for improved patient care.

Learning Objectives:

1. To learn about physics-based methods of determining image quality.
2. To understand how they are applied to projection radiography, interventional radiology and CT.
3. To identify how to bridge the gap between the physics methods and the clinical image quality assessment.

A-0184 16:51

C. Sharing the message: image quality optimisation for multiple scanners and clinics

J. Siöberg; [Stockholm/SE \(johan.a.sjoberg@sll.se\)](mailto:Stockholm/SE (johan.a.sjoberg@sll.se))

The management of quality of radiological examinations in any department with multiple CT scanners is a non-trivial task. More so in larger multi-departmental university hospital settings, as both the specialisation of the examinations and the complexity of the organisation multiplies. The situation is also exacerbated by the increasingly sophisticated and diverse imaging and reconstruction technology. A systematic approach to assuring a high-quality practice can be greatly benefited through the adoption of a quality management system, in which two key components are: 1. All quality improvement processes are documented, measured and regularly revised and 2. All quality improvement efforts are directed by the lead radiologist and thereafter initiated and executed by a multi-disciplinary working group consisting, as a minimum, of the section lead radiologist, section lead radiographer and a medical physicist. In this manner, all aspects of quality are properly managed by a representation of the relevant speciality such as consistency and balance of clinical image quality, radiation dose and patient management. Any decent quality management system in a complex high

technology environment with limited resources must also increasingly rely on the fundamental principles of automation and quantification. Efforts should be invested in automating basic and repetitive tasks, such as aggregation of data and computation of key performance indicators of image quality and equipment performance.

Learning Objectives:

1. To learn about how to apply image quality assessment techniques across multiple scanners and clinics.
2. To learn how to apply image quality assessment methods to partner clinically-indicated DRLs.
3. To understand how to ensure consistency using standardised protocols.

Clinical and methodological pitfalls in hybrid imaging: problems and solutions

Moderators:

C.C. Cyran; Munich/DE

F.A. Gallagher; Cambridge/UK

A-0185 16:00

Artefacts in hybrid imaging

T. Beyer; [Vienna/AT \(thomas.beyer@meduniwien.ac.at\)](mailto:Vienna/AT (thomas.beyer@meduniwien.ac.at))

A proposal to combine PET with CT was made in the early 1990s by Townsend, Nutt et al. In addition to the intrinsic alignment of complementary images, the anticipated benefit of PET/CT was to use the CT-images to derive the mandatory attenuation maps for the PET data. In short, CT-based attenuation correction (CT-AC) is based on the assumption that a CT image can be segmented into bone and non-bone tissues; voxels in each tissue class are then scaled with corresponding scale-factors. CT-AC is prone to several errors arising from the methodological shortcomings of the segmentation-scaling method in light of CT-transmission measurements in clinical conditions. These include truncation artefacts, artefacts from high-density implants and positive contrast agents and others. More frequently, errors from patient motion during the examination propagate through CT-AC into the final emission images and lead to distortions/bias of the reconstructed data. In addition, artefacts and biases may occur from involuntary mistakes made during the set-up/conduct of the imaging procedure. During this presentation, we will rehearse the principles of CT-AC in PET/CT and point to the source of artefacts arising from the methodology of CT-AC and from specific imaging workflow scenarios not optimised for routine PET/CT. Following this presentation, the audience will understand image distortions, artefacts and bias from methodological pitfalls in PET/CT imaging, and appreciate and understand solutions to frequent image distortions in PET/CT, also, understand the methodological limitations of PET/CT.

Learning Objectives:

1. To understand methodological pitfalls in hybrid imaging.
2. To highlight frequent image distortions.
3. To review solutions to limit clinical misinterpretation from image artefacts.

A-0186 16:30

Clinical pitfalls in FDG-PET/CT and PET/MR

C. Pfannenber; [Tübingen/DE \(christina.pfannenber@med.uni-tuebingen.de\)](mailto:Tübingen/DE (christina.pfannenber@med.uni-tuebingen.de))

Besides potential artefactual uptake patterns, the use of hybrid imaging is also prone to some potential clinical pitfalls and interpretative challenges you should be aware of when reading the images. A variety of benign conditions like physiological variants of normal tracer uptake increased FDG uptake due to inflammatory disorders, treatment-related effects (e.g. recent surgery, chemoradiation) and hypermetabolic benign tumours are sources of potential false positive interpretations of FDG-PET scans. Less frequent, lesions may be missed on FDG-PET/CT due to low FDG uptake of some tumours, small lesion size or high neighbourhood activity. To avoid misinterpretations in hybrid imaging, it is therefore very important to have a profound knowledge of normal tracer distribution and its physiological variants to reduce false positive interpretations and overdiagnosis of benign conditions. Each tracer uptake in PET should be precisely correlated with CT or MRI and interpreted in the context of all available clinical and other imaging data. Furthermore, to minimise potential artefacts and pitfalls the adequate timing of PET/CT, a careful patient preparation (e.g. diabetic patients, BAT) and an optimised scanning protocol concerning contrast agents, breathing pattern and

positioning are important factors. In the lecture, we will discuss characteristic pitfalls in PET/CT and PET/MRI and how to avoid misdiagnosis.

Learning Objectives:

1. To learn about the key imaging features of the physiological distribution of 18F-FDG and its frequently encountered normal variants.
2. To become familiar with the most common clinical pitfalls caused by non-physiological FDG uptake due to benign conditions like inflammation, medication and benign tumours.
3. To discuss the principles of adequate patient preparation and scanning protocols to avoid artefacts and misinterpretation in PET/CT and PET/MRI.

A-0187 17:00

Clinical and technical pitfalls in SPECT/CT

J. [Howard](mailto:james.howard@mft.nhs.uk); Manchester/UK (james.howard@mft.nhs.uk)

Molecular and anatomical imaging with SPECT/CT provides accurate localisation and specificity of disease. As with all imaging studies clinical and technical pitfalls are encountered, and in hybrid imaging the combination of modalities provides a new challenge. In this lecture, we will discuss how to recognise the pitfalls and limitations that can be encountered with SPECT/CT and give some recommendations to help overcome these issues.

Learning Objectives:

1. To discuss common clinical and technical pitfalls that can be encountered in SPECT/CT imaging.
2. To recognise possible clinical and technical limitations/pitfalls and correctly interpret these pitfalls.
3. To learn about solutions and recommendations to deal with clinical and technical pitfalls in routine clinical practice.

Imaging in abdominal emergencies: an (evidence-based) update

Moderator:

C.E. de Lange; Oslo/NO

A-0188 16:00

A. The acute abdomen in neonates

A. [Coma](mailto:acoma@vhebron.net); Barcelona/ES (acoma@vhebron.net)

The acute abdomen in neonates is a frequent emergency room challenge. Neonatal abdominal emergencies comprise a wide variety of congenital and acquired conditions. This review discusses the most common ones in which radiologic evaluation contributes substantially to the diagnosis. Hepatobiliary, genitourinary, gastrointestinal, intraperitoneal, retroperitoneal, and iatrogenic emergencies are discussed. Establishing the diagnosis of acute abdominal conditions in neonates requires a high index of suspicion clinically and detection of subtle findings on imaging. Several imaging techniques are available for this purpose. A general radiologic approach to these conditions is outlined, and individual investigations are subsequently analysed in each case. Although the diagnosis can sometimes be made on prenatal imaging, patients present more commonly after birth and require a prompt diagnosis to facilitate early treatment. Plain radiography, conventional contrast studies and ultrasonography have major roles in evaluating the acute abdomen in neonates. CT and MRI contribute to the diagnosis in certain situations. Particular emphasis is placed on the radiologic clues found in typical neonatal abdominal emergencies. A practical approach to the acute abdomen in neonates is discussed and illustrated. Because the findings can be subtle, use of an appropriate imaging modality and a correct differential diagnosis are essential. To provide optimal patient care radiologists should be aware of the clinical presentation and imaging tips related to the acute abdomen in neonates.

Learning Objectives:

1. To learn about typical neonatal abdominal emergencies.
2. To understand the choice of modalities in acute abdomen in neonates.
3. To appreciate typical findings and 'red flag' features.

A-0189 16:30

B. The acute abdomen in young children

A.D. [Calder](mailto:calder@london.uk); London/UK

Common causes of the acute abdomen in children beyond the neonatal period are reviewed, with a focus on three conditions with major roles for imaging: hypertrophic pyloric stenosis, intussusception and acute appendicitis. The evidence base underlying the roles imaging plays is evaluated for each condition. The role of ultrasound in pyloric stenosis is well established and is generally highly sensitive and specific. The pyloric length and muscle thickness

parameters remain robust measures for correct diagnosis but may need to be adjusted for age and size. Additional signs which may be useful, such as pyloric shape and colour Doppler findings are discussed. Surgical management remains the mainstay of treatment, despite evidence of the effectiveness of medical therapy in some children. The role of ultrasound in the diagnosis of intussusception is similarly well supported and is highly accurate even in relatively inexperienced hands. Radiologists also typically play the leading role in initial attempts to reduce intussusception and are mostly successful. Various techniques for reduction are available, each with their own advocates and evidence base. Acute appendicitis is the most common abdominal emergency requiring surgery. Pre-operative imaging diagnosis is now the norm. Ultrasound is recommended as the primary imaging tool in children but can lack sensitivity, and in most centres, equivocal sonography is followed by cross-sectional imaging. CT has a strong evidence base for accurate diagnosis of appendicitis but confers significant radiation burden. Low dose protocol CT and MRI offer alternatives with potentially similar levels of accuracy.

Learning Objectives:

1. To learn about the causes of acute abdominal pain in children.
2. To understand the choice of imaging techniques and their limitations.
3. To appreciate typical radiological features of abdominal emergencies.

A-0190 17:00

C. Polytrauma: differences between adult and paediatric protocols

M. [Raissaki](mailto:mraissaki@yahoo.gr); Iraklion/GR (mraissaki@yahoo.gr)

Trauma is a frequent cause of mortality and disability in childhood and adolescence. Emergency physicians have to thoroughly assess injured children following high-energy trauma. Traumatised children differ from adults: haemodynamically stable children may be actively bleeding. Conversely, children have smaller calibre vessels, stronger vasoconstriction, stronger solid organ capsules; bleedings may stop spontaneously, organ rupture is more difficult and delayed rupture rare. Consequently, children are imaged aggressively although few will undergo surgery or trans-arterial embolisation. Imaging is mandatory for diagnosis and management, especially during the primary survey. Its goal is to exclude life-threatening injuries, identify children that may rapidly deteriorate because of clinically silent active bleeding, increase the surgeon's confidence level by clarifying injuries that need to be treated and ultimately determine short and long-term management. Radiographs and ultrasonography play a basic role in haemodynamically unstable patients. Contrast-enhanced ultrasound is an emerging diagnostic tool in low-energy trauma and suspected isolated abdominal injuries. In stabilised patients, CT scanning has been considered a sensitive, specific, and accurate test for identification and grading of multi-organ injuries. Due to children's increased radiosensitivity, CT scans should be indicated based on appropriate early clinical evaluation of the closely monitored child and assessment of risk factors for CNS, chest, MSK and abdominal injuries. ALARA includes avoiding non-contrast scans, avoiding multiple phases, applying age/weight-dependent exposure parameters and radiation-saving reconstruction algorithms. CT should not be performed for follow-up unless there is clinical deterioration. Objective documentation of injuries is extremely important in suspected child abuse.

Learning Objectives:

1. To learn how paediatric trauma differs from adult trauma.
2. To understand how examination techniques and protocols must be tailored accordingly.
3. To appreciate the importance of multidisciplinary team collaboration in planning and conducting radiological investigations in a trauma setting.

A. Imaging-guided liver interventions in oncology

B. [Gebauer](mailto:bernhard.gebauer@charite.de); Berlin/DE (bernhard.gebauer@charite.de)

Interventional techniques in primary and secondary liver tumours play a crucial role in most therapy algorithms, especially in hepatocellular cancer (HCC). Local ablation using thermal ablation (e.g. RFA or MWA) are widely used in liver tumours smaller 35 mm, in larger tumours combined therapies together with transhepatic (chemo-) embolisation might be possible. TACE is mostly performed in HCC, but also in other entities like colorectal or neuroendocrine liver metastasis. In the follow-up imaging after TACE, a precise knowledge about the used TACE intervention and material is necessary to interpret the

Whole-body imaging in metastatic urinary tract and prostate cancer

A-0194 16:00

Chairperson's introduction

A.R. Padhani; London/UK

Current imaging tools lead to poor confidence for assigning cancer clinical states & assessing therapy benefits, particularly for bone disease. There are three major issues with profound clinical consequences. We are unable to accurately predict metastatic disease presence and extent, we have a limited ability to depict heterogeneity of the expressed biologic phenotype, and we are unable to identify who is not benefiting early after starting treatment. This leads to 3 important clinical consequences: the late detection & volume underestimation of metastatic disease extent which misdirects the therapy approach, non-detection of heterogeneity of response which predicts for poor patient outcomes, and failure to rapidly detect primary & secondary resistance; impedes patient progress to alternative therapies.

A-0195 16:06

A. WB-MRI: technique and reporting system Met Rads P

F.E. Lecouvet; Brussels/BE

The presentation first highlights the different time points in the course of prostate cancer (PCa) where imaging is needed, i.e. new diagnosis, biochemical recurrence and metastatic castration-resistant PCa. For each of these stages, the current standard of care and needs for modern imaging approaches are discussed. Whole body MRI technique is presented, with emphasis on the evolution of protocols and current minimal and optimal requirements. Examples are provided illustrating findings in the most frequently affected organs: bones and nodes. Anatomic and functional (DWI) sequences are introduced, and their respective roles and limitations are highlighted, by the time of lesion detection and for the assessment of response to treatment. A practical presentation of the Met Rads P system is provided, with emphasis on standardisation of acquisitions, reporting, quantitative evaluation of disease burden, and response assessment.

Learning Objectives:

1. To review patient selection for WB-MRI in prostate cancer.
2. To learn state of the art technical tips.
3. To learn a systematic reporting system.

A-0196 16:34

B. WB-MRI and response assessment

N. Tunariu; London/UK (nina.tunariu@icr.ac.uk)

The availability of multiple life-prolonging agents for Advanced Prostate Cancer (APC), in conjunction with the inter- and intra-patient molecular heterogeneity of this disease, present major challenges for therapy selection and treatment switch decisions. In addition, the standard imaging in APC (CT and Bone Scans), are unable to provide objective criteria for assessing treatment response of bone metastases, the dominant site of metastatic disease in APC and the only site of involvement in 40-60% of APC patients. Earlier identification of treatment failure would avoid potential toxicity, reduce the costs of ineffective treatments and decrease the time to initiation of a next-line, potentially effective treatment. WBMRI has an improved performance compared to standard imaging in the detection of active bone metastases extent, it can identify early response to therapy without the confounder of FLARE, and it has the ability to identify mixed response to treatment, reflecting clonal disease evolution. WBMR-DWI strengths come from its wide availability, lack of radiation and the opportunity of performing a "one-stop shop examination" which can stage and assess response in local disease and in the bone, nodal and visceral metastases without routine contrast administration. Like any other new technique, there is ongoing development towards optimisation and standardisation both in terms of acquisition and data interpretation.

Learning Objectives:

1. To recognise active disease.
2. To learn pitfalls of interpretation.
3. To recognise the appearance of treatment response.

Author Disclosure:

N. Tunariu: Advisory Board; Janssen, Astellas. Speaker; Janssen, Sanofi, Bayer, Siemens.

post-TACE imaging correctly. Another transarterial treatment option is radioembolisation (RE, SIRT). In RE new multicenter studies like SARAH, SIRVENIB, SORAMIC and FOXFIRE are recently published and influenced the use and indications for RE. Localised therapy has a systemic effect on micrometastasis at other sites. This effect and the combination of local ablation and systemic treatments including immunotherapeutic agents will be the next scientific challenges in hepatic interventional radiology.

Learning Objectives:

1. To learn about newly established treatment options in interventional oncology.
2. To understand the role of pre- and post-treatment imaging for improving clinical outcome.
3. To appreciate potential future applications of interventional oncology.

Author Disclosure:

B. Gebauer: Advisory Board; BAYER. Author; Pfizer. Research/Grant Support; AngioDynamics, Boston. Speaker; ROCHE, Sirtex. Other; PAREXEL, ICON.

A-0192 16:30

B. Radiomics: the role of imaging

S. Rizzo; Milan/IT (stefania.rizzo@ieo.it)

Radiomics, is an emerging translational field of research, aiming to extract mineable data from clinical images. The concept underlying radiomics is that digital images, commonly acquired for staging or follow-up of patients, contain much more information than those commonly used for reporting. The digital data may indeed reflect the pathophysiology of the tumoral tissue. The extracted information may be associated with clinical data and can be used to assess prognosis and to support a clinical decision. Specific software allows the extraction of radiomic features from digital images (CT, MR, PET), and convert them into high-dimensional data for hypothesis generation, testing, or both. The steps necessary for a radiomic study include: acquisition of the images; identification and segmentation of volumes of interest that may contain prognostic value; extraction of radiomic features; clustering of the extracted features; creation of a database; inclusion of the extracted data to develop models, possibly in combination with demographic, clinical and genomic data. Imaging is used in routine practice for oncological patients worldwide, at many stages of diagnosis and treatment. In the current era of targeted therapies, radiomics offers the possibility to quantify and monitor phenotypic changes many times during treatment. The power of a predictive classifier model is dependent on the amount of data; hence, it is desirable that the radiomic studies will consider sharing of data among different centres, with the creation of databases including radiomics data and covariates, such as genomic profiles, histology, serum markers, patient histories, and biomarkers.

Learning Objectives:

1. To learn about the concept of radiomics and personalised medicine.
2. To learn how radiomics can be extracted from standard clinical examinations.
3. To appreciate the consequences of radiomics for radiologists in the future.

A-0193 17:00

C. Is PET/MRI better than PET/CT plus MRI?

H.-P. Schlemmer; Heidelberg/DE (h.schlemmer@dkfz.de)

PET/CT has emerged as an important imaging tool to detect, characterise, stage, monitor and follow-up various cancers in clinical routine. MRI, on the other hand, is known to provide superior soft tissue contrast and functional information about, e.g. tissue perfusion and diffusion. Accordingly, sequential MR and PET/CT imaging is performed in certain clinical situations. Since 2010 fully integrated whole-body PET/MRI systems are commercially available from different vendors. Temporal and spatial coregistration of PET and MR data has been proven beneficial concerning image coregistration. Simultaneous imaging furthermore enables to improve PET imaging of moving organs by taking advantage of MR-gating. The X-ray exposure of the patients is furthermore reduced, which is important particularly for pediatric patients and patients who need multiple follow-up examinations during treatment and follow-up. Research on simultaneous PET/MR imaging has proven advantages for the diagnosis and therapy monitoring of different tumour entities, e.g. lung cancer, breast cancer, prostate cancer, rectal carcinoma, lymphoma, melanoma, etc. But until an improvement in diagnostic accuracy, influence on therapeutic management and economic reasonability has been evidenced by clinical studies, the crossfire of criticism is still justified from a practical perspective. The presentation will discuss what unmet clinical needs can be addressed by the PET/MR imaging technology. The added value of simultaneous PET/MR imaging will be discussed in comparison to sequential PET/CT and MR imaging.

Learning Objectives:

1. To learn in which clinical scenarios PET/MRI is considered to be the most helpful.
2. To understand the difference between the use of PET/MRI and PET/CT plus MRI in the patient pathway.
3. To discuss impediments for future adoption of PET/MRI.

A-0197 17:02

C. PET and PET/MRI in prostate cancer

I.A. [Burger](mailto:irene.burger@usz.ch); Zurich/CH (irene.burger@usz.ch)

The introduction of the new PET Tracers targeting the prostate specific membrane antigen (PSMA) changed the approach in patients with biochemical recurrence after radical prostatectomy dramatically. With promising detection rates of 58% and 76% for PSA ranges of 0.2-1 ng/ml and 1-2 ng/ml, PSMA-PET surpasses all other imaging modalities and enables an early localisation of recurrent disease. For restaging prostate cancer PSMA-PET/CT is usually performed, with the CT component used for attenuation correction, localisation of the tracer activity (e.g. ureter vs lymph node) and characterisation of the lesions (e.g. sclerotic vs lytic bone lesions). Given the high sensitivity for metastasis in the recurrence situation, there is an increasing interest for PSMA-PET to stage primary high-risk cancers. With PSMA-PET/MRI not only the detection of metastasis but also the utility of PSMA-PET to improve the detection of primary prostate cancer is under investigation. First results showed an improved detection rate for significant prostate cancer with PSMA-PET/MRI compared to mpMRI. However, despite these promising results it is important to keep in mind that around 10% of the prostate cancers (low grade and high-grade tumours) are PSMA negative and therefore will not be detected with PSMA-PET. Furthermore, the term "prostate specific" is misleading. It is important to know that there are physiological structures (e.g. duodenum, kidneys) as well as neovasculature with high PSMA expression, leading to potential false positive lesions on PSMA-PET such as secondary primaries (e.g. lung cancer, renal cancer), hemangiomas or Padgett's disease.

Learning Objectives:

1. To learn about the role of PET in prostate cancer.
2. To understand the advantages and limitations of PET and PET/MRI.
3. To become familiar with potential pitfalls through case review.

E³ - ECR Academies: Functional Imaging for Disease Management: Research to Medical Practice

E³ 420

Functional imaging of the heart

A-0198 16:00

Chairperson's introduction

M. [Gutberlet](mailto:gutberlet@leipzig.de); Leipzig/DE

A-0199 16:06

A. Functional techniques for clinical cardiac MR

R. [Manka](mailto:robert.manka@usz.ch); Zurich/CH (robert.manka@usz.ch)

Over the past decade, cardiovascular magnetic resonance (CMR) has become an established non-invasive imaging modality in cardiovascular medicine. CMR provides clinicians and researchers with an unmatched flexibility of diagnostic options such as cardiac morphology, function, myocardial texture, perfusion and flow. CMR is safe, free of ionising radiation and proved higher diagnostic accuracy.

Learning Objectives:

1. To learn about main functional techniques useful in clinical cardiac MR imaging.
2. To become familiar with pharmacological testing approaches.
3. To learn about some more advanced techniques.

A-0200 16:34

B. Ischaemic diseases

J. [Bogaert](mailto:Jan.Bogaert@uz.kuleuven.ac.be); Leuven/BE (Jan.Bogaert@uz.kuleuven.ac.be)

Ischemic heart disease (IHD) remains the most frequent cause of mortality. Cessation of blood flow, due to temporary or persistent occlusion of the CA lumen, causes loss of function in the myocardium downstream the occluded vessel. The impact on the pump capacity of the heart directly depends on the loss in contractile power. Therefore, functional imaging is obligatory. Amongst cardiac imaging modalities, CMR is the most comprehensive technique to study IHD, including functional imaging. The latter is achieved using bright-blood cine steady-state free-precession (SSFP) sequences. Typically, the heart is imaged along the different cardiac axes. These images allow calculating ventricular volumes, ejection fraction and myocardial mass. Moreover, the regional function can be assessed by visual analysis or by using dedicated software - e.g. feature tracking - providing data with regard to

myocardial strain (in the different directions). Cine imaging is combined with myocardial tissue characterisation and/or first-pass perfusion imaging. In this way, functional impairment can be directly related to the presence and severity of myocardial damage and/or impaired myocardial perfusion. This approach allows to describe different presentations and link them to clinical scenarios. Moreover, stress functional imaging is of valuable interest to depict hemodynamically significant stenoses and to determine myocardial viability in patients with chronic myocardial ischemia. This lecture will provide a depth view of how to use functional imaging by CMR in different clinical scenarios of IHD, i.e. acute chest pain (diagnosis/differential diagnosis) - angor pectoris - chronic IHD.

Learning Objectives:

1. To learn about the impact of functional parameters for therapeutic orientation in emergency.
2. To learn about the validated biomarkers of prognosis.
3. To learn about how to follow the patients.

A-0201 17:02

C. Non-ischaemic cardiopathies

L. [Natale](mailto:Luigi.natale@unicatt.it); Rome/IT (Luigi.natale@unicatt.it)

Non-ischemic cardiopathies potentially represent a huge amount of cardiac diseases; nevertheless, the term is frequently used for myocardial diseases. Multi-modality non-invasive imaging (Echo, MR, CT) has taken the lead in diagnosis, choice of treatment and treatment assessment. Particularly, MR has unique capabilities in morpho-functional phenotyping and tissue characterisation, but more recently CT showed new tools (i.e. spectral imaging) and potential role in this field. Inflammatory diseases of the myocardium represent an important application of multimodality imaging, particularly MRI, because of its multiparametric approach, that allows the assessment of oedema, capillary leak and necrosis/scar. Furthermore, imaging techniques can provide important data about the outcome, both with functional approach (Echo, MRI) or tissue characterisation approach (MRI). Tissue characterisation is mainly aimed to discover fibrosis: replacement fibrosis is typically assessed by late Gadolinium enhancement, while interstitial and pleomorphic fibrosis are recognised and quantified by parametric CMR imaging (T1 mapping, ECV). A huge amount of data have been published about fibrosis and prognosis, demonstrating that fibrosis is a stronger independent predictor or events than ejection fraction. Finally, morphology, function and tissue characterisation are extremely helpful in the assessment of response to treatment. Again, MR plays a major role in this field.

Learning Objectives:

1. To learn about diagnostic criteria of non-ischaemic cardiopathies.
2. To understand the impact of functional imaging for outcome prediction.
3. To learn about their impact in treatment response.

E³ 521

Emergency radiology II

A-0202 08:30

A. Urinary system trauma

V. Loqager; Copenhagen/DK (vibeke.loegager@regionh.dk)

According to the American Association of Surgeons in Trauma (AAST), approximately 10% of all trauma admissions have kidney injuries. Blunt traumas can be graded in a 5-point Renal Injury Scale. On the basis of the patient's clinical findings, an imaging algorithm is set. In general, patients that are normotensive with microscopic haematuria have less than 0.2% risk of serious kidney damage and imaging is unnecessary, whereas patients with either: (A) gross haematuria, (B) microscopic haematuria and blood pressure less than 90 mmHg or occasionally, (C) microscopic haematuria, will require imaging. Contrast-enhanced CT is the way to go. Imaging should be in 3 phases (cortico-medullary, delayed 3-5 min and late phase (more than 10 min)). Image reading should be by the multiplane approach. Most of the findings do not require surgical intervention. Some can be treated with minimal invasive therapy. Only a few cases need surgical intervention. On the basis of case presentations, findings will be analysed, discussed and correlated to the patient's clinical status and treatment possibilities, including where and which signs to look for. Which modality could be used to solve the diagnostic problem when the clinical picture does not fit with the radiological picture. Relevant questions will be asked during this session for the participants to vote and the results will be discussed.

Learning Objectives:

1. To identify the signs of trauma.
2. To outline the clinical impact of these findings.

A-0203 09:15

B. Non-traumatic urinary tract emergencies

G. Masselli; Rome/IT (gabriele.masselli@uniroma1.it)

Urinary tract (UT) obstruction secondary to urolithiasis is the most common urologic emergency in patients presenting with abdominal pain. Serious complications of acute obstruction include ureteral rupture, pyelonephrosis or abscesses. Radiologists need to define the extent of obstruction, its likely duration and whether an intervention is required, aware that ultrasound (US) is usually normal in case of acute onset. In such cases, computerised tomography (CT) is the gold standard diagnostic tool. UT infection (UTI) is another common emergency, and it may vary in severity, from ureteral to focal renal infection, emphysematous pyelonephritis or pyonephrosis. UTI diagnosis is usually clinical, but in the case of uncertainty, CT provides early diagnosis, outlining the extent and severity of the disease. Magnetic resonance diffusion-weighted imaging (DWI) is of particular value when differentiating pyonephrosis from simple hydronephrosis. DWI of the kidneys is highly sensitive for the detection of focal or diffuse infections, a reason why is gaining more and more popularity. T2-weighted (static fluid) urography is performed in pregnant women to outline the ureters in their entirety. A challenge of MR urography is the differentiation between physiologic hydronephrosis and pathologic obstruction. Vascular UT emergencies include renal infarcts (commonly of thromboembolic origin), renal vein thrombosis (typical of hypercoagulable states and neoplastic patients), and spontaneous haemorrhage (due to angiomyolipoma rupture). These are among the most common non-traumatic UT emergencies, and it is fundamental for every radiologist to be fully confident in their diagnosis. The role of each imaging modality will be interactively discussed in the different clinical scenarios.

Learning Objectives:

1. To understand the imaging technique.
2. To become familiar with the differential diagnosis.

08:30 - 10:00

Room B

GI Tract

RC 501

GI bleeding: how can the problem be solved?

A-0204 08:30

Chairperson's introduction

D. Negrù; Iasi/RO (draneg@gmail.com)

Gastrointestinal (GI) bleeding is common in the daily practice and needs rapid diagnosis and treatment. It might be acute, overt and chronic. GI bleeding has many causes and can appear anywhere throughout the GI tract. Hematemesis, melena or hematochezia are forms of acute or overt GI bleeding. Chronic GI bleeding presents as iron deficiency or positive faecal occult blood. Computed tomography (CT) is the method of choice in the diagnosis of acute massive GI bleeding. The CT examinations used are CT angiography and CT enterography depending on the clinical context. Angiography is used in well-selected cases for the treatment of GI bleeding. CT also can complement scintigraphy in chronic bleeding.

Session Objectives:

1. To define acute, overt and occult GI bleeding.
2. To learn about different imaging modalities that can be utilised in the work-up of GI bleeding.
3. To define the role of the interventional radiologist in the management of the GI bleeding.

A-0205 08:35

A. Acute GI bleeding

G.H. Mostbeck; Vienna/AT (gerhard.mostbeck@wienkav.at)

Acute gastrointestinal (GI) bleeding has high morbidity and mortality. The clinical presentation of acute GI bleeding varies with the location of the bleeding site, the cause, the amount of blood loss and the presence of comorbidities. The ligament of Treitz is the border between the upper (mouth to Treitz) and lower GI bleeding. However, it is not always possible to differentiate between upper and lower GI bleeding clinically, although the clinical presentation is different, as is the aetiology. In decreasing order, erosions and ulcer, variceal bleeding, Mallory-Weiss-tears, vascular lesions and neoplasms are responsible for upper GI bleeding. In contrast, lower GI bleeding occurs in the elderly population, with diverticular disease, angiodysplasia, neoplasms, colitis and benign anorectal lesions being the major aetiologies. The main diagnostic objective is the identification of the aetiology and site of bleeding. Endoscopy is the initial diagnostic step in upper GI bleeding, but limited in lower GI bleeding due to difficulties in colonic cleansing in an emergency situation. Accordingly, CT is the imaging method of choice (technique: no positive oral contrast, high dose /iodine content/flow of contrast material (e.g.100-150ml, 350 mg/ml, 4-6ml/sec), plain, arterial and parenchymal phases, dual-energy CT with iodine maps if available, multiplanar reformation, high anatomic resolution). We search for high-attenuation (> 80HU) luminal or wall lesions not seen on unenhanced CT data. Detection rates vary, and an amount of bleeding > 0.35 to 0.5ml/min is required. As bleeding might be intermittent, CT should be performed when active bleeding is present.

Learning Objectives:

1. To learn about the common causes of the acute upper and lower GI bleeding.
2. To understand the rationale for different investigative pathways depending on the likely site of bleeding.
3. To appreciate how to best optimise imaging protocols to identify the site and cause of bleeding, and assist with treatment planning.

A-0206 08:58

B. Occult and overt GI bleeding: the role of radiology

C. Stroszczyński; Regensburg/DE

(Christian.Stroszczyński@klinik.uni-regensburg.de)

Acute gastrointestinal bleeding often presents a challenging clinical situation. The impact on radiological imaging depends on the clinical setting and the presence or absence of sufficient endoscopic procedures. Thus, diagnostic pathways are strongly varying from hospital to hospital. Causes of GI bleeding strongly depend on the topography of the bleeding source (upper or lower GI bleeding) and age of the patient. Most common causes of upper and lower GI bleeding will be discussed in this presentation. In addition, differences between obscure, occult and overt GI bleeding in interaction with gastroenterologist and surgeons will be focused on. The clinical value of radiologic methods for imaging the GI tract such as MS-CT, MRI, scintigraphy and digital subtraction angiography will be demonstrated as well as common diagnostic pathways

Thursday

Postgraduate Educational Programme

proposed by interdisciplinary societies such as ESGE.

Learning Objectives:

1. To learn about the differences between obscure, occult and overt GI bleeding, and the most common causes of each.
2. To understand which tests to perform when imaging is indicated, and the most important diagnoses to look for.
3. To appreciate the interaction between endoscopic and radiologic investigations in managing patients with obscure GI bleeding.

A-0207 09:21

C. When is the interventional radiologist needed?

D.K. [Tsetis](mailto:tsetis@med.uoc.gr); *Iraklion/GR (tsetis@med.uoc.gr)*

Gastrointestinal (non-variceal) bleeding is a medical emergency with an associated mortality of approximately 10%. Acute significant gastrointestinal bleeding is defined as bleeding requiring transfusion of at least four units of blood within 24 hours or showing signs of hemodynamic instability. Most cases are resolved endoscopically, pharmacologically, or by correction of coagulation parameters. Due to its minimally invasive nature, endovascular treatment is the method of choice, after the failure of the previous methods. Standard access for embolisation is via common femoral, brachial or radial artery. After reaching the appropriate visceral artery through diagnostic 4 or 5F catheter, and verification of the source of bleeding, microcatheters are introduced coaxially. Embolic materials include microcoils, PVA microspheres, gelatin foam and occasionally tissue glue. The upper gastrointestinal tract is characterised by a rich network of collateral supply with a lower risk of ischemia. In the risk of rebleeding via collaterals, it is necessary to perform embolisation proximally and distally from the site of bleeding (so-called sandwich method). In the lower gastrointestinal tract, ischemia risk is higher due to the higher portion of terminal branches, and embolisation should be as selective as possible. In the case of too proximal embolisation, there is a higher risk of bowel ischemia.

Learning Objectives:

1. To learn about the role of interventional radiology in the management of acute and chronic GI bleeding.
2. To learn about the variety of techniques available to the interventional radiologist to evaluate obscure GI bleeding and control acute GI bleeding.
3. To understand when interventional radiology is clearly indicated, when it should be considered and when it should be avoided, if possible.

09:44

Radiography audit and quality management

Moderators:

F. Zarb; Msida/MT
E.J. Adam; London/UK

Session Objectives:

1. To understand the importance of Radiography Quality Management.
2. To appreciate the role of PACS in driving quality improvements.
3. To promote discussion on practical concerns in a Radiology department.

A-0208 08:30

A. Understanding PACS to support radiography quality management processes

M. [O'Connor](mailto:michelle.oconnor@ucd.ie); *Dublin/IE (michelle.oconnor@ucd.ie)*

Quality management in the field of radiography plays an important role in the improvement of the performance of and processes related to diagnostic procedures, including the selection of imaging and procedural services, the quality and safety of healthcare delivered and the effectiveness and management of all imaging services. Many factors have contributed to the growing importance of evaluating quality in radiography practice such as the rapid evolution of technology, legislative requirements, increased reliance on diagnostic imaging in healthcare, role development and patient safety factors particularly related to radiation risks. One of the key tools for evaluating services is clinical audit. Through clinical audit, healthcare staff may identify and measure areas of risk within their service. The Medical Exposure Directive 97/43/EURATOM defines clinical audit as 'a systematic examination or review of medical radiological procedures. It seeks to improve the quality and the outcome of patient care through structured review whereby radiological practices, procedures, and results are examined against agreed standards for good medical radiological procedures'. Modifications of the practices are

implemented where indicated and new standards applied if necessary. Picture archive and communications system (PACS) is commonly used to support radiography service evaluation as it contains a large database of radiology data which is easily filtered thus provides extensive audit opportunities, e.g. identifying workflow inefficiencies, image reject analysis, assessing compliance with protocols and policies etc. Practical tips to enhance audit readiness have been developed.

Learning Objectives:

1. To highlight the need for evaluating radiographic quality within clinical practice.
2. To understand the ability of PACS to support radiography service evaluation.
3. To identify practical tips to enhance audit readiness.

A-0209 09:00

B. An expert in radiography quality management

D. [Catania](mailto:cataniadiago@hotmail.com); *Milan/IT (cataniadiago@hotmail.com)*

The presentation will relay current literature on the topic of the audit with respect to patient referrals, waiting times and turnaround times. The focus will be predominantly related to radiography and radiography professional activity. The discussion will include guidelines from professional agencies such as the IAEA, Radiology professional Societies and Radiography Societies. Radiography research published on the topics above and key current/future considerations for our professional societies will be discussed. To broaden the discussion on quality management, the many aspects of radiography activity which require quality management will be proposed, and as part of the presentation, the role of a designated radiographer to manage these radiography quality needs will be discussed. Current structures which support such roles will be presented, and the presentation will explore the current evidence for developing additional roles within the profession of radiography, to support the broad spectrum of possible radiography quality needs. Consideration will be given to how professional staffing structures vary across Europe and the potential impact on effective radiography quality management. Specific examples from the clinical environment will be provided to illustrate "real world" examples of radiography quality management. These examples will cover a broad spectrum of medical imaging activity. The discussion will include how other professionals interact within the quality processes undertaken by radiographers and the need for interdisciplinary cooperation will be emphasised. Barriers to successful quality management activity performed by radiographers will be included.

Learning Objectives:

1. To understand the importance of auditing the status of referrals, waiting times and turnaround times.
2. To introduce the role of a designated radiographer to manage the radiography quality process.
3. To provide "real world" examples of radiography quality management.

A-0210 09:30

C. Back to basics: auditing radiographic technique

L. [Harding](mailto:Harding@Warrington/UK); *Warrington/UK*

"no abstract submitted"

Learning Objectives:

1. To discuss the importance of regular auditing of radiographic practice.
2. To highlight the importance of Radiology Information System (RIS) dashboards in promoting high quality imaging.
3. To understand how a departmental quality improvement team, using audit, can maintain and raise imaging standards.

Joint Session of the ESR and UEMS

ESR/UEMS

Imaging professionals in the EU: radiologists without borders

A-0211/A-0212 08:30

Chairpersons' introduction

M. [Adriaansen](mailto:Adriaansen@Heerlen/NL); *Heerlen/NL (miraude@gmail.com)*
L. [Bonomo](mailto:Bonomo@Rome/IT); *Rome/IT*

The UEMS (European Union of Medical Specialists) is the oldest European medical organisation representing the interests of more than 50 different medical specialities and involving more than 1.6 million healthcare professionals. The ESR (European Society of Radiology) is the world's biggest radiological society, encompassing more than 82,000 members from 161 different countries. It was founded in 2005 by merging the European Congress of Radiology and the European Association of Radiology, aiming at

Thursday

Postgraduate Educational Programme

establishing a single, powerful and unified voice for European radiologists. Through the section of radiology of the UEMS, UEMS and ESR share the same ambitious objective of promoting the highest quality of care and medical practice in radiology, by serving the needs of patients and the general public, harmonising radiological training and defending free movement and professional interests of European radiologists. This Joint Session will focus on the concept and importance of advocacy at the level of the European Union, with specific emphasis on the value of qualifications across borders and the consequences of a Brexit. With regard to harmonisation of radiological training, the revised European Training Curriculum will be discussed. Furthermore, you will be informed how to gain European recognition for your degree in radiology as well as for your radiology department. Finally, particular attention will be dedicated to the working methodologies of EACCME (European Accreditation Council for Continuing Medical Education) and ACI (Accreditation Council in Imaging) in the framework of CME (Continuing Medical Education) and CPD (Continuing Professional Development) programmes.

Session Objectives:

1. To describe the role of the UEMS within the EU.
2. To understand the difference between the ESR and the UEMS.
3. To understand the importance of cooperation between the ESR and the UEMS.

A-0213 08:35

Putting your interests first: UEMS and ESR advocacy in the EU (part 1)
P.M. [Parizel](#); *Antwerp/BE*

The ESR was founded in 2005 by merging the European Congress of Radiology (ECR) and the European Association of Radiology (EAR) to adequately represent a unified and powerful voice for European radiologists. In recent years, the EU institutions have increasingly shaped policies in the fields of health, research and digitalisation, which has impacted clinical practice for radiologists and biomedical research across the Member States. Under the guidance of the Board of Directors, the ESR closely monitors and assesses EU legislation and policy developments to ensure EU initiatives benefit clinical practice and patient safety. Equipped with a toolbox of instruments, the ESR participates in EU stakeholder consultations, regularly organises policy events and issues statements and position papers to get across the radiologists' point of view. Taking into account the complex EU policymaking arena, the ESR has adopted a proactive approach by successfully establishing good working relations with the EU institutions and engaging with other stakeholders active in the fields of health and research. In this respect, the ESR is widely recognised as a major healthcare stakeholder that has successfully promoted the interests of the radiology profession and patient safety at the pan-European level. As collaboration is the key to success at EU level, the ESR is grateful to have found a respected partner in the UEMS to jointly defend the interests of the medical profession and to strive for the highest standards in healthcare, teaching and research.

Learning Objectives:

1. To understand the structure of the UEMS and the ESR.
2. To understand the differences between the ESR and the UEMS.
3. To understand the importance of UEMS/ESR political involvement in EU affairs.

A-0214 08:40

Putting your interests first: UEMS and ESR advocacy in the EU (part 2)
B. [Maillet](#); *Brussels/BE (bernie.mail@skynet.be)*

One of the basic principles of the European Union is Free Movement. Of course, this concerns people, products, funds manpower but also Healthcare and can be found in this particular field in three domains. First the free movement of students organised by the Bologna Process, the free movement of physicians organised by the EU Directive on Professional Qualification Recognition (PQR) and recently the free movement of patients organised by the EU Directive on Patient Safety on Cross Border Healthcare. Concerning the PQR the first initiative was in 1993 with the first version of the Directive that was amended regularly with the last revision in 2013 (EC 2013/55), but the most important version is the EC 2005/35. This Directive recognises automatically the Diplomas of Medicine between the different Member States and also grants recognition for some specialities. The Directives have to be revised every seven years, and the next scheduled revision is planned in 2020, so this would be the ideal moment to try to "fuse" those both specialities and have only "Radiology" mentioned in Annex V and abolish "Diagnostic Radiology". A joint effort of both the UEMS and the ESR could be considered to achieve this revision.

Learning Objectives:

1. To understand the structure of the UEMS and the ESR.
2. To understand the differences between the ESR and the UEMS.
3. To understand the importance of UEMS/ESR political involvement in EU affairs.

A-0215 08:45

To be or not to be at the table: why advocacy matters for radiologists
K. [Riklund](#); *Umea/SE (katrine.riklund@umu.se)*

ESR and UEMS Radiology section work together for better patient care, harmonised professional and standards. The radiological community is affected by developments in healthcare and financial constraints for healthcare spending together with a growing demand of healthcare combined with an under-representation of the radiologist in decision making and emerging value-based concept. In the talk the need for coordinated actions to an activator for the highest standard of patient care in radiology will be discussed. We will work all through the three levels of the European legislation process and the representation of ESR in EU networks and stakeholder groups.

Learning Objectives:

1. To understand the concept of advocacy and the importance of advocacy at the EU level.
2. To understand the three levels of the European Legislation process.
3. To understand the influence of EU directives on national legislation and daily practice.

A-0216 08:53

Creating a European radiology (or healthcare) workforce: the value of qualifications across borders

H. [Käfer](#)¹, M. Frohn²; ¹Vienna/AT, ²Brussels/BE (hatto.kaefer@ec.europa.eu)

EU Member-States are free to regulate professions and thus restrict access of certain professions on their territory, as long as they respect the principles of non-discrimination and proportionality under EU law. From this derives that EU law does not primarily seek to harmonise professional qualifications and access to professions. This exists only in a few areas, such as transport and health. For doctors, Directive 2005/36/EC on the recognition of professional qualifications foresees minimum harmonisation of training based on years and hours of study and acquired knowledge and skills, which entail an automatic recognition mechanism. This applies to doctors with basic medical education, general practitioners and currently 54 medical specialist categories including radiology and diagnostic radiology, given that the professional is fully qualified in its home Member-State. Evidence of formal qualifications in medical specialist training, which are covered by the automatic recognition system, are listed in point 5.1.3. of Annex V to the Directive. For the remaining medical specialisations, EU law provides recognition mechanism with Directive 2005/36/EC, based on the principle of mutual recognition of professional qualifications. This kind of recognition allows the host Member-State to compare the substance of training and in case of substantial differences, to impose compensation measures in the form of an aptitude test or an adaptation period. Doctors are the most mobile profession in Europe under the Directive when it comes to recognition for the purpose of a permanent establishment with more than 3500 recognition decisions per year throughout Europe, including the EEA and CH.

Learning Objectives:

1. To understand the concept of advocacy and the importance of advocacy at the EU level.
2. To understand the three levels of the European Legislation process.
3. To understand the influence of EU directives on national legislation and daily practice.

Part 2: Educating the next generation of radiologists

A-0218 09:09

The benefits of harmonised training for the radiologists of tomorrow

C. [Catalano](#); *Rome/IT (Carlo.Catalano@uniroma1.it)*

One of the aims of the ESR is to harmonise and standardise training all over Europe. A major effort has been done in the past few years in the preparation of the European Training Curricula and the Undergraduate Training Curriculum, which have recently been updated and received the endorsement of the UEMS. The ETC defined the contents of training and expected learning outcomes of trainees in radiology. The ETC is a living document continuously revised in order to keep up with the developments and knowledge in radiology. The CESMA is an advisory body of the UEMS created to provide recommendation and advice on the organisation of European examinations for European medical specialists. The ESR has therefore developed the EDiR which is available to radiologists and last year radiology residents. It certifies that their level of knowledge and competency is in line with the ETC. The EDiR is an additional qualification of excellence for general radiology, fully endorsed by the UEMS and the ESR. The European Training Assessment Programme (ETAP) has been recently updated to a version 2.0, based on a new platform, which enables a quick and easy online certification process for both applicants and assessors. ETAP 2.0 ensures that the training department meets the quality of standards set by the ESR European Training Curriculum and the UEMS. All these activities of the ESR aim at improving throughout Europe the level of knowledge of Radiologists and Radiologists in training by standardising training.

Learning Objectives:

1. To get an overview of the different levels and the changes made in the revised European Training Curriculum in radiology.
2. To learn about the Council for European Specialist Medical Assessment (CESMA).
3. To know about the value of the European Diploma in Radiology (EDiR).
4. To learn about the facts and figures of the European Training Assessment Programme (ETAP) 2.0.

Short informative presentation on the structure, organisation, outcome and future projections for the European Diploma in Radiology (EDiR). Furthermore, short overview of the different levels and the changes made in the revised European Training Curriculum in radiology. Also an introduction to the Council for European Specialist Medical Assessment (CESMA). Finally, facts and figures will be discussed of the European Training Assessment Programme (ETAP) 2.0.

Learning Objectives:

1. To get an overview of the different levels and the changes made in the revised European Training Curriculum in radiology.
2. To learn about the Council for European Specialist Medical Assessment (CESMA).
3. To know about the value of the European Diploma in Radiology (EDiR).
4. To learn about the facts and figures of the European Training Assessment Programme (ETAP) 2.0.

A-0220 09:25

ETAP 2.0

L. [Oleaga Zufiria](#); *Barcelona/ES (lauraoleaga@gmail.com)*

The European Training Assessment Programme (ETAP) is a joint initiative of the European Society of Radiology (ESR) and the European Union of Medical Specialists (UEMS) Radiology section, with the aim of assessing and harmonising the radiology training department programmes in Europe. A qualitative adaptation was made in 2016 modifying the structure of a face-to-face audit to an online audit to facilitate access to a larger number of centres and lighten the work of the assessors, establishing as ETAP 2.0 programme. ETAP 2.0 represents an instrument for the centres to compare the quality of the training and assess the suitability of the program with the European Training Curriculum (ETC). It is strongly linked with the European Diploma of Radiology (EDiR); ETAP 2.0 is a certificate of excellence for training institutions that ensure that their training department meets the quality standards set by the European Society of Radiology and the UEMS. Both initiatives favour the standardisation of the European training, and they both contribute to increase the quality of training across Europe. The differential element of the ETAP 2.0 is its platform, which enables a quick and easy certification process for both applicants and assessors. Representatives of the

applicant institutions and the assessors can easily and efficiently store, access and manage all documents and information necessary for the certification process. ETAP 2.0 offers training centres an opportunity to audit their programme as an instrument to check the level of competence, attitude and development of new skills the trainees acquire during the training period.

Learning Objectives:

1. To get an overview of the different levels and the changes made in the revised European Training Curriculum in radiology.
2. To learn about the Council for European Specialist Medical Assessment (CESMA).
3. To know about the value of the European Diploma in Radiology (EDiR).
4. To learn about the facts and figures of the European Training Assessment Programme (ETAP) 2.0.

Part 3: Staying ahead of the curve with continuing professional development (CPD)

A-0221 09:33

Patient safety and job security for life: CME/CPD in Europe

P. [Ricci](#); *Rome/IT (paolo.ricci@uniroma1.it)*

CME - Continuing Medical Education - consists of educational activities which serve to maintain, develop, or increase the knowledge, skills, and professional performance and relationships that a physician uses to provide services for patients, the public, or the profession. CPD - Continuing Professional Development - can be defined as the systematic maintenance, improvement and continuous acquisition or reinforcement of the lifelong knowledge, skills and competencies of health professionals. CME-CPD is a clinical and professional duty as well as an ethical obligation for healthcare professionals. It can also be a powerful instrument free from commercial influence in the hands of the medical class which is extremely necessary in the European Union, where healthcare systems became inter-dependent, yet still inhomogeneous, with mandatory and voluntary CME-CPD systems coexisting side by side. At EU-level, the role of CPD to help safeguard patient safety within the context of cross-border mobility has been addressed in several legal instruments: e.g. Council Recommendation on Patient Safety, Directive 2011/24/EU on patients' rights in cross-border healthcare, and Directive 2013/55/EU on the recognition of professional qualifications. The UEMS - European Union of Medical Specialists actively promotes high standards in CME-CPD through the European Accreditation Council for Continuing Medical Education (EACCME), created in 1999 with the aim of encouraging high standards in development, delivery and harmonisation of CME through the international accreditation of events, and the establishment of a "currency" system for the international acceptance of CME credits (ECMEC - 1 ECMEC = 1 hour of CME).

Learning Objectives:

1. To learn about the European Accreditation Council for Continuing Medical Education (EACCME).
2. To know about the existence of European CME credits (ECMEC).
3. To learn about the importance of credits in different European countries.

A-0222 09:41

It's easier than you think: the many ways to gain European CME/CPD credits

M.A. [Lucic](#); *Sremska Kamenica/RS (milos.a.lucic@gmail.com)*

Understanding the tendency of Continuing Medical Education (CME) shift from voluntary to mandatory within Europe, European Union of Medical Specialists (UEMS) and its European Accreditation Council for CME (EACCME) introduced European Continuing Medical Education Credits (ECMEC's), as CME "tokens" reflecting objectively the CME activity, that facilitate the exchange of CME credits between European countries and comparable systems outside Europe. Considering CME as educational activities which serve to maintain, develop or increase the knowledge, skills, professional performance and relationships that physician/radiologist uses to provide services for patients or profession, ECMEC's are awarded for both live educational events, and e-learning materials, but from recently also for Continuing Professional Development (CPD), defined as the educative means of updating, developing and enhancing how physicians apply the knowledge, skills and attitudes required in their working lives. As CPD incorporates and goes beyond CME, EACCME 2.0, adopted in 2016, enabled EACCME recognition of the several CPD/CME activities, that includes reviewing and/or publishing scientific and educational material, learning by teaching, and examining in UEMS exams, including EDiR exam. Based on the surveys conducted by Accreditation Council in Imaging (ACI) during the last two years, that provided not only valuable information on accreditation systems differences in European countries, but more important, indicated important standpoints of the European radiology community, that include the recognition of ECMEC's as universal European CME "tokens", and unification of CME/CPD systems within Europe, and shall be acknowledged as the "voice of European radiologists" in future considerations.

Learning Objectives:

1. To learn about the European Accreditation Council for Continuing Medical Education (EACCME).
2. To know about the existence of European CME credits (ECMEC).
3. To learn about the importance of credits in different European countries.

Cardiac imaging in arrhythmia and sudden cardiac death

A-0223 08:30

Chairperson's introduction

P. Donato; Coimbra/PT (donato.pj@gmail.com)

Computed Tomography (CT) and Magnetic Resonance Imaging (MRI) are used to detect underlying cardiac conditions that can lead to ventricular arrhythmia (VA) and sudden cardiac death (SCD). VA includes a wide spectrum of ECG forms from premature ventricular complex to ventricular fibrillation, and a wide spectrum of clinical presentations, from a total lack of symptoms to cardiac arrest. SCD is the most common consequence of sudden cardiac arrest and is responsible for 50% of all cardiovascular deaths. The risk for VA and SCD vary with different underlying cardiac conditions, and with specific family history and with genetic variants. To prevent SCD is important to identify patients at risk and apply preventive strategies. The risk increases with age, related to the increase of ischemic heart disease, which remains the most common cause of sudden cardiac arrest. There are also various forms of cardiomyopathy leading to cardiac fibrosis or hypertrophy responsible for SCD that can be early depicted by cardiac imaging. AHA 2017 guidelines recommend that in patients presenting with VA who are suspected of having structural heart disease, cardiac MRI or CT can be useful to detect and characterise underlying structural heart disease. The strength of each technique is under study. Imaging arrhythmic patients are challenging due to difficulties on ECG synchronisation. These patients have frequently implanted devices at the time of the MR study, is also important to know the risk that each patient occurs and to know strategies to decrease artefacts caused by the devices.

Session Objectives:

1. To learn about existing imaging biomarkers to prevent sudden cardiac death.
2. To understand how to face the challenge of arrhythmia in cardiac imaging.
3. To become familiar with the prerequisites for MR in patients with active implants.

A-0224 08:35

A. The role of CMR in sudden cardiac death

D. Piotrowska-Kownacka; Warsaw/PL

Cardiovascular diseases are responsible for over 4 250 000 sudden cardiac deaths (SCD) each year worldwide, with the risk almost five times higher in men. The major cause of SCD is known or unknown coronary artery disease, but the list of cardiac diseases leading to SCD is much longer especially in the younger population. It includes cardiomyopathies, inherited primary arrhythmia syndromes, inflammatory, rheumatic and valvular heart diseases. The risk stratification for the prevention of sudden cardiac deaths includes invasive and non-invasive diagnostic procedures. Complementarily to echocardiography, cardiovascular magnetic resonance (CMR) is an important imaging technique that enables excellent morphology, function and tissue characterisation of the heart. CMR could be used for diagnostic purposes but also for risk stratification in cases of known cardiac pathology. The lecture will focus on CMR prognostic factors in acute and chronic ischemic heart disease, myocarditis, selected cardiomyopathies and systemic diseases with cardiac involvement.

Learning Objectives:

1. To become familiar with the pathophysiology of sudden cardiac death.
2. To introduce cardiac MR biomarkers to prevent sudden cardiac death.
3. To learn how to perform and how to interpret cardiac MR to prevent sudden cardiac death.

A-0225 09:00

B. Preventing sudden cardiac death with CT: pure theory or new diagnostic paradigm?

K. Nikolaou; Tübingen/DE (Konstantin.Nikolaou@med.uni-tuebingen.de)

Sudden cardiac death (SCD) is a major health problem, and there is an urgent need to establish diagnostic tools for primary prevention, e.g. by selecting appropriate patients for implantable defibrillators. Today, diagnostic methods of selecting candidates for preventive measures and therapies still have significant shortcomings. Cardiac CT and Coronary CT Angiography have seen major advancements, e.g., for detecting (malignant) coronary anomalies. But also in the field of myocardial abnormalities such as left ventricular hypertrophy, or in the assessment of vulnerable coronary artery plaques, CT shows great potential, with growing evidence on the use of cardiac and coronary CT for the detection of patients at risk for SCD. Probably in the future, a mixture of established and novel imaging biomarkers for predicting SCD, potentially including several imaging modalities, will be incorporated into clinical guidelines. The goal of this talk is to discuss the current status and future potential of cardiac CT imaging to enhance risk stratification for SCD.

Learning Objectives:

1. To learn what to look for in CT to prevent sudden cardiac death.
2. To get an overview about existing evidence of cardiac CT in this indication.
3. To discuss the possible future role of cardiac CT in preventing sudden cardiac death.

A-0226 09:25

C. Imaging of patients with arrhythmia and implantable devices

G. Pontone; Milan/IT (gianluca.pontone@cctm.it)

Evaluation of cardiac arrhythmias using both cardiac magnetic resonance (CMR) and cardiac computed tomography angiography (CCTA) represents an extremely interesting topic in cardiac imaging. CMR allows obtaining data regarding myocardial tissue characterisation as well as correct evaluation of ejection fraction. Information that CMR provides to arrhythmologist can mainly be divided as follow: sudden cardiac death risk stratification, decision-making for cardiac resynchronisation therapy with evaluation of cardiac anatomy, late gadolinium enhancement (LGE) and characterisation of an arrhythmogenic substrate in order to guide ablation of complex arrhythmias. CCTA is mainly used in patients with atrial fibrillation (AF). Indeed, in patients with AF, CCTA allows a detailed evaluation of pulmonary veins anatomy and rule out of coronary artery disease. Furthermore, in patients with AF, CCTA can play a key role for the correct planning of left atrial appendage closure, in particular, if a 3D model is printed. Furthermore, some articles highlight the role of CCTA for accurate definition and location of ventricular arrhythmias. The adverse effect of CMR on pacemaker (PM) and implantable cardioverter defibrillator can be induced by electromagnetic interference or can provide the mechanical effect. Moreover, it is important to consider the heating of cardiac leads. CMR in patients with a cardiac device should take in account safety of patients.

Learning Objectives:

1. To learn about tips and tricks for successful cardiac CT in patients with arrhythmia.
2. To learn about tips and tricks for successful cardiac MR in patients with arrhythmia.
3. To become familiar with workflow issues for MR imaging in a patient with an implanted device.

PC 5

Radiology and migrations

A-0227 08:30

Chairperson's introduction

O. Akhan; Ankara/TR (akhano@tr.net)

The total number of asylum seekers who migrate to another country to have a better job or life has increased from 15.000 to almost 1.4 million annually in last two decades in the countries of EU are fleeing from violence, torture, persecution, political or ethnic oppression and poverty. Migration is associated with different cultural, social, political outcome besides the health status of immigrants. The health of immigrants is affected by mainly infectious diseases such as Tuberculosis, HIV, viral hepatitis, Malaria, Schistosomiasis, Echinococcosis, Neurocysticercosis or similar diseases which reflect the epidemiology in the country of origin. The other include psychological problems, cancer, neurological diseases and acute or chronic malnutrition resulting in anaemia, growth disorders, mental and physical development disorders, immunosuppression and bone disorders which are easy to overlook. Therefore, impact of immigration has to be recognised as an important variable on the status of the current health system of the country which hosted the immigrants to improve the status of immigrants' health. Radiological examinations of patients with these diseases play an important role in the diagnosis of most of these diseases. Although these diseases are often incidental radiological findings in the daily practice, most of the radiologists in the western European countries are unfortunately not familiar to the features of these diseases. We should discuss how to raise awareness on migration-related diseases among radiologists. The health issues of immigrants are very challenging to physicians. Awareness of these conditions is mandatory to ensure good clinical practice for these patients' population.

Session Objectives:

1. To describe the reasons of migration.
2. To evaluate humanitarian and political consequences of migration.
3. To get an overview on the importance of migration related disease.
4. To understand how we can recognise these diseases on clinical and radiological levels.
5. To raise awareness on migration related diseases among health professionals.

A-0228 08:35

Impact of migration on health: WHO perspective

S. Severoni; Copenhagen/DK

"no abstract submitted"

Learning Objectives:

1. To describe the impact and consequences of migration on health as a global problem.
2. To teach how public health has been importantly influenced by human mobility patterns.
3. To discuss how to raise awareness among health professionals to struggle against the diseases related to migration.

A-0229 08:53

Importance of migration for neglected tropical diseases: WHO perspective

B. Abela-Ridder; Geneva/CH (abelab@who.int)

With increasing levels of conflict, civil unrest, poverty and persecution, there is an estimated 68.5 million people currently forcibly displaced worldwide. Malnourished, stressed people with poor housing and sanitation and restricted access to healthcare results in populations at a high risk of disease, especially neglected tropical diseases (NTDs). Global migration is changing the epidemiology of many of these diseases with emergence and re-emergence of NTDs in non- or low endemic countries. The lack of awareness, diagnostics and treatment available in host countries poses a challenge in appropriately diagnosing and treating affected individuals and poses a risk for endemic foci of disease to be established. Outbreaks of dengue, Leishmania and schistosomiasis have been recorded in low prevalence areas where appropriate vectors or intermediate hosts could allow for local transmission. The prevalence of Chagas disease, strongyloidiasis and schistosomiasis in migrant populations ranges from 4.2- 48.5%, 11-56.1% and 5.8 to 44% respectively. Cases of cystic echinococcosis and neurocysticercosis, have also been detected in Europe, with 53% of neurocysticercosis cases attributed to immigrants. Consideration should be given to systematically screen migrant populations on arrival to a host country using standardised screening procedures to reduce the progression and severity of health conditions. It will,

however, be important to appropriately manage that individuals are not discriminated against because of a health condition. Better data on disease prevalence and burden in migrant populations will allow increased awareness in host countries, particularly in healthcare practitioners, assure access to timely and appropriate clinical care and management of risk.

Learning Objectives:

1. To describe the importance of neglected tropical diseases on the global level emphasising its relation with poverty.
2. To evaluate how migration changes the dimensions of the problem for neglected tropical diseases in Europe.
3. To discuss how to raise awareness for neglected tropical diseases on global and European levels.

A-0230 09:11

Clinical importance of the diseases related to migration

T. Junghanss; Heidelberg/DE

"no abstract submitted"

Learning Objectives:

1. To become familiar with the list of diseases related to migration and their clinical findings.
2. To discuss how to think about unusual clinical conditions when facing these patients.
3. To teach how to make differential diagnosis on the clinical ground.

A-0231 09:29

Radiology of the diseases related to migration

T. Weber; Heidelberg/DE (tim.weber@med.uni-heidelberg.de)

Globalisation and migration impact on the spectrum of infectious diseases that health care providers are confronted with. Although a major health care problem in a global context, the majority of these diseases may be uncommon in the autochthonal European population. In several frequently imported infectious diseases, imaging studies play an important role in timely diagnosis and treatment stratification. The migration associated infectious diseases most pertinent for the radiologist include, e.g., cystic echinococcosis, schistosomiasis, and neurocysticercosis as well as tuberculosis and visceral leishmaniasis.

Learning Objectives:

1. To learn radiological patterns of diseases related to migration.
2. To discuss how to evaluate unusual radiological conditions of these patients.
3. To teach how to combine radiological and epidemiological features of the patients on the basis of imaging modalities for appropriate differential diagnosis.

09:47

Breast

RC 502

MRI for early detection, staging and management of breast cancer

A-0232 08:30

Chairperson's introduction

P.A.T. Baltzer; Vienna/AT (patbaltzer@gmail.com)

Imaging plays an important role in early detection, staging and management of breast cancer. MRI is the most sensitive method for detection of breast cancer and thus can contribute to all fields of breast cancer diagnosis and treatment. In addition, multiparametric breast MRI provides a number of imaging biomarkers that reveal diagnostic and prognostic information beyond simple cancer detection. Nevertheless, breast MRI has faced several challenges during the past decades due to controversial opinions and contradicting scientific results. Many of these can be attributed to the fact that MRI is more complicated than standard breast imaging methods including newer developments such as digital breast tomosynthesis, ultrasound elastography and contrast-enhanced dual energy mammography. In addition, breast MRI is less readily available, and its application thus needs to be applied to tailored clinical scenarios. One way of overcoming these limitations are simplified and abbreviated protocols that would allow a broader application of MRI, e.g. in intermediate or high-risk screening.

Session Objectives:

1. To understand the contribution of MRI to preoperative staging and the context within which it should be recommended.
2. To learn about the different MRI biomarkers and in which clinical setting they are of value.
3. To recognise the steps required to move to abbreviated MRI for high-risk screening.

A-0233 08:35

A. Preoperative staging with MRI: results of preoperative MRI (MIPA) trial F. [Sardanelli](#); *San Donato Milanese/IT*

The MIPA study aimed at verifying the impact of preoperative breast MRI. Up to November 2018, over 7,000 patients were recruited in 30 centres. Data from 2,425 patients were: 1,201 (49.5%) received MRI, 1,224 (50.5%) did not. Of these 1,224 MRIs, 210 (17%) were performed for screening (4%) or diagnostic purposes (13%). Of 1,014 MRIs performed as preoperative studies, 59% were ordered by radiologists alone, 32% by surgeons alone; radiologist and surgeons were involved in 68% and 40% of cases, respectively. Mastectomy rate planned at mammography/ultrasound was 185/1,201 (15.4%) in the no-MRI-group, 245/1,224 (20.0%) in the MRI-group ($p<0.001$). In the MRI group, 21 additional mastectomies (1.7%) were planned after MRI, while 25 patients planned with mastectomy shifted to conservative surgery (CS). Of the 1,004 patients planned for CS before MRI, MRI did not change surgery in 733 (73%), while prompting a wider CS in 143 (12.5%), a less extensive CS in 128 (12.7%). Mastectomy rate was 192/1,201 (16%) in no-MRI-group and 257/1,224 (21%) in MRI-group ($p<0.001$). Per-patient reoperation rate for close/positive margins were 135/1009 (13.4%) and 80/967 (8%), respectively ($p<0.001$). Most mastectomies were already planned at mammography/ultrasound, using MRI as a confirmation tool, contributing in determining a lower reoperation rate in women undergoing MRI. Additional mastectomies were compensated by mastectomies shifted to CS and CS surgery was modified by MRI according to disease extent, balancing increased and decreased tissue removal. No increase in tissue removal has been determined by MRI.

Learning Objectives:

1. To learn about the evidence for and against the use of MRI in preoperative staging.
2. To understand the background, design and early results of the MIPA trial.
3. To be able to explain the role of preoperative MRI during multidisciplinary tumour board meetings.

B. MR imaging biomarkers for the clinical setting E.A. [Morris](#); *New York, NY/US (morrise@mskcc.org)*

1. To describe MRI biomarkers for breast cancer. 2. To understand the value of biomarkers in clinical practice. 3. To know the new possibilities for the future. Biomarkers - Diagnostic Biomarker - Detection or confirmation of a disease - Risk Biomarker - Identifies women at increased risk of breast cancer - Predictive Biomarker - How is the therapy working? - Prognostic Biomarker (needed more) - Identify cancer aggressiveness relates to patient outcome - MRI BPE. Native fibroglandular tissue will demonstrate variable enhancement patterns and levels of enhancement on breast MRI. The enhancement of the existing underlying fibroglandular tissue has been termed background parenchymal enhancement. As background parenchymal enhancement is related to vascular flow, it has been proposed that this may represent an imaging biomarker of the underlying proliferation of fibroglandular tissue. Investigations have shown that there is an extremely strong association between BPE and risk of breast cancer, at least as strong as the association between mammographic density and breast cancer. As with breast density and distribution of breast parenchyma on mammography, it appears that the background parenchymal enhancement of breast MRI is also extremely variable and women have different patterns and intensity of background parenchymal enhancement. In fact, it has been observed that not all mammographically dense breasts demonstrate increased background parenchymal enhancement. Therefore, it is possible that MRI can further stratify women at high risk for developing breast cancer on the basis of background parenchymal enhancement.

Learning Objectives:

1. To learn about the different biomarkers that are available and the evidence for using them in patients with breast cancer.
2. To understand in which clinical settings biomarkers might be of value.
3. To appreciate the newer techniques that are being developed and tested clinically.

A-0235 09:25

C. Screening with abbreviated protocols C.K. [Kuhl](#); *Aachen/DE (ckuhl@ukaachen.de)*

Early diagnosis improves the survival of women with breast cancer. Mammographic screening improves early diagnosis of breast cancer. And yet, there appears to be room for improvement. Major shortcomings of mammographic screening are overdiagnosis of prognostically unimportant cancer, as well as underdiagnosis of cancers that are indeed relevant. Failure to detect biologically relevant breast cancer with mammographic screening is driven by host-related factors, i.e. breast tissue density, but also tumour-related factors: Biologically relevant cancers may exhibit imaging features that renders them indistinguishable from normal or benign breast tissue on mammography. These cancers will then progress to become the advanced-stage interval cancers observed in women undergoing mammographic screening. Since breast cancer continues to represent a major cause of cancer death in women, the search for improved breast cancer screening method continues. Abbreviated breast MRI has been proposed for this purpose because it will greatly reduce the cost associated with this method, due to a greatly reduced magnet time (down to 3 minutes), but especially also due to a greatly abridged image interpretation time, i.e. radiologist reading time. This lecture will review the current evidence and presents the EA1141 trial designed to investigate the utility of abbreviated breast MRI for screening average-risk women with dense breast tissue.

Learning Objectives:

1. To learn about the evidence for abbreviated MRI and the comparison with standard protocols.
2. To understand the different protocols for abbreviated MRI and the merits of each sequence used.
3. To appreciate the advantages and limitations for abbreviated MRI.

How to face the tsunami of pancreatic intraductal papillary mucinous neoplasia (IPMN)

A-0236 08:30

Chairperson's introduction

M. [Zins](#); *Paris/FR (mzins@hpsj.fr)*

Intraductal Papillary Mucinous Neoplasm of the pancreas are cystic pancreatic injury, often fortuitous discovered, increasingly recognised in recent years due to improved diagnostic techniques. IPMNs are mucin-producing neoplasms, causing pancreatic duct (main duct and/or branch duct) dilatation. From adenoma to adenocarcinoma, IPMNs present a broad spectrum of development. Accurate initial diagnosis with CT, MRI and EUS and Follow up using mainly MRI are needed.

Session Objectives:

1. To briefly introduce the diagnostic challenge in patients presenting IPMN lesions.
2. To learn the main differentials in patients with cystic neoplasms.
3. To understand the imaging strategy when organising follow-up of patients with IPMN lesions.

A-0237 08:35

IPMN: when to watch and when to resect

W. [Schima](#); *Vienna/AT (wolfgang.schima@khgh.at)*

With the development of thin-slice MDCT and MRI of the pancreas the prevalence of incidentally found pancreatic cysts has skyrocketed. It ranges from 2.6% (MDCT) to 10-45% (MRI) in large series of individuals without the known pancreatic disease. Prevalence of cystic lesions increases with age. The majority of cystic lesions may be IPMN of branch-duct type, although non-neoplastic cysts (in subtle chronic pancreatitis or even simple cysts) may also be found. The presence of IPMN constitutes an increased risk to develop pancreatic cancer. Several guidelines worldwide have addressed this issue by establishing imaging criteria to assess lesions. Most commonly used is the Fukuoka guideline, which defines "worrisome features" and "high-risk stigmata". Worrisome features include the presence of a cyst ≥ 3 cm, enhancing mural nodule, thickened cyst wall, and main duct size of 5-9 mm, and rapid

growth rate of >5mm/2years. EUS should evaluate these patients. High-risk stigmata (including enhanced mural nodule >5mm, main duct size ≥10mm, or obstructive jaundice in cystic lesion of the head) should prompt resection in surgically fit patients. However, the vast majority of cystic lesions is <3cm and do not show worrisome features. Follow-up schedules have been suggested, stratified according to cyst size. Fukuoka guidelines suggest indefinite F/U, whereas ACR recommendations suggest stop of F/U, if a cyst is unchanged for ten years. In younger patients, an abbreviated F/U MR protocol without IV contrast could save resources. An important consideration should be directed toward clinical consequences of imaging F/U in elderly patients.

Learning Objectives:

1. To become familiar with the imaging features of different types of IPMN.
2. To discuss the different international guidelines that define the management of the patients.
3. To understand the multidisciplinary team approach necessary when deciding between conservative or surgical management.

A-0238 08:58

Diagnosis of IPMN: the mimickers and how to sort them out

M.-P. Vullierme; Clichy/FR (marie-pierre.vullierme@bjn.aphp.fr)

IPMN develops on the abnormal ductal mucosa. Abundant mucus secretion is related with enlargement of pancreas ducts, main duct and/or branch ducts. Enlargement of the main duct upstream to stenosis could be misinterpreted as IPMN. Stenosis must be ruled. The enlarged ductal lumen should be continuous with the duodenal lumen. When all MPD is enlarged, it remains difficult to locate the exact place of the abnormal mucosa. Because the mucus flows downstream to be excreted in the duodenal lumen, downstream enlargement could appear. Then, for example, IPMN of the tail could be associated with enlargement of the body's MPD, but without IPMN of this body. Enlarged branch duct appears as a round cyst communicating with the main pancreatic duct through an enlarged sinuous branch duct, appearing as a tubular pattern. This communication must be obvious to affirm IPMN. Particularly serious cystadenoma is made of cysts, but without enlarged ducts and without communication. The thickening of the mucosa is often too thin to be visible with CT or MR. Intraluminal nodule could be seen when this thickening is larger. This nodule when present could locate with a good specificity the exact place of IPMN. Desiccated mucus could appear as a lacuna in the lumen, usually with a marked hyposignal with T2, and without enhancement after contrast injection. Chronic pancreatitis could appear upstream to obstructive mucus into the MPD. Ductal and parenchymal abnormalities have the same aspect than with other cause of chronic pancreatitis.

Learning Objectives:

1. To highlight the imaging features, which distinguish IPMN from other cystic pancreatic neoplasms.
2. To specifically discuss the differential diagnosis with chronic pancreatitis.
3. To understand the value of the integration of the imaging modalities that define the correct diagnosis.

A-0239 09:21

Follow-up of IPMN: how many MRs do we need?

R. Pozzi-Mucelli; Stockholm/SE (raffaella.pozzi-mucelli@sl.se)

IPMN is the most frequent pancreatic cystic lesion, which is often incidentally detected by CT or MR. Since IPMN has variable malignant potential, it should be followed-up until the patient is considered fit for surgery. MR should be preferred to CT for the surveillance of IPMN, as it does not expose the patient to ionising radiation and it has a higher sensitivity for the identification of mural nodules. Clinicians/surgeons need to tailor the follow-up and its intervals according to several aspects, such as the patient's age and comorbidity, "first-time" detection without previous imaging, presence or absence of risk factors (i.e., diameter of the main pancreatic duct, cyst size, enhancing mural nodules, growth rate), previous pancreatic surgery for IPMN and family history of pancreatic cancer. The surveillance of IPMN might be life-long as this lesion poses the patient at risk of developing an associated invasive carcinoma or a concomitant adenocarcinoma, arising somewhere else in the pancreatic gland. Thus, multiple follow-up MRs are needed, leading to high health-care costs. Therefore, it is essential to customise MR's protocols. We will discuss the indications and pitfalls of extensive protocols (i.e., including MRCP and contrast agent) compared with shorter protocols (i.e., without MRCP and contrast agent).

Learning Objectives:

1. To discuss the methods, intervals and length of surveillance in branch ducts IPMN.
2. To understand why MR is an adapted tool for surveillance and which protocol should be proposed.
3. To specifically discuss the development of distinct ductal adenocarcinoma of the pancreas during follow-up of branch duct IPMNs.

A-0240 09:44

Panel discussion: Management of IPMN: what is the Achilles heel of our current concept?

M. Zins; Paris/FR (mzins@hpsj.fr)

Intraductal Papillary Mucinous Neoplasm of the pancreas are cystic pancreatic injury, often fortuitous discovered, increasingly recognised in recent years due to improved diagnostic techniques. IPMNs are mucin-producing neoplasms, causing pancreatic duct (main duct and/or branch duct) dilatation. From adenoma to adenocarcinoma, IPMNs present a broad spectrum of development. Abdominal emergencies

Moderator:

B. Marincek; Kilchberg/CH

A-0241 08:30

Perforation of the GI tract

V. Maniatis; Aabenraa/DK (vmaniatis67@gmail.com)

Perforation of the GI tract represents an emergency and life-threatening condition. Causes of perforation may be traumatic (endoscopy, blunt trauma, ingested foreign body), inflammatory (peptic ulcer disease, diverticulitis, appendicitis, Crohn's disease or other enteritides), bowel ischemia or neoplasms. Clinical diagnosis may be challenging, and patients may be first radiologically evaluated with plain radiographs or ultrasound, although with limited information in cases of perforation. CT scanning is the imaging method of choice in these patients. CT findings of GI tract perforation are divided to direct and indirect. Direct findings include free air or/and oral contrast either intra- or retroperitoneal. Indirect findings comprise mainly an inflammatory mass surrounding an appendicolith or a radiopaque foreign body. Non-specific findings include bowel wall thickening, mesenteric infiltration, interloop free fluid and abnormal bowel wall enhancement. The sensitivity of CT in diagnosing GI tract perforation is up to 92%. False-positive results usually occur in post-operative patients, where free air as a result of the previous operation can be misdiagnosed as a sign of an anastomotic leak or iatrogenic bowel trauma. CT is also able to depict both the site (with an accuracy of 82-90%) and the cause (in up to 67% of cases) of perforation. It is well documented that CT plays a crucial role in the assessment of acute abdomen, including patients with GI tract perforation, by offering fast and accurate essential information to the clinicians and enabling the essential therapeutic choice.

Learning Objectives:

1. To review the aetiologies of the perforation.
2. To present current imaging techniques for evaluation of the perforation.
3. To describe the typical features of the perforation.

A-0242 09:00

Bowel obstruction

A. Filippone; Chieti/IT (filipponea378@gmail.com)

Nowadays imaging has become the primary focus in the treatment of bowel obstruction (BO). Therefore, radiology assumes considerable relevance in assisting the therapeutic decision of the surgeon in cases of BO by addressing the following questions: Is the bowel obstructed? How severe is the obstruction, where is it located, and what is its cause? Is strangulation present? Plain abdominal radiography continues to be the initial examination in these patients due to its wide availability and relatively low cost. However, radiographs are diagnostic in only 50%-60% of cases. Nevertheless, the results of this modality should serve as a basis for triage for further imaging workup and assist in the therapeutic decision. Ultrasound, although not commonly used for the evaluation of BO, may be useful when the obstructed bowel segments are filled with fluid, because allows detecting the level as well as the cause of the obstruction by using the fluid-filled bowel as a sonic window. Multidetector CT scanners with multiplanar reformation capability are significantly more effective in the evaluation of BO. Owing to the early demonstration of strangulation, CT is now considered the best modality for determining which patients would benefit from conservative management and close follow-up and which patients would benefit from immediate surgical intervention. An algorithmic and schematic approach will be proposed for imaging workup and evaluation of patients with BO, based on a review of the literature and the current approach to this entity.

Learning Objectives:

1. To review the most common causes of bowel obstruction.
2. To present current imaging techniques for evaluation of bowel obstruction.
3. To become familiar with the typical findings of bowel obstruction.

A-0243 09:30

Vascular emergencies

V.E. [Sinityn](mailto:vsini@mail.ru); Moscow/RU (vsini@mail.ru)

Abdominal vascular emergencies are life-threatening conditions which are very difficult to recognise with the physical examination. Clinical signs may be unspecific and delay with correct diagnosis could lead to catastrophic consequences. Knowledge of the underlying disease and high clinical suspicion help to use modern imaging modalities for diagnosis. Acute vascular emergencies could be arterial or venous. Their major types are active haemorrhage due to rupture or laceration of vessel or occlusion (thrombosis, compression) of the artery or vein. Contrast-enhanced MDCT is a modality of choice for timely diagnosis of acute mesenteric ischemia (arterial or venous). Its diagnostic performance is equal to invasive catheter angiography. The abdominal US also could be used for this purpose. CT with contrast enhancement can see not only blood clots and hematomas but also sites of active bleeding seen as extravasation of contrast media. In case of acute vessel occlusion sign of organ ischemia (malperfusion) could be detected with CT. Diagnostic pitfalls may be related to the small rate of blood extravasation and mucosal bleedings. Late complications of arterial injuries are the formation of pseudoaneurysm and dissection. In case of life-threatening vascular emergencies, different types of radiological interventional procedures such as thrombolysis, embolisation, stenting or grafting could be used for the rapid treatment of the patient without the need for open abdominal surgery.

Learning Objectives:

1. To review the most common causes.
2. To present current imaging techniques.
3. To be familiar with the role of interventional radiology.

Special Focus Session

SF 5b

Basic interventional radiology for non-interventionalists: let's start with biopsy!

A-0244 08:30

Chairperson's introduction

J.I. [Bilbao](mailto:jibilbao@unav.es); Pamplona/ES (jibilbao@unav.es)

Percutaneous biopsy (PB) procedures, which includes both fine needle aspiration biopsy (FNA) and core needle biopsy (CNB), remain essential in the management of oncological patients. In spite of some concerns related with its safety and yield and also with the adventment of liquid biopsy (circulating DNA), PB allows the detailed analysis (i.e., genomics) of heterogeneous tumours allowing a personalised therapeutic approach. This is particularly relevant, for example, in cases in which post-therapeutic imaging (i.e., PET-CT) shows a non-uniform pattern of response and more information is needed from the different parts of a tumour. Therefore, the radiologist that will perform the PB needs to be part of a team in which the individualised management of each patient is being decided. This team (the multidisciplinary tumour board-MDTB) is essential, among other roles, to facilitate decision-making and improve/accelerate the process, to extend treatment options offering cross-speciality knowledge and to sequence therapies by collaboration between equals after the identification of all available options. Within this MDTB radiologists should progress from skilful-technicians performing procedures to clinical consultants treating patients, participating in the continuity of care, offering evidence, planning research and swiftness from not just technological aspects to clinical outcomes. Radiologists should be aware of the different levels of sedation/analgesia that are needed depending on the characteristics of the procedure. For PB, in some cases, it would be needed some analgesia (minimum sedation) maintaining spontaneous ventilation and normal responsiveness to verbal stimulation.

Session Objectives:

1. To learn about the role of percutaneous biopsy in patient management.
2. To explain the crucial role of being part of a multidisciplinary board.
3. To learn about intra-procedure patient analgesia.

A-0245 08:35

How to decide indications and pre-treatment evaluation

P. [Popovic](mailto:peter.popovic@kclj.si); Ljubljana/SI (peter.popovic@kclj.si)

Percutaneous imaging-guided biopsy (PB) is used extensively in daily clinical practice for the pathologic confirmation of certain diseases in the area of thorax, abdomen and musculoskeletal system. Indications for PB include, but are not limited to the following: to establish the nature of diffuse parenchymal disease; to obtain material for microbiological analyses in suspected or known infections; to establish the benign or malignant nature of a suspected tumour; to classify a malignancy (including immunohistochemistry evaluation); to stage a patient with known (or suspected) malignant tumours elsewhere; to evaluate response to therapy or to confirm recurrence and to obtain material for molecular analysis. Patient clinical assessment and preparation are critical for the success of PB. Before the procedure, special attention should be paid to the review of relevant medical history, medications and laboratory data. The evaluation of coagulation status is essential. When possible, antiplatelet/anticoagulation medications should be discontinued before the procedure in particular for biopsies with a moderate or significant risk of bleeding. Procedure planning starts with choosing the most proper imaging modality and technique of access and choice of biopsy needle and device. This is followed by the careful planning of the needle access taking into account the lesion type and location, patients' compliance and technique availability. PB performed by experienced operators are generally safe procedures with a low rate of complications, these still do occur. Therefore a proper and detailed informed consent should be obtained from the patient with presenting the benefits and potential complications of the procedure.

Learning Objectives:

1. To become familiar with indications for percutaneous biopsy.
2. To learn what to check before your procedures, taking in mind patients' safety first.
3. To explain how it is possible to obtain a really informed consent.

A-0246 08:53

How to guide your procedure

L. [Crocetti](mailto:laura.crocetti@med.unipi.it); Pisa/IT (laura.crocetti@med.unipi.it)

Once indication to perform a biopsy has been established, the careful review of pre-procedural images allow procedural planning, including the selection of the most proper imaging guidance, patient's position and access routes. Percutaneous needle biopsy (PNB) can be performed under a variety of imaging modalities, including US, CT, MR and fluoro-CT. The selected imaging modality should allow complete visualisation of the target and surrounding relevant anatomy, visualisation of the needle during the procedure, comfortable patient positioning and operator' manoeuvres; finally, after the execution of the procedure, an adequate evaluation of possible complication should be guaranteed. Each imaging modality has its own features that allow the radiologist to choose the most advantageous according to different anatomical compartments. US is widely used as a guidance modality for PNB in solid organs such as liver and kidney. The puncture of lesions located in the lung, mediastinum and bone, as well as of masses in the retroperitoneal and peritoneal spaces is usually performed by CT-guidance. MR guidance can be useful for lesions not detectable with other imaging modalities, provided that special non-magnetic needles are used. Once imaging guidance modality has been chosen, selection of an adequate access route is critical to ensure the success of PNB. Generally, the route should be as short as possible and should avoid all risky structures (lung fissures and bullae, large vessels, bowel, etc.). In specific situations, a longer route is recommended, i.e. in subcapsular liver lesions when a longer tract with intervening normal liver parenchyma reduces the risk of hemoperitoneum.

Learning Objectives:

1. To appreciate the importance of pre-procedure planning and selection of image-guidance technique.
2. To learn about advantages and disadvantages of different imaging modalities for guidance.
3. To learn about new techniques and future prospective for improving your results.

A-0247 09:11

How to do your procedure

P.M. [Vilares Morgado](mailto:vilares.morgado@porto.pt); Porto/PT

"no abstract submitted"

Learning Objectives:

1. To become familiar with needles, and how to handle the biopsy specimen.
2. To learn which device is needed for which patient and lesion based on indication.
3. To highlight how to minimise potential complications.

A-0248 09:29

How to follow-up on your patients

M. [Seidensticker](mailto:seidensticker@med.uni-muenchen.de); Munich/DE (max.seidensticker@med.uni-muenchen.de)

Biopsy procedures bare - although commonly at a low rate - potentially life threatening risks. To know about potential complications and proper patient monitoring is the key to identify the complications and to react accordingly. The lecture will give informations about common and uncommon complications after biopsy procedures, and help will be given to identify the patient at risk and how to avoid/reduce specific complications. Further on, the management of complications will be addressed. Of note, not all complications are avoidable, but proper patient follow-up helps to reduce associated morbidity and mortality.

Learning Objectives:

1. To learn how to check your patients in the immediate post-procedure.
2. To become familiar on how to follow-up on patients.
3. To learn about management of post-procedure complications.

7 Tesla MR goes clinical

A-0249 08:30

Chairperson's introduction

S. [Trattinig](mailto:siegfried.trattinig@meduniwien.ac.at); Vienna/AT (siegfried.trattinig@meduniwien.ac.at)

There is growing interest in the ultra-high field (UHF) MRI because of improved clinical results with regard to morphological as well as functional and metabolic capabilities. Moreover, recently one 7T MR system was CE certified, and FDA approved, which raises the question if the huge investments for the installation of a 7T system provide sufficient added clinical value or can even be a game changer in MR. As the signal-to-noise ratio scales supralinearly with the field strength ($Bo^{1.65}$) of the scanner, the most obvious application at 7T is to obtain higher spatial resolution in the brain, musculoskeletal system and breast. The dynamic and static blood oxygenation level-dependent contrast increases supralinearly with the field strength, which significantly improves fMRI and SWI in the brain. The better spectral resolution at 7T with higher SNR allows high-resolution MR spectroscopic imaging in tumours and MS. Multi-nuclear clinical applications, such as sodium imaging for the evaluation of repair tissue quality after cartilage transplantation and ^{31}P spectroscopy for the differentiation between non-alcoholic benign liver disease and potentially progressive steatohepatitis, are only possible at ultrahigh fields. In this session from basic information on the benefits of an ultra-high field, advantages of UHF in clinical neuro and MSK applications as well as in the challenging cardiovascular field will be covered.

Session Objectives:

1. To understand the tendency to higher static magnetic fields in clinical MRI.
2. To learn about the additional benefits of 7T in Neuroimaging and MSK.
3. To become familiar with challenges and technical solutions in body MR at 7T.

A-0250 08:35

Why is there a benefit to higher static magnetic field in MR?

P. [Jezzard](mailto:peterj@fmrib.ox.ac.uk); Oxford/UK (peterj@fmrib.ox.ac.uk)

Increasing the static magnetic field strength in an MRI scanner leads to a corresponding increase in signal-to-noise ratio, which can be used in a variety of ways, including improving the spatial resolution of the image, or the spectral separation of an MRS experiment, or the acquisition of time-limited data in less time. Examples of novel scientific insights that have been obtained at ultra-high field include exquisite cortical fMRI, enabling the directionality of input and output flows of information via prior anatomical layer information. There are challenges to realizing high-quality ultra-high field MRI, however, including difficulties in achieving a homogeneous transmit field and hence a uniform image contrast, associated challenges in the amount of tissue RF heating that may result, and difficulties in coping with increased effects from artifacts caused by interfaces between regions of differing magnetic susceptibility, leading to poor static field shim. The talk will overview both the opportunities afforded by ultra-high field MRI and also some of the challenges of realising them.

Learning Objectives:

1. To become familiar with scanner and coil technology at ultra-high field.
2. To learn about the benefits of increased SNR and spectral resolution at 7 T.
3. To understand why 7 T is the best for BOLD imaging (fMRI and SWI).

A-0251 08:53

Neuroimaging at 7 T: where does it make the difference?

J. [Hendrikse](mailto:Hendrikse@umcutrecht.nl); Utrecht/NL (J.Hendrikse@umcutrecht.nl)

7Tesla MRI in clinical practice has been exploited for high-resolution imaging combining the increased signal to noise ratio (SNR) for an increased contrast to noise ratio (CNR). With this increased contrast to noise ratio, small pathology could be delineated. Examples of this small-sized pathology at the brain tissue level are imaging of the total burden of microbleeds and demonstration for the first time the presence in-vivo of cortical microinfarcts. The knowledge of the cortical microinfarcts at 7Tesla was used for the translation and detection of this cortical microinfarcts at 3Tesla MRI field strength. The detection and characterisation of brain tissue lesions at 7Tesla MRI has been used in dementia patients to unravel for instance the vascular contribution to (vascular) cognitive impairment and ageing in general. In acute (stroke) and chronic cerebrovascular disease or risk factors (hypertension) 7Tesla wall imaging can identify the causes of stroke in an individual patient and quantify the burden of intracranial atherosclerosis. The clear delineation of brain tissue lesions at 7Tesla was also used for the detection and characterisation of multiple sclerosis (MS) lesions including the detection of cortical lesion burden in MS patients. Furthermore, 7Tesla MRI was used for the detection of brain tissue lesions in epilepsy patients especially in epilepsy patients with a negative MRI result at lower MRI field strengths. Finally, 7Tesla has been used in patients with suspected pituitary adenomas with negative MRI results at lower field strengths. 7Tesla MRI may show pituitary adenomas in patients and guide neurosurgeons.

Learning Objectives:

1. To learn about the benefits of 7 T for intracranial vessel wall imaging, microbleed detection and microinfarct detection.
2. To become familiar with clinical applications of 7 T MR in brain tumour imaging including pituitary gland imaging.
3. To understand the added value of 7 T MR in MS, epilepsy and dementia.

A-0252 09:11

MSK imaging at 7 T: what are the additional clinical benefits

S. [Trattinig](mailto:siegfried.trattinig@meduniwien.ac.at); Vienna/AT (siegfried.trattinig@meduniwien.ac.at)

There is growing interest in the use of ultra-high-field (UHF) (7T) for vivo applications in MRI of musculoskeletal tissues. Higher SNR with increasing main magnetic field B_0 can be exploited for improving spatial resolution, which allows for examination of small structures which are difficult to see at lower field strength such as the thin cartilage in ankle and wrist joints. Macromolecular content of the connective tissues of joints determines their correct function. Collagen fibre mesh defines the static biomechanical properties whilst glycosaminoglycans define the dynamic biomechanical properties. Early detection of connective tissue microstructure defects is a crucial deciding factor for appropriate treatment or intervention. MRI techniques capable of non-invasive detection of connective tissues macromolecules strongly benefit from ultra-high field MRI. First signs of tendinopathy and meniscus degeneration are associated with the collagen fibre decomposition and can be detected by T_2^* analysis and high resolution at 7T. The low sensitivity of sodium MRI and the low abundance of sodium require the high SNR of UHF. Several studies have demonstrated sodium MRI as a quantitative marker for cartilage degeneration and monitoring the cartilage transplant maturation by direct quantification of the glycosaminoglycan content. In addition, sodium MRI has been used as a marker for Achilles tendinopathy and treatment monitoring, but also for effects of systemic diseases on joint structures and the possible side effects of drug on tendons. Musculoskeletal MRI at ultra-high field benefits from higher SNR and lower acquisition time, however, optimised protocols and dedicated coils are required.

Learning Objectives:

1. To appreciate the important role of coil technology and optimised sequence protocols in MSK at 7 T.
2. To learn about the improvements of morphological MSK at 7 T MRI.
3. To become familiar with the benefits of biochemical MSK using x-nuclei and CEST.

A-0253 09:29

Cardiovascular and abdomen MR at 7 T - still a challenge?

J. [Schulz-Menger](mailto:schulz-menger@charite.de); Berlin/DE (jeanette.schulz-menger@charite.de)

7Tesla MR has entered the clinical arena in neurology and musculoskeletal imaging, but its capabilities in body imaging including Cardiovascular Magnetic Resonance (CMR) and Abdominal MR (AMR) are still reflected as a challenge. That is caused by the perception of technical challenges as well based on uncertainty regarding clinical need and/or indication. No doubt, the new methodology has always challenges - it is changing our habits. Increasing the

Postgraduate Educational Programme

field strength comes along with increases in signal- and contrast-to-noise ratio. This benefit is expected to be translated into higher spatial and temporal resolution and faster imaging techniques. Translation into histology like images as well as in the evaluation of pathophysiology are the offers we are getting using 7Tesla. The main technical challenges like field inhomogeneity, lack of coils, gating problems or inconvenient handling are meanwhile nearly solved. Technical improvements by experienced physicists and engineers are still ongoing. That offers completely new insights like sodium-, potassium-imaging as well as cardiac functional de-oxygenation-imaging. A significant step is given by the excellent quality of non-contrast angiography allowing the delineation of small peripheral as well as abdominal vasculature. It was already shown, that CMR is reliable at 7T and has added value by identifying tiny structures like gaps in the myocardium. AMR seems to give the chance to detect small lymph nodes, but MRA is the current focus. There are still challenges at 7T, but solving them will be a significant step towards personalised medicine. Driving this development means establishing the additional value.

Learning Objectives:

1. To understand the current challenges in this field at 7 Tesla.
2. To become familiar with dedicated technical solutions at 7 T for patient handling.
3. To learn about the added diagnostic value and unique opportunities in cardiovascular and abdomen MR.

Imaging of chronic forefoot pain

Moderator:

K. Wörtler; Munich/DE

A-0261 08:30

A. Articular disorders

E.G. McNally; Oxford/UK

Forefoot pain has a wide differential diagnosis. Biomechanical causes are common, often related to subtle foot deformity. Other causes include: Biomechanics (Hallux Valgus, MPV, Bunionette, H Rigidus, Hammer/Claw toe, Fallen transverse arch), Bone (Sesamoids, Osteochondritis, Stress, Insufficiency), Joint (RA, Seroneg, Crystal, Infection, Implants), Joint capsule (Capsulitis, Plantar plate, Collateral ligaments).

Learning Objectives:

1. To explain the pathophysiology and disease spectrum of articular sources of chronic forefoot pain.
2. To describe the imaging findings of articular disorders that present with chronic forefoot pain.

A-0262 09:00

B. Extra-articular source of pain

G. Bierry; Strasbourg/FR (guillaume.bierry@chru-strasbourg.fr)

After a brief review of forefoot soft tissue anatomy and of the mechanical consequences of the loss of normal foot architecture, we will review the main extra-articular (not related to joint or bone disorders) causes of chronic forefoot pain. The two first, plantar plate injury and Morton neuroma, are thought to be secondary to foot modified strains and are, with fatigue fracture, part of the second ray syndrome. Even if asymptomatic in the vast majority of cases, bursitis will be discussed in the section as well. Last, soft tissue tumours and infection, far less frequently encountered than neuromas and plate injury will be briefly reviewed.

Learning Objectives:

1. To explain the pathophysiology and disease spectrum of extra-articular sources of chronic forefoot pain.
2. To describe the imaging findings of extra-articular conditions that are present in chronic forefoot pain.

A-0263 09:30

C. Imaging-guided percutaneous treatment of forefoot pain

R.L. Cazzato; Strasbourg/FR

The forefoot is the most common location for foot pain in adults. Women are more likely to be affected than men, and it has been estimated that forefoot pain causes disabling symptoms in more than 1/3 individuals older than 70. The most common causes of forefoot pain are related to acquired deformities of the toes (e.g. hallux valgus, hammertoes) or of the plantar surface (e.g. corns, calluses), for which a conservative or surgical treatment is routinely proposed and effectively applied. Nevertheless, there are some less common causes of forefoot pain for which percutaneous image-guided interventional treatments have been progressively proposed in the last few years, with results that are encouraging although preliminary in many cases. In such perspective, infiltrative or ablative treatments are becoming increasingly popular to treat degenerative, tumoral or tumour-like painful conditions of the forefoot. Such tendency is mainly related to the main advantages of percutaneous image-guided treatments including their minimally invasive profile accounting for a low post-interventional morbidity rate and a fast convalescence period, and the possibility to be repeated over time.

Learning Objectives:

1. To explain the rationale behind the imaging-guided percutaneous treatment of forefoot pain.
2. To describe the imaging-guided percutaneous procedures for the treatment of forefoot pain.

Big data and the big picture: deep learning in optimisation of medical imaging (part A)

Moderators:

J. Damilakis; Iraklion/GR

P. Gilligan; Dublin/IE

A-0264 08:30

Chairperson's introduction

J. Damilakis; Iraklion/GR (damilaki@med.uoc.gr)

Deep learning methods can be used for a large number of tasks in medical imaging. These tasks may cover image production steps such as image reconstruction, dose optimisation, image processing etc. Deep learning can also support research in the field of medical imaging. Machine-learning algorithms and deep-learning methods can be used to develop non-invasive imaging-based biomarkers. Radiomics refers to a method designed to extract a large amount of quantitative and reproducible characteristics from medical images, thereby enabling data mining. Coupled with machine learning methods, radiomics allows for several types of pathologies discovered on radiological images to be automatically classified. Big data and deep learning will be used in everyday medical imaging in the future to improve quality and safety. However, there are several technical, medico-legal and ethical challenges. Medical physicists must be prepared for facing this new technology by updating their training and education programs.

Session Objectives:

1. To become familiar with the concept of big data and their management.
2. To discuss the opportunities provided by big data repositories in clinical practice.
3. To understand how big data can support research.

A-0265 08:35

Imaging and dose biobanks

E. Neri; Pisa/IT (emanuele.neri@med.unipi.it)

"no abstract submitted"

Learning Objectives:

1. To provide an overview of imaging and dose biobanks.
2. To understand how to gain access to the data.
3. To learn about obstacles in obtaining validated and annotated images and dose data in a systematic fashion.

A-0266 09:05

Statistical methods for analysis of multidimensional imaging data

K. Van Leemput; Copenhagen/DK

This presentation will provide an introduction to two complementary approaches for computationally analysing medical images, namely discriminative vs generative models. The pros and cons of each of these approaches will be highlighted, with a specific emphasis on the role of training

Postgraduate Educational Programme

data and the (lack of) acquisition standardisation across clinical imaging sites. The presentation will conclude with an example of a generative model for modality-adaptive segmentation of brain tumours and organs-at-risk for radiation therapy planning.

Learning Objectives:

1. To learn about the main features of a system for collection and analysis of multidimensional imaging data.
2. To become familiar with different analytical uses of collected imaging data.
3. To understand the difference between the current approaches used in statistical analysis/deep learning in medical imaging.

A-0267 09:35

The use of radiomics in medical imaging

P. Lambin; Maastricht/NL

"no abstract submitted"

Learning Objectives:

1. To understand how convolutional neural networks can be used for features extraction in medical imaging.
2. To become familiar with the different capabilities of features extraction tools and their connection with image analysis and interpretation.
3. To identify the possible limitations of radiomics in providing meaningful relationships between features and their clinical interpretation.

Pulmonary neuroendocrine proliferations and neoplasms

Moderator:

M. Silva; Parma/IT

A-0268 08:30

A. Diffuse idiopathic pulmonary neuroendocrine cell hyperplasia (DIPNECH)

G. Chassagnon; Paris/FR (gchassagnon@gmail.com)

Diffuse Idiopathic Pulmonary Neuroendocrine Cell Hyperplasia (DIPNECH) is an under-recognised disease characterised by proliferation of neuroendocrine cells in the bronchial wall. DIPNECH preferentially affects middle-aged women. It is considered a pre-invasive lesion for lung carcinoid tumours and is found in 5.4% of patients undergoing surgical resection for lung carcinoid tumours. Other manifestations of DIPNECH include bronchial obstruction and formation of tumorlets. On computed tomography (CT), an association of mosaic attenuation with multiple small nodules is very suggestive of DIPNECH diagnosis.

Learning Objectives:

1. To learn about the diagnostic criteria of this syndrome.
2. To understand the correspondence between imaging and pathology.
3. To know when to suggest this diagnosis on CT.

A-0269 09:00

B. Carcinoid tumours

H. Prosch; Vienna/AT (helmut.prosch@meduniwien.ac.at)

Neuroendocrine tumours of the lung arise from neuroendocrine cells of the bronchial tree and are subdivided into the low-grade typical and atypical carcinoids, as well as the malignant small-cell lung carcinomas (SCLC) and large-cell neuroendocrine lung carcinomas (LCNET). Carcinoids of the lungs are rare tumours comprising only up to 5% of all lung cancers. Most carcinoids (80%) are typical carcinoids, which are primarily located in the lung periphery. Only about 20% of pulmonary carcinoids are atypical, which are more frequently found in the lung core. Since carcinoids originate from the bronchial system, the most common presenting symptoms are attributable to the consequences of obstruction (wheezing, post-obstructive pneumonia, atelectasis) or hemoptysis. While the prognosis for carcinoids is good in most patients, the prognosis for SCLCs and LCNETs is usually very poor. As imaging plays a key role in the diagnosis, staging, and follow-up of neuroendocrine tumours, radiologists need to be familiar with the peculiarities of these tumours.

Learning Objectives:

1. To learn about the radiological features of central and peripheral carcinoids.
2. To know when to suspect a carcinoid tumour in case of bronchial obstruction.
3. To learn about the role of FDG and DOTATOC PET/CT in the evaluation of carcinoid tumours.

A-0270 09:30

C. Small cell lung cancer

M. Das; Duisburg/DE (Marco.Das@helios-gesundheit.de)

Small cell lung cancer (SCLC) is one of the most aggressive tumours, with a 5-year survival rate of only 5-10%. Most of the patients present with advanced disease at diagnosis. SCLC is classified by recent TNM classification and UICC criteria, as well as traditional as limited and extensive disease. As SCLC is usually treated by chemotherapy/radiation therapy patients, undergo frequent imaging for response control. The role of radiology is to assess initial diagnosis and extent of disease as well as follow up assessment and tumour response.

Learning Objectives:

1. To learn about the common radiological manifestations of small cell lung cancer.
2. To learn how to distinguish between limited or extensive forms.
3. To learn how the TNM staging system should be integrated into the classification of SCLC.

SF 5c

MSK intervention: the road from low to no invasion

A-0271 08:30

Chairperson's introduction

J. Hodler; Zurich/CH (juerg.hodler@usz.ch)

Musculoskeletal interventions commonly are performed as an elective procedure. Radiologists, therefore, have a special responsibility to reduce side effects. Correct indication for any procedure, reduction of radiation dose, avoiding medication-related side effects and technically correct procedures are relevant aspects. Technical innovation may assist radiologists in making image-guided interventions safer. These aspects and more will be presented and discussed by experts in their field.

Session Objectives:

1. To appreciate the prevalence and importance of complications in MSK interventions.
2. To learn about strategies reducing side effects and complications of MSK procedures.
3. To become familiar with innovations leading to reduced invasiveness in MSK interventions.
4. To appreciate the role of radiologists in developing less invasive interventions.

Author Disclosure:

J. Hodler: Research/Grant Support; Siemens Healthineers, Guerbet, Bayer.

A-0272 08:35

Avoiding side effects and complications by using MR guided high-intensity focused ultrasound

A. Napoli; Rome/IT (alessandro.napoli@uniroma1.it)

Current treatments for patients with bone metastases include localised therapies (radiation and surgery), systemic therapies (chemotherapy, hormonal and radiopharmaceutical therapies, and bisphosphonates), and analgesics. External beam radiotherapy (EBRT) is the current noninvasive standard for local pain palliation; however, 20%-30% of patients do not achieve symptom relief, and pain may recur in up to 25% of patients following treatment. Magnetic resonance-guided focused ultrasound (MRgFUS) is already clinically approved in the European Union for the palliative care of bone metastases. MRgFUS combines focused ultrasound energy to thermally ablate tissue in combination with continuous MR imaging and thermal feedback. The treatment is noninvasive, does not require ionising radiation, and usually conducted in an outpatient setting. Because focused ultrasound energy is nonionizing, there is no dose limit; treatment can be repeated if needed. The major advantages of MRgFUS include MR-guided three-dimensional visualisation for high-accuracy treatment planning, real-time monitoring of thermal damage in the target zone

Postgraduate Educational Programme

using MR thermometry and immediate post-treatment assessment of therapy. An additional advantage of MRgFUS is that it can be administered during chemotherapy. MRgFUS ablation is indicated in patients who are considered radiation failures. In our department, we have evaluated the safety and efficacy of MRgFUS treatment for the pain palliation of lesions from different known primary tumours even as a first line modality. In conclusion, MRgFUS ablation is an extremely promising alternative therapy for pain palliation in patients suffering from bone metastases. Focused ultrasound might have a future role in local tumour control.

Learning Objectives:

1. To understand the physics of high-intensity focused ultrasound.
2. To understand the role of MR guidance in high-intensity focused ultrasound.
3. To appreciate effects and side effects of high-intensity focused ultrasound.
4. To become familiar with indications for high-intensity focused ultrasound.

A-0273 08:50

The 10 most important side effects and complications in MSK interventions

M. [Obradov](mailto:Obradov@maartenskliniek.nl); Nijmegen/NL (m.obradov@maartenskliniek.nl)

The musculoskeletal radiologist has to tailor interventional procedures to a patient's specific anatomy, pathology and comorbidities. Before the start of each procedure, the radiologist has to follow the guidelines to help avoid simple errors. Those guidelines consist of: reading the request, looking at recent radiographs/imaging, patient interview, an explanation of the procedure and obtaining informed consent. The most common general complications during musculoskeletal intervention procedures are haemorrhage, infection and drug-related reactions including complications of intra- and peri-articular steroid and anaesthetic injection. Anticoagulation alone is not a contraindication to most interventional musculoskeletal radiology procedures. The risk of bleeding if therapy is continued against the possibility of a thromboembolic occurring when anticoagulation therapy is withheld or reversed must be weighted. Since musculoskeletal procedures are generally considered clean, the guidelines recommend absolute sterile technique which would include scrub attire, hair coverings and masks in the presence of open instruments/trays, sterile gowns and gloves for participants, use of sterile drapes allowing for generous coverage of the sterile field, minimization of traffic in the procedure area. Adverse events associated with corticosteroid injection can be minimised by ensuring appropriate injecting procedures by a well-trained radiologist and limiting steroids into an annual dose of 3 mg/kg of triamcinolone or its equivalent. An allergic reaction has a higher incidence of local anaesthetics of ester type. Image guidance with smaller gauge needle helps minimise the risk of misadventure and complications. With proper planning and precautions, the consequences of possible complications can be minimised.

Learning Objectives:

1. To become aware of potential side effects and complications in MSK interventions.
2. To appreciate the relative importance of side effects and complications in MSK interventions.
3. To recognise the requirements regarding patient information before MSK interventions.
4. To become familiar with the imaging appearance of complications in MSK interventions.

A-0274 09:10

Radiation exposure: from reduction to avoidance

D.J. [Wilson](mailto:Wilson@btconnect.com); Oxford/UK (davidwilson.stlukes@btconnect.com)

The advent of ultrasound for needle guidance has to move the need for radiation exposure in the injection of joints. It also increases the precision as the technique allows real-time confirmation that the injectate is entering the joint. It is also allowed precise placement of needles into tendon sheaths and adjacent to ligaments. There are strong arguments that some injection procedures should only be undertaken using ultrasound guidance. Unfortunately, until recently spine injections including facet joint injections, disc injections, nerve root blocks and procedures at the vertebral bodies have not been practical using ultrasound guidance and required radiation exposure either by fluoroscopy or CT. Now we have ultrasound MRI or ultrasound CT fusion imaging which permits placement of needles and a real-time ultrasound examination with considerable precision and no radiation to the operator, and none to the patient and MRI images are used. Needle tracking techniques allow prediction of the route that the needle will take as well as direct tracking of the needle tip. The only disadvantage of this method it cannot administer contrast agents to identify where injection materials will track. This is a particular disadvantage when will that the needle might be inadvertently placed in a vessel that supplies the spinal cord or the brain. In this presentation, I will present examples of how fusion imaging has changed the preferred technique for complex musculoskeletal injections.

Learning Objectives:

1. To learn about the current knowledge in radiation exposure associated with MSK interventions.
2. To understand the need to reduce radiation exposure in MSK interventions.
3. To become familiar with radiation minimisation strategies in MSK interventions.
4. To appreciate alternative image guidance methods in MSK interventions.

Preventing side effects and complications by new procedures: management by radiologists

A. [Bazzocchi](mailto:Bazzocchi@inwind.it); Bologna/IT (abazzo@inwind.it)

The endpoint of the "road from low to no invasion" is focused on obtaining the desired effect with no complications or side effects; thus the ultimate purpose is the highest possible therapeutic index. This can be reached by developing new and minimally invasive techniques and tools. The achievement is based on an in-depth knowledge of the procedure itself and on the further investigation about how it works on a biological system. To be able to predict the reaction of the human body is essential. The awareness of different pathophysiological mechanisms involved in processes is also important to stimulate effective and safe approaches and treatment strategies. The management of the radiologist is crucial. The patient needs the radiologist to fully undertake and play this role.

Learning Objectives:

1. To become familiar with new methods in MSK interventions.
2. To appreciate solutions to reduce side effects and complications in MSK procedures.
3. To promote the role of radiologist in advancing new technology.
4. To appreciate responsibilities of radiologists in reducing side effects and complications in MSK procedures.

Intensive care paediatric radiology: the very sick neonate

A-0276 08:30

Chairperson's introduction

S. [Stafrace](mailto:Stafrace@yahoo.com); Doha/QA (samstafrace@yahoo.com)

Imaging of neonates in the intensive care setting is somewhat restricted by the fact that these infants are very unstable and best imaged at their bedside, if at all possible. Portable plain films play a vital role - often these neonates have multiple supporting tubes and lines that are prone to displacement and that require correct localisation. Knowing the appropriate landmarks for tube and line positioning and being able to identify pitfalls is very important for the radiologist reporting radiographs in such a setting. Ultrasound is the next big player - mobile, radiation-free, and in the trained hands, often gives the answer serving as a problem solver. Other modalities will come to play once plain films and ultrasound reach their limitations. This session, presented by experts in their field, offers a deep dive into the imaging of the neonate in intensive care, specifically focusing on the brain, the chest and the abdomen.

Session Objectives:

1. To learn about the most common neurological emergencies in the intensive care neonates.
2. To understand the wide variety of thoracic devices that may be used in these patients.
3. To discuss the role of US in abdominal emergencies in the critically ill child.

A-0277 08:35

A. Neuroimaging in the neonatal intensive care unit

M.I. [Argyropoulou](mailto:Argyropoulou@cc.uoi.gr); Ioannina/GR (margyrop@cc.uoi.gr)

The imaging modality of choice to evaluate the neonatal brain in the intensive care unit is the Ultrasound (US) coupled with Colour Doppler. State of the art technique should be applied by using the anterior fontanel and accessory acoustic windows. Sectorial and high frequency linear transducers should be used for detailed evaluation of the neonatal brain. Knowledge of the age-related changes of the brain are necessary to assess what is abnormal. The most common abnormalities in premature babies are brain hemorrhage

Oncologic Imaging

RC 516

Role of imaging in cancer of unknown primary (CUP)

A-0280 08:30

Chairperson's introduction

S. Gourtsoyanni; Athens/GF (sgty76@gmail.com)

Radiologists involved in CUP MDTs are essentially asked to guide the clinical team to solve the mystery of patients presenting with metastatic disease and an unclear primary, via imaging. The workhorse of oncologic imaging is CT of the torso and based on the spread of disease more dedicated imaging examinations might be requested. PET-CT certainly plays a role in reducing the number of confirmed CUP cases. In addition involved radiologists are able to select the most suitable lesions amenable to biopsy so that tissue diagnosis can be performed. CUP serves as a very good example of rad-path collaboration, as the two disciplines truly join forces for the best possible treatment to be provided. During this session, important issues such as avoiding unnecessary investigations and how to best follow up these patients will be also discussed.

Session Objectives:

1. To discuss the role of imaging for the diagnosis of CUP.
2. To review the role of the interventional radiologist in the management of suspected CUP.
3. To learn how to best assess treatment response.

A-0281 08:35

A. MDCT: the imaging workhorse for suspected CUP

C. Kelly-Morland; Framlingham/UK (christian.kellymorland@gmail.com)

Cancer of unknown origin is a heterogeneous subset of metastatic malignancy in which the primary tumour of origin remains elusive despite exhaustive imaging and often invasive investigation. It accounts for approximately 2% of all new cancer diagnoses, and the initial presentation varies widely. This lecture aims to outline common patterns of presentation and present to the audience a systematic approach to imaging evaluation in these patients with examples from a tertiary centre. Issues relating to CT protocoling and multimodality imaging will be addressed with a focus on review areas and important benign mimics of disease. A brief outline of key diagnostic adjuncts including immunohistochemical indices will be provided along with suggestions for disease response assessment methodology.

Learning Objectives:

1. To discuss the different patterns of disease spread in CUP.
2. To review optimal protocols and how not to miss important findings.
3. To learn how to best assess treatment response.

A-0282 08:58

B. Role of PET/CT in suspected CUP

L. Umutlu; Essen/DE

"no abstract submitted"

Learning Objectives:

1. To review the role of PET/CT in localised versus widespread metastatic disease.
2. To discuss potential false positive and false negative findings.
3. To learn when PET/CT is most appropriate in treatment response assessment.

A-0283 09:21

C. The role of the interventional radiologist

F. Corneils; Paris/FR (francois.corneils@aphp.fr)

Interventional Radiology is occupying an increasingly prominent role in the care of patients with cancer, with involvement from initial diagnosis, right through to minimally invasive treatment of the malignancy and its complications. However, approximately 3% to 5% of new diagnoses of cancer are classified as cancer of unknown primary (CUP). Imaging and management of these patients are often frustrating for both clinicians and patients. Adequate diagnostic samples can be obtained under image guidance by percutaneous biopsy and needle aspiration in an accurate and minimally invasive manner. In biopsy planning, modern cross-sectional imaging techniques help define lesion location, accessibility, and suitability for biopsy and aid in ensuring the correct lesion is sampled in the context of multiple lesions. It is important in analysing the patient with CUP to determine where the metastases are and if they have any suggestive imaging features that may allow a tailored search for the likeliest primary site. The advent of PET scanning may have a significant

disease (BHD) and periventricular leukomalacia (PVL). BHD is easily depicted and the different grades can be evaluated as well as complications such as venous infarct and post-hemorrhagic hydrocephalus. The focal form of PVL in early stages appears as heterogeneous hyperechogenicity and later as multiple periventricular cysts of different size. In the early stages of the diffuse form of PVL, US does not show any abnormality, but later on, ventricular enlargement with regular ventricular outlines appears. In full-term babies, hypoxia-ischemia is one of the main morbidities. Dependent on the duration and the severity, US may depict hyperechogenicity of the cortex, hyperechogenicity of the basal ganglia and in the most severe cases heterogeneity along with extensive encephalomalacia lesions. MRI is the gold standard for brain imaging and in neonates can be used to give additional information. MR compatible incubators are useful to provide a safe environment for those fragile babies.

Learning Objectives:

1. To learn the most common neurological emergencies in the intensive care patient.
2. To understand the preferential use of US and MRI as imaging techniques.
3. To discuss the key findings that may be useful for differential diagnosis.

A-0278 09:00

B. Chest imaging in the ICU: tubes and catheters

M.L. Lobo; Lisbon/PT (mluisalobo@gmail.com)

A large number of tubes and catheters are required to ensure life support and proper management of the very sick neonate. These include, among others, endotracheal tube, gastric tube, umbilical lines, central venous catheters and peripherally inserted venous central lines and chest drain tubes. A correct position of these devices is crucial to ensure their adequate function and to avoid complications, that can be serious or even fatal. Chest x-ray (or babygram) is the imaging modality of choice to check for the position of tubes, catheters and other devices. A good quality radiography is essential for adequate imaging interpretation; basic simple rules, such as a proper position of the baby and deviation of overlap external lines, should not be overlooked. Additional imaging, such as a lateral film and ultrasound, are helpful in doubtful cases. Knowledge of the optimal position for each device, early recognition of wrong or dangerous positions and their resultant complications, and understanding pitfalls in imaging interpretation (and how to overcome them) are basic requisites that every radiologist should know.

Learning Objectives:

1. To learn the crucial role of simple views in critically ill children.
2. To understand the variety of devices that is used in the intensive care unit.
3. To discuss how to avoid the most common pitfalls.

A-0279 09:25

C. The role of imaging in emergencies in the critically ill neonate: abdominal US applications and beyond

M. Riccabona; Graz/AT (michael.riccabona@medunigraz.at)

The objective is to list the various imaging modalities, particularly ultrasound, in imaging emergencies of critically ill neonates at the NICU. Besides refreshing the typical ultrasound approach to urgent neonatal abdominal queries typical findings of common findings in this patient group will be presented; furthermore, restrictions of an ultrasound exam will be discussed. The role of other imaging in these emergency situations will be revisited in the light of patient care, gentle handling, and therapeutic implications in critically ill pre-terms and neonates. Finally, some typical image examples of FAST and other essential emergency US applications at the NICU will be presented. Ultrasound is the mainstay of emergency imaging in the very sick neonate at the NICU, complemented by plain film. Rarely other modalities such as fluoroscopy, CT or MR may become necessary or are feasible.

Learning Objectives:

1. To learn about typical body (abdomen, chest and other) emergencies that can be addressed by US in the NICU.
2. To understand some typical findings that may help in the disease characterisation.
3. To appreciate the considerable impact on the prognosis and survival of the critically ill neonate.

09:50

Panel discussion: Is there a role for FAST scan in the paediatric IC unit?

impact in the future, since it allows a survey of the entire body in a single study, and may greatly simplify the search for a primary site in some cases.

Learning Objectives:

1. To learn the importance of tissue diagnosis in CUP.
2. To discuss how to choose the optimal target lesion for biopsy.
3. To review the relative risks and benefits in acquiring tissue samples.

09:44

Tumour relapse in gynaecological cancer

A-0284 08:30

Chairperson's introduction

R.A. Kubik-Huch; *Baden/CH* (rahel.kubik@ksb.ch)

Despite recent advances in diagnosis and therapy of gynaecological cancer, tumour relapse will be seen in about one-third of patients usually within 24 months from the time of diagnosis and often with the dismal prognosis. In the first part of this session, the role of MRI (including functional imaging with DWI and DCE) and PET/CT for the differentiation of postoperative or inflammatory changes and tumour relapse and the best imaging strategy to assess local pelvic recurrence will be reviewed. Defining the treatment of choice for tumour relapse of gynaecological cancer remains a challenging issue, depending on several factors including the type of primary tumour and therapy or the site and extent of recurrence. In radiation-naïve loco-regional recurrence, radiotherapy is usually the salvage therapy of choice. Pelvic exenteration, a radical surgical treatment removing all organs from the pelvic cavity, has emerged as a beneficial option in selected patients with isolated pelvic recurrences. A multimodality imaging approach allows the precise preoperative assessment and therefore individualised tailoring of the surgical treatment, as discussed in the second lecture. Stereotactic body radiotherapy has emerged as an alternative treatment in recurrent disease in the previously irradiated pelvis. CT and MRI fusion techniques exploiting the advantages of both modalities for the planning of the procedure will be demonstrated. The imaging considerations for stereotactic radiotherapy and the potential future role of MR-guided HIFU in a palliative setting will be discussed during the third part of the session.

A-0285 08:36

A. Differentiating relapse from post-treatment appearances

R. Forstner; *Salzburg/AT* (r.forstner@salk.at)

In Western countries, the incidence of cervical cancer is continuously decreasing. Nevertheless, it continues to be challenging as the peak rate of cervical cancers is at age < 30 years, and an advanced stage is associated with a recurrence rate of more than 30%. The risk of relapse is highest within the first three years, and 90% occur by year five after treatment. The type of treatment, surgery or chemoradiation, mainly depends on the stage and size of a tumour. This results in completely different posttreatment findings. Imaging plays an important role in clinically suspected recurrence, in high-risk conditions and if clinical assessment is inadequate, as in trachelectomy. MRI including DWI and contrast-enhanced techniques is the single best imaging test to assess local recurrence, either central in the pelvis or along the pelvic sidewall. Owing to its higher sensitivity and specificity PET/CT is complemented in suspected recurrence for treatment stratification, particularly to assess the retroperitoneal lymph nodes or presence of distant metastases. However, despite multi-modality approach differentiation of relapse from short-term and long-term complications of radiotherapy, e.g. inflammatory changes, radiation necrosis, extensive fibrosis and fistulation still remains challenging.

Learning Objectives:

1. To learn post radiotherapy appearances in cervix cancer.
2. To recognise the appearances of disease relapse.
3. To be familiar with the complications of treatment seen on imaging.

A-0286 09:04

B. Planning exenterative surgery

H.A. Vargas; *New York, NY/US*

In the past, patients with relapsed gynaecological cancers had limited salvage treatment options and a dismal prognosis. Under those circumstances, imaging detection of recurrence after treatment served the mere purpose of labelling patients with untreatable disease and initiating palliative efforts. More recently, pelvic exenteration has emerged as a valuable option for selected patients, with refinements in surgical technique leading to the reported 5-year overall

survival of over 50% for patients with the recurrent gynaecological disease. As such, more precise delineation of location and extent of disease on imaging have become increasingly important. The procedure involves resection of all pelvic viscera involved by disease, including the female genital organs, bladder and/or rectum. It is a radical surgical procedure with a potentially high rate of morbidity and mortality, and therefore careful preoperative planning is essential to optimise the balance between the clinical benefit and potential morbidity. This session will review a multimodality imaging approach to optimise the clinical indications, patient selection and individualised tailoring of this procedure (anterior, posterior, total perineal, total pelvic).

Learning Objectives:

1. To learn the important criteria for patient selection.
2. To learn the critical anatomy for surgical planning.
3. To be familiar with the post-surgical appearances and follow-up plan.

A-0287 09:32

C. Salvage treatment with image directed therapy: high-intensity focused US (HIFU) and stereotactic RT

N.M. deSouza; *Sutton/UK* (nandita.desouza@icr.ac.uk)

Despite surgery and radiotherapy delivered with curative intent in early stage gynaecological cancers, up to 30% of patients recur in the pelvis (10-15%). Treatment of isolated pelvic recurrences depends on previous treatment, site of recurrence, disease-free interval, and patient-related factors (morbidity, performance status). Total pelvic exenteration carries high morbidity. In radiation-naïve, locally recurrent gynaecological cancer, radiotherapy is the salvage treatment of choice. Stereotactic body radiotherapy (SBRT) enables dose escalation while reducing dose to organs-at-risk (OARs). However, to deliver SBRT effectively, accurate delineation of the gross tumour volume (GTV) is vital. Tissue contrast on CT is inadequate where pelvic anatomy is distorted by previous surgery and/or radiotherapy. MRI provides superior soft-tissue contrast for GTV delineation but requires that motion and distortions are recognised and corrected for. Differences in observer interpretation of the tumour outline are greater with CT, while MR does not provide the required electron density information for radiation dosimetry. Therefore, fusion techniques between CT and MRI are frequently employed. Where salvage treatment is not possible, palliative treatment is employed. High intensity focused ultrasound (HIFU) is a non-invasive ablative therapy with the potential to achieve this under MR guidance. Its current worldwide experience is limited. Challenges in delivering this extremely precise ablative technology are related to the depth and site of recurrence, adjacent bowel, bladder and vascular structures, and the thickness of overlying fat and muscle layers, which affect the placement of the ablative focus. Nevertheless, MR guided HIFU is a feasible and viable means of managing these difficult-to-treat patients.

Learning Objectives:

1. To be familiar with the imaging considerations for stereotactic radiotherapy in relapsed disease.
2. To be familiar with the concepts of imaging in directing RT treatment plan.
3. To be familiar with the use of HIFU for treatment of pelvic relapse.

A. Perfusion methods for vascular and airway diseases (CT/MRI)

M. Rémy-Jardin; *Lille/FR* (martine.remy@chru-lille.fr)

Over the last decade, lung perfusion has progressively left pure clinical research to enter clinical routine, based on the availability of new CT technological advances. This should not lead to forgetting basic approaches proposed with MDCT like the evaluation of dynamic changes within vessels of interest, analysis of bolus speed and propagation time of bolus peak. An important step was the introduction of dynamic CT which allowed evaluation of perfusion changes over time, mostly applied to oncologic indications. Iodine maps resulting from dual-energy CT acquisitions have revolutionised this concept as they can be derived from the same data set as that used for morphological imaging. This combination has mostly been investigated, then

Imaging and management of the incidental scrotal lesions

A-0292 08:30

Chairperson's introduction

M. Bertolotto; Trieste/IT (bertolot@units.it)

The widespread use of scrotal US in urology and andrology has caused an increase of incidentally detected testicular lesions. Many such lesions are simple cysts which require neither surgery nor follow-up. When the incidental nodule is solid in nature, it raises the concern for a malignant tumour. Most of these lesions are nonpalpable, presenting as small hypoechoic, asymptomatic nodules with negative markers. In such cases, there is the clinical dilemma of whether to perform orchiectomy or to adopt a more conservative approach. This is justified by the high prevalence of benign nodules presenting in this way, accounting for up to 80% of cases. There is increasing evidence that the multiparametric US, combining the use of grey-scale, Doppler, elastography, and CEUS improves lesion characterisation. Moreover, most of the incidentally detected testicular lesions do not show significant growth during the long-term evaluation and can be safely surveilled with close follow-up. The para-testicular area includes a variety of anatomic structures. US is nearly 100% sensitive for lesion detection, but specificity is lower. The multiparametric US may improve lesion characterisation. However, the overlap of the imaging findings of benign and malignant tumours may always be possible and should be kept in mind. MRI represents a useful supplemental imaging technique in the characterisation of scrotal masses, particularly recommended in cases of nondiagnostic ultrasonographic findings.

Session Objectives:

1. To understand the clinical issues about diagnosis and management of incidental scrotal lesions.
2. To understand the role of conventional US modes, CEUS and elastography in scrotal lesion characterisation.
3. To learn how to fit in a multidisciplinary team to manage patients with incidental scrotal lesions.

A-0293 08:35

Incidental testicular lesions: can we characterise them at multiparametric US?

P.S. Sidhu; London/UK (paulsidhu@btinternet.com)

The use of high-resolution ultrasound and the wide availability of this technique has altered the perception of testicular lesions. The traditional clinical view that nearly all focal intra-testicular lesions are malignant is no longer valid, as a large number of incidental intra-testicular lesions are now routinely discovered on ultrasound. The practice of ultrasound is also altering rapidly, without the clinical management keeping pace; the ultrasound techniques of B-mode, colour and spectral Doppler have been strengthened by the addition of contrast-enhanced ultrasound (CEUS) and elastography, further improving diagnostic capabilities. The combination of all these ultrasound techniques is termed multi-parametric ultrasound (MPUS). The ability to detect non-palpable intra-testicular lesions presents a problem for the urologist; should all intra-testicular lesions be managed by orchiectomy as is the tradition. The ability to combine all the various imaging techniques allows a comprehensive assessment of the indeterminate small non-palpable lesion, allowing for the possibility of 'watchful waiting' or 'testis-sparing surgery'. The ability for CEUS to assess the vascularity of the focal lesion is paramount, with an absence of vascularity paramount. The ability to ascertain the presence of vascularity points to a neoplasm and the use of time-intensity curves allows for the assessment of the wash-out curves and possible malignancy. The addition of strain elastography allows for the assessment of the stiffness of the lesion, and the probability of malignancy. With all the aspects of MPUS the ability to be confident in the assessment and the ability to dictate clinical management becomes possible.

Learning Objectives:

1. To become familiar with the features at multiparametric US that improve testicular lesion characterisation.
2. To learn about the potential of multiparametric US in imaging testicular lesions.
3. To understand the specific role of conventional US modes, CEUS and elastography in testicular lesion characterisation.

applied, in the context of pulmonary vascular diseases, with the objective of improving the diagnostic value of chest CT examinations. It can also be proposed in the evaluation of airway diseases where the combination of perfusion and ventilation is of major interest for the proper understanding of impaired gas exchange. The purpose of this presentation is to highlight some practical issues related to perfusion analysis in clinical situations and to make radiologists familiar with new semiologic features that have to be integrated into daily interpretations.

Learning Objectives:

1. To review most useful CT and MRI perfusion methods for lung imaging.
2. To understand the role of perfusion information in airway diseases.
3. To learn about the impact of functional imaging in pulmonary hypertension.

A-0290 09:04

B. Quantitative CT-imaging biomarkers in airways diseases

H.-U. Kauczor; Heidelberg/DE (Hans-Ulrich.Kauczor@med.uni-heidelberg.de)

CT-based quantitative imaging biomarkers in airway disease are related to lung attenuation and airway dimensions. Quantification of low attenuation areas (LAA) reflecting emphysema is based on a threshold value, e.g., 950 HU. Commonly emphysema volume, total lung volume and their ratio called emphysema index (EI) are measured. Another possibility is the percentile defined by the density threshold, below which a defined percentage of lung voxels are distributed, such as the 15th percentile. For the assessment of air trapping expiratory scans with a threshold of -856 HU as well as the ratio of expiratory to inspiratory mean lung attenuation are advised. A more complex approach is the parametric response map (PRM) spatially aligning the expiratory to the inspiratory scan by a deformable volumetric registration process. Then the lung voxels are categorised by using their expiratory and inspiratory attenuation values as normal parenchyma, functional small-airways disease and emphysema. Volumetric data-sets allow for a skeletonised visualisation of the bronchial tree. Quantitative parameters of the airways mainly focus on total diameter, lumen area (LA), wall thickness and wall area (WA) of 1st-8th generation airways as well as the so-called Pi10 which is the square root of the bronchial wall area of a hypothetical bronchus with an internal diameter of 10 mm. An important task is the segmentation of the individual lobes and the detection of the fissures and their integrity. This allows for lobar analysis of LAA as well as patient selection for successful endoscopic lung volume reduction and therapy response assessment.

Learning Objectives:

1. To review main functional CT methods of the lungs in airway diseases.
2. To learn about their impact in differential diagnosis.
3. To learn how these methods may help in treatment follow-up.

A-0291 09:32

C. Lung cancer, tumour heterogeneity and tumour response

J.M. Goo; Seoul/US (jmgoo@plaza.snu.ac.kr)

Malignant tumours are biologically complex and show genomic and phenotypic heterogeneity. Morphologic tumour heterogeneity has been recognised regarding differences in regional tumour cell proliferation, immune infiltration, differentiation status, and necrosis on pathology and differences in attenuation, enhancement, and necrosis on imaging. Recently, understanding of intratumour genetic heterogeneity has been deepened with the progress in deep-sequencing technologies and is closely related with prognostic significance, response to therapy and drug discovery. Imaging can quantify the spatial variation of a tumour by quantifying CT, MR, or PET parameters, which can be used in explaining the tumour blood flow, hypoxia, metabolic and other phenotypic features. These methods can establish whether one tumour is more or less heterogeneous than another and can identify subregions with differing biology. Intratumour heterogeneity is a dynamic process and tends to increase as tumours grow. Heterogeneous tumour frequently shows poor clinical prognosis and is related with emerging treatment-resistant subpopulations of tumour cells after therapy. Although imaging plays a central role in diagnosis, staging, response assessment, and recurrence surveillance in oncologic patients, the assessment has been focused on the measurement of tumour size and average parameter values. In this process, spatially rich information is discarded. There has been considerable effort to extract more information by quantifying overall tumour spatial complexity or identify the tumour subregions. In this lecture, the strengths and weaknesses of methods that measure intratumour spatial heterogeneity and introduce current understanding in intratumour genetic heterogeneity.

Learning Objectives:

1. To learn about modern imaging of lung tumours.
2. To understand the role of functional criteria of tumour heterogeneity.
3. To learn about main functional biomarkers of tumour response.

Incidental extra-testicular lesions: can we characterise them?

M. [Secil](mailto:Secil@deu.edu.tr); Izmir/TR (mustafa.secil@deu.edu.tr)

The principal method of examination for the extratesticular structures is an ultrasound (US). The capability of US for detection of lesions is almost 100%. However, the specificity of the method is around 70-90%, depending on the location and character of the lesions. Magnetic resonance imaging (MRI) may be an additional tool for characterisation of these lesions. Incidental non-neoplastic cystic lesions may easily be characterised by the US which includes tunica albuginea, epididymis, and spermatic cord cysts. Spermatic cord lipomatosis and polyorchidism are rare solid non-neoplastic conditions that can be diagnosed by US most of the time, MRI rarely is needed. Fibrous pseudotumour may be characterised by MR with the demonstration of very low signal intensity on T2W images. Incidental neoplastic lesions of benign tumours such as lipoma, adenomatoid tumour and leiomyoma when present with typical features may be diagnosed by the US and/or MR. Papillary cystadenoma having a bunch of grape-like cystic and papillary solid appearance may be diagnostic for von Hippel Lindau disease. The imaging features of most of the solid benign and malignant mesenchymal tumours overlap and render difficulties in characterisation. Malignant mesenchymal tumours of this region rarely present incidentally and are commonly big at the time of diagnosis. They are heterogeneous solid tumours that may contain cystic/necrotic areas and are commonly highly enhancing. Fat content may lead to the diagnosis of liposarcomas, umbilicus type of necrosis of a compact solid lesion may be a clue for leiomyosarcoma but these, of course, are not invariable findings.

Learning Objectives:

1. To become familiar with the imaging features of the commonest extra-testicular lesions.
2. To learn about the role of multiparametric imaging (US/MR/CT) in characterisation of extra-testicular lesions.
3. To understand the potential and limitations of imaging in extra-testicular lesion characterisation.

A-0295 09:10

Incidental testicular lesions: the role of MRI and ESUR recommendations

L. [Rocher](mailto:laurence.rocher@bct.aphp.fr); Le Kremlin-Bicêtre/FR (laurence.rocher@bct.aphp.fr)

The majority of non-palpable testicular small lesions seen on ultrasound are benign. Testis tumour characterisation is still based on Color Doppler US. Leydig cell tumours are the most frequent benign solid lesions with spheric or ovoid slightly hypoechoic pattern, circumferential vascularisation. The presence of microliths, macrocalcifications and hypoechoic areas surrounding the nodule are findings suggestive of the malignant disease. Nevertheless, as the percutaneous biopsy is still forbidden, other modalities as multiparametric MRI including dynamic injection and diffusion are useful to approach the diagnosis and therefore the management which may consist in follow up, tumorectomy, or orchiectomy regarding the supposed diagnosis. Almost non-cystic tumours are in hyposignal on T2, isosignal on T1. Leydig cell tumours demonstrate a high vascularisation (with a higher area under the curve) compared to seminomas. Burned out tumours, which may be underestimated at an ultrasound, show a nodular pattern in hyposignal on T2, defect or weak enhancement, and increased ADC value. Striated pattern are benign. MRI can depict with more sensitivity very small bilateral nodules in case of Leydig cell hyperplasia.

Learning Objectives:

1. To become familiar with MR appearance of testicular lesions.
2. To understand when MRI can have a role in the clinical practice for lesion characterisation.
3. To illustrate the ESUR recommendations to help characterisation and management of incidentally detected testicular lesions.

A-0296 09:25

Testicular-sparing surgery: a teamwork of radiologist and urologist

N. [Pavan](mailto:nicpavan@gmail.com); Trieste/IT (nicpavan@gmail.com)

Nowadays, the clinical and instrumental evaluation of testicular masses consents an accurate selection of patients eligible for the organ-preserving approach. Testis-sparing surgery leads good functional and aesthetic results in patients with benign lesions; it is a safe option for small testicular masses with a reliable pathologist performing frozen section examination and is an important goal in young patients with fatherhood desire. An optimal collaboration between the surgeon and the radiologist is essential to achieve good results.

Learning Objectives:

1. To learn about the current EAU recommendations for the diagnosis and management of the incidental testicular lesion.
2. To understand the current trends for the workup of incidental testicular lesion.
3. To become familiar with the value of a multidisciplinary team in planning and performing testicular sparing surgery.

A. Lung cancer: key signs in the new TNM

A.R. [Larici](mailto:annarita.larici@unicatt.it); Rome/IT (annarita.larici@unicatt.it)

Lung cancer is a leading cause of cancer-related mortality worldwide. A correct staging is the prerequisite for an adequate management of patients with lung cancer. Recently the 8TH edition of the TNM classification introduced relevant changes of the descriptors T and M. Regarding T, it has been demonstrated by survival analyses that from 1 to 5 cm of diameter every centimetre counts, and those larger tumours are best aligned with either T3 (tumour size of more than 5 to 7 cm) or T4 (tumour size of more than 7 cm). This finding further confirms the common intuition that the larger the tumour, the worse the prognosis. Regarding M, the category of extrathoracic lesions has been distinguished in M1b and M1c to indicate respectively one (oligometastatic disease) and more than one lesion. In this context, it is advisable that radiologists report the number of lesions if only one organ is involved and the number of organs if many. This approach has a relevant clinical impact because oligometastatic disease nowadays is managed and treated differently respect to an extensive M stage disease. Several limitations remain, as the classification of a tumour adjacent to the chest wall, mediastinum and diaphragm, as well as the categorisation of lymphangitic carcinomatosis as an independent descriptor and the evaluation of multiple lung lesions. Certainties and controversies on the topic will be argued in this session, taking into account that cancer staging should be always considered a multidisciplinary process.

Learning Objectives:

1. To learn about the new staging system for lung cancer.
2. To highlight the differences in the meaning of CT findings between the new system and the previous one.

A-0307 11:15

B. Incidental findings in oncologic patients

M.-P. [Revel](mailto:marie-pierre.revel@aphp.fr); Paris/FR (marie-pierre.revel@aphp.fr)

Incidental findings are unanticipated findings discovered in the course of medical care, which can affect the way the oncologic disease is managed. Among incidental findings in oncologic patients, incidental pulmonary embolism (PE), lung nodules and adrenal masses are frequent findings. Incidental PE is more frequently peripheral, and thus more difficult to diagnose. The recurrence risk in untreated patients is 12%, versus 6% with anticoagulation. Thus, anticoagulant treatment is recommended for cancer-associated incidental PE. The annual incidence of VTE in patients receiving chemotherapy is estimated at 11%. This risk can climb to 20% or higher depending on the type of drug(s) being administered. Incidental PE is not associated with an increased risk of death when adjusted for tumour stage and performance status. Incidental lung nodules are frequently found in oncologic patients. As indicated in the 2005 Fleischner guidelines for management of small pulmonary nodules, patients should be cared for according to the specific clinical situation. Pertinent factors include the site, cell type, and stage of a primary tumour and whether early detection of lung metastases will affect care. Among differential diagnosis of metastasis, Langerhans cell histiocytosis, DIPNECH (Diffuse Idiopathic Pulmonary Neuro Endocrine Celle Hyperplasia) and infectious nodules should be discussed. Regarding incidental adrenal masses, benign adenoma can be diagnosed if the attenuation on unenhanced CT acquisition is below 10 Hounsfield units. If it is not the case, PET CT should be performed and in case of increased FDG uptake, histological assessment is required.

Postgraduate Educational Programme

Learning Objectives:

1. To recognise the importance of different incidental findings in patients with cancer.
2. To learn how to manage patients with incidental findings.

10:30 - 12:00

ESR meets Africa

EM 1

Radiology in Africa: facing challenges and opportunities

Presiding:

L.E. Derchi; Genoa/IT
H.A. Gharbi; Tunis/TN

A-0308 10:30

Chairpersons' introduction (part 1)

L.E. Derchi; Genoa/IT (derchi@unige.it)

Africa is a large continent, with people of different cultures and habits, which may be difficult to understand as a whole. Therefore, a number of speakers from different African regions have been selected to present an overview of Radiology in Africa from a variety of perspectives. They will present topics about professional issues such as referral guidelines, radiation protection, use of radiological services and promotion of Radiology in their regions. Furthermore, there will be a discussion on how to develop cooperation between African Radiological Societies and the ESR. This point, specifically, will underline the bilateral nature of the relationship, discussing what ESR can do to help African radiologists as well as on what African radiologists, can offer to European societies.

Session Objectives:

1. To give an overview of radiology in Africa.
2. To list the existing cooperation programmes of the European Society of Radiology in Africa.
3. To point out what African radiologists can do for the ESR and what the ESR can do for radiology in Africa.

A-0309 10:35

Chairpersons' introduction (part 2)

H.A. Gharbi; Tunis/TN (hassen.gharbi@planet.tn)

Africa is a real mosaic of 54 different countries with a population of more than 1.200 Million inhabitants, making up 16% of the world's population. The diversity of mosaic is multifaceted. There are variable socioeconomic levels with GNPs ranging from less than 500 USD, in Somalia to more than 38000 USD in Equatorial Guinea. There are many different cultures and languages, but fortunately English, French, Arab and Portuguese, and internet facilities are widespread, adapted and efficient means of communications. The impact study of medical imaging on a diverse continent is challenging for several reasons. No complete official statistics are available in all countries. The medical imaging market is often very disorganised. There are enormous differences between the different countries and even between different regions in the same country. The number of radiologists varies from less than one radiologist for one million inhabitants, to more than 80 radiologists per one million inhabitants. We can divide the radiological situation in Africa into two regions; the North including Egypt, Tunisia, Algeria and Morocco and South Africa where the situation is more or less acceptable and the centre including 49 countries and 75% of the population where the situation require an urgent solution. In fact, the needs are everywhere and require more or less the same solution from the European Society of Radiology, training, collaborating programs, but Radiation Protection rules must be established and respected so that we can guaranty an efficient and good development of the Radiology.

Session Objectives:

1. To give an overview of radiology in Africa.
2. To list the existing cooperation programmes of the European Society of Radiology in Africa.
3. To point out what African radiologists can do for the ESR and what the ESR can do for radiology in Africa.

A-0310 10:40

Structured strategies to combat radiation protection challenges in Africa.

What can the ESR do?

D. Husseiny Salama; Cairo/EG (drdinahusseiny@yahoo.com)

The advances in health technology continue opening new horizons for the applications of ionising radiation in health care in Africa. This has resulted in an increase in the number of medical procedures, professionals and patients involved, and in the need for structured strategies and a holistic approach towards the full integration of radiation safety and the clinical imaging

guidelines in the African health sector. There have been proactive actions in Africa to improve the situation and enhance the implementation of radiation protection in several African countries, however further actions and joint activities are needed to enhance the process. The European Society of Radiology and its Eurosafe campaign have always been at the forefront trying to promote the safe use of ionising radiation in medicine, and this presentation will address strategic planning through which the ESR- African cooperation can act through to impact the future of radiology and radiation-protection in Africa and similar countries in the globe.

Learning Objectives:

1. To give an overview on the situation of imaging referral guidelines and clinical decision support (CDS) in Africa.
2. To update on the European societies' activities in the region in regard to guidelines.
3. To give tips from African radiologists on solutions and the way forward.
4. To present the bilateral strategic planning with the ESR to improve the performance of radiation protection.

A-0311 10:50

Is imaging underused in Africa? East Africa as an example. Solutions: what can the ESR do?

S. Vinayak; Nairobi/KE

The challenges faced by underdeveloped countries are immense; manpower, education, lack of equipment, maintenance of equipment etc. are just a few examples. Radiology equipment is often unaffordable, so innovative solutions have to be found, tried and tested so that communities can benefit. There are only 500 radiologists serving a population of 200 million inhabitants in Eastern Africa. For ultrasound, WFUMB already has three established COEs (centres of education) providing regular CMEs, training courses and other activities related to education on a regular basis. In addition, Bergen University trains physicians in Addis Ababa. In Khartoum, doctors are being trained to perform abdominal ultrasounds. All these initiatives are in conjunction with MASU & WFUMB. The current use of imaging can be robustly stimulated by using innovative ideas and technology. The WFUMB centre of education (COE) in Nairobi trained midwives to perform basic obstetric ultrasounds on a tablet ultrasound machine with a view to identifying high-risk pregnancies. The scans were transmitted using mobile phone internet technology for validation by radiologists. Imaging is still underutilised in East Africa, and governmental bodies are looking for local solutions to these problems. Help from European societies of radiology can take the form of education and training. How this can be implemented will be articulated in detail. Also, universities of this region can work with radiologists from Europe to carry out research. ESR can help coordinate these activities in a well-structured and robust format that is sustainable.

Learning Objectives:

1. To present the current situation in Eastern Africa.
2. To describe what we are doing to promote radiology in Africa.
3. To present what we would like to request from the ESR.

How to promote radiation protection in West Africa. Needs and expected role of the ESR

E.H. Niang; Dakar Fann/SN

"no abstract submitted"

Learning Objectives:

1. To summarise the radiation protection situation in West Africa, discuss workforce aspects and present an overview of educational facilities and maintenance services.
2. To update on the role of European societies in our region, what is done in general and in the field of radiation protection in particular.
3. To explain what we, as African radiologists, can offer to European societies.

A-0313 11:15

Most important challenges for imaging in North Africa

L. Rezgui Marhouf; Tunis/TN (lamia.rezgui@rns.tn)

The Maghreb region refers to five countries, three from North West Africa, Morocco, Algeria and Tunisia, also known as the Small Maghreb and two Central Maghreb countries, Mauritania and Libya. It has about 89 million inhabitants. The distribution of medical equipment using ionising radiation in this region is very disparate and depends on multiple factors. The number of radiologists is also very variable from one region to another. Radiation protection has made great strides in some countries, and much work remains

to be done in others. Rigorous regulations applied at different levels to guarantee quality and safety in terms of radiation protection exist in some countries, but challenges remain to be faced by others. The Maghreb enjoys a considerable level of development in terms of health development and radiation protection. He remains dependent on deficiencies. These are not all of the same nature and do not require the same solutions.

Learning Objectives:

1. To give an overview of the radiology situation in North Africa.
2. To enlist the cooperation programmes between North African societies and the European societies with bilateral exchanges in radiodiagnosis and interventional radiology.
3. To understand what North African radiologists can bring back to the table for European radiology.
4. To propose a plan for the promotion of collaboration between North Africa and ESR.

A-0314 11:30

The WHO's programme in Africa: the past, the present and the future

M.d.R. [Perez](#); *Geneva/CH* (perezmd@who.int)

The World Health Organization (WHO) coordinates the international health work with the objective of attaining by all peoples the highest possible level of health. The WHO's programme of work establishes a "triple billion" target: 1 billion more people enjoying better health and well-being, 1 billion more people benefiting from universal health coverage and 1 billion more people better protected from health emergencies. Medical imaging plays a key role in the achievement of this "triple billion" target because diagnostic radiology and image-guided interventions are linked to the entire healthcare pathway (e.g. health promotion, preventive services, diagnosis, treatment, follow-up, rehabilitation, palliative care). WHO is conducting a Global Initiative on Radiation Safety in Health Care Settings to enhance global access to safe and appropriate use of radiation in health care services. This initiative is currently focused on supporting the implementation of the 10 priorities to improve radiation protection in medicine identified in the Bonn Call for Action. WHO has contributed to the development and launching of the AFROSAFE Campaign to enhance radiation safety and quality in health care in Africa and continues cooperating with local and international partners to support its implementation. A culture of radiation safety and quality can be embedded into policies, processes and institutions as the health care systems grow and develop as it is the case in many African countries. This, which represents at the same time a challenge and an opportunity, can be achieved with good leadership, robust planning and strategic investment.

Learning Objectives:

1. To present the WHO's role, objective, core functions, structure and where/how radiology fits into them.
2. To explain the WHO's programmes in Africa and the place of radiology and radiologists in the context of the current priorities in the global public health agenda.
3. To understand the WHO's views about radiation protection in Africa.
4. To present the WHO's radiology programmes/activities in Africa. What has been done? What is currently being done? What is planned in the future?

A-0315 11:40

Panel discussion: Radiology in Africa, reality and dreams

Conclusion

L.E. [Derchi](#); *Genoa/IT* (derchi@unige.it)

H.A. [Gharbi](#); *Tunis/TN* (hassen.gharbi@planet.tn)

Challenges to African radiology are great, but even more significant are the opportunities for growth facing radiologists in this continent. As a matter of fact, the end of this session "ESR meets Africa" is just a beginning. From here reciprocal knowledge and reciprocal cooperation must start, aiming at a strong commitment to excellence and safety and increased availability and use of Radiology worldwide, and especially in Africa.

10:30 - 12:00

Room F1

E³ - Rising Stars Programme: Joint Session with ESOR

BE 6

Radiologic anatomy: head and neck

Moderator:

M. Becker; *Geneva/CH*

A-0318 10:30

Neck spaces

A. [Trojanowska](#); *Lublin/PL* (agnieszka30@yahoo.com)

A knowledge of neck spaces not only allows for better communication between radiologists and specialists familiar with imaging of this region but also aid in diagnosis as each space has a distinct group of pathologies. It considerably narrows down the differential diagnosis. The anatomy of the neck can be divided into suprahyoid and infrahyoid portions: suprahyoid neck which encompasses the deep spaces between skull base and hyoid bone and infrahyoid neck which lies inferiorly between the hyoid bone and both clavicles. These divisions are arbitrary in there is some continuation of suprahyoid neck spaces into the infrahyoid neck spaces and continuation of some infrahyoid neck spaces into the superior mediastinum.

Learning Objectives:

1. To understand the concept of neck spaces and their boundaries.
2. To review the content of each space with emphasis on differential diagnosis.
3. To become familiar with pathological findings typical for each space.

A-0319 11:00

Temporal bone

J.W. [Casselman](#); *Bruges/BE* (jan.casselmann@azsintjan.be)

The anatomy of the external auditory canal, middle ear and bony inner ear is best studied with CT. The highest resolution can be achieved when ConeBeam CT is used, and this technique also has the advantage that there is no quality loss in the axial, coronal and double oblique plane, the planes needed to study the temporal bone anatomy in detail. Double oblique images are indispensable to visualise the stapes, stapes footplate and oval window. Anatomical knowledge is especially needed at those sites where pathology most frequently occurs and changes the anatomy. The footplate, stapes, lenticular and lengthy process of the incus, facial nerve canal, Jacobson's canal, the scutum, round window, ligaments etc. are some of these structures and they should be studied in detail in every single patient. MR is better suited to demonstrated the anatomy of the membranous labyrinth, inner ear fluid spaces and nerves in the internal auditory canal. Heavily T2-weighted images are best suited to see these structures, but high resolution is needed. Not only the fluid inside the labyrinth must be evaluated but also the normal size of the different nerve branches in the internal auditory canal must be known in order to be able to detect nerve atrophy or hypoplasia. The most important anatomical structures of the temporal bone, as they can be visualised in different planes on (CB)CT and MR will be illustrated in this presentation.

Learning Objectives:

1. To know which technique is best suited to visualise specific anatomical structures of the temporal bone.
2. To recognise the clinically most important anatomical structures of the middle and inner ear.
3. To learn how the anatomical structures of the temporal bone look like in the transverse, coronal and double oblique plane.

Larynx

R. [Maroldi](#); *Brescia/IT* (roberto.maroldi@unibs.it)

The larynx is a specialised organ placed at the separation between the respiratory and the digestive tracts. Beyond protecting the airways against food aspiration, it is involved in breathing, swallowing and voiced sounds production. These functions are mostly accomplished by the action of three diaphragms: the epiglottis, the false and vocal cords. All of them, when closed, contribute to seal the larynx during swallowing. When opened, they permit the passage of the air into the trachea. The vibration of the vocal cords (the most caudal of the three sphincters) generates voiced sounds. The vibration is produced by the coordinated action of a group of laryngeal muscles. These muscles are inserted on rigid structures, provided in the larynx by a framework of ossified cartilages: cricoid, thyroid and arytenoid. Cricoid and thyroid cartilage form also a rigid box, a sort of shield. Muscle contraction results in a

significant shortening and change of shape. To accommodate these changes, a malleable material (fat) fills the "gap" between muscles and the rigid shield. The lateral "fat-filled-gap" between muscles involved in vocal cord vibration and the cartilage framework is named paralaryngeal space. A midline "fat-filled-gap" separates the epiglottis from the rigid thyroid laminae. CT and MR may precisely delineate the submucosal structures: muscles, fat-filled-gaps (paralaryngeal and pre-epiglottic spaces) and depict un-ossified and ossified cartilages.

Learning Objectives:

1. To understand the anatomy and signals of the cartilage framework of the larynx.
2. To learn the surgical subdivision of the paraglottic space of the larynx into key compartments.
3. To learn the anatomy and signals of the muscles within the larynx.

Big data and the big picture: deep learning in optimisation of medical imaging (part B)

Moderators:

M. Brambilla; Novara/IT
M. Kortesiemi; Helsinki/FI

A-0324 10:30

Chairperson's introduction

M. [Brambilla](mailto:marco.brambilla@maggioreosp.novara.it); Novara/IT (marco.brambilla@maggioreosp.novara.it)

The purposes of this session are to provide an overview of the application of deep learning (DL) methods in image optimisation and to understand why DL methods are capable of supporting research. Improvement in radiological optimisation requires patient-specific and indication-specific adjustment of imaging parameters and image analysis methods. DL has been used increasingly in radiology because typical imaging objects such as lesions and organs presented in medical images are in most occasions far too complex to be represented reliably by a certain simple equation and, therefore, robust analysis methods are needed. This session will first introduce an application of DL in the computerised analysis of chest imaging emphasising the complementary role of visual reading and computer-aided diagnosis. The application of DL methods in medical physics such as scatter removal, spatial resolution improvement, noise reduction and dose estimation will be outlined as an example of how such methods can impact on quantitative aspects of medical imaging. The illustration of a paradigm shift: from image quality to care outcome, driven by the introduction of DL methods, will conclude the session together with an analysis of the challenges which must be faced for the introduction of DL in the clinical practice, namely: 1. gaining access to medical archives according to ethical and legislative requirements and 2. obtaining validated and standardized image data in a systematic fashion.

Session Objectives:

1. To provide an overview of application of deep learning methods in image optimisation.
2. To understand the need for a deep learning approach in medical imaging.
3. To understand why deep learning algorithms are capable of supporting research.

A-0325 10:35

Computer analysis in chest imaging: from rule-based to machine learning to deep learning

B. [Van Ginneken](mailto:bram.vanginneken@radboudumc.nl); Nijmegen/NL (bram.vanginneken@radboudumc.nl)

Half a century ago, the term "computer-aided diagnosis" (CAD) was introduced in the scientific literature. Pulmonary imaging, with chest radiography and computed tomography, has always been one of the focus areas in this field. In this study, I describe how machine learning became the dominant technology for tackling CAD in the lungs, generally producing better results than do classical rule-based approaches, and how the field is now rapidly changing: in the last few years, we have seen how even better results can be obtained with deep learning. The key differences among rule-based processing, machine learning, and deep learning are summarised and illustrated for various applications of CAD in the chest.

Learning Objectives:

1. To give an overview of application of deep learning methods in the diagnosis of thoracic lesions.
2. To understand issues related to the technical implementation of these methods.
3. To learn about the complementary role of visual reading and computer-aided diagnosis.

Deep learning in CT optimisation

M. [Kachelriess](mailto:marc.kachelriess@dkfz.de); Heidelberg/DE (marc.kachelriess@dkfz.de)

With the introduction of deep learning in general, and with deep Convolutional Neural Networks (CNN) in particular, machine learning has spread into many medical areas with great success. In particular medical imaging may benefit from the new technology. Important applications such as image analysis, image segmentation and object recognition are well-known and start to become widely available. The applications of machine learning to the field of CT image formation, which describes the process of data acquisition, preprocessing, image reconstruction and post-processing, however, are less known, not as mature and hardly available, yet. Here, the use of machine learning can be mainly categorised into the categories 1) replacement of missing data (sparse view acquisition, limited angle tomography, ...), 2) replacement of time-consuming computations (image reconstruction, scatter prediction, material decomposition, ...), and 3) the incorporation of a priori knowledge (non-contrast CT from contrast-enhanced CT, pseudo CT from MR, ...). This lecture discusses the underlying technology and selected application examples. Not all proposed methods may keep their promises. This may be partially attributed to the fact that the field of deep learning in CT optimisation is rather young and by far not mature. Other methods, in contrast, are highly promising and it appears as if the future will bring CT images at a lower patient dose and with fewer artefacts in clinical routine. Thus, deep learning has the potential to significantly improve and optimise CT image formation.

Learning Objectives:

1. To provide the rationale of deep learning methods in image optimisation.
2. To describe application of deep learning methods in medical physics tasks such as scatter removal, spatial resolution improvement, noise reduction, dose estimation.
3. To understand how these methods will impact on quantitative aspects of medical imaging.

A-0327 11:35

From image quality to care outcome

M. [Kortesniemi](mailto:mika.kortesniemi@hus.fi); Helsinki/FI (mika.kortesniemi@hus.fi)

Medical physicists have a long tradition of measuring image quality with objective metrics including contrast, noise and resolution, and their frequency-based derivatives. These methods have supported our main tasks related to quality assurance and optimisation. Along with the technical imaging modality development, the optimisation process has transformed into a more demanding and multi-professional challenge where the image quality metrics should evolve accordingly from technical towards clinical presentation. In the parameter level, this development may include clinical task function and observer-related parameters supplementing the traditional MTF and NPS parameters. New methods enable model observer based detectability and diagnostic accuracy estimates. Ultimately, we should aim beyond the concept of technical quality, to extend our methods and knowledge towards measuring and optimising the diagnostic value in terms of care outcome. Improved optimisation process and more consistent imaging quality (evaluated by target value, its uncertainty and precision) require objective and quantitative connections from diagnostic and technical parameters to clinical outcome parameters. Comprehensive methodology to enable this approach involves combining several types of data together. Deep learning methods - including data quality control and validation - are prerequisites for this kind of data analysis, due to inherent non-linearity of the problem and a large amount of heterogeneous data which is not equitable by traditional methods. Our medical physicist professional role should follow this development and incorporate AI & in-depth learning topics accordingly into our educational programs.

Learning Objectives:

1. To introduce the need of measuring the diagnostic value in terms of outcome.
2. To discuss its relevance and limitations regarding the traditional concept of image quality.
3. To introduce the challenges in deep learning based artificial intelligence methods.

E³ 619

Tumour relapse in urological cancer

A-0328 10:30

Chairperson's introduction

V. [Logager](mailto:vibeke.loegager@regionh.dk); Copenhagen/DK (vibeke.loegager@regionh.dk)

Relapse of cancer is one of the most difficult tasks. First, you have to know what kind of treatment the patient has undergone? Was it surgical, chemotherapy, radiation or a combination of these? Maybe the patient has undergone some newer minimal invasive therapy that you are not familiar with? The treatments could be in the form of proton therapy, cryotherapy, focused ultrasound or theranostics? There are different organs and different treatments. Nonetheless treated tissue and organs all have ways of reaction that we can get to know and recognise. Within these tissues, we shall find the vital cancer tissue, and this could be relapsing cancer, residual cancer or even a new clone of disease. It is therefore mandatory to learn the imaging strategies in post-treatment follow-up and relapse including the strength and weakness of the different modalities. When relapse has been found, a decision of treatment can be made.

A-0329 10:36

A. Prostate cancer relapse

V. [Panebianco](mailto:valeria.panebianco@uniroma1.it); Rome/IT (valeria.panebianco@uniroma1.it)

An elevated serum PSA is a first sign of relapse and imaging is needed to determine the localisation of the recurrence, which may be locally in the prostatic area and/or metastatic. The precise localisation of the local recurrence by imaging is needed if this localisation could change treatment planning. Treatment for prostate cancer can significantly change the appearance of the residual prostate gland or the prostate bed, complicating imaging evaluation. It's necessary to discern post-therapy changes from local recurrence. An overview of current imaging procedures and their performance in local recurrent PCa will be done, focusing on mpMRI. Therefore, mpMRI protocol (consists of T2W images, DWI/ADC and DCE-MRI) and evaluation of the images require specific considerations based on treatment received. For this reason, a standardised method of image assessment is needed to help in image analysis and reporting and to diminish variation in the acquisition, interpretation and reporting of prostate mpMRI in case of local recurrence. The relationships with PSA values will be also discussed. MpMRI can be currently considered as the most reliable imaging biomarker to detect local PCa recurrence in patients with biochemical failure after RP, especially for those PSA values where PET/CT is not recommended (0.2 - 1 ng/mL).

Learning Objectives:

1. To learn the follow-up strategy post radical prostatectomy.
2. To recognise relapse and know the patterns of spread.
3. To learn the use of imaging in planning salvage therapy.

A-0330 11:04

B. Non prostate urological cancer relapse

H.A. [Vargas](mailto:valeria.panebianco@uniroma1.it); New York, NY/US

Tumour relapse is an undesirable reality in all cancer patients, and short of minimising its occurrence by applying to optimal treatment modality at the time of diagnosis, the best outcomes are achieved by early detection of recurrence and prompt initiation of salvage therapies. Early detection on imaging is facilitated by understanding the expected post-treatment findings and learning common patterns of recurrence for different cancers. In this session, we will review the patterns of recurrence and multimodality imaging appearance of cancers involving the urinary system (kidneys, ureters, bladder).

Learning Objectives:

1. To recognise the expected post treatment appearances.
2. To know follow-up strategies for detection of relapse.
3. To learn to recognise pitfalls by case review.

A-0331 11:32

C. Theranostics in urological cancer

M. [Hartenbach](mailto:markus.hartenbach@meduniwien.ac.at); Vienna/AT (markus.hartenbach@meduniwien.ac.at)

Emerging techniques and new targets in nuclear medicine have enabled new therapeutic approaches following the very own concept of biomarker imaging and therapy. Performing imaging and therapy using identical biochemical structures and metabolic properties as targets are summarised with the portmanteau-word "theranostics". But theranostics can be seen in a broader spectrum of applications, especially when focusing on diagnostics that lead to

an impact on therapeutic decisions. This lecture will give an overview of biomarker imaging in urological cancer, that has a direct impact on therapeutic decisions as well as treatment with the same target structure focusing on prostate cancer. A prime example is given by the use of bone scintigraphy for imaging osteoblastic activity which is targeted by ²²³RaCl₂ therapy, proven to provide a survival benefit in castration-resistant prostate cancer patients. Beyond this, PSMA ligand positron emission tomography, as a specific method for imaging the folate hydrolase, has emerged as an almost routinely applied procedure in high-risk prostate cancer primary staging, biochemical recurrence and advanced tumour stages. Recent studies have proven its impact on therapeutic decisions in almost a third of the patients with primary disease and even 75% of the patients with biochemical recurrence who were negative on conventional imaging. Applying the direct theranostic approach in patients who underwent ¹⁷⁷Lu-PSMA therapy (RLT), PSMA ligand PET response correlated with overall survival, overcoming the known issues of RECIST criteria. In summary, the theranostic approach enables a more personalised concept with highly specific therapeutic effect and low side effect profile.

Learning Objectives:

1. To learn about theranostic options in urological cancers.
2. To understand the advantages and limitations of theranostic approaches.
3. To become familiar with new the indications and outcomes of theranostic approaches.

Functional imaging of the liver

A-0332 10:30

Chairperson's introduction

L. [Martí-Bonmati](mailto:marti_lui@gva.es); Valencia/ES (marti_lui@gva.es)

Functional imaging is the study of human organs and related lesions by the analysis of imaging data. As opposed to structural imaging, functional imaging focusses on revealing biological and physiological activities based on either image features or signal modelling. Results are obtained throughout computer-based image processes for the detection and depiction of specific tissue changes. If successfully implemented, the main advantages of functional imaging will relate to the evaluation of quantitatively measured characteristics, as objective expressions of normal biological and processes, pathological changes, or pharmaceutical responses. The subrogated imaging biomarkers can be shown as features or parameters extracted from medical images, giving information on the regional distribution and magnitude change of the target process. The obtained organs and lesions properties are resolved in space (parametric images and analysis) and time (longitudinal and delta studies). Considered as a non-invasive virtual biopsy, functional imaging and related data will provide fundamental information on the presence, distribution and amount of different pathological changes in diffuse liver diseases and liver tumours. Despite the major progress on their implementation over the last decades, the lack of consistency in the heterogeneous-source medical images has deeply limited replication studies, leading to the failure of most multicentre projects and clinical trials validation. Most efforts are devoted to decrease uncertainty and biases in this precision radiology/medicine approach before they can be used to phenotype, predict treatment and evaluate prognosis. External validation studies. External validation studies are essential before implementing functional imaging in clinical practice and trials.

A-0333 10:36

A. Diagnostic and staging of diffuse liver diseases using functional MRI

B.E. [van Beers](mailto:bernard.van-beers@aphp.fr); Cligny/FR (bernard.van-beers@aphp.fr)

Quantitative MR imaging offers a multiparametric approach to assess the severity of hemochromatosis, nonalcoholic fatty liver disease, chronic viral hepatitis, and cirrhosis. The most validated methods are multi-echo gradient-echo MR imaging to quantify hepatic iron and fat, as well as MR elastography to quantify liver fibrosis, cirrhosis, and potentially liver inflammation. Alternative methods for liver fibrosis staging include apparent diffusion measurements and T1 relaxometry, without or with gadoteric acid enhancement. The diagnostic performance of these methods should be further compared to that of MR elastography. MR imaging has the potential to become a method of virtual biopsy that may decrease the need for invasive reference examinations in diffuse liver diseases. The integration of ultrasound and MR imaging biomarkers with blood sample biomarkers to further improve the assessment of diffuse liver diseases is a point of current research.

Postgraduate Educational Programme

Learning Objectives:

1. To review functional MRI approaches of liver diseases.
2. To learn about their impact in characterising diffuse liver diseases.
3. To be aware of validated biomarkers of prognosis.

A-0334 11:04

B. Diagnostic and staging of diffuse liver diseases using multiparametric US

P.S. Sidhu; London/UK (paulsidhu@btinternet.com)

The use of contrast-enhanced ultrasound (CEUS) to assess focal liver lesions is now well established, with superb ability to characterise lesions visually. The ability to measure parameters of the CEUS examination objectively is realised by the fact that the microbubble contrast agent is truly intravascular and has a linear dose response. This differs from the dynamics of other contrast agents used in CT and MR imaging. The drawback of CEUS is the ability to identify the lesion clearly. The use of time intensity curves, particularly calculating washout is undergoing continuing research, and the usefulness is extended to other organs such as the kidney and testis to evaluate different enhancement patterns. Segmentation, colour mapping and use of artificial intelligence will move the usefulness of objective measurements of dynamic CEUS imaging, particularly of liver lesions. The development of ultrasound elastography has allowed the definition of the levels of liver fibrosis, with different techniques available, impacting on clinical management of chronic liver disease. All these new techniques, combined as multiparametric ultrasound (MPUS), as advanced the practice of ultrasound imaging, and is a robust, patient-friendly imaging tool.

Learning Objectives:

1. To review functional US approaches of liver diseases.
2. To learn about their impact in characterising diffuse liver diseases.
3. To be aware of validated biomarkers of prognosis.

C. Characterisation of liver tumours and prediction of tumour response

B. Taouli; New York, NY/US (bachir.taouli@mountsinai.org)

We will discuss the role of multiparametric MRI including T2-weighted imaging (T2WI), diffusion-weighted imaging (DWI) and dynamic post-contrast T1WI imaging for the characterisation of focal liver lesions: to differentiate benign and malignant lesions and characterise subtypes of malignant lesions based on a combination of imaging features. We will also discuss the role of DWI and dynamic contrast-enhanced MRI for assessing tumour response. Finally, we will discuss future directions such as radiomics methods used for assessing liver tumours and tumour response.

Learning Objectives:

1. To learn about multiparametric imaging of liver tumours.
2. To understand the role of functional criteria of tumour characterisation.
3. To learn about main functional biomarkers of tumour response.

Chronic pancreatitis

Moderator:

C. Matos; Lisbon/PT

A-0340 12:30

How to diagnose and classify

G. Zamboni; Verona/IT (gzamboni@hotmail.com)

Chronic pancreatitis is a chronic inflammation of the pancreas resulting in the destruction of the pancreatic parenchyma, leading to endocrine and exocrine insufficiency. Chronic pancreatitis has many different recognised etiologies: toxic, idiopathic, genetic, autoimmune, recurrent, obstructive. Different pathogenetic theories have been proposed, but the common final pathway is the development of parenchymal fibrosis. Recurrent episodes of clinical or subclinical acute pancreatitis lead to chronic pancreatitis. In the early stages of chronic pancreatitis, imaging has a role in diagnosing the disease, especially with MRI and MRCP, and in identifying a possible aetiology, for example, recognising the presence of variant ductal anatomy, e.g. pancreas divisum. In the more advanced stages, the diagnosis is easy. Imaging has then a role in differentiating between the different morphological types of pancreatitis (macro- or micro-obstructive), in the differential diagnosis, especially with tumours, and in the follow-up.

Learning Objectives:

1. To learn about diagnosis of chronic pancreatitis.
2. To understand classification of chronic pancreatitis.
3. To appreciate the role of imaging in the follow up of chronic pancreatitis.

A-0341 13:00

Functional evaluation of chronic pancreatitis

M.A. Bali; Brussels/BE (mbali@ulb.ac.be)

Chronic pancreatitis (CP) is a continuing inflammatory process, responsible for irreversible morphologic changes, pain and exocrine/endocrine impaired function. Parenchymal changes consisting of loss of functional parenchyma and vascularity with fibrotic replacement precede ductal abnormalities. The detection of early stages (the initial parenchymal changes prior to parenchymal/ductal abnormalities not detectable on conventional imaging) and the differential diagnosis between solid focal pancreatic lesions still represent challenges for conventional imaging. Secretin-enhanced MRCP (S-MRCP) allows depiction of ectatic secondary ducts (not visible on conventional unenhanced MRCP) present in early CP. Pancreatic exocrine reserve estimation: differences were reported between severe CP and normal, but not between mild CP and normal. S-MRCP may be useful in differentiating focal CP and pancreatic adenocarcinoma (PAC): the "duct penetrating sign" has been associated more frequently to focal inflammatory mass rather than PAC. New MR innovative technologies such as T1-mapping and MR elastography (MRE) may appreciate parenchymal changes in early CP. T1 relaxation time is a tissue-specific property, independent of imaging parameters: T1 relaxation time seem to be greater in mild CP compared with normal. Fibrotic parenchymal replacement is responsible for increased stiffness which can be detected by MRE prior to ductal and parenchymal abnormalities detectable on conventional imaging. DW-MR imaging allows the evaluation of microscopical properties of the tissue at a molecular level. Several clinical investigations have evaluated quantitative DWI for differentiating pancreatic solid lesions: overlapping ADC and D values have been reported for CP and PAC. More promising seem to be perfusion-related parameters.

Learning Objectives:

1. To appreciate functional evaluation of chronic pancreatitis.
2. To learn about the role of imaging in recurrent pancreatitis.

Bone tumours

K. Wörtler; Munich/DE (klaus.woertler@tum.de)

The diagnosis of a bone tumour is based on clinical findings, the age of the patient, the anatomic location of the lesion, its radiologic appearance, and if imaging does not allow for a specific diagnosis, its histopathologic features. Radiography remains the initial imaging modality for evaluation of the location of the lesion with respect to the longitudinal and axial planes of the involved bone, for estimation of its biologic activity by analysing the patterns of bone destruction and periosteal response, and for the depiction of matrix mineralisation. CT is typically used to obtain "radiographic" information in regions of complex skeletal anatomy such as the skull, spine, pelvis and shoulder girdle. MR imaging is best suited to determine the local extent of a bone tumour (local staging), but can also be helpful to narrow the differential diagnosis in specific lesions such as cysts and cartilage-forming tumours. With a clear emphasis on conventional radiography, this course will review the basic imaging features of the most common benign and malignant bone tumours. Important radiographic findings, such as bone destruction patterns, types of periosteal reactions and matrix mineralisation, will be explained step by step in correlation with histopathology as well as advanced imaging techniques.

Learning Objectives:

1. To become familiar with the imaging features of benign and malignant bone tumours.
2. To appreciate their imaging characteristic hallmarks on plain film radiography.
3. To learn how best to use imaging modalities in differential diagnosis.

Joint Session of the ESR Ultrasound Subcommittee and the Undergraduate Education Subcommittee

ESR US SC/UES

US teaching to undergraduate students: why, how and from whom?

Moderators:

C. Nyhsen; Strasbourg/FR

V. Válek; Brno/CZ

A-0337 12:15

Why: US anatomy and pathology teaching, US in clinical practice and as a career choice

T. Fischer; Berlin/DE (thom.fischer@charite.de)

Ultrasound training is time-consuming limiting its presence, especially during medical school curricula. Today, ultrasound is the most used interdisciplinary non-ionizing imaging technique in daily clinical routine. While students have to learn pathology early in their medical curricula, ultrasound should be taught parallel to pathology to create a better understanding of imaging. One major limitation of ultrasound is the accurate image acquisition and interpretation by the use of real-time non-standardized planes (contrarily to standardised planes in CT or MRI). While some organic parts are not visible by ultrasound, the focus of US anatomy and pathology should be on orientation and localisation of the organs or cavities. Therefore, the combination of anatomic structures (in cadavers) and US image fusion with CT or MRI may help to understand the anatomy of organs and landmarks in ultrasound. Focused assessment for sonography in trauma (FAST) represents the most used ultrasound examination. Therefore, US courses of FAST should be offered to each student to learn both anatomical (relationship of organs, landmarks) and technical (knobology, settings) basics of abdominal ultrasound. The introduction of artificial intelligence (AI) in ultrasound during the common years will improve the diagnostic performance in image interpretation. Therefore, radiologists in the future will focus on US-guided interventions and coordinating

an interdisciplinary team. While US has to be performed manually, a replacement by robots/AI or sonographers is not predicted. To generate good quality standards in the performance of US, education and practical training by medical professionals are irreplaceable.

Learning Objectives:

1. To learn how ultrasound may be used effectively when teaching anatomy and pathology to undergraduate students, including access to hands on practice.
2. To understand how the importance of ultrasound as an imaging modality in daily clinical practice may be highlighted to students.
3. To learn how US teaching can be used to raise students' interest in radiology as a career choice.

A-0338 12:35

How: US teaching in the radiology department and hands-on classroom teaching using living models and simulators

M. Bachmann Nielsen; Copenhagen/DK (mbn@dadnet.dk)

The number of medical students in a large university may bring an overwhelming demand for ultrasound equipment and for hands-on training. Students can train by scanning each other but getting enough patients may be difficult. Also, the level of competencies the students should aim for is different in preclinical and clinical part of the study and likely at a lower level than in medical doctors. Normal anatomy and point-of-care ultrasound cases are to be preferred for students. One way to achieve a uniform training for medical students would be to use ultrasound simulators. Some simulators are useful for the initial probe/eye coordination training and for getting a limited overview of simplified abdominal organs while other are fully digitized 3D volumes. Radiologists in training will typically want a more advanced simulator with a higher image quality than students. Available ultrasound simulators are mainly for abdominal examinations. Including US simulators should be based on educational research and a validated test to ensure the quality of learning. Tips for setting up a simulator study room will be given. In Copenhagen we estimate that 30 hours of ultrasound teaching is given during six years in medical school divided among different medical specialties and without a clear curriculum or practical test to ensure competencies. Our experience with offering an eight weeks practical stay in an US department will be given.

Learning Objectives:

1. To learn how students may be integrated in clinical US sessions in the radiology department.
2. To understand which different classroom hands on teaching environments can be created, using living models and simulators.
3. To become familiar with the use of simulators in ultrasound, from low cost to the high end spectrum and what the future may offer.

A-0339 12:55

From whom: the importance of radiologists delivering US teaching and staying experts in this field

K. Rosendahl; Bergen/NO (karen.rosendahl@helse-bergen.no)

Traditionally, ultrasound (US) has been an important part of the radiologist's integrated imaging approach. The US findings, together with additional information provided by the patient during the bed-side examination often help tailor further imaging, be it radiography, CT, MRI or nuclear medicine. During the past decades, specialties other than radiology, ranging from trauma surgeons to obstetricians and cardiologists, have taken an interest in ultrasound in order to answer very specific questions during the clinical examination; so-called point-of-care US. While ultrasound technicians and midwives are formally trained to perform the US, standardised training curriculum for clinicians are lacking. As radiologists we are medical expert consultants on imaging, and as such should have a key role in the initial training and setting of standards for diagnostic ultrasound procedures by non-radiologists and medical students. During this lecture, I will discuss how radiologists can continue to be regarded as experts in US through teaching and suggest ways to show students how radiologists provide an effective clinical service in this technique.

Learning Objectives:

1. To understand the importance of radiologists maintaining an interest in US and in US teaching in an era where US technology is more affordable and will be used by many specialties other than radiology.
2. To learn how radiologists can continue to be regarded as experts in US through teaching.
3. To become familiar with ways to show students how radiologists provide an effective clinical service in this technique.

A. Errors in chest radiograph

D. Tack; Baudour/BE (denis.tack@skynet.be; denis.tack@epicura.be)

Missing lesions on chest radiographs are frequent and the largest source of medico-legal issues. In this course, we report reasons for missing lesions, we distinguish perception and cognitive errors, and we comment on missing nodules, consolidations and infiltrative lung diseases. We provide tips to reduce our error rate, and in particular, we comment on the importance of learning and applying key signs for optimising the detection of abnormalities on both the frontal and the lateral views of the chest.

Learning Objectives:

1. To learn to recognise ambiguous signs in plain films.
2. To learn to avoid the most common pitfalls in reading plain chest films.

A-0357 14:45

B. Errors in CT of the chest

J. Vilar; Valencia/ES (vilarsamper@gmail.com)

Observer errors in Chest CT: The aetiology of error in radiology is multifactorial. In this presentation, I will concentrate on errors attributed to the radiologist. Not seeing a lesion (perceptual error) and not recognising a pathology (interpretative error) are by far the most common causes. In a study of 500 cases, perceptual errors accounted for 80% and 20% were interpretative errors. Perceptual errors occur in CT, as in chest radiographs, despite the fact that CT is a tomographic technique. These errors may be related to technical factors such as noise, resolution, and use of adequate technical protocols including the use and timing of contrast media. Vigilance errors are those due to an insufficient time (reading too fast), satisfaction of search (interrupting vigilance), or inadequate clinical information (ignoring suspicion of pathology). Erroneous interpretation of the findings may be related to ignorance and inadequate information. The radiologist could avoid these errors by applying simple rules such as using checklists, taking enough time to read the studies, comparing with previous examinations, and using the clinical data. In this interactive presentation of cases, I will analyse some common causes of errors in chest CT and offer simple clues to avoid them.

Learning Objectives:

1. To learn to interpret ambiguous chest CT signs.
2. To learn to avoid the most common pitfalls in reading chest CT images.

ESOR Session

ESOR

Artificial intelligence: presented with new lecture formats

Moderator:

V. Vilgrain; Clichy/FR

A-0368 14:00

Introduction

B. Brkljačić; Zagreb/HR (boris@brkljacic.com)

In this session, the European School of Radiology (ESOR) will present new lecture formats with an emphasis on artificial intelligence (AI). Three speakers will discuss the concept of AI and machine learning applied in radiology, how neural networks can extract patterns from images and how deep learning can extract radiomics data.

A-0369 14:05

ESOR in action 2019

V. Vilgrain; Clichy/FR

Artificial intelligence (AI) and machine learning (ML) in medical imaging

W.J. Niessen; Rotterdam/NL

"no abstract submitted"

Learning Objectives:

1. To define the concept of AI and the underlying techniques that can be applied to radiology.
2. To learn the needs and resources involved in the generation of new machine learning solutions for radiology.
3. To understand how AI can be integrated as a clinical tool to assist radiologists in their daily practice.

A-0371 14:30

Deep learning (DL) in medical imaging

A. Alberich-Bayarri; Valencia/ES

Deep Learning in Radiology can either be applied to reports by deep neural networks (DNN) or to images through convolutional neural networks (CNN). The main applications of deep learning in radiology include image reconstruction, image segmentation, classification, regression, content-based image retrieval and natural language processing of radiology reports, among many others. Specifically, CNN are generally outperforming deterministic computer vision algorithms used for filtering and segmentation. Nowadays, CNN-based algorithms allow for the automated segmentation of organs and tissues within the body with applications like 3D liver segmentation from MR, 3D prostate segmentation from MR, vertebrae detection and labelling from CT, 3D lung and emphysema segmentation from CT, 3D brain lesion detection and segmentation in MR. Deep learning has dramatically changed image analysis pipelines in radiology and has become a key piece in the automation of imaging biomarkers quantification within radiology departments.

Learning Objectives:

1. To learn the concept of DL and how neural networks (NN) can extract patterns from images.
2. To understand how DL can extract information from big radiomics data through training/test process.
3. To learn how convolutional NN can automatically extract imaging features.

Cavitary and cystic diseases of the lung

A-0373 14:00

Chairperson's introduction

J. Biederer; Heidelberg/DE (biederer@radiologie-darmstadt.de)

Air-filled lung lesions are an important diagnostic feature on chest X-ray and CT with a wide range of differential diagnoses. They may result from different conditions such as central necrosis of solid lung lesions and consolidations (malignant or inflammatory), congenital disorders, degeneration (emphysema, bronchiectasis) or trauma. Typically they are an incidental finding and radiology often plays an important role in routing further management of the case. The keys for the most probable diagnosis are on the one hand a precise description for the differentiation of cysts (round, circumscribed, thin-walled space) and cavities (gas-filled space inside a consolidation, nodule or mass) as well as size, profusion and ancillary findings of the lesions on imaging. On the other hand, age, gender, history (tobacco fume exposure) of the patient and other clinical parameters contribute to the interpretation of the case. This session aims to review the diagnostic criteria for air-filled lung lesions by discussing cavitary lesions, cystic lung lesions (focusing on Langerhans cell histiocytosis and lymphangioleiomyomatosis) and their differentials. The attendees will be provided with a practical approach for image interpretation in everyday work based on CT features and clinical background information.

Thursday

A-0374 14:06

A. Cavitory lung lesions

A.P. [Parker](mailto:apparkar@gmail.com); Bergen/NO (apparkar@gmail.com)

A cavity is defined as "a gas-filled space, seen as a lucency or low-attenuation area, within pulmonary consolidation, a mass, or a nodule". The wall thickness may vary considerably. There is a continuous transition from cavities to cysts. Cysts are usually thin-walled (i.e., < 2 mm). A wall thickness < 7 mm is highly specific for the benign disease, a thickness >24 mm is highly specific for malignant disease. However, this is not absolute, as thin-walled carcinomas do exist. An additional indicator for malignancy is the lack of perilesional centrilobular nodules around a cavity. The cavity content is unhelpful in differentiating benign and malignant lesions. Wall rim enhancement on contrast-enhanced CT is common in abscesses. A connecting pulmonary artery may be seen in smaller metastases, but not in larger ones, as the larger nodules tend to compress the vessels, so no feeding artery does not always imply benign nodules. The acute onset of symptoms is sometimes helpful to distinguish malignant and non-malignant disease. Hemoptysis is not a useful symptom to differentiate between benign and malignant cavities. Benign diseases may also cause fatigue and weight loss similar to malignancies. Acute onset of fever is usually helpful to distinguish benign disorders from malignant, but pulmonary cancer may cause a super-infection secondary to the tumour. However, the combination of symptoms, laboratory results, past clinical history, and imaging findings leads to recognition of the correct diagnosis. This presentation will guide you through the most commonly encountered cavitory lung in adults.

Learning Objectives:

1. To review the diagnostic criteria and differentials of cavitory lung lesions.
2. To learn about the most common causes.
3. To learn about an algorithmic approach to narrow the differential diagnosis.

A-0375 14:34

B. Langerhans cell histiocytosis (LCH)

A. [Devaraj](mailto:devaraj@ucl.ac.uk); London/UK

The presentation will review the typical and atypical features of Langerhans cell histiocytosis (LCH) on HRCT, and the differential diagnosis when faced with cystic lung disease on CT. The evolution of CT appearances of LCH over time, the complications of LCH, as well as the pathological correlates will be discussed.

Learning Objectives:

1. To understand the pathophysiology of LCH.
2. To review key features on CT.
3. To learn about the various stages of the disease.

A-0376 15:02

C. Lymphangioliomyomatosis

A. [Oikonomou](mailto:oikonomou@sunnybrook.ca); Toronto, ON/CA (anastasia.oikonomou@sunnybrook.ca)

Lymphangiomyomatosis (LAM) is a rare cystic lung disease caused by infiltration of the lung with smooth muscle cells. It occurs in patients with tuberous sclerosis complex (TSC-LAM) and in a "sporadic" form in patients without tuberous sclerosis (S-LAM). S-LAM is seen exclusively in women of reproductive age while TSC-LAM may also be seen in men. Parenchymal lesions in LAM include cysts, which are thin-walled, well-defined, rounded, usually small in size up to 2 cm and may reach large numbers. They have no zonal lung predominance. Nodules are extremely rare in S-LAM and are more commonly seen in TSC-LAM. They may either be solid or ground-glass and usually tiny. They represent multifocal micronodular pneumocyte hyperplasia. Pleural manifestations include chylothorax and pneumothorax. Chylous pericardial effusions may be seen. Recent guidelines for LAM from the European Respiratory Society LAM task force classify LAM as definite, probable and possible. LAM is differentiated by other cystic lung diseases such as Langerhans histiocytosis (PLCH), Birt-Hogg-Dubbe (BHD), lymphocytic interstitial pneumonia (LIP) and amyloidosis. In PLCH the cysts have a bizarre shape, are variable in number and are upper and middle lobe predominant. In LIP the cysts are round and variable in size but usually small and random in distribution surrounded by ground glass opacity. In BHD the cysts are elliptical in shape and have a subpleural, lower zone predominance adjacent to vessels. In amyloid, the cysts are variable in size but usually large and diffusely distributed. Nodules are seen in PLCH and amyloid.

Learning Objectives:

1. To learn about the current concepts on pathogenesis.
2. To review the typical and atypical CT features.
3. To learn about the tuberous sclerosis complex.

E³ - ECR Academies: Functional Imaging for Disease Management: Research to Medical Practice

E³ 720

Functional imaging of the kidneys

A-0377 14:00

Chairperson's introduction

H.C. [Thoeny](mailto:harriet.thoeny@h-fr.ch); Fribourg/CH (Harriet.thoeny@h-fr.ch)

Thanks to advances in technology functional imaging of the kidneys allow to assess various physiological and pathophysiological aspects of the kidneys including perfusion, diffusion, glomerular filtration and provides noninvasive information on the oxygen content of the kidneys and also allows assessment of the single kidney noninvasively. Functional imaging in contrast to anatomical imaging allows noninvasive detection of diffuse renal diseases preceding changes in morphology and therefore allowing to start the accurate treatment in a timely manner. Especially in diffuse renal pathologies underlying chronic kidney diseases such as in diabetic patients where serum creatinine is a laboratory parameter which is often decreased in advanced stage disease, for instance, early detection and characterisation of chronic kidney disease might improve prognosis thanks to early treatment. The functional MR imaging techniques applied today include dynamic contrast-enhanced (DCE) MRI, diffusion-weighted MRI (DW-MRI) providing information on the underlying microstructure of the renal parenchyma, Blood Oxygen Level Dependent (BOLD) MRI providing indirect information on oxygen content as well as arterial spin labelling (ASL) providing noninvasive information on renal perfusion. Although all these techniques are promising there are still several challenges to overcome including technical improvements, standardisation, validation of quantitative models, reproducibility studies and clinical applications in larger scale studies as most of these functional techniques, for the time being, are mainly applied in a research setting.

A-0378 14:06

A. MR measurement of split renal function

D. [Mandry](mailto:damien.mandry@univ-lorraine.fr); Nancy/FR (damien.mandry@univ-lorraine.fr)

Amongst the MRI techniques that carry functional data of the kidney, dynamic contrast enhancement (DCE) is well-established for the assessment of the renal perfusion, especially for the calculation of the split renal function. Its principle is to repeat for several minutes (usually, 6 to 10 min) the same T1-weighted acquisition on the kidneys, following the injection of an exogenous contrast agent. It requires a high temporal resolution for assessment of the vascular phase and preferably a volumic sequence to enable assessment of the whole parenchyma. The first step of the analysis usually is the application of a registration algorithm to correct for breathing-related motions. Then, the different renal compartments have to be segmented to measure the parenchymal volume and derive time-intensity curves. Calculation of the split renal function is based either on the comparison of the curves from left and right kidneys, the calculation of the area-under-the-curve, or preferably on the Patlak-Rutland plot method. On top of the absence of ionising radiations, functional MRI provides a morphological analysis of the kidneys as compared to renal scintigraphy, but evaluation of severely dilated kidneys is more challenging.

Learning Objectives:

1. To review the principles of functional DCE of kidneys.
2. To learn about post-processing methods.
3. To understand differences with renal scintigraphy.

A-0379 14:34

B. Renovascular diseases (RVD)

M. [Notohamiprodjo](mailto:mike.notohamiprodjo@uni-tuebingen.de); Tübingen/DE (Mike.Notohamiprodjo@uni-tuebingen.de)

Renovascular disease, especially atherosclerotic renal artery stenosis, causes gradual deterioration of renal function and thus individual patient outcome. Despite increased awareness due to advances in vascular imaging, renal revascularisation is less commonly performed, likely as a result of several prospective, randomised, clinical trials which fail to demonstrate major benefits of renal revascularisation beyond medical therapy alone. The goal of this lecture is to discuss the available imaging methods to study renal flow and function. Furthermore, we review other non-invasive imaging methods to study the ultrastructure of renal tissue. We also explore the potential of these methods for management of renovascular disease, by triaging patients for revascularisation and to monitor the effects of medical and invasive therapy.

Postgraduate Educational Programme

Learning Objectives:

1. To review main methods of renal perfusion measurement.
2. To learn about the place of functional approaches in strategy management of RVD.
3. To understand its impact for therapeutic decision.

A-0380 15:02

C. Characterisation of chronic kidney diseases (CKD)

N. Grenier; Bordeaux/FR (nicolas.grenier@chu-bordeaux.fr)

Renal physiology is complex with two compartments functioning under highly different conditions. The cortex is highly perfused with a high level of oxygen whereas medulla shows a poor perfusion level and works under hypoxic conditions. Water movements are multiple along the nephrons to maintain normal homeostasis. Glomerular filtration rate is a major marker of renal function, but its measurement is complex to obtain in clinics. All these parameters can be approached using functional MRI with DCE, DWI, BOLD. Some of these techniques may reflect changes within the extracellular matrix of renal tissue during the process of renal scarring. However, validation of these tools and their impact on patient management still requires further prospective studies.

Learning Objectives:

1. To understand the link between functional approach and renal physiological and tissue changes.
2. To learn how functional approach can help in differentiating renal diseases.
3. To be aware of their role in evaluating prognosis of CKD.

E³ 821

Gastrointestinal radiology

A-0390 16:00

A. Inflammatory bowel disease

J. Rimola; Barcelona/ES (jrimola@clinic.ub.es)

Bowel imaging had experienced relevant clinical advances in the last decade and represents the first diagnostic tool for assessing bowel inflammation in patients with Crohn's disease (CD). There is growing evidence that cross-sectional imaging is able to accomplish main endpoints in the diagnosis of CD, including the detection of active disease, especially severe lesions, and the achievement of healing of inflammatory lesions. The identification of structuring and penetrating complications is also a key aspect that has implications in therapeutic management as well as in the determination of bowel damage. The lecture will provide the key points to confidently diagnose activity and complications related to CD.

Learning Objectives:

1. To review the spectrum of imaging findings in inflammatory bowel disease, mainly in Crohn's disease.
2. To learn about the management options.

SF 8a

Artificial intelligence (AI): our future cannot be predicted, but we have to be prepared

A-0392 16:00

Chairperson's introduction

G. Langs; Vienna/AT (Georg.langs@meduniwien.ac.at)

Machine learning and radiology are rapidly gaining joint momentum as an interdisciplinary research field. After initial expectations start to transition into joint research, it is time for a reality check to understand where we are and which are the most promising and difficult efforts for this emerging interdisciplinary field. The session will give an overview of the current state of machine learning in medical imaging and will explore valuable directions of joint research. Four distinguished speakers from areas covering radiology, machine learning and medical image computing will provide a realistic assessment of where we are, and offer their views about most directions that will have advance both fields having an impact on research in novel biomarkers, and clinical applications. The session will highlight challenges in methodology, the integration of machine learning in radiological routine, and the enablers of successful development of novel and reliable machine learning approaches in medicine. As both fields evolve, and the role of radiology and machine learning is expanding, the session will give a forum for critical, informed discussion.

Session Objectives:

1. To learn about the basics of machine learning and deep learning, its current capabilities and limitations and its contribution to research and routine.
2. To understand the current state-of-the-art, where ML/DL techniques struggle and in which directions the major methodological and application advances are being made right now.
3. To appreciate the need for interdisciplinary research and conscious creation of means to exploit the capabilities of AI, and to coordinate development across machine learning and radiology communities.
4. To become familiar with examples of how AI can be used in radiology.

General Radiography (Radiographers)

RC 814

Forensic imaging

A-0397 16:00

Chairpersons' introduction (Part 1)

A. [Dominguez](#); Lausanne/CH (Alexandre.DOMINGUEZ@hesav.ch)

The implementation of radiographers in forensic medicine is becoming more and more widespread. The use of the technical skills of a radiographer increases the quality of services, especially in the field of postmortem imaging angiography. The multi-disciplinary collaboration between pathologists, the radiologists and the radiographers allows the implementation of these new practices. Thanks to the contribution of forensic imaging, the sensitivity of the post-mortem examination within medico-legal investigations are increased.

Session Objectives:

1. To provide insights into the role of imaging, and radiographers, in forensic imaging.
2. To appreciate the key aspects of a quality forensic imaging service using angiography.
3. To understand the challenges associated with forensic imaging.

A-0398 16:03

Chairpersons' introduction (Part 2)

H.T. [Patel](#); Ahmedabad/IN (hemantmri@gmail.com)

Forensic Radiology is a segment within the field of medical imaging that focuses on using radiology imaging techniques where evidence may be gathered in a court of law. The use of radiography in support of evidence has a long history dating back to the first few months after Wilhelm Roentgen's discovery in 1895. A bullet seen using an x-ray was used for cases of attempted murder. Pathologists commonly use radiographs when performing autopsies. The images can help them identify elements that are out of place or questionable and then allows them to investigate further. As the radiologic sciences have advanced over the years to include MRI's, CT's, and ultrasound, the accuracy has increased to a much greater degree and has made it even more relevant for investigating crimes and gathering evidence.

Session Objectives:

1. To provide insights into the role of imaging, and radiographers, in forensic imaging.
2. To appreciate the key aspects of a quality forensic imaging service using angiography.
3. To understand the challenges associated with forensic imaging.

A-0399 16:05

A. The chain of evidence

M. [Davis](#); Dublin/IE (michaela.davis@ucd.ie)

Diagnostic imaging is a useful tool for and clinical case management. Radiographers by the nature of their work create material which can be potentially used as evidence. This material may be in a variety of formats. It is important that radiographers maintain continuity of evidence within their working practices as the material, may be used by other professionals as part of their decision-making process as well as the courts including both the child and family and criminal courts. The presentation will draw upon examples and discuss potential pitfalls in this area.

Learning Objectives:

1. To appreciate the importance of continuity of evidence and record keeping.
2. To learn about essential steps for radiographers to follow.
3. To discuss potential pitfalls when conducting forensic examinations.

A-0400 16:28

B. Post-mortem cardiac angiography

H. [Precht](#); Odense/DK (hepr@ucl.dk)

Computed Tomography (CT) is a widely used imaging tool with high diagnostic accuracy and prognostic value. Cardiac CT Angiography (CCTA) scanning is often used to diagnose cardiology patients as coronary atherosclerosis is a worldwide disease and counts for millions of deaths every year. The CT technology is developing rapidly given new possibilities for optimisation. A CCTA scan can identify elements as coronary stenosis, coronary atherosclerotic-, low attenuation- and spotty calcification plaques, positive remodelling. These components have been considered as important features of coronary plaque vulnerability and instability. As the coronary arteries have an average diameter of 1-4 mm, the CCTA images need to image small details with low attenuation. The CT scanner is challenged to image small details with good contrast and temporal resolution; therefore optimisation of the CT protocol is necessary. New developed CT techniques need to be implemented with caution to ensure the images not change coronary plaques size or content inappropriate. To evaluate new CCTA technique influence of coronary plaques, a correlation with the gold standard of histopathology could give us useful information. To be able to reflect these results to in-vivo CCTA it is important to prepare the heart and arteries with correct pressure, contrast filling in the arteries as contrast/water in the heart chambers. Scattered radiation from the surrounding tissue needs to be included as the most challenging parts is an exact procedure for three-dimensional alignment procedure for PMCCTA and the histopathology data.

Learning Objectives:

1. To learn about the development of multiphase post-mortem cardiac angiography (MPMCCTA).
2. To appreciate the benefits and limitations of MPMCCTA examinations.
3. To understand the role of the radiographer in the MPMCCTA.

A-0401 16:51

C. Paediatric forensic imaging

A.L. [Brookes](#); Fulwood/UK

Forensic imaging is the application of any form of diagnostic radiography to the law and is used to provide evidence for a potential criminal investigation. This sub-speciality of radiology is ever expanding, and recent developments have seen forensic imaging utilised and researched more widely, particularly the use of CT in post-mortem settings. Paediatric forensic imaging is the mainstay of routine forensic cases undertaken in imaging departments. Most often, this is the investigation of Suspected Physical Abuse (SPA) in both living and deceased children. In these cases, imaging is used as an adjunct to other evidence collected in the detection of SPA. However, recognition and further prevention of child abuse can be achieved through the use of radiological findings. Nevertheless, forensic imaging in paediatrics extends beyond use for detection of SPA, and in almost all types of forensic imaging, paediatric cases will be found.

Learning Objectives:

1. To appreciate the role of the radiographer in paediatric forensic imaging.
2. To understand the challenges associated with conducting paediatric forensic examinations.
3. To discuss the imaging options available for paediatric forensic imaging.

Brain imaging in psychiatry

A-0402 16:00

Chairperson's introduction

J.-P. [Pruvo](#); Lille/FR (jean-pierre.pruvo@chru-lille.fr)

This session will introduce the potential of MRI use in Psychiatry. First, the prevalence and burden of the main psychiatric disorders will be presented by Dr Amad. He will notably synthesise the available findings in first-episode of psychosis and the rationale for systematic MRI in this indication. Then, Pr Pruvo will discuss the choice of structural/ functional MRI sequences in this

Thursday

context. He will present a collaborative psychiatry-radiology network in France as proof of concept. Dr Lopes will then develop the perspective of high-field MRI in psychiatry research together with clinical applications based on advanced Machine-Learning adapted to the field of Psychiatry. Finally, Pr Jardri will conclude on applications of image-guided therapy to relieve drug-resistant hallucinations.

Session Objectives:

1. To introduce the potential of MRI use in psychiatry.
2. To present the context and introduce the faculty.

A-0403 16:05

The epidemiology of psychiatric disorders: why is MRI needed?

A. Amad; Lille/FR (ali.amad@chru-lille.fr)

The prevalence, severity, and overall burden of morbidity and mortality represented by psychiatric disorders reflect an urgent global public health priority. According to a systematic review of data and statistics from community studies in European Union (EU) countries, the WHO estimated that 27% of the adult population (18-65 years old) had experienced at least one of a series of psychiatric disorders in the past year representing about 83 million people being affected. Despite psychiatric disorders are now defined as brain disorders, the use of brain imaging, especially brain MRI, in psychiatric clinical practice remains limited. Currently, the main indication of brain MRI in psychiatric clinical practice corresponds to the identification of differential diagnoses as many diseases (e.g. brain tumours, neuroinflammatory disorders, aneurysms) can cause and/or be associated to psychiatric symptoms. In this talk, we are going to answer to the question "why MRI is needed in psychiatry", with a focus on the first psychosis episode, by highlighting that considerable research is indicating that the potential uses of brain MRI in clinical practice are numerous for both diagnostic and prognostic purposes but also to guide treatments.

Learning Objectives:

1. To know the prevalence and burden of the main psychiatric disorders.
2. To synthesise the available findings in the case of the first-episode of psychosis.
3. To discuss the rationale for systematic MRI in first-episode psychosis.

A-0404 16:23

Strengths of structural and functional MRI in psychiatry

J.-P. Pruvo; Lille/FR

Being able to predict as soon as possible the clinical outcome following a first episode of psychosis (FEP) is crucial, and should allow providing the most appropriate care to patients. Several biomarkers for FEP outcome have already been proposed, including anatomical and functional neuroimaging, neuropsychological and biological biomarkers, but they still lack large-scale validation. In the Hauts-de-France region, the Federation for mental health research (F2RSM) constituted radiologists-psychiatrists pairs and harmonised magnetic resonance imaging sequences to be used in FEP, forming the "PSYMAC clinical network". This procedure also includes follow-up visits to maintain harmonisation over time. The choice of the most adapted sequences to be conducted in this context will be discussed. We expect to later develop and generalise such a network nationwide.

Learning Objectives:

1. To discuss the choice of structural/functional MRI sequences in this context.
2. To present a collaborative psychiatry-radiology network in North of France.
3. To present the clinical perspective of the PREDIPSY project.

A-0405 16:41

Advanced MRI and clinical applications: the structured report

R. Lopes; Lille/FR (renaud.lopes@gmail.com)

In this presentation, we will talk about the interest of advanced MRI in clinical applications with a focus on a structured report. First, we will discuss the interest of 3T MRI in a better understanding of the physiopathology of neurological and psychiatric diseases. We will synthesise 5-years of 3T MRI research in biomarkers of these diseases. Next, we will present some studies using ultra-high field MRI in psychiatric diseases and will show the complementarity with 3T MRI. Finally, we will conclude by demonstrating the interests of these biomarkers identified at 3T and 7T MRI in the diagnosis of psychiatric and neurological diseases using artificial intelligence and structured report.

Learning Objectives:

1. To synthesise 5-years of 3T-MRI research in psychiatry and neurology.
2. To present the perspective of ultra-high field MRI in psychiatry research.
3. To present clinical applications of machine-learning on MRI-data in the field of psychiatry.

A-0406 16:59

From fMRI capture of hallucinations to innovative image-guided treatments

R. Jardri; Lille/FR (renaud.jardri@chru-lille.fr)

Hallucinations have held the fascination of science since the dawn of humanity. However, their study has become critical with the recent development of functional brain imaging that allowed to explore the neural underpinnings of these experiences. This presentation with briefly summarise the available methods to analyse per-hallucinatory fMRI signal, called "hallucination capture" methods. Recent developments using Machine-Learning will also be presented. Crucially, these methods pave the way to innovative fMRI-guided treatment of drug-resistant hallucinations, including neuro-navigated brain stimulation (e.g. rTMS) and fMRI-based neurofeedback.

Learning Objectives:

1. To know the neural bases of hallucinations.
2. To know the different fMRI strategies used to capture hallucinations.
3. To present fMRI-guided treatments of refractory hallucinations.

Diagnostic reference levels (DRLs) based on clinical indication

Moderators:

G. Frija; Paris/FR
G. Simeonov; Luxembourg/LU

A-0408 16:00

Chairperson's introduction

G. Frija; Paris/FR (guy.frija@aphp.fr)

This session will focus on the concept of clinical diagnostic reference levels (CDRLs) and will provide the European Commission's perspective on the concept. Moreover, the European Commission-funded tender project EUCLID (European Study on Clinical Diagnostic Reference Levels for X-ray Medical Imaging), which is implemented by the European Society of Radiology (ESR), will be presented. EUCLID aims to establish clinical DRLs for the most important, from a radiological perspective, CT and interventional imaging tasks in Europe, and to stimulate national and local efforts in this area. The session will be concluded with presentations on the national experiences of Ireland and Switzerland in the establishment of CDRLs.

Session Objectives:

1. To learn about the concept of clinical DRLs (CDRLs).
2. To understand the goals of CDRLs.
3. To understand the methodology of the establishment of CDRs.

A-0409 16:05

European Commission perspective

G. Simeonov; Luxembourg/LU (georgi.simeonov@ec.europa.eu)

The European legislation for radiation protection of patients has been evolving for more than 30 years. The most recent revision - Council Directive 2013/59/Euratom (Basic Safety Standards, BSS) - brings important changes with an implementation deadline of February 2018. In the absence of dose limits and dose constraints, the diagnostic reference levels (DRLs) are the main operational and regulatory tool for optimisation of radiation protection of patients in diagnostic imaging. The BSS directive introduces, inter alia, new requirements for the establishment, regular review and use of diagnostic reference levels (DRLs). Furthermore, the directive expands the application of DRLs to interventional radiology procedures. The European Commission (EC) supports the implementation of legal requirements, e.g. through studies and guidance. The EC guidance on DRLs from 1999 is now largely considered outdated. Guidance on paediatric DRLs was issued in 2018, based on the European PiDRL project. Recent reviews show that, in EU countries, DRLs exist only for a limited number of widely defined imaging procedures without specification of the clinical task/indication. The EUCLID project, to be completed in 2020, is expected to advance the implementation of clinical DRLs. The implementation of the BSS directive remains a national responsibility. Nevertheless, the EC will consider further action to support the implementation of DRLs in clinical practice.

Postgraduate Educational Programme

Learning Objectives:

1. To learn about the Euratom legal basis for radiation protection of patients and the European Commission's support for implementation of the Euratom requirements for DRLs.
2. To understand the place and the importance of DRLs in the Euratom system for radiation protection of patients.
3. To appreciate the progress made in recent years with respect to DRLs and the key role of Euratom as the driver of progress in this area.

A-0410 16:20

One shoe does not fit all: clinical indication based DRLs

G. Frijia; Paris/FR (guy.frija@aphp.fr)

Diagnostic reference levels (DRLs) are an important tool for optimisation. DRLs are usually established for specific anatomical locations. However, different image quality is needed for different clinical indications of the same anatomical area. Thus, the use of DRLs based on clinical indications is suggested instead. Some countries have already established DRLs based on clinical indications, or are in the process of establishing them. This talk will introduce the concept of clinical DRLs (CDRLs) in computed tomography and interventional radiology, and point out the importance of the establishment of local DRLs. It will provide an update on DRLs available in Europe and propose the way forward to promote the establishment of CDRLs.

Learning Objectives:

1. To learn about the concept of CDRLs in CT and in interventional radiology.
2. To understand the importance of local DRLs.
3. To appreciate the need to develop local repositories covering the field of quality and safety.

A-0411 16:35

Experience from the EUCLID (European study on clinical DRLs) Project

J. Damiak; Iraklion/GR (damiaki@med.uoc.gr)

The European Commission launched the 'European study on clinical diagnostic reference levels for x-ray medical imaging' (EUCLID) project to provide up-to-date clinical dose reference levels (DRLs). The main objectives of the project are to a) conduct a European survey to collect data needed for the establishment of DRLs for the most important, from the radiation protection perspective, x-ray imaging tasks in Europe and b) specify up-to-date DRLs for these clinical tasks. EUCLID started on August 1, 2017, and the duration of the project is 33 months. A comprehensive review has been carried out to identify the status of existing clinical DRLs for CT, interventional radiology and radiography in Europe and beyond by analysing recent studies, standards and publications. Information about existing clinical DRLs has also been collected from competent national authorities and other organisations involved in the project. A survey has been developed for the collection of data needed for DRLs determination from 14 European countries. Data are collected for 10 CT clinical indications and four fluoroscopically guided interventional procedures. While the hospitals are collecting data and uploading them to a secure platform, literature is reviewed, and different methods of data analysis are investigated by EUCLID experts. Preliminary results will be summarised during this presentation.

Learning Objectives:

1. To learn about methodological requirements for establishing DRLs.
2. To learn about the current status of DRLs in adult imaging in Europe and beyond.
3. To understand why clinical DRLs are needed in adult imaging.

A-0412 16:50

Experience with a national survey based on clinical indications

S.J. Foley; Dublin/IE (shane.foley@ucd.ie)

In 2017 an online survey was distributed to all Irish CT centres on behalf of the National Population Dose and Optimisation Sub-committee, which aimed to determine the total collective dose of radiation to patients nationally from the use of CT and to enhance patient safety through promoting the principle of optimisation. The objectives were to identify the median dose administered for the most frequently performed CT procedures in both paediatric and adult services and to inform national diagnostic reference levels (DRLs) for the most common CT procedures. For the first time, DRL data collection requested dose data specific to clinical indications based on a list of the thirteen most common presenting complaints that require a CT imaging procedure. The findings demonstrated that DRLs based on clinical indication, although based on smaller exam numbers, were significantly different from DRLs generated by anatomical area. However, the findings were limited by the interpretation applied to each particular optimisation protocol. This can possibly be overcome by increased standardisation of practices, applying uniform terminology and adopting common information systems.

Learning Objectives:

1. To learn about the 2017 Irish national CT survey.
2. To understand DRL differences when derived from clinical indications in contrast to anatomical region.
3. To appreciate aspects for improvement of future surveys.

A-0413 17:05

Update of the national DRLs for CT in Switzerland

S.T. Schindera; Aarau/CH (sschindera@aol.com)

The substantial contribution of computed tomography (CT) to the collective population dose requires efforts to optimise CT radiation doses. Diagnostic reference levels (DRLs) are a useful tool to support this optimisation. Recently, the DRLs for CT have been updated in Switzerland compared to the previous national assessment from 2010. Radiation dose data from 50 CT scanners were collected with locally installed dose management software solutions between 2014 and 2017. Compared to the previous DRLs, a clear trend towards lower doses was observed. The average relative change in CTDIvol was -30% (0% to -47% depending on the protocol) and -22% for dose length product (+20% to -40%). Furthermore, comparing to other European countries, the recently updated national DRLs for CT in Switzerland is lower. The substantial reduction of the DRLs reflects well the efforts of the Swiss radiological community towards the use of dose-efficient protocols.

Learning Objectives:

1. To learn about the methodology of updating the national DRLs for CT in the era of dose management software.
2. To learn about the main differences of the updated national DRLs for CT.
3. To understand the impact of the updated national DRLs for CT.

Special Focus Session

SF 8c

The art to transmit and to receive: how to communicate critical information to our patients

A-0414 16:00

Chairpersons' introduction (Part 1)

M.H. Fuchsjaeger; Graz/AT (michael.fuchsjaeger@medunigraz.at)

This session is aimed at all radiologists to learn to understand the power of communication as such, as well as the communication of critical information to our patients. During the last two decades, the term of the invisible radiologist has been coined, something that does not at all reflect the true clinical work of any radiologist which is in many subspecialties very close to our patients. Still, many medical universities do not have communication skills training incorporated into their curricula. In this session stress is laid on the fact that active communication is important, acknowledging that active listening is perhaps the most important part of it. We will learn about the fundamentals of physician-patient communication, the patients' needs as well as the patients' perspective of physician-patient communication, as well as strategies to improve our communication with our patients.

Session Objectives:

1. To understand the importance of direct communication with patients.
2. To learn about the differences between delivering and receiving critical information.
3. To become familiar with the needs of patients for communication with medical specialists.

A-0415 16:03

Chairpersons' introduction (Part 2)

C. Loewe; Vienna/AT (christian.loewe@meduniwien.ac.at)

The continuous transformation of Radiologists from very technical Physicians far away from patients and clinical decision making towards clinically involved doctors playing a central role in tumour boards and treatment decisions has changed the demands on modern clinical Radiologists. Besides the traditional needs for a highly accurate and precise language for written reports, clinical Radiologists nowadays should also be skilled in direct communication with clinical colleagues and - even more important - with patients. There is an increasing number of situations and occasions where clinical Radiologists are the first ones to inform patients about a possibly unfavourable finding. It is during an ultrasound, but also when it comes to breast care and image guided intervention and therapy when patients are asking questions about their

situation. And they do have the right to receive appropriate answers then! Facing the shortage of clinicians in many countries leading to further intensified schedule in usual outpatient services the number of - especially oncological patients - asking for direct communication with the Radiologists right after staging CT is continuously increasing as well. Consequently, Radiologists are leaving the closed box - and they should find the right empathic words in direct communication. Within this Chairman's introduction, we will recall the need for facing the challenge of direct communication with patients in modern Radiology. Furthermore, we will point out again the possible problems while transmitting critical information's to the patients and how big the difference between delivery and receive might be in this situation.

Session Objectives:

1. To understand the importance of direct communication with patients.
2. To learn about the differences between delivering and receiving critical information.
3. To become familiar with the needs of patients for communication with medical specialists.

A-0416 16:05

How patients feel about communication

C. Justich; Vienna/AT (cjustich@me.com)

A bigger picture has become the basic requirement in today's medical world. High expectations demanded from physicians have to be met on a professional level and with compassion for the patient. The key to success lies in recognising the importance of communication resulting in a doctor-patient-relationship based on trust. The secret is, how you say what by whom. How: Radiologist with limited time need to find quick and effective ways to communicate, in most cases, they are the first ones to approach a patient (technique examples). Who: Each patient should have one medical leader who guides them. Patients tend to hand over the total responsibility to doctors, and they should be empowered to take it back and to play an active role in their care and healing process. The medical leader has to be the single point of communication to all persons involved. The time between examination and issuing its results must be kept short, the information being provided only after a decision has been made (personal example liver). Today we know, that a positive expectation together with the care of an acknowledged expert, can work better than a placebo. As physicians, you have the power to reduce your patients' stress and anxiety but also to increase them. Statistics are fabulous but be careful about giving prognoses and taking away hope. To set up your wording in the right way will improve the outcome (examples). Making an effort is well worth it, the benefits will be yours.

Learning Objectives:

1. To understand the immense impact of communication.
2. To demonstrate how different ways of communication influenced me as a patient.
3. To appreciate benefits of good communication for the physician.

A-0417 16:30

Fundamentals of physician/patient communication

L. Fallowfield; Brighton/UK

Learning Objectives:

1. To understand what questions and information are important to patients.
2. To learn some basic principles and techniques of doctor-patient communication.
3. To apply these principles to some common clinical situations.

A-0418 16:55

How can we improve communication with our patients?

F.J. Gilbert; Cambridge/UK

The interaction of radiologist with patient varies in type of examination undertaken. With mammograms, there may be no interaction, with ultrasound it's challenging to avoid communication with the patient who is anxious and will ask questions during the procedure. This is similar to image guided procedures where sometimes informed consent is required. A clear explanation of interventional procedures is essential as patients are giving consent implicitly if no direct consent is being requested. The communication of radiological findings with patients depends on the nature of the discussion. Often when there is an uncertainty of diagnosis, radiological findings are explained together with next steps for patient management. Commonly there is uncertainty about mammographic findings, i.e. microcalcification or asymmetry and further imaging or biopsy is required. The importance of conveying the same message as the clinician in charge of the patient cannot be emphasised enough. Essentially the radiologist must not undermine or contradict the clinician who has to take the ultimate responsibility for the patient. An agreed management plan is important and is often developed in the Multidisciplinary team meeting (MDT). Patients appreciate clear communication together with a written plan of management. Communication courses give practical tips on

effective communication strategies together with advice on how to check whether or not the patient has understood what is being said. An empathetic approach is important in breaking bad news.

Learning Objectives:

1. To understand the communication of radiological findings with patients.
2. To discuss communication of uncertainty about radiological findings and why further tests are required.
3. To appreciate the importance of conveying the same messages as the clinician in charge of the patient.

Non-contrast MR angiography: ready to go?

A-0419 16:00

Chairperson's introduction

R. Iezzi; Rome/IT (roberto.iezzi.md@gmail.com)

MR angiography represents an accepted non-invasive alternative to conventional angiography in vascular imaging. Furthermore, using MR to delineate vascular anatomy has changed dramatically due to continuous technological evolution which provided more advanced equipment and complex software, making it faster with more detailed information obtained. Advantages of MRA over CTA include increased signal-to-noise ratio, easier 3D post-processing, and utility in young patients or in patients who require recurrent follow-up imaging given its lack of ionising radiation. One of the biggest concerns in radiology in recent years is the safety of gadolinium-based contrast agents used in MR imaging. It is well-known that patients with moderate to severe renal insufficiency and vascular or metabolic disorders cannot filter the gadolinium, being at risk for developing the debilitating and possibly life-threatening disease of nephrogenic systemic fibrosis. However, there has been little evidence showing patient safety issues in those with normal renal function. These points will be discussed during the session, also highlighting the renewed interest on non-contrast MRA imaging, obtained with improvements in MR hardware and software, as reported in recent literature, that could overcome MRA. Interestingly, phase-contrast NCE-MRA methods could also offer the potential to provide additional hemodynamic information that currently is obtained using invasive methods.

Session Objectives:

1. To understand the role of MR angiography in vascular imaging.
2. To become familiar about the risk of gadolinium injection.
3. To learn about the existing literature on the usefulness of non-contrast MRA imaging.

A-0420 16:05

Non-contrast MR angiography techniques

T. Leiner; Utrecht/NL (t.leiner@umcutrecht.nl)

Magnetic resonance angiography is a highly reliable tool for detection of presence, extent and severity of arterial narrowing in virtually any vascular bed in the body except the coronary arteries. In clinical practice, most radiologists use contrast-enhanced MR angiography (CE-MRA) techniques due to wide availability and ease of use. However, recent advances in scanner hardware and pulse sequence design have led to the development of a set of methods that utilise the intrinsic properties of blood to generate images with high vessel-to-background contrast without the need for an injection of an extrinsic contrast agent. These methods are also known as native or non-contrast MRA (NC-MRA). NC-MRA methods rely on a variety of contrast mechanisms. The most commonly used mechanisms are Flow-independent MRA; non-subtractive inflow-dependent MRA; subtractive 3D MRA, and velocity-selective 3D MRA. In my lecture, I will discuss these mechanisms as well as the evidence for clinical efficacy in various body regions.

Learning Objectives:

1. To become familiar with MRI technologies and innovations.
2. To learn about the alternative sequences to study vascular structures.
3. To learn what you need to technically optimise your protocols.

A-0421 16:23

Non-contrast MR angiography for large vessels

T. [Hazirolan](#); Ankara/TR (tuncyhazirolan@yahoo.com)

Determining that gadolinium contrast agents caused NSF and brain accumulation led to the preference of non-contrast MRI applications more frequently. In recent years, there has been an increase in the number of non-contrast MR angiography techniques. The most preferred method in the non-contrast angiographic evaluation of the aorta is the ECG and navigator-gated 3D-SSFP (3D-SSFP) sequence. Protocols that includes cine SSFP, ECG gated 2D black blood TSE, ECG gated white and black blood single shoot sequences, and 3D-SSFP provide a comprehensive assessment of aortic pathologies. In this presentation, advantages, disadvantages and artefacts of non-contrast MRI protocols used in the evaluation of aorta will be discussed.

Learning Objectives:

1. To understand the role of MR angiography in aortic imaging.
2. To discuss how non-enhanced MRI sequences could replace gadolinium-enhanced sequences.
3. To learn how to optimise your protocols to avoid the use of intravenous gadolinium.

A-0422 16:41

Peripheral non-contrast MR angiography

G. [Roditi](#); Glasgow/UK (Giles.Roditi@glasgow.ac.uk)

For evaluation of peripheral vascular disease non-contrast, TOF MRA was hampered by long acquisition times plus in-plane flow saturation effects and was soon supplanted by gadolinium-based contrast-enhanced techniques. The extensive craniocaudal coverage and necessity for high spatial resolution required to evaluate the lower limb arteries down to the feet accurately has remained challenging for NC-MRA. Nevertheless, there has been significant progress with both ECG-triggered subtraction FSE (exploiting arterial and venous flow differences, e.g. FBI) and flow-independent bright-blood techniques such as SSFP with IR (NATIVE SPACE, TRANCE) and (ECG)-triggered quiescent interval single shot (QISS) MRA being refined. There is increasing evidence of the accuracy (particularly for QISS); however, the uptake of these techniques has been relatively limited and this presentation will explore the reasons behind this which are in part due to technical limitations & competition from alternative techniques but also more prosaic challenges in the implementations that impact on workflow.

Learning Objectives:

1. To understand the role of MR angiography in peripheral disease.
2. To discuss how non-enhanced MRI sequences could replace gadolinium-enhanced sequences.
3. To learn how to optimise your protocols to avoid the use of intravenous gadolinium.

A-0423 16:59

Non-contrast MR angiography in paediatric vascular imaging

M. [Argyropoulou](#); Ioannina/GR (margyrop@cc.uoi.gr)

Contrast-enhanced MR angiography (CE-MRA) has been long considered the modality of choice for vascular imaging in children. The main contraindication of CE-MRA has been the renal failure because of the risk for developing nephrogenic fibrosis. State of the art CE-MRA necessitates lack of motion, a good intravenous access and collaboration of the patient in breath holding, conditions that may be difficult to obtain in young children. Over the last years, there is an increasing concern about the deposition of gadolinium in the brain of pediatric and adult patients leading to an increasing interest in developing new non-contrast-enhanced MRA (NC-MRA) techniques. NC-MRA has been successfully applied in imaging the thoracic and abdominal aorta and its branches. "Black blood" and "white blood" sequences have been used in the evaluation of aortic rings and pulmonary slings. NC-MRA and cine-MRI have been used for the evaluation of coarctation of the aorta and complications such as residual stenosis or restenosis, development of a false aneurysm and aortic dissection. NC-MRA has been successfully used evaluation of aberrant vessels crossing the ureteropelvic junction resulting in hydronephrosis and in the evaluation of the splenoportal vessels. NC dynamic MRA techniques based on arterial spin-labelling can be used in the evaluation of brain vessels offering the possibility to separate arteries from veins and to detect temporal flow differences between the anterior and posterior circulation.

Learning Objectives:

1. To learn about the risk of gadolinium injection in the paediatric patient.
2. To discuss the implications of the new knowledge for clinical practice in paediatric radiology.
3. To learn how to optimise your protocols to avoid the use of intravenous gadolinium.

17:17

Breast imaging in pre-menopausal women

A-0424 16:00

Chairperson's introduction

I. [Thomassin-Naggara](#); Paris/FR (isabelle.thomassin@tnn.aphp.fr)

This session will present the physiological changes and benign breast diseases and highlight the challenges and opportunities of breast MR imaging in pre-menopausal women. The objective is to provide an overview of how to manage the enhancement of parenchyma. Then, will be discussed the place of breast screening in pre-menopausal women and present the risk factors that define groups of women that would benefit a breast screening the balance between risk and benefit of radiation dose. Finally, an overview of breast diseases associated with pregnancy will be done in order to learn which imaging techniques could be used to investigate pregnancy-associated breast lesions and breast cancer.

Session Objectives:

1. To highlight the different pathologies we may encounter in pre-menopausal women.
2. To present controversies about screening in pre-menopausal women.
3. To become familiar with breast diseases associated with pregnancy.

Author Disclosure:

I. Thomassin-Naggara: Advisory Board; SIEMENS. Speaker; GE, Samsung, Canon, Guerbet.

A-0425 16:05

Physiological changes and benign breast diseases in young women

F. [Kilburn-Toppin](#); Cambridge/UK

Breast imaging in pre-menopausal women presents particular challenges for the radiologist. Benign breast disorders are much more common in this age group and are multifactorial including genetics and hormone-related causes. Diagnosis of benign disorders is important because they may be accompanied by clinical symptoms, but also to exclude malignancy and lesions of increased risk of cancer which may mimic benign breast disease on imaging. High mammographic density in premenopausal women makes sensitivity limited, and furthermore, the risk of radiation-induced malignancy is much higher in the young glandular breast than beyond the age of 40. Similarly, on ultrasound, a higher proportion of hyperechoic glandular tissue versus hypoechoic fatty tissue can provide a challenge to the interpreting clinician. A limitation of breast MRI in pre-menopausal women is that hormonal fluctuations during the menstrual cycle affect gadolinium uptake in normal breast tissue, which can make MRI examinations challenging to interpret due to false-positive findings, or risk masking malignancy. Studies have suggested performing scans during the follicular phase (day 3-14) to minimise tissue enhancement, and for this reason scheduling of the MRI examination in pre-menopausal women is recommended during the second week of the menstrual cycle. Particular patterns and degree of non-mass enhancement can be associated with benign background parenchymal enhancement, but repeat short interval imaging has been advocated in some circumstances if there is diagnostic uncertainty. Further challenges occur in premenopausal women who lack normal cyclical menses.

Learning Objectives:

1. To present the physiological changes and benign breast diseases.
2. To highlight the challenges and opportunities of breast MR imaging in pre-menopausal women.
3. To provide an overview on how to manage enhancement of parenchyma.

A-0426 16:30

Breast cancer screening in pre-menopausal women

P. [Clauser](#); Vienna/AT (clauser.p@hotmail.it)

The risk of developing breast cancer increases with age, and approximately 5% of breast cancers appear before the age of 40. Cancers in young women are often characterised by more aggressive behaviour and a higher recurrence rate. Women with breast cancer below 40 often have a positive family history or mutations. Imaging findings in young women are not significantly different from those in older women. Currently, many programs begin screening mammography at the age of 50, despite the evidence that screening can reduce mortality between 40 and 50 years. In women below 40, cancer detection with mammography is lower, and the risk of false positives is increased. This is related to the lower cancer incidence and the higher breast

Postgraduate Educational Programme

density, which reduces the sensitivity of mammography. Tomosynthesis can improve cancer detection in women above 40, but due to the use of radiation and the suboptimal accuracy in very dense breasts, it might not be the best screening modality below 40. Ultrasound or MRI have a higher sensitivity in dense breast and could be used for early detection in young women. The costs of the examinations, the number of false positives and the need for a contrast agent make the introduction of these techniques in screening challenging. To optimise early detection, women could be tested for breast cancer risk at an early age, and screening could be optimised based on personal risk. Personalised screening is needed in the follow-up of women after premenopausal breast cancer.

Learning Objectives:

1. To discuss the place of breast screening in pre-menopausal women.
2. To present the risk factors that define groups of women that would benefit a breast screening.
3. To evaluate the balance between risk and benefit of radiation dose.
4. To learn about the value of tomosynthesis with synth2DMG and MRI in this group of women.

A-0427 16:55

Pregnancy-associated breast cancer (PABC)

C. [Van Ongeval](#); *Leuven/BE (chantal.vanongeval@uz.kuleuven.ac.be)*

The incidence of PABC is estimated at 1:1000 to 2000 pregnancies. Initially, pregnancy-associated breast cancer (PABC) was defined as breast cancer during pregnancy or within 1 to 2 years postpartum. Because of different physiology and treatment, more appropriate definitions are: BC diagnosed during pregnancy and BC diagnosed in the postpartum period. Correct staging is essential in the selection of treatment. BCP women are almost always present with a palpable mass. Physiological changes of the breast during pregnancy may cause the patient's and doctor's delay. The differential diagnosis ranges from benign lesions (lactating adenoma, galactocele, abscess, cystic disease, fibroadenoma) to malignant epithelial BC and sarcoma or lymphoma. Local staging starts with ultrasound (US) and additional core-needle biopsy of all US abnormalities (distortion, heterogeneity of parenchyma, mass lesion). Additional evaluation of the axilla is mandatory. The physiological changes of the breast composition and lymph nodes during pregnancy and breastfeeding will be discussed. The rate of complication of CNB is low. In case of a histologically proven malignancy, to find additional information on DCIS related microcalcifications, mammography (2 views) is mandatory: radiation safety rules will be described. The sensitivity of MRI during pregnancy may be compromised by physiological changes, but also the prone position may be difficult if pregnancy is farther along. The rules of admission of intermediate and lowest risk gadolinium contrast media are described in the ESUR-contrast-medium-safety protocol. An alternative for Gd-admission is the use of diffusion-weighted (DWI) breast imaging. For systemic staging, whole-body-DWI MRI seems very promising.

Learning Objectives:

1. To become familiar with breast diseases associated with pregnancy.
2. To recognise specific characteristics of pregnancy-associated breast cancer.
3. To learn which imaging techniques could be used to investigate pregnancy-associated breast lesions and breast cancer.

A. Imaging myelin maturation disorders

N. [Wolf](#); *Amsterdam/NL*

"no abstract submitted"

Learning Objectives:

1. To learn about normal and pathological patterns of myelination.
2. To understand the role of imaging with respect to narrowing the differential diagnosis and supporting the clinical diagnosis.
3. To appreciate the importance of pattern recognition for the diagnosis of myelination disorders in children.

A-0430 16:28

B. Imaging of developmental disorders

B. [Ertl-Wagner](#); *Toronto, ON/CA (Birgit.Betina.Ertl-Wagner@sickkids.ca)*

To understand congenital abnormalities of the brain, it is important to be familiar with the embryologic development. Neuronal proliferation, migration and cortical organisation are important steps in the development of the cortex. Group I disorders of cortical development are disorders of neuronal and/or glial apoptosis or proliferation. Among these are congenital microcephalies (I.A), congenital megalencephalies (I.B), and diffuse or focal cortical dysgenesis or dysplasia (I.C). Microlissencephaly is characterised by a reduced gyration and microcephaly. Hemimegalencephaly is a hamartomatous overgrowth of one cerebral hemisphere or parts thereof. Group II disorders are disorders of neuronal migration. Among these are periventricular (subependymal) heterotopia (II.A), lissencephalies (II.B), focal subcortical heterotopia (II.C), or disorders of terminal migration, e.g. cobblestone lissencephalies (II.D). Heterotopia are defined as areas of grey matter in an ectopic location; they are isointense to the cortex. Group III disorders are disorders of postmigrational development. Among these is polymicrogyria with schizencephaly (III.A), polymicrogyria without clefts or calcifications (III.B), focal cortical dysplasia (III.C), or postmigrational microcephaly. In schizencephaly, there is a cleft that extends from the ependymal to the cortical surface, and that is lined by dysplastic grey matter. In polymicrogyria, there are too many too small gyri and sulci and an irregular grey matter-white matter interface. Important infratentorial congenital abnormalities include Chiari malformations, cystic abnormalities of the posterior fossa / the Dandy Walker spectrum, molar tooth malformations/ Joubert syndrome and dysplastic cerebellar gangliocytoma/Lhermitte-Duclos syndrome.

Learning Objectives:

1. To learn about the spectrum of developmental disorders of the brain.
2. To understand the key imaging features that lead to the correct diagnosis.
3. To appreciate the importance of making a correct imaging diagnosis.

A-0431 16:51

C. Imaging in paediatric neuro-oncology

G. [Morana](#); *Genoa/IT (giovannimorana@gaslini.org)*

Central nervous system tumours are the most common solid neoplasms in children and encompass a wide spectrum of heterogeneous neoplasms, each with its own biology, prognosis, and treatment. Paediatric brain tumours may share similarities with their corresponding adult variants, but incidence rates, locations, molecular and genetic features, and even certain histopathological characteristics are often different and thus may be considered biologically distinct entities. Conventional MRI represents the backbone of brain tumour identification and characterisation but has limitations in distinguishing tumours from tumour mimics, defining tumour grade, evaluating treatment response and predicting patient outcome. Advanced MRI modalities, such as diffusion-weighted imaging, perfusion weighted imaging and magnetic resonance spectroscopy have improved our understanding of brain tumours, overcoming some of the main limitations of conventional MRI and providing additional microstructural, hemodynamic and metabolic information of brain tumours. Beyond MRI, metabolic imaging with PET provides further insights into a tumour biological activity; indeed, PET imaging combined with MRI, either by off-line co-registration or via hybrid PET/MR systems, is emerging as a valuable imaging modality not competing with but rather complementing MRI. Depending on the radiotracer used, different molecular processes can be assessed, and a growing body of evidence supports the promising role of radiopharmaceuticals that target amino-acid transport. The contribution of these methods to the evaluation of paediatric brain tumours is the focus of the present work.

Learning Objectives:

1. To learn about the spectrum of neuro-oncological diseases in children.
2. To understand the role of imaging beyond the diagnostic process.
3. To appreciate the increasing clinical relevance of advanced imaging techniques in paediatric neuro-oncology.

Renal, adrenal and urinary tract pathologies

Moderator:

C.S. Baileyaquier; Villejuif/FR

A-0432 16:00

Renal pathologies

H.C. [Thoeny](mailto:Harriet.thoeny@h-fr.ch); Fribourg/CH (Harriet.thoeny@h-fr.ch)

The most common renal pathologies are focal renal masses (cystic or solid) and are incidentally detected on cross-sectional imaging during the workup of other pathologies. The main task of the radiologist is to categorise these lesions: cystic lesions are stratified according to the Bosniak classification, whereas solid renal masses often correspond to renal cell carcinomas; angiomyolipomas and oncocytomas as benign lesions are less frequent and sometimes show typical imaging findings. Unenhanced CT is the method of choice for the detection of renal calculi and allows to provide information on the size, location and composition of the stone as well as evaluation of upper urinary tract dilatation. Imaging to detect upper urinary tract infection is only performed in case of a search for complications such as abscesses, renal vein thrombosis and pyonephrosis needing intervention. In this context, MRI including diffusion-weighted sequences allows differentiating an abscess from a complicated cyst or a cystic renal cell carcinoma. In addition, imaging of the kidneys is also performed to detect obstruction due to various underlying diseases including intrinsic and extrinsic ureteral pathologies. For the evaluation of most renal pathologies, CT is the method of choice. In pregnant woman and children, ultrasound is preferred, whereas MRI can be helpful as a problem-solving tool to better characterise focal renal masses, to detect diffuse renal pathologies or assess pyelonephritis noninvasively, e.g. in young and/or pregnant woman or children.

Learning Objectives:

1. To review the most common pathologies.
2. To present current imaging techniques for evaluation of renal pathologies.
3. To demonstrate the most important imaging findings of the common renal pathologies.

A-0433 16:30

Adrenal pathologies

M. [Stajgis](mailto:stajgis@gmail.com); Poznan/PL (stajgis@gmail.com)

Adrenal glands can be affected by a variety of lesions. Still growing number of cross-sectional imaging worldwide has led to an increase in the percentage of incidentally discovered nodules in adrenals. According to the recent data, adrenal masses are seen up to 5-6 % of all abdominal CT examinations, more often in the older population. Therefore a strategy for determining the characteristics of these nodules at possible low cost and high effectiveness is mandatory. The role of diagnostic imaging is to differentiate benign from malignant lesions. Ultrasonography has still the role in the incidental detection of adrenal masses and in monitoring the changes in morphology and size of lesions during treatment or simple observation. CT is recognised as 'gold standard' method in evaluation of adrenal pathologies. Due to CT capability in the estimation of the quantity of fat in the defined volume, it is easy to recognise lipid-rich and lipid-poor adenomas, which represent the largest group of adrenal pathology. Multiphase CT protocols in adrenal imaging and some specific calculations based on these techniques will be presented. MR has limited indications in adrenal imaging, this method does not offer additional spatial resolution and is mainly used in patients when iodine contrast media administration is contraindicated. The simple diagnostic imaging algorithm will be presented at the end of the lecture. Some open questions will be addressed to the audience.

Learning Objectives:

1. To review the most common pathologies.
2. To present current imaging techniques for evaluation of adrenal pathologies.
3. To demonstrate the most important imaging findings of the common adrenal pathologies.

A-0434 17:00

Ureter and bladder

M.N. [Özmen](mailto:mozmen@hacettepe.edu.tr); Ankara/TR (mozmen@hacettepe.edu.tr)

Imaging has a very important role in evaluating the urinary tract. Over the past years, computed tomographic urography (CTU) has become the main imaging modality for this purpose in various clinical settings. Dose reduction techniques

have also enabled to obtain CTU's with very low radiation doses. Several anomalies of the ureter, the muscular conduit between the renal collecting system and bladder, may be seen, including duplication, muscular dysfunction (UPJ-stenosis, primary megaureter) or abnormal termination (ectopic ureteral orifice, ureterocele, vesicoureteral reflux). Intraluminal disease process in ureter might cause obstruction. Ureteral stone is by far the most frequent, with high attenuation values on unenhanced CT and independent of the chemical composition. Size of the stone is predictive of the likelihood of spontaneous elimination. A filling defect is seen on CTU usually raises the suspicion of urothelial neoplasm. Other entities such as a clot, metastasis, pyeloureteritis cystica, and tuberculosis might also (partially) obstruct the ureter and must be considered in differential diagnosis in selected patients. Urothelial cancer has to be considered as a 'systemic' disease, with often multiple, synchronous or metachronous lesions. CTU not only depicts the neoplastic lesion but also enables the examination of entire urothelium during staging or follow-up. Several treatment options are available and must be patient-tailored. In the case of hematuria, where CTU is the main diagnostic tool for upper urinary tract evaluation, cystoscopy is the primary diagnostic tool for screening for bladder neoplasms.

Learning Objectives:

1. To review the most common pathologies.
2. To present current imaging techniques for evaluation of ureter and bladder.
3. To demonstrate the most important imaging findings of the common ureter and bladder pathologies.

Blunt polytrauma: CT protocols, CT interpretation and interventional radiology options

A-0435 16:00

Chairperson's introduction

K.H. [Nieboer](mailto:koenraad.nieboer@uzbrussel.be); Brussels/BE (koenraad.nieboer@uzbrussel.be)

Blunt polytrauma patients. As radiologists, we want the highest standards on imaging, interpretation and treatment for this subgroup. But do we agree on the most optimal CT imaging protocol? Is there a "one scan fits it all whole-body CT scan protocol" solution, or can we use clinical parameters to create subgroup WBCT scan protocols? How do we describe and score solid organ injuries? Do we pay enough attention to intraparenchymatous non-vascular and vascular lesions? How can we optimise our screening technique for these injuries? Who do we call? The surgeons or our interventional radiology colleagues? What is the actual place of IR in the polytrauma setting, what is established and what is new? In this refresher course, we will highlight these questions.

Session Objectives:

1. To understand the different CT and contrast protocols that can be performed in blunt polytrauma patients and when to apply them.
2. To be able to quickly identify and classify solid organ injuries.
3. To recognise injuries that can be treated with interventional radiology.

A. CT protocols in blunt polytrauma

E. [Kashef](mailto:elikadoc@icloud.com); London/UK (elikadoc@icloud.com)

Trauma is a global pandemic with a high incidence of disability and death. Whole-body Multi-detector Computed Tomography (MDCT) is now the default imaging of choice in the severely injured patient with demonstrable results that early use improves survival. The CT imaging protocol usually includes two separate "dual-phase" arterial and porto-venous phases of the Chest, abdomen and pelvis. Some centres perform an unenhanced CAP CT first, which is becoming less commonplace due to the delay to treatment with little clinical yield. At our centre, patients with blunt or major trauma undergo single-pass biphasic or "combi" CT imaging. However, patients with penetrating injuries or major haemorrhage protocol activation continue to undergo the classic dual-phase imaging. The standard Dual-phase and Combi scan can diagnose or exclude solid organ injury including, liver, spleen, pancreas, kidney injuries as well as hollow viscous injuries which will be shown at this lecture. Imaging in urogenital and Neck injuries require extension or modification of the classic protocols, which can aid in the diagnosis of supra-aortic or non-vascular renal injuries. Follow up imaging in solid organ injury is equally important as delayed bleeding and pseudoaneurysm formation are associated with

M. Smits; Rotterdam/NL

A-0439 16:00

An overview of the roles of radiographers in research

J. McNulty; Dublin/IE (jonathan.mculty@ucd.ie)

Research and evidence-based practice (EBP) underpin modern healthcare and can lead to enhanced patient safety, improved patient outcomes, and efficiencies in service delivery. The contribution of radiographers, academic and clinical, to this evidence through undertaking quality research, and subsequent dissemination is essential and will also serve to raise the profile and standing of radiographers beyond our profession. This applies equally to all three recognised branches of the profession: medical imaging, nuclear medicine, and radiotherapy. Radiographers are much more than facilitators, or data providers, in medical imaging research and some of the leading radiography researchers in the world can be found in Europe. These individuals lead large research groups, successfully compete for national and international research funding, collaborate beyond their profession, and publish in high-impact journals. In 2016, the European Federation of Radiographer Societies (EFRS) published a Statement on Radiography Research which clearly sets out the EFRS position on encouraging, supporting and developing high-quality radiographer-led research in order to strengthen our professional knowledge base. This statement, together with the 2015 Statement on Evidence-Based Practice in the Undergraduate Curriculum, and the European Qualifications Framework (EQF) Level 6(Bachelors) and Level 7(Masters) Benchmarking documents for radiographers, clearly set-out the importance of clear research focus in educational programmes. Radiographers can add value at all stages of the research process and for medical imaging or radiation oncology research to have a true impact and to benefit our patients it must be inclusive and multidisciplinary and span the academic-clinical divide.

Learning Objectives:

1. To understand how professional development is supporting the development of radiographer research roles.
2. To consider the opportunities for radiographer research.
3. To gain an insight into the impact of radiographer research in improving patient outcomes.

A-0440 16:20

Establishing the scientific and clinical value of advanced imaging

M. Smits; Rotterdam/NL (marion.smits@erasmusmc.nl)

In this presentation, glioma is used to exemplify the current challenges on oncological imaging. Gliomas constitute a group of tumours with heterogeneous clinical behaviour, with many therapeutic agents under investigation for their effectiveness. The assessment of treatment effect is not without difficulty. It is on the one hand hampered by therapy-related changes which can be indistinguishable from tumour progressions, such as pseudoprogression or radiation necrosis; and on the other hand by a phenomenon called pseudoresponse, occurring in the context of anti-angiogenic treatment, in which contrast enhancement diminishes unrelated to an actual anti-tumoural effect. New, preferably quantitative, markers of response are desperately needed to assess treatment response as accurately and early as possible within the context of a clinical trial. Furthermore, recent insights indicate that the clinical heterogeneity of glioma behaviour can - at least in part - be attributed to the tumour genotype. In the context of clinical trials, it is adamant that patients are correctly stratified according to their tumour genotype, which at this point in time can only be determined from tumour tissue acquired through biopsy/surgery. To avoid such invasive procedures, as well as to obtain a full overview of the tumour and its heterogeneity, and to be able to follow changes over time, advanced imaging can play an important role using a radiogenomic approach. In this presentation, I will discuss the current and potential imaging markers of glioma biological behaviour and response to treatment, and the challenges for implementation in clinical, multicentre trials.

significant mortality. By integrating radiology into the ABCDE approach of trauma care, we can ensure the correct protocol and imaging pathway is personalised per trauma case while following the most optimal protocol.

Learning Objectives:

1. To understand the advantages and disadvantages of different CT protocols adopted in blunt polytrauma patients.
2. To learn the goal in the use of single and dual phase contrast injection protocols in trauma.
3. To become able to incorporate the most suitable CT protocol in defined clinical scenarios.

A-0437 16:30

B. Solid organs injuries: a tailored approach

M. Patlas; Hamilton, ON/CA (patlas@HHSC.CA)

Multi-detector computed tomography (MDCT) is the modality of choice for the comprehensive imaging evaluation of solid organ injuries in clinically stable patients with blunt abdominal trauma. In spite of the high sensitivity of MDCT for detection of vascular injuries in solid organs, in trauma centre audits, the disproportionate number of misses resulting in mortality (a quarter of patients) are caused by delayed intervention for haemorrhage. The presentation will focus on the critical imaging features of blunt solid organ injuries, particularly vascular injuries (haemorrhage, pseudoaneurysms, and arteriovenous fistulae) of solid organs. The presentation will also review numerous challenges in accurate prospective MDCT detection of blunt pancreatic injuries. The role of emergency/trauma radiologist in time management and proper communication of these complex injuries will be elucidated. The misses and misinterpretations related to suboptimal technique and inadequate follow up of critical solid organ injuries will be highlighted. The scenarios requiring interventional radiology and /or surgical intervention will be discussed. Recent radiological and surgical literature will be reviewed.

Learning Objectives:

1. To learn about the main traumatic injuries to be detected in solid organs.
2. To understand which crucial findings will change patient management.
3. To understand what surgical and intensive care teams need to know about detected injuries.

A-0438 16:55

C. Interventional radiology in trauma: diagnosis and management

T. Jargiello; Lublin/PL (tojarg@interia.pl)

Blunt trauma may affect any part of the human body. It is devastating because of high kinetic energy usually evoked by motor vehicle accidents or fall from elevations. The most serious conditions are blunt injuries of abdominal solid organs and great vessels. When we consider solid organ blunt trauma we think of the liver, spleen and kidneys. Frequent venous injuries of the liver are usually treated conservatively when stable, and they need surgery in unstable patients. Arterial hepatic trauma is subjected to embolisation. Management of splenic injuries is controversial, but surgeons operate most of them. Renal injuries are less common but when active extravasation happens endovascular therapy is the first-line treatment. Among great vessels, the aorta is the most frequently injured. A spectrum of injury includes aortic transection, false aneurysm and less common dissection. Majority of these injuries are located at isthmus. Aortic root or descending aortic injuries are less frequent as well as iliac or mesenteric transections. Aortic stent-grafts or covered stents are a very good solution in these cases. Conversely, venous interventions (especially IVC rupture) usually need immediate surgery. Traditionally, endovascular methods were offered to hemodynamically stable patients. Now the role of IR increased greatly, and there are lots of encouraging data of unstable patients treatment. Minimally invasive embolisation and stent-grafting have much to offer as the definitive treatment or as an initial adjunct before surgery. The use of hybrid rooms giving both methods of treatment at the same time is possibly the best choice.

Learning Objectives:

1. To learn which vascular injuries in solid organs can be treated with interventional radiology.
2. To become familiar with the imaging findings of great vessel injuries.
3. To understand how vascular injuries can be treated.

17:20

Panel discussion: What is the best CT protocol in the evaluation of blunt trauma patients?

Learning Objectives:

1. To understand the importance of imaging in supporting oncology research.
2. To learn about the range of trials evaluating imaging techniques.
3. To appreciate the importance of team working in enabling effective research.

Fostering excellence in radiation oncology research through a clinical research culture

H. [McNair](#); London/UK (Helen.McNair@rmh.nhs.uk)

Research provides the evidence base for good clinical practice and is an essential component of any health care delivery service. However, conducting research in the clinic by radiography and radiotherapy staff can be difficult. Few research mentors may be available because of the lack of clinical academic positions. Clinical service takes priority when there are staff and time pressure. To create a research culture within these constraints is often difficult but not unachievable. Clinical staff are best placed to pose and answer research questions around the patient pathway and patient technology interface. The first step is to define a research question, consider what needs to be measured and the tools required to measure. The research method may be an audit, service evaluation or trial. Audits are extremely useful tools and are easily accessible to clinical staff. BSc(Hons) educated radiographers, having developed their research skills in training should be ready to engage in research on qualification. Postgraduate courses can also be a driver. Patient and public input (PPI) from idea conception to the dissemination of results is essential. PPI gives insight into the research question from the patient perspective and is essential when developing patient information sheets. To apply for funding output is critical, posters, presentations and papers. Finally, examine the academic pathways of doctors, physicists and other allied health professionals to determine if a similar academic career path can be created for radiography. Radiographers are an essential part of research activity.

Learning Objectives:

1. To understand the barriers and enablers which impact upon delivering effective research.
2. To learn how clinical departments can utilise the resources already available with the goal of developing a more confident and competent clinician-researcher culture.
3. To appreciate the importance of patient and professional input into trial design.

A-0442 17:00

Radiation therapy quality assurance (RTQA) in clinical trials: the role of the radiographer/radiation therapy technologist

M. [van Os](#); Rotterdam/NL (m.j.h.vanos@erasmusmc.nl)

The European Organisation for Research and Treatment of Cancer (EORTC) is involved in many multicentre trials in Radiotherapy. It is mandatory that included patients are treated similarly in all internationally participating institutes, and that outcome of the treatment is consistent for analysis. Therefore quality assurance per trial is required checking the equipment and procedures per participating institute. Within the Radiation Oncology Group, this task is assigned to the multidisciplinary RTQA-team consisting of radiation oncologists, physicists and radiotherapy technologists (RTTs). While overall survival or progression free survival are common endpoints to many trials, secondary endpoints often include toxicity. Since radiation induced toxicity is related to delineated volumes, it is of importance that the outlining of the organs at risk (OAR) is performed consistently enabling to ascribe differences in outcome to treatment and discrepancies in OAR delineation. It is also important to be able to disentangle radiation-induced from drug-induced toxicities. However, delineation has proven to show large interobserver variability and especially in delineation of OAR there often is no consensus on clear guidelines. While increasingly more RTTs are involved in the process of treatment planning and volume delineation, the RTT subcommittee initiated the RTQA Delineation Project aiming to develop clear guidelines for OAR delineation in EORTC trials. In this presentation, I will describe the role of RTTs within the EORTC RTQA-group initiating a delineation study on OAR in the male pelvic area and consequently analysing and improving volume definition during two EORTC trials by means of questionnaires and delineation workshops.

Learning Objectives:

1. To understand the essential role of the radiographer/radiation therapy technologist in RTQA.
2. To appreciate the potential impact of poor RTQA practices on clinical trials.
3. To consider best practice in multi-centre RTQA for clinical trials.

MR imaging of the knee

Moderator:

M. Tzalonikou; Athens/GR

A-0443 16:00

A. Cruciate ligaments: what to know and what to do

A. [Alcalá-Galiano](#); Madrid/ES (aalcalagaliano@gmail.com)

Cruciate ligaments play a key role in knee kinematics and stability. Cruciate-deficient knees are predisposed to early osteoarthritis due to chronic instability. ACL is the most commonly injured major ligament of the knee. PCL lesions are far less common, but more frequently associated with multiligamentous injuries. MRI is the study of choice to evaluate acutely and chronically injured cruciate ligaments, associated injuries and for postoperative imaging following ligament reconstruction. Understanding the variations of their anatomy (double bundle configuration and insertion sites) is key to performing a tailored anatomic reconstruction. Accurate description and grading of cruciate tears and associated injuries are essential for preoperative planning of ligament reconstruction. Primary and secondary signs and indirect imaging findings of acute and chronic ligament injury will be reviewed. Atypical findings and imaging pitfalls will also be discussed. ACL reconstruction is one of the most common orthopaedic procedures, while PCL reconstruction is on the rise. Knowledge of ligament reconstruction techniques allows differentiation of normal postoperative findings from complications, which may be related to graft placement, the graft itself or the donor site. Any standard knee MRI protocol must ensure adequate detection of both soft tissue and bony injury, including the cruciate ligaments. However, protocols may be tailored for specific needs, including oblique acquisitions, 3D or metal artefact reduction sequences to better demonstrate the anatomy and facilitate detection of small tears.

Learning Objectives:

1. To describe the normal anatomy and MR imaging appearances of ACL and PCL and discuss pitfalls.
2. To explain the imaging appearances of ACL and PCL pathology and discuss imaging sequences and protocols.
3. To discuss the imaging sequences and protocols relevant to ACL and PCL conditions.

A-0444 16:30

B. Meniscal tears: obvious and subtle

P. [Omoumi](#); Lausanne/CH (patrick.omoumi@chuv.ch)

This lecture will review the basic aspects of MRI of meniscal pathology, including some elementary technical and anatomical considerations, as well as the description of the basic semiology of meniscal tears and their classification. Common pitfalls and errors that need to be avoided will be presented. MRI is the modality of choice for the diagnosis of meniscal pathology as well as treatment planning. A certain number of technical considerations need to be understood by the radiologist. The standard sequence to image the meniscus is intermediate-weighted fast spin-echo sequences, in 2D or 3D. Certain acquisitions parameters may influence the diagnosis of meniscal tears, including the choice of the echo time. Meniscal tears can manifest either as morphological changes or intrameniscal signal changes, with specific diagnostic criteria that will be reviewed. An appropriate terminology, based on standard arthroscopic classifications, needs to be used by the radiologist in order to properly communicate the description of the tear to the referring surgeon. Secondary signs of meniscal tears, including parameniscal cyst and meniscal extrusion, should be used to increase the diagnostic performance for the presence of meniscal tears. Common pitfalls include anatomical variants (i.e. inter-meniscal meniscal and menisco-femoral ligaments, discoid meniscus), as well as other causes for false positive findings such as meniscal flounce, CPPD and meniscal ossicles. Knowledge of common mistakes and patterns of injury helps avoid unnecessary mistakes and improve diagnostic accuracy.

Learning Objectives:

1. To describe the anatomy of the menisci and the classification of meniscal tears.
2. To explain unusual imaging appearances of meniscal tears and potential pitfalls.

Postgraduate Educational Programme

A-0445 17:00

C. Looking around the corners: posteromedial and posterolateral
U. [Aydingoz](#); Ankara/TR (uaydingo@hacettepe.edu.tr)

Posteromedial and posterolateral corners of the knee (PMC, PLC) can be injured along with anterior (and, less commonly, posterior) cruciate ligament tears. If an injury to the PMC and/or PLC is not properly addressed, cruciate ligament surgery may fail. Although rare, isolated injuries to the PMC and PLC may also occur. Radiologists need to be familiar with the MR imaging appearances of the PMC and PLC structures, and their injury patterns. Semimembranosus is the principal stabiliser of the PMC, while posterior oblique ligament is the main PMC structure that needs repair or reconstruction after an injury to this corner. Popliteus tendon is the key structure that helps in identifying on MR imaging the arcuate and popliteofibular ligaments at the PLC.

Learning Objectives:

1. To describe the anatomical structures of the posteromedial and posterolateral corners of the knee.
2. To explain the imaging appearances of pathological conditions that affect the posteromedial and posterolateral corners of the knee.

The 3D printing lab from bench to bedside

A-0446 16:00

Chairperson's introduction

F. [Kainberger](#); Vienna/AT (franz.kainberger@meduniwien.ac.at)

3D printing has been in use for medical applications since more than 20 years but is currently under strong technological development as the use of machine types for 3D printing labs has become more feasible with improvements in spatial resolution. Radiologists have to define the role of biomedical imaging within this interdisciplinary field, in which advances are mainly driven by surgeons and medical physicists. Current clinical applications of 3D printing are mainly in cardiovascular interventions, maxillofacial, orthopaedic and trauma surgery as well as in health economy. Major goals are the customising surgical devices, personalised surgical training with a focus on complex anatomic situations, and patient empowerment by explaining the procedures with a 3D print. Non-clinical applications are in classic anatomy and related disciplines for educational purposes. With 3D printing, the radiological workflow is changing dramatically, as it is moving from the traditional stepwise referral-report approach to a totally different device-oriented process. There are trends to centralise 3D printing which, on the other hand, have a high potential for personalising the radiological service. As such, 3D printing should be regarded as a holistic approach and substantially influences the personalisation of imaging diagnostics with a prognostic, a preventive and a participatory impact.

Session Objectives:

1. To understand the requirements for building a 3D printing lab.
2. To learn the assessment of the impact of 3D printed models for cardiovascular interventions.
3. To understand the value of customising surgical tools and prostheses and to inform the patient.
4. To become familiar with the management changes due to centralised 3D printing.

A-0447 16:05

Creating a 3D printing lab in radiology

F. [Moscato](#); Vienna/AT (francesco.moscato@meduniwien.ac.at)

As 3D printing and its role in medicine receive greater attention, dedicated labs with this focus become more and more common. When planning such a 3D lab an understanding of the variety of different available principles, technologies, methods, and printed material properties is necessary. This technological understanding is complemented by the appreciation of the central role clinical imaging plays. In particular how image planning, resolution and overall image quality impact the whole process of 3D printing. Finally, creating a 3D printing lab takes on the challenges of combining and coordinating knowledge from different technical and clinical disciplines while at the same time guaranteeing strict adherence to medical regulations. In this talk, all these key aspects for the establishment of a 3D printing lab will be discussed drawing upon state-of-the-art knowledge, best practices and examples at our Institution.

Learning Objectives:

1. To learn the principles of 3D printing in terms of printer technology, methods, properties of printed material and other requirements when planning a 3D lab.
2. To appreciate and specify the role of radiologists in image planning during the 3D printing process.
3. To understand the correlation of spatial resolution and other image quality parameters among 3D printing, 3D and 2D visualisation.

A-0448 16:23

Cardiovascular applications of 3D printing

M. [Tam](#); Southend/UK (matthewtam2005@gmail.com)

How to print your first vascular model? I will share personal experience into all steps of the printing process, from patient to model, using aortic aneurysms as cases. The various steps from image acquisition, DICOM editing, segmentation, the creation of a printable mesh or STL file, through to the final print are discussed. What is the current state of the art? A literature review and multi-source update into cardiovascular applications are offered. From bench to bedside! Personal insights are offered on the potential value and limitations of embedding 3D printing into a hospital practice from different perspectives - that of a clinician, but also from business and entrepreneurial perspectives.

Learning Objectives:

1. To learn the potential applications for aortic and cardiac diseases to facilitate decision making.
2. To appreciate the impact of 3D models for interventional treatment planning.
3. To understand the value of 3D models for diagnosis and treatment in situations with complex anatomy.

A-0449 16:41

Supporting the surgeon with 3D printing

P. [Brantner](#); Basle/CH (philipp.brantner@usb.ch)

3D Printing is becoming an increasingly relevant part of the surgical workflow. It has the potential to improve patient care, shorten operating time and reduce costs in surgical interventions. The lecture will introduce three main concepts with which 3D printing can help the surgeon: anatomical representation, virtual surgery and customised training models. While anatomical models will help surgeons to understand complex anatomy before surgery and allow to pre-contour plates, virtual surgery serves as a template to create patient-specific jigs and guides as well as patient-specific implants. 3D prints can also be used for training purposes allowing residents to become more proficient in common procedures while helping experienced surgeons to prepare for difficult cases. Specific examples will be shown for each concept illustrating how 3D printing can be a radiologic extension to improve patient outcome.

Learning Objectives:

1. To learn the standardised and the emerging surgical applications of 3D printing and their dependency on the anatomic complexity.
2. To appreciate the high potential in customizing and shortening the workflow of planning, pre-contouring and conducting surgery.
3. To understand the potential of 3D printing as an extension of diagnostic imaging with view on patient outcomes.

A-0450 16:59

Challenges of centralised 3D printing

K.A. [Eley](#); Cambridge/UK (Karen.a.eley@gmail.com)

Three-dimensional (3D) printing continues to attract considerable attention in the medical community, fuelled by improvements in technology and an associated reduction in costs. However, capital investment for high-end 3D printers (which provide the accuracy required for complex anatomical shapes), combined with the annual maintenance and software licensing fees remain prohibitive for many hospitals, particularly those within the National Health Service (NHS). Housing 3D printing services within the hospital afford a number of advantages, including close communication during image preparation to ensure that the resultant 3D model meets the expectations of the requesting clinician. Whilst individual clinical departments have strived to acquire their own 3D printers. This is not the most cost-effective solution due to replication of costs, including the time commitment for segmentation and post-processing of 3D models. In an attempt to address these issues, we established a fully centralised 3D printing facility employing a full-time dedicated 3D technician. The interdisciplinary approach of centralisation results in a cross-pollination of ideas and provides a centre point of expertise benefitting all specialities across the hospital and wider community. However, centralisation is not without its challenges. The ever-tightening financial constraints of the NHS requires ongoing adaptation and innovation to ensure long-term sustainability.

Learning Objectives:

1. To learn the strategies behind a centralisation of 3D printing.
2. To appreciate the potential added value of sharing biomedical print files and other data related to 3D printing.
3. To understand the workflow changes and the potential of quality control and education in treatment planning with 3D printing support.

Challenging HRCT patterns: tips and tricks from the experts

A-0451 16:00

Chairperson's introduction

J. Babar; Cambridge/UK (jude_babar@yahoo.co.uk)

In this session, the focus will be on the central role of HRCT in investigating a broad spectrum of pulmonary diseases. The session aims at demonstrating the pathophysiological correlation of the principal imaging patterns encountered on CT, (airspace disease, nodules and reticulation), and the significance of these patterns in diagnostic decision-making, clinical outcomes and prognosis.

Session Objectives:

1. To understand HRCT patterns in relation to the anatomy of the secondary pulmonary lobule and small airways.
2. To revise the causes and pathologies of various HRCT patterns with case based examples and image interpretation pearls.
3. To revise how the pattern and distribution of disease helps in formulating a differential diagnosis.

A-0452 16:05

The mosaic attenuation pattern

M.-P. Revel; Paris/FR (marie-pierre.revel@aphp.fr)

The mosaic attenuation pattern is characterised by a patchwork of regions of decreased, normal and increased attenuation. If there is no asymmetry of vessels among the different regions, the mosaic attenuation pattern usually represents patchy interstitial disease, characterised by focal ground-glass opacity. In this situation, areas of increased attenuation represent the diseased lung whereas areas of lower attenuation represent the normal lung. When there is an asymmetry of vessels among areas of increased and decreased attenuation, this should be termed mosaic perfusion. There are two main causes of mosaic perfusion. The first one is occlusive vascular disease, during which there is a redistribution of the arterial pulmonary blood flow towards lung areas which remain patent. The areas of increased attenuation represent the preserved lung, showing more numerous vessels or vessels of larger size than hypodense areas, corresponding to occluded lung areas. The second cause of mosaic perfusion is an obstructive bronchial disease. There is vasoconstriction in lung areas with abnormal ventilation, causing the redistribution of the pulmonary arterial blood flow towards normally ventilated lung areas.

Learning Objectives:

1. To understand the pathophysiology of mosaic attenuation pattern.
2. To revise the common causes.
3. To discuss the common pitfalls in diagnosis.

A-0453 16:20

Inter-and intralobular septal thickening

N. Sverzellati; Parma/IT

A number of linear abnormalities may be evident on HRCT scans, including either interlobular septal lines and intralobular opacities. Interlobular septal thickening is the most diagnostically useful. Thickening of interlobular septa may be seen in conditions associated with dilatation of the pulmonary veins, infiltration of the pulmonary lymphatics, or with infiltration of the pulmonary interstitium by cells, fluid, or fibrosis. Thickened septa should be characterised as smooth, nodular, or irregular. Smooth interlobular septal thickening is commonly seen with pulmonary oedema and lymphangitic carcinomatosis, although nodular interlobular septal thickening is more characteristic of the latter disease. Intralobular interstitial thickening reflects infiltration and thickening of the interstitial framework of the secondary pulmonary lobule and may be caused by pulmonary fibrosis or inflammation in the absence of fibrosis. When underlying fibrosis is present, the reticulation often appears coarse, and traction bronchiolectasis and architectural distortion may also be seen.

Learning Objectives:

1. To understand the pathophysiology of this pattern.
2. To revise the common causes.

A-0454 16:35

Approach to nodular pattern

O. Hamer; Regensburg/DE (okka.hamer@klinik.uni-regensburg.de)

Multiple lung diseases present with multinodular densities as the dominant feature. The differential diagnosis can be challenging though is of utmost importance for guiding therapy. In order to determine the correct diagnosis, several aspects should be considered: First, the imaging modality of choice is HRCT. Second, nodule morphology in terms of size, margination and density has to be evaluated. Third, the distribution of nodules relative to the pulmonary lobule must be determined. Here the radiologist should be familiar with three different distribution patterns, namely centrilobular (with tree-in-bud as a subtype of centrilobular), perilymphatic and random. Fourth, collateral HRCT findings, clinical, functional and laboratory data have to be integrated into radiological considerations. When considering these aspects in most cases, a short list of differentials including the most likely diagnosis can be given. The talk will give a review of anatomic considerations regarding the pulmonary lobule. Differences in nodule morphology will be highlighted. A step-by-step analysis of HRCT images in order to determine nodule distribution will be presented. Differential diagnoses will be discussed.

Learning Objectives:

1. To understand the pathophysiology of this CT pattern.
2. To revise the common causes.
3. To discuss the common pitfalls in diagnosis.

A-0455 16:50

Perilobular consolidation

T. Frauenfelder; Zurich/CH (thomas.frauenfelder@usz.ch)

If you search with the search term "perilobular consolidation" in the PubMed, you will find exactly 11 publications. Anatomically the perilobular region is defined as the region bordering the periphery of the secondary lobulus. In the glossary of the Fleischner Society, the perilobular consolidation or pattern is characterised by the alteration of the structures that border the pulmonary lobules (i.e., interlobular septa, visceral pleura, and vessels). The appearance on HRCT is bowed or polygonal opacities with poorly defined margins around the interlobular septa, whereas the thickening is related to the activity of the disease. Perilobular opacities are accompanied by consolidation and/or GGO in the same region. The term has the close relation to organising pneumonia.

Learning Objectives:

1. To understand the pathophysiology of this CT pattern.
2. To revise the common causes.

A-0456 17:05

Mixed ground-glass opacification and reticulation

S.J. Copley; London/UK

"no abstract submitted"

Learning Objectives:

1. To understand the pathophysiology of this combined CT pattern.
2. To revise the common causes.
3. To discuss the common pitfalls in diagnosis.

Predicting fracture risk in children

A-0460 16:00

Chairperson's introduction

K. [Halliday](mailto:kath.halliday@nuh.nhs.uk); Nottingham/UK

Assessment of fracture risk in children and babies is of vital importance, not only in those children who are known to have issues with their bone health but also in cases of suspected physical abuse. Issues around bone density and strength often arise both clinically and in court and it is essential that any radiologist involved in the care of children is conversant with new developments in this rapidly changing field. This promises to be an excellent session with an overview of all available techniques.

Session Objectives:

1. To learn the diverse factors that may influence fracture risk in the paediatric population.
2. To understand the role of the various techniques in predicting fracture risk in children.
3. To discuss the limitations of the different techniques.

A-0461 16:05

A. Radiographs and DXA

R.A.J. [Nivelstein](mailto:R.A.J.Nivelstein@Utrecht.nl); Utrecht/NL

Fractures are common in children. It is estimated that by the age of 16 years about 50% of boys and 30% of girls will have sustained a fracture, whereas 20% of children will have sustained 2 or more fractures. The major challenge of the clinician lies in the early detection of those children with skeletal pathologies related to an increased risk of fractures. Investigations of those children at risk are aimed to determine whether the child is suffering from an underlying bone fragility disorder and its aetiology in order to guide management. Besides laboratory investigations, radiology plays an important role in the diagnosis and follow up of these children, and Conventional Radiography (CR), as well as Dual-Energy X-Ray Absorptiometry (DXA), are often the imaging techniques of the first choice. This lecture will focus on the role of CR (including Digital X-ray Radiogrammetry (DXR) of the hand) and DXA in the assessment of bone health and prediction of fractures in children. Strengths and limitations of the different techniques will be discussed, and guidelines for its use in daily practice will be presented.

Learning Objectives:

1. To learn about the principles for the technique.
2. To understand the potential for use.
3. To discuss the limitations.

A-0462 16:23

B. Quantitative ultrasound

H.-J. [Mentzel](mailto:hans-joachim.mentzel@med.uni-jena.de); Jena/DE

Quantitative ultrasound (QUS) of bone is intended for identifying the children who could have an increased risk of osteoporosis in adulthood. QUS is a safe, portable, easy to use and cheap technology for the estimation of bone quality. Measurements can be performed on peripheral skeletal sites (calcaneus, tibia, phalanges), but not on the spine. Several parameters are used to estimate bone elasticity and stability, the speed of sound and broadband ultrasound attenuation. Using age and sex-matched reference values QUS Z-scores can be calculated in children. QUS Z-scores cannot be compared to the golden standard DXA scores. The number of false positives or negatives obtained with QUS depends on the cut-off value utilised. QUS may be a screening method at the moment and can be used to monitor patients previously diagnosed on osteoporosis.

Learning Objectives:

1. To learn about the principles for the technique.
2. To understand the potential for use.
3. To discuss the limitations.

Author Disclosure:

H.-J. Mentzel: Consultant; Bayer Schering, Siemens. Equipment Support Recipient; Sunlight. Research/Grant Support; Bayer, Bracco, Novartis, Sunlight. Speaker; Bayer, Bracco, Novartis, Pflizer. Other; Scientific societies (ECR, DRG, GPR, DEGUM, TGRN).

additional lesions. In addition, they offer the potential for a more efficient "one-stop-shop" imaging approach. Iterative reconstruction algorithms and faster processing power facilitate radiation dose reduction and increased image resolution. The clinical utility of SPECT/CT is diverse, and a cross-spectrum of applications in musculoskeletal, oncological, cardiological, endocrine, hepatobiliary and GI tract imaging will be presented.

Learning Objectives:

1. To learn the basic principles of hybrid SPECT/CT imaging.
2. To understand what complementary information can be provided by SPECT/CT.
3. To learn the clinical applications of SPECT/CT.

A-0458 16:30

B. Hybrid imaging with PET/MRI

F.M.A. [Kiessling](mailto:kiessling@ukaachen.de); Aachen/DE

In this talk, an overview of the technological state of the art in PET-MRI, as well as an outlook on emerging new technologies, will be provided. In this context, there will be a brief explanation of new detector set-ups providing higher sensitivity and spatial resolution as well as methods to improve absorption correction and quantification. Furthermore, new PET-insert solutions for Preclinical Research and clinical application will be highlighted. An example of the latter, the concept and initial results for a new PET-insert dedicated to human Breast imaging will be presented. In the final part of the talk, the focus will be set on the medical applications of PET-MRI. In this context, it will be discussed, which applications inevitably demand PET-MRI hybrid imaging. Thus, with this talk, I will try to convince the audience of the high potential and clinical value of PET-MRI and its potential future role in patient management.

Learning Objectives:

1. To learn the basic principles of hybrid PET/MRI.
2. To understand what new information can be provided by PET/MRI.
3. To learn about emerging clinical applications of PET/MRI.

A-0459 17:00

C. Hyperpolarised MRI

F.A. [Gallagher](mailto:gallagher@cam.ac.uk); Cambridge/UK

There is increasing evidence to support a role for metabolism in tumour development; for example, deregulation of cellular energetics is considered to be one of the key hallmarks of cancer. Changes in tumour metabolism over time are now known to be early biomarkers of successful response to chemotherapy and radiotherapy. There are a number of imaging methods that have been used to probe cancer metabolism: the most widely available is 18F-fluorodeoxyglucose (FDG), an analogue of glucose, used in PET. Hyperpolarised carbon-13 MRI (13C-MRI) is an alternative and emerging molecular imaging method for studying cellular metabolism. This technique allows non-invasive measurements of tissue metabolism in real-time. To date, the most promising probe used in conjunction with hyperpolarised MRI has been 13C-labelled pyruvate: pyruvate is metabolised into lactate in normal tissue in the absence of oxygen, but in tumours, this occurs very rapidly even in the presence of oxygen. Results from many animal models have shown that there is a reduction in the metabolism of pyruvate following successful treatment with chemotherapy. Tumour lactate labelling has also been shown to correlate with the grade of some tumour types. There are now a small number of sites performing human hyperpolarised carbon-13 MRI imaging. This talk will discuss the progress that has been made in this field within the area of oncology and potential clinical applications.

Learning Objectives:

1. To learn the basic principles of hyperpolarisation.
2. To understand what new information can be provided by hyperpolarised MRI.
3. To learn about oncological and non-oncological applications of hyperpolarised MRI.

Author Disclosure:

F.A. Gallagher: Grant Recipient; GSK. Research/Grant Support; GE healthcare, Medimmune.

A-0463 16:41

C. Bone quantification with MRI

C. [Raiapakse](#); Philadelphia, PA/US

Millions of people worldwide suffer from bone diseases, predisposing them to fractures and related comorbidities that have devastating consequences. Imaging plays an important role in fracture risk assessment, diagnosis, staging, and treatment monitoring of patients with bone diseases. In particular, the flexibility of MRI has paved the way for non-invasive assessment of bone quality at multiple levels, including trabecular and cortical bone. For example, it is now possible to assess many aspects of bone quality in patients using MRI, including trabecular bone microstructure, cortical bone porosity, bone water content, bone mineral density, marrow composition, and bone strength. Specific MRI pulse sequences used for bone imaging include SPGR, CSI, UTE/ZTE. Many of these new MRI techniques have been developed and applied for assessment of bone quality in adults. This lecture will discuss how pediatric bone imaging could potentially benefit from novel MRI methods.

Learning Objectives:

1. To learn about the principles for the technique.
2. To understand the potential for use.
3. To discuss the limitations.

A-0464 16:59

D. CT (including HRpQCT)

A.C. [Offiah](#); Sheffield/UK (amaka.offiah@nhs.net)

The advantages of quantitative computed tomography (QCT) over the more commonly utilised dual-energy x-ray absorptiometry (DXA) include its ability to distinguish cortical from trabecular bone and its ability to assess the geometric properties of the bones using finite element (FE) engineering techniques. QCT using standard clinical scanners may be performed at central (spine) or peripheral (distal radius or tibia) sites. Radiation dose deters the use of central QCT as a primary tool for assessing bone health in children. The maximum resolution of peripheral QCT (pQCT) with standard scanners is approximately 600µm. Dedicated portable pQCT scanners exist, with a resolution of 200µm, and recently, high-resolution pQCT scanners (HRpQCT) have been developed with a resolution around 80µm. This presentation will review the techniques of QCT, pQCT and HRpQCT, comparing the advantages and disadvantages of each in the paediatric population. Using images from healthy children and those with osteopenic conditions for illustration, the talk will cover the parameters that can be determined, including finite element analysis and show how (or if) any of these parameters correlate with bone strength/fracture risk. A few minutes will be used at the end to demonstrate how CT can be used to develop FE models to assess the fracture mechanism. By the end of the talk, delegates will be in a position to develop an informed opinion as to whether CT can be used to predict fracture risk in children.

Learning Objectives:

1. To learn about the principles for the technique.
2. To understand the potential for use.
3. To discuss the limitations and disadvantages of this technique.

RC 816

Multidisciplinary approach to cancer care

A-0465 16:00

Chairperson's introduction

R.H. [Oyen](#); Leuven/BE (Raymond.Oyen@uzleuven.be)

The multidisciplinary team approach has become widely accepted in the care of cancer patients. Radiologists must be part of the team as an expert consultant in imaging, advising and/or performance of imaging-guided diagnostic and therapeutic procedures, and must contribute to outlining future imaging strategies in the individual patient. Preparation of the cases to be discussed, active participation and continuous education are essential prerequisites for radiologists to become/remain a respected partner of the team. Care for the individual patient is at least as important as care or adherence to guidelines or rules.

Session Objectives:

1. To learn about the role of the radiologist in the multidisciplinary team for soft tissue, colorectal and breast tumours.
2. To understand the relevant questions from the team and how they can be answered with imaging.
3. To review current multidisciplinary approaches and potential difficulties.

A-0466 16:05

A. The soft tissues team

E. [Khristenko](#); Heidelberg/DE (ekkasatkina@gmail.com)

The role of radiologists is crucial in diagnosis and differentiation of malignant and benign soft tissue tumours. MRI is the most sensitive tool in local staging and assessment of resectability such as neurovascular encasement, contact between tumour, vessels and nerves. Regrettably, it's not always possible to make a correct assessment of malignancy grade by preoperative imaging, but radiological studies are the best tool for biopsy planning, for CT/US-guided biopsies and incisional/excisional biopsies. The most complicated issue in postsurgical follow up examinations is the ability to distinguish between local recurrence and postoperative or post-radiation changes, which can be very prominent and cause confusion. The important questions to radiologist are the differentiation between tumours and tumour mimics, as the next step to distinguish between benign and malignant tumours and the assessment of resectability. As neoadjuvant chemotherapy is increasingly used for patients with locally advanced and high-risk primary malignancies, also the role of MRI is emerging for response evaluation. The difficulty in the interpretation of imaging and histology in soft tissue tumours, wide selection of treatment modalities and the complexity and intensity of the treatment contribute to the need for systematic multidisciplinary team management. In our institution, we use a personalised, multidisciplinary approach with each case being reviewed on tumour board, which includes orthopaedic oncologist, tumour surgeon, oncologist, pathologist and MSK-radiologist. Plastic or vascular surgeons could be involved if needed. As treatment protocols may vary significantly depending on the correct interpretation of imaging, the role of a radiologist is critically important.

Learning Objectives:

1. To learn about the role of the radiologist in the evaluation, treatment planning and follow up of soft tissue tumours.
2. To understand the relevant questions from the team and how they can be answered with imaging.
3. To review current multidisciplinary approaches: how we do it in our institution.

A-0467 16:28

B. The colorectal team

R.G.H. [Beets-Tan](#); Amsterdam/NL

"no abstract submitted"

Learning Objectives:

1. To learn about the role of the radiologist in the evaluation, treatment planning and follow up of colorectal tumours.
2. To understand the relevant questions from the team and how they can be answered with imaging.
3. To review current multidisciplinary approaches: how we do it in our institution.

A-0468 16:51

C. The breast team

C.K. [Kuhl](#); Aachen/DE (ckuhl@ukaachen.de)

In breast cancer MDTs, the role of the radiologist is that of a powerful clinical partner. In many, if not most instances, the breast radiologist is the referring physician to the breast surgeon and will know the patient and her family, will have biopsied the patient and discussed the finding with her and will have localised the tumour to enable surgical removal. The radiologist helps with surgical treatment planning by demonstrating local disease extent or will help select patients for neoadjuvant chemotherapy, by providing biopsy of the cancer, or by providing evidence of systemic spread. The radiologist will assess response to neoadjuvant systemic treatment. In patients with therapy-refractory local recurrences or oligo-metastatic disease, the radiologist offers the full range of local percutaneous or trans-arterial treatment strategies to improve local control. With improving methods of radio-genomics, the radiologist will also provide predictive and prognostic information for treatment stratification.

Learning Objectives:

1. To learn about the role of the radiologist in the evaluation, treatment planning and follow up of breast tumours.
2. To understand the relevant questions from the team and how they can be answered with imaging.
3. To review current multidisciplinary approaches: how we do it in our institution.

CT and intervention in vascular pulmonary diseases

A-0469 16:00

Chairperson's introduction

J.D. [Dodd](#); *Dublin/IE*

Pulmonary vascular disease covers a wide spectrum of disease entities, many of which have overlapping clinical and imaging features. CT of the pulmonary vasculature has become an integral part of the work-up of such entities. In this session, we will evaluate three distinct disease subcategories of pulmonary vascular disease: pulmonary arterial hypertension, pulmonary vasculitis and hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu syndrome). The first talk will discuss pulmonary hypertension, the current clinical classification of pulmonary vasculitis, CT signs suggestive of the diagnosis, and CT signs that help discriminate between different causes. The comprehensive nature of CTPA in evaluating the mediastinum, vasculature and lung parenchyma will be shown. The second talk covering pulmonary vasculitis will emphasise the importance of combining CT signs with clinical features and laboratory results since vasculitis may mimic other disorders and sometimes the clinical features can be the major clue. CT findings in granulomatosis with polyangiitis and eosinophilic granulomatosis with polyangiitis will be shown, particularly emphasising the imaging differences between the two entities. The imaging findings of pulmonary haemorrhage will also be shown alongside the commonest causes. Finally, the association between interstitial lung disease and the ANCA associated vasculitis will be discussed. The third talk covering hereditary hemorrhagic telangiectasia will show the typical imaging features of this disease with a particular emphasis on those imaging aspects that determine outcome and treatment strategies. The talk will also cover contemporary aspects of endovascular treatment and their complications.

A-0470 16:06

A. CT imaging of pulmonary hypertension

N.J. [Screaton](#); *Cambridge/UK (Nicholas.Screaton@papworth.nhs.uk)*

Pulmonary hypertension (PH) typically presents insidiously with non-specific symptoms and is usually progressive with poor outcome independent of aetiology. CT plays a vital role both in suggesting the possibility of pulmonary hypertension, whether initially clinically suspected or not, and in identifying a specific cause of pulmonary hypertension. The causes of pulmonary hypertension can be broadly divided into those affecting primarily the small vessels, PH secondary to left heart disease or chronic lung disease/hypoxia (the most common causes), chronic thromboembolic PH, and multifactorial causes. CT is widely available, inexpensive, and permits a comprehensive assessment of the heart, pulmonary vasculature and lung parenchyma. CT signs such as dilatation of the proximal pulmonary arteries and right heart chambers can be considered as generic features associated with PH of any cause. Signs of a specific cause may lie in the mediastinum (left heart disease, shunt, oesophageal varices, oesophageal dilatation), vasculature (signs of CTEPH, tumour, large vessel vasculitis, fibrosing mediastinitis) or lungs (parenchymal lung disease, mosaic perfusion in CTEPH, signs of a small vessel vasculopathy). CTEPH is a not uncommon sequela of previous acute embolism. If the distribution is proximal, it is potentially cured by surgical pulmonary endarterectomy or by balloon pulmonary angioplasty. Imaging in general and CT in particular play fundamental roles in both identification of CTEPH, its differentiation from acute PE, and in characterising its distribution. Imaging signs in CTEPH can be a subtle and systematic evaluation of a CTPA is essential.

Learning Objectives:

1. To learn about the CT signs of pulmonary hypertension (PHT).
2. To become familiar with the current classification of PHT.
3. To be aware of the imaging features suggesting a thromboembolic origin.

A-0471 16:34

B. Evaluating the pulmonary vasculitis

E. [Castañer](#); *Sabadell/ES (ecastaner@tauli.cat)*

We will emphasise the importance of combine CT signs with the clinical features and laboratory results, as vasculitis may mimic other disorders and sometimes the clinical features are the clue. We will describe the findings in granulomatosis with polyangiitis (GPA) and eosinophilic granulomatosis with polyangiitis, highlighting the differences. Diffuse alveolar haemorrhage (DAH) is one of the manifestations of primary pulmonary vasculitis, among other entities (idiopathic alveolar haemorrhage, collagen vascular diseases, drug reactions, anticoagulation disorders). GPA and microscopic polyangiitis are the most common causes of DAH. Radiologic signs of DAH are nonspecific and variable but must be considered in patients with otherwise unexplained alveolar infiltrates, particularly when seen with new-onset renal insufficiency or a connective tissue disease. Finally, we will mention the association between interstitial lung disease and ANCA associated vasculitis.

Learning Objectives:

1. To learn the common imaging features of granulomatosis with polyangiitis (GPA).
2. To learn how to differentiate between GPA and eosinophilic granulomatosis with polyangiitis (Churg-Strauss).
3. To learn about the imaging features and differential diagnosis of pulmonary haemorrhage.

A-0472 17:02

C. Rendu-Osler and Behçet's diseases

B. [Peynircioglu](#); *Ankara/TR (borapeynir@gmail.com)*

Behçet disease is a rare multisystem condition associated with HLA-B51 positivity. Arterial involvement in Behçet's disease (BD) is less common than venous lesions. The most commonly affected arteries are: the aorta, lower extremity arteries, mesenteric, femoral, coronary, renal, subclavian and pulmonary arteries. Behçet-related pulmonary vasculitis is an uncommon and heterogeneous group of conditions, often with associated pulmonary artery thrombus formation. These microthrombi can result in a misdiagnosis of acute pulmonary embolism. Hereditary hemorrhagic telangiectasia also known as Osler-Weber-Rendu syndrome is an autosomal dominant disease that occurs due to vascular dysplasia associated with the disorder in the signalling pathway of transforming growth factor β (TGF- β). The clinical consequence is a disorder of blood vessels in multiple organ systems with the existence of telangiectasia which causes dilation of capillaries and veins, are present from birth and are localised on the skin and mouth, respiratory, gastrointestinal and urinary tract. Many patients with gastrointestinal and other organ manifestations are frequently clinically asymptomatic; therefore, organ screening is essential to avoid later complications and should be performed in centres with particular expertise. Hemoptysis is a life-threatening complication that is likely related to pulmonary artery aneurysm (PAA). Diagnostic imaging is the key to success in the management of these patients pulmonary vasculature. CT is the tool with some known advantages and drawbacks. Vascular interventional radiology may offer effective emergency and or elective therapeutic option. Transcatheter embolotherapy should be considered as the first-line emergency treatment for PAA-related hemoptysis, in association with the immunosuppressive regimen.

Learning Objectives:

1. To become familiar with the CT manifestations of these diseases.
2. To identify imaging features determining outcome and treatment strategies.
3. To learn about endovascular treatment modalities and complications.

Functional imaging of breast and female pelvis

A-0473 16:00

Chairperson's introduction

K. [Kinkel](#); *Chêne-Bougeries/CH (karen.kinkel@grangettes.ch)*

The introduction to this functional imaging session in the field of breast and female pelvis will present a short historical overview of what has been developed and accomplished in the last 20 years. Examples of clinical situations where functional imaging is crucial in daily practice are illustrated to raise interest in the three following lectures. Common problems in image characterisation/staging, and solutions detailed in the lectures to overcome these problems are briefly presented.

A-0474 16:06

A. Breast tumours

J. [Camps Herrero](#); *Valencia/ES (juliacamps@gmail.com)*

Imaging biomarkers (IBM) yield anatomic, molecular or functional characteristics that can be measured as indicators of underlying normal or pathologic biologic processes. IBM can be further divided into quantitative and qualitative, and those that will be the topic of this talk will be the functional quantitative or qualitative IBM derived from image bio-signals (electromagnetic or photonic). These include not only MRI but also mammography and ultrasound. IBM can also be characterised as risk-prediction BM, tumour characterisation and prognosis or therapy (response) monitoring. Risk prediction IBM can be analysed quantitative- or qualitatively in the mammographic breast density or the amount of fibro-glandular tissue or background parenchymal enhancement that can be seen through MRI. IBM of tumour characterisation and prognosis, as well as response evaluation to therapy, are mainly extracted from MRI images that analyse neo-angiogenesis (DCE-MRI), tissue microstructure and cellularity (DWI) and metabolism ((MR spectroscopy). The lecture will focus mainly on these IBM of risk prediction, tumor characterization and response evaluation but will also briefly explain IBM in ultrasound that analyze tissue stiffness (elastography) and angiogenesis (Doppler and contrast-enhanced ultrasound) and will also briefly mention the new IBM (Sodium imaging, spectroscopy with 13P MRSI, Saturation transfer CEST MRI and hyperpolarized MRSI).

Learning Objectives:

1. To review actual functional methods of breast imaging.
2. To learn about functional biomarkers of tumour grading.
3. To understand functional approach of tumour response.

Author Disclosure:

J. Camps Herrero: Consultant; BD BARD.

A-0475 16:34

B. Tumours of the uterus

E. [Sala](#); *Cambridge/UK (es220@cam.ac.uk)*

The standard MRI uterus protocol includes axial SE T1WI with a large FOV to evaluate the entire pelvis and upper abdomen for lymphadenopathy as well as bone marrow changes; and high-resolution FSE T2WI in the sagittal, axial and coronal planes. Other extra planes and imaging sequences are specific and designed to answer a specific clinical question. Functional MRI sequences such as DCE-MRI and DW-MRI are now part of routine protocols. DCE-MRI is very useful for assessment of the depth of myometrial invasion in endometrial cancer. DW-MRI is now part of routine MRI protocol for evaluation of uterine malignancies. It should be performed at two or more b-values, which include one or more low b-values (50-100 s/mm²) since perfusion contribution to diffusion is then eliminated and a very high b-value (750-1000 s/mm²). Both breath hold and non-breath hold DW sequences can be used. However, the type of DW sequence differs among manufacturers, and the radiologist should be familiar with the strengths and limitations of their own scanners. Combination of DWI with conventional MRI sequences improves lesion detection and radiologist confidence in imaging interpretation. DW-MRI can be useful for accurately determining the depth of myometrial invasion in endometrial cancer. In addition, ADC values are inversely related to the cellularity of tumours which may be useful for distinguishing between benign and malignant tissues and for monitoring tumour response to treatment in cervical cancer.

Learning Objectives:

1. To review functional methods for female pelvic imaging.
2. To learn about functional impact for characterising uterine tumours.
3. To be aware of validated biomarkers of prognosis.

A-0476 17:02

C. Ovarian tumours

A.G. [Rockall](#); *London/UK (a.rockall@imperial.ac.uk)*

Ovarian cancer remains the gynecologic malignancy with the highest mortality. This poor prognosis is partly due to late presentation, with disseminating disease in most cases. Researchers are actively trying to identify methods to improve patient outcomes. Accurate characterisation of adnexal masses has been improved by the development of standardised imaging and reporting methods, both in ultrasound and MRI. MRI characterisation has benefitted by the use of dynamic contrast enhancement of adnexal masses, with the categorisation of curves and the use of diffusion and T2 signal intensities, to allow risk stratification for the likelihood of cancer. Accurate risk stratification should, in turn, allow optimal treatment planning, identifying high-risk tumours for the referral to the gynecologic oncology team and conversely ensuring that low risk, likely benign tumours, are managed appropriately. In patients presenting with disseminated disease, advanced imaging techniques, including diffusion and contrast MRI of the peritoneal cavity, allow better delineation of the extent of disease. In addition, the use of radiometric prognostic vector on CT can predict phenotypically distinct tumours types, with biological and prognostic associations. Current reports of prognostic biomarkers will be discussed as well as the need for robust validation to allow translation into clinical practice.

Learning Objectives:

1. To learn how functional methods help in characterising ovarian tumours.
2. To review their role for patient management.
3. To be aware of validated biomarkers of prognosis.

The "prostate unit" at work

A-0477 16:00

Chairperson's introduction: My PSA is elevated...what now?

G.M. [Villiers](#); *Ghent/BE*

An increased or persistently elevated serum PSA can be the first sign of developing prostate cancer. In the modern "prostate unit at work", multiparametric MRI of the prostate has become an essential tool in the early diagnosis of prostate cancer and in the optimal decision making between the various treatment options.

Session Objectives:

1. To understand the role of imaging in the diagnosis and management of prostate cancer.
2. To become familiar with the various treatment options for prostate cancer.
3. To appreciate the role of multidisciplinary discussions.

A-0478 16:05

The radiologist: non-invasive explorer of the prostatic realm

P. [De Visschere](#); *Ghent/BE (pieter.devisschere@uzgent.be)*

Multiparametric magnetic resonance imaging (mpMRI) is the current state of the art imaging technique used in the assessment of patients with suspected or confirmed prostate cancer (PC). A mpMRI consists of morphological T2-weighted images supplemented with diffusion-weighted imaging and dynamic contrast-enhanced imaging. mpMRI has excellent accuracy for detecting high-grade PC, but low-grade PC may be missed. In patients with elevated PSA, mpMRI may be used as triage test before biopsy: when mpMRI is normal, a biopsy may safely be postponed, but when mpMRI shows a suspicious lesion, a targeted biopsy can be performed. There are three methods for targeted biopsy: cognitive transrectal ultrasound (TRUS) guided biopsy, TRUS-MRI fusion biopsy or in-bore MRI-guided biopsy. Recent large randomised controlled trials have shown that a pathway using mpMRI before biopsy in patients with elevated PSA results in avoiding biopsy in about one-third of men, in reduced detection of clinically insignificant PC and in equal to slightly increased detection of clinically significant PC. mpMRI may also be useful in local staging of patients with biopsy-proven PC and to detect local recurrence in patients treated for PC. Interpretation of mpMRI may be difficult, because some benign conditions such as (granulomatous) prostatitis may mimic PC.

Postgraduate Educational Programme

In the radiology report, the PI-RADS score is used to communicate the imaging findings to the clinician.

Learning Objectives:

1. To become familiar with the technique of mpMRI of the prostate.
2. To understand the role of mpMRI in the detection of clinically significant prostate cancer.
3. To appreciate the importance of image-targeted biopsy.

A-0479 16:25

The pathologist: guardian of the truth

S. Verbeke; Ghent/BE

Prostate cancer (PCa) is one of the most frequent tumours in men. The diagnosis is based on the microscopic evaluation of prostate tissue. The current standard of care is to obtain at least 10-12 systematic 18-gauge prostate core biopsies. The evolutions in imaging (MRI fusion biopsies) and histological assessment (Grade Group system) have improved the diagnostic and clinical accuracy of this technique. The most common histological type of PCa is acinar adenocarcinoma and accounts for more than 95% of the PCas. Different histological variants have been described which can be of significance due to difficulty in diagnosis (e. g. deceptively benign-looking atrophic variants) and due to prognostic differences (e. g. signet ring-like variants has a worse prognosis). Furthermore, other subtypes such as ductal carcinoma, small-cell neuroendocrine tumours, intraductal carcinoma, urothelial carcinoma, squamous neoplasms, basal cell carcinoma, sarcoma and lymphoma are less common. The worldwide used grading system initially created by Dr. Gleason for PCa is uniquely and solely based on the architectural pattern of the tumour. The grade is defined as the sum of the two most common grade patterns (Gleason score). The grading of PCa was revised in 2014: the initial Gleason patterns 1 and 2 are no longer in use since these patterns are more likely a benign condition. Furthermore, different patterns have been re-categorised, and a set of different grade groups associated with a unique prognosis have been introduced. Hereby, a more accurate grade stratification and simplified categorisation have been accepted which has also implications for treatment.

Learning Objectives:

1. To appreciate the importance of good tissue sampling.
2. To become familiar with the different histological subtypes of prostate cancer.
3. To understand the reasons for false positive and false negative results.

A-0480 16:40

The urologist: knight of swords in the prostatic badlands

N. Lumen; Ghent/BE (Nicolaas.Lumen@uzgent.be)

Radical prostatectomy is a standard treatment option for intermediate and high-risk localised prostate cancer and can be an option for locally advanced prostate cancer. When offering radical prostatectomy to the patient, surgical morbidity and functional complications (urinary incontinence, erectile dysfunction) must be taken into account. Appropriate patient selection for radical prostatectomy is thus of utmost importance, and MRI can help to this. Radical prostatectomy obtains the removal of the whole prostatic gland with the prostatic urethra and seminal vesicles. However, some modifications are possible to reduce the functional complications of the surgery. These modifications include bladder neck sparing, nerve sparing, posterior dissection and urethra sparing. MRI can help to decide whether one or more of these modifications are possible for the individual patient.

Learning Objectives:

1. To understand the role of imaging in the choice for prostatectomy.
2. To become familiar with open and robotic prostatectomy techniques.
3. To appreciate the importance of imaging in the preservation of clear margins.

The radiation-oncologist: smooth irradiator of the rogue elements

V. Fonteyne; Ghent/BE (valerie.fonteyne@uzgent.be)

External beam radiotherapy (EBRT) is an established treatment option for prostate cancer (PC) patients. A dose-response relationship for biochemical control is extensively described. The implementation of modern radiotherapy techniques and improvements in patient positioning during treatment enable the safe delivery of 74-78 Gy to the prostate. However, the close vicinity of surrounding organs at risk (OARs), limits further dose escalation to the entire prostate. The incidence of local failure after EBRT is dose-dependent supporting the hypothesis that aggressive tumours are more radioresistant. To avoid excess in toxicity, one can increase the dose exclusively to the area that is at highest risk of local relapse, i.e. the location of the initial tumour site called the dominant intraprostatic lesion (DIL). Theoretically, this might improve local

control and positively impact on the risk of developing distant metastases and PC death. Of course, none of these developments are possible without the integration of modern imaging and more precisely magnetic resonance imaging (MRI). The implementation of MRI in the treatment planning has resulted in a refined delineation of the target volume with a clear impact on target volume and enables the precise delineation of the DIL for simultaneous integrated boost. Also, a correct daily positioning is of utmost importance when considering high dose EBRT, again illustrating the benefit of incorporating imaging in the radiotherapy treatment. The combination of an MRI machine with a linear accelerator in one device allows greater precision in cancer treatment and is currently being investigated in clinical practice.

Learning Objectives:

1. To become familiar with the various prostate irradiation techniques.
2. To appreciate the need for imaging in radiotherapy planning.
3. To illustrate the importance of imaging in radiotherapy monitoring.

A-0482 17:10

Multidisciplinary case presentation and discussion

G.M. Villeirs; Ghent/BE

The prostate unit is the heart of every multidisciplinary team that treats the man with suspected or confirmed prostate cancer. In this session, the role of all players in the team (radiologist, pathologist, urologist and radiation oncologist) will be explained, with emphasis on the importance of radiology for each of them.

Friday, March 1

08:30 - 10:00

Room A

E³ - ECR Academies: Interactive Teaching Session for Young (and not so Young) Radiologists

E³ 921

Cardiac imaging

A-0483 08:30

A. Grown-ups with congenital heart disease

A.M. Taylor; London/UK (a.taylor76@ucl.ac.uk)

This session will describe how MRI and CT can be used to image adults with congenital heart disease. The common conditions that occur in childhood will be described (acyanotic and cyanotic heart disease) and what operations they undergo that will be important for imaging them when they become adults. Finally, those CHDs that may be diagnosed in adulthood will be described.

Learning Objectives:

1. To be familiar with the clinical and radiologic presentations of these patients.
2. To learn about imaging findings and management options.

A-0484 09:15

B. Imaging cardiac valves

R. Salgado; Antwerp/BE (rodrigo.salgado@uza.be)

Valvular heart disease forms an important part of the workload in every cardiology practice. While echocardiography remains a cornerstone in the assessment and follow-up of valvular heart disease, an important role is reserved for MR and CT imaging, although in different contexts. MR, with its ability to investigate the valvular morphology as well as the haemodynamic consequences on the cardiac chambers, forms an important complementary tool to the echocardiographic findings. It provides a reproducible quantification of transvalvular flow and has in recent years gained further importance in tissue characterisation with the introduction of T1/T2 mapping techniques for the detection and distribution of fibrosis. CT has recently gained a prominent place in the non-invasive investigation of the aortic root before transcatheter aortic valve replacement and is also becoming a primary imaging modality in emerging mitral valve interventions. Furthermore, its role in the evaluation of prosthetic heart valves is currently the subject of intense investigation, providing valuable additional information not easily acquired through other imaging methods. During this lecture, the different advantages and limitations of valvular imaging with CT and MR will be discussed, and practical recommendations for clinical practice will be given.

Learning Objectives:

1. To understand the impact of imaging.
2. To know the limitations and potential pitfalls of CT and MR techniques.
3. To learn about the imaging technique.

08:30 - 10:00

Room B

Abdominal Viscera

RC 901

Imaging of the complicated postoperative abdomen

A-0485 08:30

Chairperson's introduction

C.J. Zech; Basle/CH (christoph.zech@usb.ch)

Imaging of the postoperative abdomen is a crucial part in the evaluation of postoperative complications and will lead the clinician in the decision for treatment of postoperative complications with either re-laparotomy, interventional-radiology treatment or conservative/medical treatment. Knowledge of the performed surgical techniques and procedures, the normal imaging appearance postoperative and typical findings of frequent complications are inevitable to successfully treat patients with complications. Good interaction between the surgeon and the abdominal radiologist is needed. Nowadays, radiology should be able to diagnose most complications and minimise the number of mere diagnostic laparoscopies to evaluate a complicated postoperative clinical course.

Session Objectives:

1. To learn about the most common indications for abdominal surgery.
2. To understand the normal imaging findings in a postoperative abdomen.
3. To describe and identify the most common postoperative complications.

A-0486 08:35

A. Liver

C. Ayuso; Barcelona/ES (cayuso@clinic.ub.es)

Resection is proven to achieve long-term survival in selected patients with primary or secondary focal liver lesions. Advances in surgical techniques including robotic liver surgeries, systemic adjuvant chemotherapy and postoperative intensive care improved the outcome of liver resection. An adequate liver remnant is crucial to guarantee the correct liver function after radical potentially curative liver resection. In borderline cases, portal vein embolisation (PVE), or associating liver partition and portal vein ligation for staged hepatectomy (ALPPS) has been proposed before surgery to increase the liver remnant. Preoperative volumetric analysis of the liver based on imaging plays an essential role in the preoperative workup previous to liver resection. Also, the knowledge of the hepatic vascular anatomy and possible variants of the biliary system are also key aspects to avoid postoperative complications. Imaging tools based on multidetector computed tomography (MDCT) and magnetic resonance (MR) influencing preoperative decisions and surgical approaches will be discussed. The role of different imaging techniques as plain ultrasonography (US) contrast-enhanced ultrasound (CEUS), MDCT and MR for the detection and management of hepatic complications after liver resection or transplantation (infectious, vascular, biliary, parenchymatous (liver rejection) will be analysed.

Learning Objectives:

1. To learn about indications for liver interventions and different surgical approaches to focal liver lesions.
2. To understand the role for the different imaging techniques (US, CEUS, CT and MRI) in assessing different types of complications.
3. To appreciate the spectrum of parenchymal, biliary and vascular complications occurring after liver resection or transplantation.

Author Disclosure:

C. Ayuso: Speaker; Speaker fees and travel grants from Bayer.

A-0487 08:58

B. Pancreas

R.M. Gore; Evanston, IL/US (rgore@uchicago.edu)

Both benign and malignant pancreatic disease carry significant morbidity and mortality. Because of the fastidious nature of the pancreas and its local and regional anatomy, treatment of these disorders also carries significant morbidity. Indeed, perioperative morbidity of pancreaticoduodenectomy is approximately 30-40%. Due to the diversity of pathology, detection and characterisation of postoperative complications can be challenging. Familiarity with the normal imaging appearances of the spectrum of surgical procedures and their complications is vital. In this presentation, the common pancreatic surgical procedures performed for tumour resection (i.e. the Whipple's operation, enucleation, central and distal pancreatectomy, spleen-preserving distal pancreatectomy) and chronic pancreatitis (i.e. Puestow procedure, Beger procedure, Frey procedure) and their normal postoperative appearances are discussed. The common post-surgical complications including pancreatic fistulas and leaks, abscess formation, haemorrhage, and delayed gastric emptying are then described in detail.

Learning Objectives:

1. To learn about the various surgical approaches for acute and chronic pancreatitis, benign and malignant pancreatic neoplasms.
2. To understand the profound impact that the partial and complete pancreatectomy have on the adjacent abdominal organs.
3. To appreciate the common postoperative complications of pancreatic surgery.

A-0488 09:21

C. Bowel

D.J.M. Tolan; Leeds/UK

"no abstract submitted"

Learning Objectives:

1. To learn about the most common types of major oesophago-gastric, small bowel and colorectal surgical procedures and the expected postoperative anatomy and imaging findings.
2. To understand how to optimise imaging protocols to maximise the opportunity to detect postoperative complications after enteric surgery.
3. To appreciate and identify early and late complications after bowel surgery.

Special Focus Session

SF 9b

Clinical simulation and its role in radiography education

A-0489 08:30

Chairpersons' introduction (Part 1)

L. Oleaga Zufiria; Barcelona/ES (lauraoleaga@gmail.com)

There is a diversity of requirements and training schemes for radiographers within European countries. A current challenge is the importance to harmonise and standardise radiography training and accreditation across borders. The digital revolution in Radiology and Radiography continues to advance rapidly. Informatics and information technology evolution are going to substantially reshape the practice of Radiology and Radiography over the next decade. There are a number of interesting developments within informatics, which may have a significant impact on Radiology and Radiography education, and training in the near future. These include the extended functionality of handheld computers, web-based skill and knowledge assessment, standardisation of procedural training using simulated or virtual patients and worldwide online learning. Simulation programmes have proved to be effective in other specialities as a method for teaching and learning. There are mannequin-based simulation programmes, computer-based and simulators for an ultrasound and interventional radiology. Simulation training impacts on the learning curve with numerous benefits for the preparation of radiology/radiography students which will, in turn, benefit the service provided to patients. Simulation provides an option for training, but the place of this within any curricula needs to be carefully determined to promote the highest levels of competency. The education of the future must be a learner-centred education. Trainees must have an active role in the learning process. The teachers are not suppliers of knowledge and information, but organisers of activities and directors of learning experiences.

Session Objectives:

1. To review the evolution of training and radiology education in Europe.
2. To evaluate the challenges facing radiology education with the expanding use of informatics.
3. To analyse how clinical simulation methods can transform education in radiology.

Author Disclosure:

L. Oleaga Zufiria: Consultant; Telemedicine Clinic.

A-0490 08:33

Chairpersons' introduction (Part 2)

F. Zarb; Msida/MT (francis.zarb@um.edu.mt)

Radiology and Radiography education are evolving in line with developments in informatics which has provided a range of new tools for teaching and learning, which are going to substantially reshape the practice of Radiology and Radiography over the next decade. These include the extended functionality of handheld computers, web-based skill and knowledge assessment, standardisation of procedural training using simulated or virtual patients and worldwide online learning. Simulation programs have proved to be effective in other specialities as a method for teaching and learning. Simulation training impacts on the learning curve with numerous benefits for the preparation of radiology/radiography students which will, in turn, benefit the service provided to patients. Simulation provides an option for training, but the place of this within any curricula needs to be carefully determined to promote the highest levels of competency.

Session Objectives:

1. To review the evolution of training and radiology education in Europe.
2. To evaluate the challenges facing radiology education with the expanding use of informatics.
3. To analyse how clinical simulation methods can transform education in radiology.

A-0491 08:35

Clinical radiography education across Europe: an overview

J. McNulty; Dublin/IE (jonathan.mculty@ucd.ie)

The European Federation of Radiographer Societies (EFRS) represents over 8,000 radiography students through a unique part of our organisation, namely, the Educational Wing which consists of 61 educational institutions. Education and training are at the heart of several strategic priority areas of the EFRS. The educational aim of the EFRS is to promote and develop all levels of radiography education and research across Europe. Objectives include: the development and advancement of educational standards for radiographer

education in Europe; the development of European Qualifications Framework benchmarking documents for radiographers at Bachelors and Masters levels; to research, disseminate and publish materials and knowledge generated by the Educational Wing; and to provide assistance to those institutions wishing to develop or enhance their radiography programmes; and to develop evidence-based practice and radiographer-led research. High educational standards for radiographers are of utmost importance for our profession. This is especially true for the clinical training components of radiography education programmes. However, the clinical components of our curricula present many challenges, some of which were identified through recent EFRS surveys. While similarities exist in the provision of clinical radiography education across Europe, some major differences were also identified in terms of the amount of clinical time in programmes, the supervisory structures, and the governance and oversight of these placements. Professional societies should work collaboratively to establish guidelines for effective clinical placements. This will help ensure our graduates are fit for purpose.

Learning Objectives:

1. To present the developments of radiography education.
2. To discuss the current status of radiography education in Europe.
3. To evaluate the challenges and future of radiography education.

A-0492 08:50

Innovation in education: virtual education/computer-based simulator vs patient imaging

A. England; Salford/UK (A.England@salford.ac.uk)

Full-body high-fidelity simulations have formed part of healthcare education for a number of years, especially within the nursing and medicine disciplines. These lifelike mannequins are operated from a computer system with the ability to generate complex events and respond to multiple stimuli. The author, as a radiography educator, has a number of years of experience in integrating patient simulation into radiography training. Such teaching sessions are typically divided into the pre-simulation experience, the simulation and the post-simulation experience. Such an approach is essential to promote realism and also identify feedback and development opportunities. Within the undergraduate radiography programme, a case scenario on contrast anaphylaxis is commonly undertaken using high-fidelity simulation. Within this presentation the contrast anaphylaxis scenario is used as an example of clinical simulation, the advantages and disadvantages of this teaching method, as identified by teaching staff and students, are also discussed. Comparisons are also made with alternative teaching and learning approaches. It is important to stress that simulation is an extremely valuable pedagogical approach, but its merits must be considered amongst the other available teaching and learning methodologies. A diverse curriculum is essential for a high-quality radiography degree programme.

Learning Objectives:

1. To demonstrate the benefits of using new teaching approaches.
2. To show how new teaching instruments can improve and shorten the learning curve.
3. To evaluate the pros and cons of radiography education through simulation and patient imaging.

A-0493 09:05

High fidelity: clinical simulation for undergraduate radiography

A. Louw; Johannesburg/ZA (amandal@uj.ac.za)

Within the radiography domain, Simulation-Based Education (SBE) is valued as a pedagogical approach, but the design of simulation experiences, incorporating educational and cognitive theories, still needs exploration to advise best practice guidelines. Educational psychologists indicate that no new knowledge is created in passive manners and they emphasise the need for interaction and stimulation from the environment. Creative teaching methods that capture the interest and imagination of students are also said to stimulate the creative problem-solving ability that radiography students need in their daily working environment - an ability which various researchers point out as lacking among radiography students. SBE offers interaction, stimulation and various opportunities for creativity, but to optimise learning and teaching, educators must also consider the impact of cognitive load, scaffolding and reflection, when they develop simulation experiences. Whereas SBE in the health professions initially developed in response to the awareness that it is unethical to use patients as teaching aids and skills practice commodities, the call for equal and optimal training opportunities that will result in optimal patient centred care now provides further impetus. The increasing authenticity of simulation experiences, however, presents with unexpected ethical issues of concern. Students experience high fidelity manikins often as real-life patients, and the deterioration and demise of these patients can have a major emotional impact on them. Educators should acknowledge that the principle of beneficence applies to both patients and students and must be aware of the possible emotional effect on students and how to manage it.

Friday

Joint Session of the ESR and ESTRO

ESR/ESTRO

Current status and future challenges in MR-integrated radiotherapy

A-0496/A-0497 08:30**Chairpersons' introduction**L.E. [Derchi](#); [Genoa/IT](#)U. [Ricardi](#); [Turin/IT](#)

This session is dedicated to the building of stronger relationships between diagnostic radiology and radiation therapy specialists. Diagnostic radiologists must be aware of the technical advances of radiotherapy and oncology and have to learn how to provide expert support to patients undergoing radiation therapy. Knowledge of technological advances is the first thing to get; changes of our working habits is the second, through the development of new examination techniques to meet the clinical needs of these patients; dialog between the different specialists is the third, and most important one. This session will be repeated at the next meeting of the European Society for Radiotherapy and Oncology (ESTRO). This indicates that both Societies believe that working together, and growing together, is quite important to ensure optimal patient care.

Session Objectives:

1. To be aware of the technical advances in radiotherapy and oncology.
2. To know how diagnostic radiologists have to provide expert support to patients undergoing radiation therapy.
3. To understand how to develop strong clinical collaboration between the two specialities.

A-0498 08:35**Clinical status of MR-integrated photon therapy**L. [Boldrini](#); [Rome/IT](#) (lucaboldrini@hotmail.it)

The introduction of MR integrated delivery units represents one of the most significant and promising innovations of the last years in radiotherapy delivery technology. The advantages assured by the better visualisation of the therapy volumes allowed by onboard MR imaging and the possibility to use active gating and motion management solutions embedded in this novel workflow need to be further explored and quantified both from a technical and a clinical perspective. The aim of this talk is to describe the current clinical status of the MR-integrated photon radiotherapy and to present the clinical evidence to date available. Its most common applications will be reported, ranging from the patient selection methods to the choice of the most appropriate therapy delivery protocol. Furthermore, the possibility to implement innovative hypothesis-generating approaches (movement management, radiomics, new delivery techniques) in clinical MR-integrated radiotherapy will be presented.

Learning Objectives:

1. To learn about the current clinical status of the MR-integrated photon therapy.
2. To understand the most common clinical applications of the MR-integrated photon therapy.
3. To appreciate the possibilities of hypothesis-generating approaches with this new technology (movement management, radiomics, new delivery techniques).
4. To become familiar with the clinical MR-integrated photon therapy workflow, from patient selection to therapy delivery.

Author Disclosure:**L. Boldrini:** Consultant; Varian Medical Systems. Speaker; ViewRay Inc..**A-0499** 08:55**Integration of MR and particle therapy: how far are we**A. [Hoffmann](#); [Dresden/DE](#) (aswin.hoffmann@oncoray.de)

Precise targeting in proton therapy (PT) is even more important than in conventional photon-based radiation therapy (XT), because PT is more sensitive to anatomical variations than XT. This is due to the steep dose fall-off behind the Bragg peak and to the fact that the range of the proton beam depends on the material composition in the beam path. Especially for moving tumours, these uncertainties currently translate into large safety margins, thus compromising the dosimetric benefit of PT. This urges the need for real-time image guidance during PT dose delivery. Magnetic resonance imaging (MRI) offers real-time image guidance with unparalleled soft-tissue contrast and absence of radiation dose. PT is therefore expected to benefit even more from the integration with real-time MRI than XT. However, so far no hybrid system for MR-integrated PT (MRIPT) has been realised due to a number of hitherto open technological problems. To study the technological feasibility of MRIPT, mutual interactions between the PT and MRI system have to be taken into

Learning Objectives:

1. To discuss ethics in simulation practices.
2. To provide an overview on how to prepare and execute a simulation experience.
3. To highlight the challenges and opportunities of clinical simulation at the undergraduate level.

A-0494 09:20**How simulation can help prepare students and have a positive impact on interprofessional working**A. [Henner](#); [Oulu/FI](#) (anja.henner@oamk.fi)

Interprofessional education is a collaborative approach to develop healthcare students as future interprofessional team members. Interprofessional teams can address complex medical issues. Training future healthcare providers to work in such teams improve healthcare outcomes for patients. With the didactic program, interprofessional collaboration skills, knowledge of professions, patient-centred care, service learning and the impact of culture on healthcare delivery are improved. The community-based experience demonstrates how interprofessional collaborations provide service to patients and how the environment and availability of resources impact one's health status. The interprofessional-simulation experience describes clinical team skills training in both formative and summative simulations. In a simulation-based experience, formative assessment or summative evaluation can be used. Formative assessment fosters personal and professional development and helps participants progress toward achieving objectives. Assessment of student learning in a simulation is no longer a passive activity in which the educator determines how well individual or group performs. Summative evaluation focuses on measurement of outcomes or achievement of objectives and supports the assessment or evaluation of behaviours cognitive (knowledge), affective (attitude), and psychomotor (skills) areas. A successful experience in simulation helps students to understand their professional identity while gaining an understanding of other professional's roles on health care team and offers a safe environment exercise even difficult tasks. Commitment from departments and colleges, diverse calendar agreements, curricular mapping, mentor and faculty training, a sense of community, adequate physical space, technology, and community relationships are critical resources for a successful simulation and positive attitude to work together.

Learning Objectives:

1. To demonstrate how interprofessional collaborations improve a service to patients.
2. To describe clinical team skills training in formative summative simulations.
3. To discuss the benefits of student preparation through simulation.

A-0495 09:35**Providing opportunities for practical ultrasound training**B. [Kraus](#); [Vienna/AT](#) (barbara.kraus@fh-campuswien.ac.at)

The major challenge in the education of Radiographers in Ultrasound or "Sonographers" all over Europe is, to create a training scenario closely related to clinical reality. To perform Ultrasound in a proper way, hands-on training is mandatory and cannot be replaced by anything else. One option is Skill Lab Training Sessions. Students train on each other to learn and strengthen the major skills by correctly using the Ultrasound probe, implementing the theoretical knowledge about physics and optimization in correctly manipulating scan parameters to adequately demonstrate and be able to visualise anatomical structures in a correct manner. These are the key points in diagnostic ultrasound performance. Other options are different web-based skill and knowledge assessments and simulator-based training settings. Utilities from different providers are for example augmented with real patient scans, including haptic feedback by using a probe, real-time assisted guidance and comprehensive metric-based assessment in one system. Trainers and tutors are able, to upload their own patient scans/cases and share them with other users. The major difference between simulated practice and scanning on each other is the benefit of simulating real clinical case scenarios, including pathological findings during training. However, a balanced combination of hands-on training (Students on each other), simulator-based/web-based training and clinical experience under medical supervision in compliance with all ethical aspects is the ultimate goal in practical ultrasound education.

Learning Objectives:

1. To know the role of hands-on training in ultrasonography.
2. To appreciate the value of learning ultrasonography through hands on training.
3. To discuss the opportunities for radiographers training in ultrasound.

09:50

Panel discussion: Is simulation enough to meet the current challenges facing radiography education? Can simulation replace hands-on patient experience?

account. Recent research efforts have realised a proof-of-concept system where first MR images of tissue-mimicking phantoms have been successfully acquired with a clinical in-beam MR scanner during proton beam irradiation. This offers the prospect that the development of a clinical prototype MRiPT system within the next five years should not be considered beyond the realms of possibility. This contribution provides an overview of the current status of MRiPT research achievements and discusses technology issues that need further investigation.

Learning Objectives:

1. To learn about the current state-of-the-art in image-guided proton therapy.
2. To understand the rationale for the need to integrate MRI and proton therapy.
3. To become familiar with the technical risks and challenges to integrate MRI and proton therapy.
4. To appreciate which risks and challenges have been overcome by recent research efforts.
5. To discuss the technology issues that need further research.
6. To become familiar with the implications for future developments and clinical treatment workflow.

MR-based functional imaging

R.G.H. [Beets-Tan](#); *Amsterdam/NL*

"no abstract submitted"

Learning Objectives:

1. To learn about functional MRI.
2. To appreciate its value as the guidance of radiation treatment.
3. To understand the synergy of an interdisciplinary collaboration between radiologists and radiation oncologists.

A-0501 09:35

Adaptive workflow: current status and challenges

S. [Kharuzhyk](#); *Minsk/BY*

MRI is used at different stages of oncological patient management including tumour staging, treatment (surgery, radiation therapy) planning and tumour response assessment. Traditional radiation therapy planning workflow integrates high contrast resolution and anatomical details provided by MRI with electron density values obtained from CT. More recently MRI-only radiotherapy planning workflow has been implemented with synthetic CT images generated from MRI data. On-treatment MRI-guidance is a new paradigm of precision radiotherapy that enables a scan-plan-treat approach or adaptive radiotherapy. MRI linac machines integrating clinical MRI scanner with linear accelerator are the current reality in some cancer centres around the globe.

Learning Objectives:

1. To understand the role of image-guidance in adaptive radiotherapy.
2. To become familiar with the advantages of MRI guidance compared to CBCT guidance.
3. To learn principles of real-time MRI guidance in radiotherapy.
4. To discuss the current state and further perspectives of MR-guided adaptive radiotherapy.

Reporting and communication today and tomorrow: challenges to implement structured reporting (RS) and deal with artificial intelligence (AI)

A-0502/A-0503 08:30

Chairpersons' introduction

A. [Brady](#); *Cork/IE (adrianbrady@me.com)*

E. [Neri](#); *Pisa/IT (emanuele.neri@med.unipi.it)*

Structured reporting is rapidly replacing free-text forms of reporting in radiology, in response to the desires of referring clinicians, and as part of ongoing radiology efforts to optimise quality by standardising the format, content and structure of our principal work output, radiology reports. This session will explain how report template structures are developed, how the elements contained within structured reports can be utilised for information extraction and the potentialities for utilising artificial intelligence in supporting radiologists' reporting activity. The value of using structured formats in communicating with referrers will be explained and demonstrated.

Session Objectives:

1. To understand what is meant by structured reporting in the context of the likely future of radiology.
2. To appreciate the requirements for and potentialities of radiology structured reporting.
3. To learn about the role of structured reporting in communication with referrers and patients.

Author Disclosure:

E. Neri: Advisory Board; QUIBIM. Speaker; GE/Healthcare.

A-0504 08:36

Update on developments for structured reporting: Radreport 2.0, TLAP, MRRT

P. [Mildenberger](#); *Mainz/DE (mildenbe@uni-mainz.de)*

Structured Reporting is in the discussion for many years. There is a broad interest, and consensus to improve quality by providing more precise and focused reports. ESR and RSNA have formed a joint committee (Template Library Advisory Panel, TLAP) to review and validate templates. The development of templates is time-consuming, using approved templates could facilitate the process in a relevant way. Such template, based on the internationally accepted IHE MRRT profile, could be incorporated into radiological information system or dedicated reporting solutions. Especially for epidemiological or research activities, the use of consensual templates could be a huge step forward, because data aggregation would be enabled directly. End of 2018, the new template repository has been launched and is now open for radiologists.

Learning Objectives:

1. To learn about new concepts for supporting structured reporting.
2. To appreciate the opportunities of consensual templates based on international standards.
3. To become familiar with the template repository.

A-0505 08:52

The concept of common data elements (CDE) for reporting

C.E. [Kahn](#); *Philadelphia, PA/US (cekahn@gmail.com)*

Today's radiology reports typically convey the results of imaging studies using unstructured text. This format limits the ability to automatically extract data to support patient care, quality improvement, and medical research. A common data element (CDE) defines the attributes and allowable values of a unit of information. CDEs are "data elements that are collected and stored uniformly across institutions and studies and are defined in a data dictionary." The data dictionary specifies the item's name, data type (e.g., number or text), allowable values, and other attributes. In essence, a CDE is a predefined question and a set of allowable answers to that question. CDEs provide the structure that allows automated systems to extract and exchange key data in a uniform way. This presentation describes the efforts to develop CDEs to support clinical reporting, research, and the application of artificial intelligence systems in radiology.

Postgraduate Educational Programme

Learning Objectives:

1. To learn about the difference of templates and CDE.
2. To appreciate the flexibility of CDE.
3. To understand how to use CDE in a SR-solution.

A-0506 09:08

Decision support and artificial intelligence (AI) to improve reporting in radiology

T.K. [Alkasab](#); Boston, MA/US (TALKASAB@mgh.harvard.edu)

Artificial intelligence (AI) tools form a natural synergistic pairing with structured reporting (SR) to enable a new, data-enabled paradigm for imaging workflow. As SR modules and templates are defined, they specify a data model for AI tool designers to aim their products at. SR modules also form a natural integration point for the output of AI tools into the clinical workflow. Finally, SR modules can capture feedback from radiologists about AI-generated data elements, which can be fed back to improve the AI tools incrementally. However, in order to realise this vision, the radiologist reporting workflow and toolset will have to re-orient away from prose text creation and more toward data flow. In this new environment, radiologists will review incoming data, augment it through their own interpretation of images, and provide structured data to downstream systems.

Learning Objectives:

1. To learn about the next steps for IT-support in reporting.
2. To appreciate the opportunities for quality improvement.
3. To understand the concept of how to implement AI-support in a SR-solution.

Communication with referring physicians and patients: what is relevant?

J.M.L. [Bosmans](#); Ghent/BE (janbosmans@telenet.be)

A radiology department creates two products from each patient visit: an imaging study and a report interpretation of the findings. Dimensions of service quality can be defined as reliability, assurance, tangibles, empathy and responsiveness. Multiple surveys have shown that, in case of complex studies, referring clinicians prefer structured reporting (SR) examinations over free text reporting. Moreover, the number of studies reporting the benefits of SR in daily practice is increasing. Despite this, questions have been raised concerning the lack of completeness and flexibility of SR and their influence on radiologists' performance. Patient empowerment is a key element of patient-centred healthcare. Patient empowerment requires that patients have enough information to make decisions concerning their health. Nowadays, as technologists perform the imaging procedure and the radiologist reports the results at another location, the radiologist has become invisible to the patient. In popular media and television shows, radiology is prominently present, but radiologists are virtually absent. A survey among 1146 patients has shown that patients are even ill-informed as to the question whether radiologists are medically qualified and enjoy all the privileges thereof. Despite this, most patients find radiologist consultation beneficial. Patients are comfortable hearing results from the radiologist. Many patients would also like to view their images and receive copies of their reports, potential avenues through which radiologists could add value. It is essential that radiologists learn how to communicate with patients, both directly and through patient-oriented reports.

Learning Objectives:

1. To learn about communication pitfalls.
2. To appreciate the potential of SR in communication with referrers and patients.
3. To become familiar with best practice examples.

A. Carotid plaque imaging: tool or fool?

L. [Saba](#); Cagliari/IT (lucasabamd@gmail.com)

Nowadays, stroke represents a critical health problem, and about 25% of all ischemic strokes are due to thromboembolism caused by an atherosclerotic carotid disease. Current guidelines for prevention of stroke in patients with carotid plaques are based on the quantification of the degree of stenosis, and this parameter is currently considered the key element for stratifying the severity of carotid artery atherosclerosis and for the choice of strategies to prevent the occurrence of stroke. The evolution of imaging techniques has allowed for the routine characterization of carotid plaque features and the traditional concept of using degree of luminal stenosis as the sole imaging marker for the selection of the optimal therapeutic approach is challenged by evidence that some types of plaques, so-called "vulnerable plaques", have a high likelihood to cause ischemic stroke, independent of the degree of stenosis. In this lecture, the first main topic will be to present the radiological method to analyse plaque morphology and recent developments in the assessment of imaging of carotid vulnerable plaque and their potential clinical implications. The second main topic will be the influence of plaque morphology on actual treatment guidelines whereas in the last main topic the possible future role of carotid plaque imaging for treatment decision making will be discussed together with the unmet needs that should guide future research.

Learning Objectives:

1. To learn about radiological methods to analyse carotid plaque morphology.
2. To critically review the influence of plaque morphology on actual treatment guidelines.
3. To discuss the possible future role of carotid plaque imaging for treatment decision making.

Learning Objectives:

1. To provide an overview about inflammatory arterial disease.
2. To become familiar with involvement of supraaortic arteries in inflammatory arterial disease.
3. To learn about Radiological diagnosis of supraaortic involvement in inflammatory arterial disease.

A-0510 09:30

C. Carotid stent: medical history or part of the future?

K. [Hausegger](#); Klagenfurt/AT (klaus.hausegger@kabeg.at)

Since carotid artery stenting (CAS) has been introduced as a technique for treatment of extracranial carotid artery stenoses this technique has been compared to carotid endarterectomy (CEA) in several prospective randomised trials. None of these trials could show a clear clinical benefit of one method over the other in the long-term. In the periprocedural phase, minor strokes occurred more often during CAS, whereas myocardial infarcts were seen more often during CEA. Although the overall results of CAS are not inferior compared to CEA, the majority of patients with significant carotid stenoses are treated with CEA. Nevertheless, the tendency towards minimal invasive treatment is still there. With the introduction of mechanical thrombectomy (MTE) as the first line treatment of acute ischemic stroke (AIS) the number of CAS procedures in combination with MTE is increasing, because 10-15% of the patients with AIS have tandem lesions (stenosis of the extracranial internal carotid artery combined with an intracranial large vessel occlusion). There is clear evidence that symptomatic carotid stenoses should be treated. However, there is less evidence for asymptomatic stenoses. Although the historical NASCET and ECAS trials could show a benefit for treatment (CEA) over best medical treatment in the late 1990ies, best medical treatment has significantly improved over time with the availability of effective platelet inhibitors and lipid lowers. Therefore several on-going trials aim the access the indication for invasive treatment (CEA or CAS) of asymptomatic carotid artery stenosis. Future results for CAS may be influenced by better new stent designs.

Friday

Learning Objectives:

1. To learn about the technique of carotid stent implantation.
2. To review current indications for carotid stent implantation.
3. To discuss the future role of carotid stent implantation.

Pain palliation in cancer patients

A-0511 08:30

Chairperson's introduction

A. [Gangi](mailto:Gangi@chru-strasbourg.fr); Strasbourg/FR (Afshin.Gangi@chru-strasbourg.fr)

The prevalence of pain in newly diagnosed cancer patients is approximately 30% but 75% of cancer patients in the advanced stages of the disease deal with a pain every day. Approximately 10% of patients will have pain that is difficult to manage, and in a small group (2% to 5%), the pain is refractory. Interventional procedures may be indicated in some patients with chronic, refractory, and/or severe pain. This percutaneous image-guided interventions in selected patients offer the potential for improved quality of life, function, and independence. These interventional procedures also broaden the ability of palliative care providers to control pain and limit medication side effects.

Session Objectives:

1. To learn about the percutaneous pain palliation techniques in cancer patients.
2. To learn about pain evaluation and clinical selection of the patients.
3. To learn about when to propose these methods during an MDT.

A-0512 08:35

Pain from bone metastases

G. [Tsoumakidou](mailto:Tsoumakidou@yahoo.com); Strasbourg/FR (gtsoumakidou@yahoo.com)

Different interventional radiology procedures can be used to alleviate pain from bone metastases resistant to analgesic therapies (non-opioids, mild and strong opioids). As metastatic bone disease usually represents a complex clinical scenario, a case-based approach is necessary. The origin and type of pain (mechanical or not) should be predefined. The degree of bone destruction, the location of the painful lesion (flat vs long bones, cortical vs medullary lesions) and the presence or absence of cortical rupture and will define the treatment strategy. Cement injection is usually sufficient to treat pain from an impending compression fracture of painful bone tumours involving flat weight-bearing bones without invasion of the surrounding soft tissues. In specific regions, percutaneous bone osteosynthesis (femoral neck, displaced pelvic fractures etc.) can be further proposed. For painful bone tumours with extension into the surrounding soft tissues, thermal ablation (radiofrequency, cryoablation, microwave ablation) is required to treat pain caused by the soft tissue invasion. An additional consolidation technique (percutaneous cement injection for flat bones and surgical stabilisation in cases of long bones) may be also required. In cases of spinal metastasis with epidural extension not responding to EBRT and when surgery is contraindicated, thermal ablation (combined with insulation techniques, temperature and electrophysiologic monitoring) can be proposed in order to limit tumour burden and prevent spinal cord compression. In all cases, the precise clinical evaluation of the patient is mandatory and should include previous treatments, patient-tolerated anaesthesia and life expectancy.

Learning Objectives:

1. To learn about the indications and techniques of MSK tumours pain palliation.
2. To learn about patient selection and clinical and imaging follow up.
3. To learn about the indication of consolidation techniques.
4. To become familiar with how to promote interventional procedure in MDT.

A-0513 08:58

Abdominal pain management with minimally invasive techniques

D.C. [Madoff](mailto:Madoff@med.cornell.edu); New York, NY/US (dcm9006@med.cornell.edu)

Chronic abdominal pain occurs as a complication of various malignant diseases including pancreatic cancer, and when present may contribute to a lower quality of life and higher mortality. Though various pain management strategies are available as part of a multimodal approach, they are often incompletely effective and accompanied by side effects. Pain originating in abdominal viscera is transmitted via the celiac plexus, an autonomic plexus located in the retroperitoneum at the root of the celiac trunk. Direct intervention at the level of the plexus, referred to as celiac plexus block or neurolysis depending on the injectate is a minimally invasive therapeutic strategy which has been demonstrated to decrease pain, improve function, and reduce opiate dependence. Various percutaneous techniques have been reported, but, with

appropriate preprocedural planning, use of image guidance, and postprocedural care, the frequency and severity of complications is low and the success rate high regardless of approach. The main benefit of the intervention may be in reduced opiate dependence and opiate-associated side effects, which in turn improves quality of life. Celiac plexus block and neurolysis are safe and effective treatments for chronic abdominal pain and should be considered early in patients experiencing such symptoms. Other minimally invasive strategies, including catheter placement for malignant bowel obstruction and embolisation for tumour-related pain, will also be discussed.

Learning Objectives:

1. To learn about the indication and patient selection.
2. To learn the techniques of pain palliation in abdominal cancer.
3. To learn about patient and clinical follow up, complication management and pain evaluation.
4. To become familiar with how to promote interventional procedure in MDT.

A-0514 09:21

Pelvic pain management with minimally invasive techniques

B. [Kastler](mailto:kastler@noos.fr); Paris/FR (b.kastler@noos.fr)

Pain is the most fearsome symptom patient cancer and relatives will experience. It is estimated to be present in pelvic pain in a wide-ranging prevalence of 40 % up to 100% in patients with advanced stages particularly. In the end stages of the disease, pain usually becomes refractory to 3rdstep WHO analgesic drugs as strong opioids. To address these pelvic pain issues, various interventional techniques CT-guided techniques can be performed. - Patients with osseous structure involvement (mets or local invasion) usually respond well to analgesic cocktail infiltrations, bone ablation and/or cementoplasty. We will demonstrate how we proceed under local anaesthesia and tumoral block.- Patients with pelvic pain due to non-neural tumours pelvic pain are more difficult to manage. Initially, they suffer from nociceptive pain due to inflammation and irritation of nerves and later on, via traction and destruction of neural structures, neuropathic pain (causalgia and deafferentation). These patients may be treated by blocks and neurolysis: hypogastric plexus aimed procedures (presacral and/or hypogastric nerves) are used to relieve various pelvic cancer pain syndromes. Ganglion impar block to treat lower pelvic or perineal pain, coccydynia, troublesome tenesmus and anorectal pain from local malignancy. Pudendal infiltration in pelvic posterior or sacral involvement by tumours can also be considered. Radiation-induced or surgical pelvic pain patients may also benefit from these techniques.

Learning Objectives:

1. To learn about the indication and patient selection.
2. To learn the techniques of pain palliation in pelvic pain in cancer patients.
3. To learn about patient and clinical follow up, complication management and pain evaluation.
4. To become familiar how to promote interventional procedure in MDT.

Post-treatment emergencies in oncologic patients

A-0515 08:30

Chairperson's introduction: The role of imaging in the early detection of complications in oncologically treated patients

D.R. [Kool](mailto:Kool@amsterdam.nl); Amsterdam/NL

Oncology patients can present with life-threatening conditions. Those conditions may be caused by local expansion of a primary tumour or metastases, for example, haemorrhage, vena cava superior syndrome or spinal cord compression. Furthermore, complications can be caused indirectly by malignancies, for instance, thromboembolic disease or paraneoplastic metabolic or neurological symptoms. Life-threatening complications can also be an unwanted consequence of tumour therapy. Surgery, radiotherapy, interventional radiology (IR) procedures, chemotherapy and immunotherapy, each have their own set of potential complications that can present in the emergency setting. Hematologic and metabolic complications are mainly

diagnosed with clinical and laboratory findings. For other complications, diagnostic imaging is essential for making the correct diagnosis and imaging will influence treatment. Complications of surgery, radiotherapy and IR procedures will mostly be near the treated area. Adverse effects of systemic therapies, chemotherapy and immunotherapy, can occur at remote sites. Complications of oncological treatment can be life-threatening. However, when treated in time they often are reversible. Recognising the imaging findings of complications of tumour therapy timely and accurately is important. Immunotherapy is a more recent treatment, and the adverse effects differ from the more familiar complications of the other tumour therapies. Immunotherapy is increasingly used, and a radiologist will encounter these complications more frequently. In this session complications in the chest and abdomen and of IR procedures will be discussed and their imaging findings will be demonstrated. Interventional techniques used in the treatment of complications of different tumour therapies will be discussed as well.

Session Objectives:

1. To learn about different approaches in modern tumour therapy.
2. To understand the radiological appearance of complications following treatment in oncologic patients.
3. To appreciate the role of different imaging modalities in further management of patients.

A-0516 08:35

A. Chest

H. [Prosch](mailto:helmut.prosch@meduniwien.ac.at); Vienna/AT (helmut.prosch@meduniwien.ac.at)

Lung cancer is the most common cause of cancer-related death in Western countries. Treatment in lung cancer is based on three pillars: surgery; radiation therapy; and systemic therapy. Imaging plays a major role in treatment decisions, response evaluation, and last, but not least, also in assessing adverse events following therapy. After surgery, acute (early) complications include pulmonary oedema (hydrostatic, permeability), atelectasis, hemothorax, acute infections, and broncho-pleural fistulas. Acute complications after radiation therapy include mainly early radiation pneumonitis and infections. Following systemic therapy, in addition to infections, non-infectious pneumonitis and sarcoid-like reactions are important complications that must be considered when investigating a patient who presents with acute symptoms.

Learning Objectives:

1. To become familiar with the modern approach to malignant chest tumour therapy.
2. To learn how to differentiate clinically important complications.
3. To understand how to look for the early signs of severe and urgent conditions.

Author Disclosure:

H. Prosch: Advisory Board; Boehringer Ingelheim, Roche, MSD, BMS, AstraZeneca.

A-0517 09:00

B. Abdomen

R. [Basilico](mailto:basilico@unich.it); Chieti/IT ([rbasilico@unich.it](mailto:basilico@unich.it))

Despite many improvements in perioperative, post ionising radiation therapy or pharmacological morbidity in abdominal tumour treatments, acute complications after tumour therapies in the abdomen are still common. A number of different therapies, including surgery, by means of a laparoscopic approach or minimally invasive robotic surgery, radiotherapy, chemotherapy and immunotherapy, may be effectively used to treat abdominal tumours. However, these kind of treatments are not devoid of complications and, last, abdominal emergencies may also occur after therapies used for extra-abdominal tumours. Cross-sectional imaging and particularly CT plays a crucial role in the diagnosis and management of most common abdominal emergencies after tumour therapies. The main complications following abdominal, urologic or gynecologic surgery include peritonitis, abscesses, haemorrhage, small-bowel obstruction and anastomotic leaks. Specific complications following hepatobiliary surgery include bile leakage and bile duct injuries: US and MRI with Magnetic Resonance Cholangiopancreatography (MRCP) sequencers are the preferred modalities for assessment of the postoperative biliary tract. Less common postoperative emergencies are vascular complications such as pseudoaneurysms. Small-bowel obstruction caused by radiation enteritis represents one of the most frequent abdominal complications after radiotherapy of prostate and rectal cancer. Whereas, a less known disease such as pneumatosis cystoides intestinalis, may be associated with systemic chemotherapy. Due to the increasing use of immunotherapy for different type of tumours, new inflammatory and immune-related adverse events also occur in the abdomen, and they need to be managed by a multidisciplinary approach.

Learning Objectives:

1. To learn about different therapies used in abdominal tumours.
2. To become familiar with possible complications.
3. To understand the effectiveness of imaging modalities in the evaluation of emergent complications.

A-0518 09:25

C. How can interventional radiologists help in the management of oncological treatment complications?

K.K. [Pyra](mailto:pyra@poczta.fm); Lublin/PL (k.pyra@poczta.fm)

Patients being treated for cancer frequently experience adverse effects. Interventional radiology plays an important role in the management of oncological treatment complications. Managing these effects improves quality of life and reduces mortality. The most commonly used interventional radiology techniques include embolisation, thermal ablation, vertebral augmentation, cementoplasty, percutaneous internal fixation, drainage of an intraabdominal abscess, radiologically guided peripheral insertion of central catheters, parenteral nutrition, percutaneous transhepatic cholangiography, inferior vena cava filter implantation and many others. IR can manage the majority of procedure-related complications so that surgical reintervention is required in only a small percentage of patients. Even than presurgical endovascular treatment can be invaluable. Blocking pain signal with ablation of the nerve is one of the examples. It is important for clinicians to understand the goals of endovascular treatment and recognise the importance and role of the IR in the management of these patients undergoing oncological treatment.

Learning Objectives:

1. To understand the role of interventional radiology in modern tumour therapy and the complications.
2. To be familiar with interventional techniques used in the treatment of complications of different tumour therapies.
3. To learn which tumour therapy complications can be treated with interventional radiology.

Update on cerebrospinal fluid (CSF) diseases

Moderator:

Z. Merhemic; Sarajevo/BA

A-0519 08:30

A. Imaging strategies for hydrocephalus

C.A.J. [Romanowski](mailto:charles.romanowski@sth.nhs.uk); Sheffield/UK (charles.romanowski@sth.nhs.uk)

The classical bulk flow hypothesis of CSF production and flow is still widely taught in medical schools and textbooks. In recent years however new scientific evidence has led to some groups challenging this hypothesis. There is now much evidence to support the view that CSF is filtered and reabsorbed across the whole capillary bed of the CNS. In addition, MRI studies have confirmed that CSF flows not simply in a unidirectional manner from the choroid plexus to the subarachnoid space but in a bidirectional manner driven by a systolic expansion of intracranial arteries during the cardiac cycle. This refresher lecture will begin by looking at these new views regarding CSF physiology and flow. The different aetiologies leading to hydrocephalus will be examined. The role MRI in assessing normal CSF flow and disturbances of CSF flow will be examined. This refresher lecture will also include the clinical imaging assessment of the planning and follow-up of modern neurosurgical treatments of hydrocephalus.

Learning Objectives:

1. To learn about different types of hydrocephalus and how to distinguish them in imaging.
2. To understand the pathophysiology of CSF circulation.
3. To appreciate MR imaging techniques for diagnosing abnormalities of the CSF flow.

A-0520 08:53

B. Diagnosis and treatment of intracranial hypotension

E. [Papadaki](mailto:fpapada@otenet.gr); Iraklion/GR (fpapada@otenet.gr)

Spontaneous intracranial hypotension (SIH) usually involves middle age women presented with orthostatic headaches. It is caused by spinal CSF leakage due to dural weakness involving nerve root sleeves and rupture of the protruded arachnoid layer, ventral tears of the dura caused by calcified disc herniations and spiculated osteophytes or CSF-venous fistulas within a spinal epidural vein. Although the International Classification of Headache Disorders (ICHD) provides diagnostic criteria for SIH, based on CSF pressure measurements and imaging evidence of CSF leakage, misdiagnosis is

common, and there is not a single diagnostic test that can rule out SIH with certainty. A CSF opening pressure of <6 cm H₂O during lumbar puncture facilitates the diagnosis of SIH, however, most patients with SIH have normal CSF pressure. Brain MRI findings include diffuse dural enhancement, brain sagging with descent of the brainstem, the third ventricular floor and the mammillary bodies, narrowing of the interpeduncular and prepontine cisterns and cerebellar tonsillar ectopia, pituitary gland enlargement, dilation of the intracranial venous sinuses ("venous distention sign") and bilateral subdural collections (simple or haemorrhagic), while spinal MRI may reveal epidural collections. For the localisation of the spinal CSF leakage CT myelography (including ultrafast CT myelography and digital subtraction myelography) is considered to be the modality of choice, although MR myelography, even with intrathecal gadolinium, could also be used in certain cases. Nuclear medicine myelography can also be employed. Treatment includes conservative therapy with bed rest, caffeine, and oral hydration, targeted or not epidural patching, or even surgery.

Learning Objectives:

1. To learn about the underlying pathophysiology of spontaneous intracranial hypotension (SIH).
2. To understand imaging strategies for this condition.
3. To clarify myths and misperception of intracranial hypotension.

A-0521 09:15

C. RCVS, PRES and others

F. Bonneville; Toulouse/FR (bonneville.f@chu-toulouse.fr)

Reversible Cerebral Vasoconstriction Syndrome (RCVS) and Posterior Reversible Encephalopathy Syndrome (PRES) are disorders of the cerebrovascular autoregulation and are likely to share a common pathophysiology. PRES is mostly due to acute hypertension, that causes blood-brain barrier disruption. It occurs in case of preeclampsia/eclampsia, uremic encephalopathies or drug toxicity such as cyclosporine, tacrolimus or cisplatin. Patients with PRES present with headaches, seizure, altered consciousness or even neurological deficit. Most cases are regressive after blood pressure normalisation or withdrawal of causal agent. CT and MRI typically demonstrate bilateral posterior vasogenic oedema, that involves cortex and subcortical white matter in the temporal, occipital and parietal lobes, as well as in the watershed zones and the cerebellum. Basal ganglia and brainstem may be involved too. Patchy enhancement may be observed in the cortex. Haemorrhage is not rare and may be depicted in the subarachnoid spaces or in the brain parenchyma. CTA and MRA may demonstrate multifocal areas of distal arterial narrowing, a finding similar to RCVS. The latter is a rare disorder characterised by recurrent severe thunderclap headaches, with or without neurological symptoms, and transient narrowing of the cerebral arteries which is reversible within three months. RCVS onset is often associated with vasoactive medications or illicit drugs and the post-partum state. An ischemic or hemorrhagic stroke develops in about one-third of cases.

Learning Objectives:

1. To learn about the current controversial mechanism of posterior reversible encephalopathy syndrome (PRES).
2. To understand therapeutic and prognostic implications of PRES and reversible cerebral vasoconstriction syndrome (RCVS) diagnosis.
3. To appreciate imaging features of PRES, RCVS and their differentials.

A-0522 09:38

D. Hypertension-associated brain changes

A. Krainik; Grenoble/FR (akrainik@chu-grenoble.fr)

Acute intracranial hypertension (ICH) is among the most critical emergencies in medicine, which requires active management in neurointensive care and neurosurgery. Increasing pressure within the rigid spaces of the skull may lead to brain herniation through the dural openings, at risk of compression of the central nervous system and cerebral arteries. Besides arterial compression at risk of stroke, the compression of the mesencephalon is at risk of coma, and the compression of the medulla oblongata is at risk of respiratory, cardiac, and blood pressure dysregulations. Thus, careful analysis of the subarachnoid spaces is mandatory in order to identify acute intracranial hypertension that might worsen the short-term prognosis of any expanding lesion. Additionally, daily CSF production is three times its total volume. Thus any acute obstacle on its circulation may also lead to acute ICH. Chronic intracranial hypertension is mostly due to resorption dysfunction of arachnoid granulations and venous drainage into dural sinuses. Because of brain volume changes with ageing, morphological consequences and semiology depend on age, from benign ICH in younger patients with subtle subarachnoid spaces enlargement into the sella and the optic nerve sheaths, to chronic hydrocephalus without intracranial hypertension in elderly.

Learning Objectives:

1. To understand the causes of intracranial hypertension.
2. To understand the threats of intracranial hypertension on central nervous system and arterial integrity.
3. To recognise intracranial hypertension and its complications on CT and MR.

Ischaemic stroke: diagnosis

M. Taina; Kuopio/FI

The five etiological stroke categories are large artery atherosclerosis, cardioembolism, small-artery occlusion, stroke of other determined aetiology, and stroke of undetermined aetiology (cryptogenic). This classification of stroke is based on the patient's clinical status and imaging and laboratory data. With the improved spatial resolution of computed tomography angiography (CTA), CT not only excludes acute intracerebral haemorrhage but also helps to define stroke aetiology, clot location and distribution of compromised circulation. It is pivotal to evaluate the cervicocranial vasculature soon after the onset of acute cerebral ischemia to aid in the determination of the mechanism of the stroke, to help in treatment decisions, and prevent a recurrence. CTA also provides a possibility to evaluate collateral circulation. Potential utility for CT perfusion imaging in acute stroke includes the identification of the irreversibly infarcted core and at-risk brain regions (penumbra) that may be salvageable with successful intra-arterial thrombectomy beyond the standard 4.5-hour window for intravenous thrombolysis. The acute stroke CT protocol including CT, CTA, and CT perfusion helps triage patients with at-risk brain regions to available therapies, such as mechanical thrombectomy, induced hypertension or intensive monitoring of patients who are candidates for craniectomy. Accurate imaging also yields us valuable information for the management of wake-up stroke patients for whom the precise time of onset is unknown.

Learning Objectives:

1. To become familiar with the most common aetiologies of stroke.
2. To present current imaging techniques for evaluation of stroke.
3. To recognise the imaging signs of stroke.

A-0525 09:30

Ischaemic stroke: treatment

T. van der Zijden; Antwerp/BE (thijsvanderzijden@hotmail.com)

Acute ischemic stroke is a major cause of death and significant disability worldwide. The main goal in primary acute ischaemic stroke treatment is to achieve as fast as possible reperfusion of the brain area at risk for infarction. Endovascular mechanical thrombectomy has proven to be effective in doing this. Although very fast procedure times with impressive recanalisation rates can be achieved, it is vital to select the correct patients for endovascular treatment in order to avoid futile recanalisation and to prevent additional harm to ischemic stroke patients. Besides proper clinical work-up, adequate neuroradiological work-up should be performed to select the correct patients for recanalisation therapy. Imaging should not only be focused on the exclusion of haemorrhage and/or stroke mimickers and structural imaging of craniocervical arteries but also should give an idea about the extent of potentially salvageable brain tissue versus already infarcted brain. Implementing additional imaging tools, such as perfusion techniques and multiphase CT angiography, might give a better insight of prediction of clinical outcome after a potential recanalisation procedure in a given patient. During the past years, mechanical thrombectomy was mostly done by the use of stent retrievers. Due to ongoing technological developments and experiences on the job, other approaches, such as thrombus aspiration and mixed techniques, has emerged as effective treatment tools as well. Besides knowledge about the criteria and used endovascular techniques, it is also important to recognise the potential complications after mechanical thrombectomy, in order to get the best clinical outcome after treatment.

Postgraduate Educational Programme

Learning Objectives:

1. To become familiar with the criteria for the endovascular treatment.
2. To present current methods of the endovascular treatment.
3. To recognise complications of the treatment.

Screening for breast cancer

A-0526 08:30

Chairperson's introduction

F.J. Gilbert; Cambridge/UK (fig28@cam.ac.uk)

In 2003 the European Council recommended that mammography is offered two years between the ages of 50-70 years. All countries offer two yearly mammography or digital breast tomosynthesis (DBT) apart from the UK at three yearly. Nine countries start at age 40 or 45 years with 18 commencing at age 50 years. Three countries stop at 64 years, with the majority at stopping at age 69 years although three countries continue until age 74 years. Uptake varies between 37-85%, Latvia and Poland the lowest uptakes and Finland, Ireland and Holland the highest rates. Some countries have adopted DBT while others are conducting large randomised controlled trials to establish the impact, costs and benefits. It is important to ascertain whether or not this will result in a survival benefit and not merely increase overdiagnosis. Some countries offer supplemental screening with ultrasound to women with increased breast density as this increases the likelihood of developing breast cancer by two-fold in the over 50 year age group and increases the chance of cancer being missed or not being detected until the tumour is larger in size. In women at higher family history risk, a multimodal approach is justified. The increased sensitivity of MRI, especially in younger women with denser breasts, means that this more expensive modality is justified where there are more cancers to be found. However, it is important to balance the risks and benefits of MR based screening.

Session Objectives:

1. To learn about the strengths and weaknesses of different forms of breast cancer screening.
2. To understand the value of the various screening modalities and how they should be used in practice.
3. To recognise that no single screening strategy serves every patient equally well.

Author Disclosure:

F.J. Gilbert: Advisory Board; Google DeepMind. Grant Recipient; GE Healthcare, Hologic. Research/Grant Support; Hologic, GE Healthcare, volpara. Speaker; GE Healthcare.

A-0527 08:35

A. Screening with mammography and digital breast tomosynthesis alone

R.M. Pijnappel; Utrecht/NL (r.m.pijnappel@umcutrecht.nl)

Mammographic screening is beneficial to the population. Apart from a reduction in mortality less intense treatment is often possible due to the fact that the tumour burden is lower compared to a non-screening situation. Despite these advantages screening also creates inevitable harm to women. It is the challenge to balance the benefits and harms in order to optimise a screening program. Compared to FFDM tomosynthesis has advantages and disadvantages regarding recall, detection and clinical outcome. The differences between FFDM and tomosynthesis in a screening environment will be highlighted. Errors in screening are inevitable. The main errors are false-positives and false-negative results. The reasons for these errors, consequences for women and possible solutions will be discussed.

Learning Objectives:

1. To learn about the benefits and limitations of population-based mammography screening.
2. To become familiar with the advantages and disadvantages of digital breast tomosynthesis.
3. To appreciate sources of error in mammography screening.

Author Disclosure:

R.M. Pijnappel: Equipment Support Recipient; GE, Hologic, Volpara. Research/Grant Support; Hologic, Bayer.

A-0528 09:00

B. Combined screening with mammography and ultrasound

T.H. Helbich; Vienna/AT (Thomas.Helbich@meduniwien.ac.at)

The sensitivity and specificity of mammography are limited in highly fibroglandular /dense breasts. Digital mammography provides increased sensitivity in young women and those with moderately dense breasts, and

digital three-dimensional mammography (Tomosynthesis) promises further improvement. For women with the densest breasts, however, radiography is unlikely to be the optimum solution. MRI, although not affected by breast density, is expensive and access is often limited. Ultrasonography is attractive for breast cancer screening because, likewise, it is not impaired by breast density, and it avoids the use of ionising radiation and the need for breast compression. Nevertheless, enthusiasm for the use of ultrasonography has been limited because its specificity has been much lower than that of mammography, but technical developments have given rise to sharper, more informative images. These improvements foster the use of ultrasound particular in those women with higher breast density. Different trials have been performed, and promising results have been reported.

Learning Objectives:

1. To learn about the added value of ultrasound in screening and its indications.
2. To become familiar with the current level of evidence for screening with ultrasound.
3. To appreciate the role of ultrasound in clinical practice.

Author Disclosure:

T.H. Helbich: Grant Recipient; EU Grants. Research/Grant Support; Siemens, Guerbet, Bard,.

A-0529 09:25

C. Personalised multimodality screening with MRI

U. Bick; Berlin/DE (Ulrich.Bick@charite.de)

High-risk women with a genetic predisposition will develop breast cancer not only more frequently but also at a much younger age than average-risk women. Traditional population-based mammography screening programs aiming primarily at postmenopausal women are therefore not sufficient as surveillance for these women. Contrast-enhanced breast MRI with its high sensitivity independent of breast density has been shown to be the ideal screening tool for young premenopausal high-risk women. Depending on the age and risk constellation of the individual patient, this can be supplemented by mammography and/or tailored second-look ultrasound. To be effective, high-risk multimodality screening should be offered annually starting at age 25 to 30. However, even annual multimodality screening with MRI may not be sufficient in BRCA1-mutation carriers to detect a sufficiently large proportion of cancers in a curable stage, and risk-reducing mastectomy may be considered as a viable alternative in these patients. Whereas age-specific breast cancer incidence is fairly well established for BRCA1/2 mutation carriers, breast cancer risk prediction in high-risk patients without such a mutation is much more difficult, and substantial variations in calculated risk exist between the currently available models. This is of great importance, as accurate breast cancer risk prediction is vital for correctly tailoring the high-risk screening program. If the observed breast cancer incidence in the screened population is too low, the positive predictive value will decline to unacceptable levels and screening will become ineffective.

Learning Objectives:

1. To learn about multimodality screening strategies for high-risk patients.
2. To become familiar with the difficulties in predicting individual breast cancer risk.
3. To appreciate the careful balance of risks and benefits in MRI-based screening.

Career planning

A-0530 08:30

Chairperson's introduction: What do new graduates need to look like?

G. Ioannidis; Larissa/GR (i.giorgio@yahoo.gr)

The world of radiology is an everyday evolving science. Its development entangles all those involved in its everyday life. Radiographers are the main characters in the development of radiology. Young graduates who have the basing training from their school start offering their services to patients, although they have the duty to develop their knowledge as well as the science of radiology. This is achieved by participating in specialised training courses, participating in radiology courses, in research protocols as well as enriching

Postgraduate Educational Programme

their knowledge from other specialities. The most important thing though is to gain experience. Experience is gained from daily contact with radiology. Taking part in an everyday service of a radiology lab confers self-confidence to the radiographer, especially if there is a possibility of attending a large hospital curacy. Feeling confident for his knowledge the radiographer is ready to look for the specialised knowledge in his subject and consequently to develop his speciality. Finds out what he can offer to the other specialities and increases with his knowledge the demands by doctors.

Session Objectives:

1. To understand how best to prepare your professional profile.
2. To appreciate the potential for radiographers to work in various jurisdictions.
3. To consider the utility of professional development planning in achieving your professional goals.

A-0531 08:35

The role of preceptorship in first post-radiography positions

A. [Martin](#); Manchester/UK (amanda.martin@boltonft.nhs.uk)

Many radiographer vacancies are filled by newly qualified radiographers who are stepping away from the supportive and safe environment afforded to them as a student, where they are supervised closely and move into clinical practice as an accountable and autonomous practitioner. Confidence levels may be low as they suddenly find themselves being wholly responsible for their decisions for the first time in their radiography journey. Add to this the lack of familiarity in a new department, along with the expectations of staff, the pressure put on the newly qualified radiographer, by themselves or by others, may soon become too much. This may lead to mistakes being made, which could cause patient harm. It could also lead to increased stress levels, periods of sickness or resignation from their post. The provision of a structured support framework for newly qualified radiographers in the first few months of employment is pivotal in their transition into confident and effective practitioners who are likely to stay in post and develop further into valued, experienced and highly skilled radiographers. There are different approaches to preceptorship, but all should share the same key components, leading into the appraisal cycle. The models of preceptorship will be explained before one department approach to preceptorship is discussed.

Learning Objectives:

1. To understand the value of preceptorship.
2. To become familiar with common preceptorship programmes.
3. To be aware of how preceptorship programmes can benefit patients, radiographers and health care institutions.

A-0532 08:58

Practising radiography around the world

C. [Buissink](#); Groningen/NL (c.buissink@pl.hanze.nl)

Globalisation and collaboration in an international setting can no longer be ignored. This also applies to the profession of the radiographer. That is why it is important for us as Radiographers to deepen our knowledge and to look for opportunities in the international field. International collaboration has always been strong in research. However, this is not the only place where internationalisation is visible. An international mindset starts at the beginning of a Radiographer career. Therefore, many universities have included internationalisation in their curricula. The first steps could be internationalization@home (Crowther et al. 2001). Students often come into contact with internationalisation through internships, exchange programs or Summer schools. But in recent years, working for shorter or longer periods abroad has also become more common. A difficult challenge is recognition of the diploma, within Europe there are different forms of education and level of education. These are also important discussion points for national and European associations. Working as a radiographer around the world is still quite a challenge. Exchanging experiences is the first step.

Learning Objectives:

1. To be aware of the potential to use your radiography qualification in various jurisdictions.
2. To consider barriers to practicing as a radiographer abroad.
3. To appreciate the potential for charitable/voluntary work in developing countries.

A-0533 09:21

The importance of professional registration and CPD

L.A. [Rainford](#); Dublin/IE (louise.rainford@ucd.ie)

Medical imaging is becoming increasingly diverse with the continued development of multiple sub-specialities. The manner in which radiographers work within these sub-specialities and how professional work structures have developed across different countries all place a need on radiographers to continually develop and increase their knowledge and understanding of the areas of imaging they work within. Medical imaging technology and changes in practice alter rapidly. The importance of professional development planning for radiographers will be discussed in maintaining, developing and improving radiographer competencies to ensure optimal practice and service delivery, in

our ever-changing and challenging clinical environment. Mandatory or voluntary CPD is becoming a common requirement across European Radiography professional societies. The importance of CPD for radiographers will be discussed, and the EFRS CPD guidelines will be outlined. Profession registration and its importance to Radiography will be discussed in the context of professional society registration and state registration of our profession by government regulators. The benefits and challenges of registration will be outlined and "real world" details will be provided to evidence points addressed in the presentation.

Learning Objectives:

1. To understand the importance of professional development planning for radiographers in maintaining, developing and improving radiographer competencies.
2. To be aware of the essential role of CPD and further education for radiographers.
3. To appreciate the importance of professional registration.

Inflammatory and infectious diseases of the spine: how to differentiate from degeneration

Moderator:

J.L. Bloem; Leiden/NL

A-0541 08:30

A. Spondyloarthritis: a diagnostic chameleon

V. [Zubler](#); Zurich/CH

The group of spondyloarthritides comprises a number of closely related rheumatic diseases with common clinical features: Ankylosing Spondylitis, Psoriatic Arthritis, Arthritis and Spondylitis related to inflammatory bowel disease, and Reactive Arthritis. Patients can also be grouped into two categories based on their predominant clinical presentation: axial or peripheral. Axial Spondyloarthritis is inflammatory arthritis primarily involving the sacroiliac joints and the spine. Presumably, the process of inflammation starts as enthesitis, mainly visible as bone marrow oedema at the insertion of ligaments or tendons into bone. However, bone marrow oedema is an unspecific feature and occurs amongst others frequently in the context of mechanical changes and degenerative processes of the axial skeleton. Imaging is an important component of the classification criteria for axial Spondyloarthritis. Conventional radiography is an essential part of the internationally accepted modified NY criteria for Ankylosing Spondylitis but visualises only the late structural changes of the inflammatory process after years. Magnetic Resonance Imaging can detect the early changes in up to four months after clinical onset. MRI of the sacroiliac joints has been integrated as a key diagnostic criterion of axial Spondyloarthritis according to the Assessment of SpondyloArthritis International Society (ASAS) in 2009.

Learning Objectives:

1. To explain the pathophysiology and disease spectrum of spondyloarthritides.
2. To describe the imaging findings of spondyloarthritides.

A-0542 09:00

B. Crystals: may also affect the spine

P.J. [O'Connor](#); Leeds/UK (philip.oconnor@nhs.net)

Crystal deposition in the spine is unusual. The presentation varies from acute pain syndromes to subclinical disease usually detected as an incidental finding on cross-sectional imaging. The pathophysiology, clinical presentation and imaging appearances of crystal disease will be presented. Spinal gout, acute longus colli hydroxyapatite deposition and Crown dens syndrome resulting from either hydroxyapatite or pyrophosphate deposition will be described. Differentiating crystal disease from ligamentous ossification, degeneration and other deposition diseases such as amyloid will be discussed. Gout is a common inflammatory arthritis most commonly seen on men and post-menopausal women. The prevalence of gout is currently increasing over time. Spinal gout typically presents with localised pain, incidental lytic vertebral lesions usually detected on cross-sectional imaging or with symptoms resulting from neurological compromise. Spinal gout most commonly affects the posterior elements of the spine. Crowned dens syndrome results from crystal deposition around the odontoid peg of the cervical spine. It presents with acute neck pain and unless recognised often leads to misdiagnosis and inappropriate treatment. The deposition can be either pyrophosphate or hydroxyapatite

crystals with both having identical imaging appearances. A similar clinical presentation is also seen in Acute calcific longus colli hydroxyapatite deposition. This is a rare cause of severe neck pain, dysphagia and odynophagia is often mistaken for other common causes of neck pain. Similar to crowned dens syndrome prompt recognition is important to prevent unnecessary imaging or treatment.

Learning Objectives:

1. To explain the pathophysiology and disease spectrum of crystal deposition diseases that affect the spine.
2. To describe the imaging findings of crystal deposition diseases that affects the spine.

C. Infection: imaging, indication and techniques for biopsy
J.-L. [Drapé](mailto:jean-luc.drape@cch.aphp.fr); Paris/FR (jean-luc.drape@cch.aphp.fr)

The diagnosis of spinal infections is often made by a combination of clinical symptoms and radiologic abnormalities. Magnetic resonance imaging is the main imaging modality for this diagnosis. Confirmation is based on histopathologic findings and/or identification of pathogens from biopsy specimens or blood cultures. Percutaneous biopsies are widely practiced in this indication, with the more accurate and safer guidance of computed tomography (CT). Two main types of percutaneous biopsies are available: fine needle aspiration biopsy and core needle biopsy. Specific techniques and approaches with varying needle systems are described for each spinal region. It is the procedure of choice in the definitive diagnosis of pathologic lesions of the spine.

Learning Objectives:

1. To describe the imaging findings of spinal infection.
2. To explain the biopsy indication and techniques in spinal infection.

Joint Session of the ESR and EFOMP

ESR/EFOMP

Medical imaging and emerging issues in occupational radiation exposure

Moderators:

M. Brambilla; Novara/IT
W.R. Jaschke; Innsbruck/AT

A-0544 08:30

Is fear of radiation-induced occupational cancer irrational?
P. Vock; [Spiegel](mailto:Spiegel@CH)/CH

Starting with a short overview of the development of occupational dose limits, this presentation will concentrate on the quantitative estimation of the risk of radiation-induced occupational cancer. While facts are often statistically solid in the higher dose range, below around 50 mSv of effective dose the linear-no-threshold (LNT) model of dose-risk relation has been questioned by a number of radiobiological studies; existing epidemiological data, due to limited power, do not differentiate between LNT, non-linear and threshold-based models. In other words, the LNT model might either overestimate or underestimate the risk. Furthermore, even for the same physical dose the gender, age at exposure, the temporal distribution of exposure, whole-body vs regional exposure, and individual radiosensitivity will modify the biological impact and, thus, the cancer risk. Known and unknown influences of these modifications will be discussed. Despite open questions, enough facts are established to give the exposed workers clear rules to protect themselves. The communication, therefore, has to show known and disputed risks and to clarify that a medical worker (above all an interventional radiologist) can avoid a lot of unnecessary exposure and reduce the risk to a low, tolerable level by his/her behaviour and skills that are based on a solid training, and the proper use of technical options of the equipment as well as of protective devices. In conclusion, while professional exposure to ionising radiation asks for our respect and a continuous ALARA culture, nonspecific fear of cancer is not justified.

Learning Objectives:

1. To learn how occupational dose limits have been established by ICRP to reduce the probability of stochastic effects.
2. To appreciate the order of magnitude of additional risk of cancer induced by occupational exposures.
3. To understand how these risks should be properly communicated to workers.

A-0545 08:50

Eye lens radiation dose and cataractogenesis
J. Damilakis; Iraklion/GR (damilaki@med.uoc.gr)

Several recent studies have shown a significant association between long-term exposure to low-dose radiation and increased risk of cataract formation. It is evident that the eye lens is more radiosensitive than previously estimated and thus protection of the eyes of occupationally exposed personnel is very important. Radiation-induced opacities and cataracts may take years or decades to develop. It is not entirely clear whether radiation-induced cataracts are stochastic or deterministic effects. However, it is known today that cataracts can occur after receiving radiation doses as low as 0.5 Gy. For this reason, the International Commission on Radiological Protection (ICRP) has accepted the dose threshold of 0.5 Gy for radiation-induced cataracts. The equivalent dose limit for the lens of the eye for occupational exposure has been reduced from 150 mSv per year to 20 mSv per year averaged over defined periods of 5 years, with no annual dose in a single year exceeding 50 mSv. Interventional radiologists may reach cumulative lens doses that put them at risk for developing cataracts. Eye lens dose monitoring methods will be presented and discussed. To keep lens doses as low as possible, exposed personnel must use radio-protective glasses.

Learning Objectives:

1. To become familiar with published data on lens opacities among interventionalists.
2. To discuss current methods for monitoring of eye lens doses.
3. To learn how effectively lead glasses protect the eyes of interventional radiologists.

A-0546 09:10

Occupational exposure from interventional radiology procedures: how to measure it, how to reduce it

W.R. Jaschke; Innsbruck/AT (werner.jaschke@i-med.ac.at)

The occupational dose of the Operator in fluoroscopically guided interventions can be assessed by personal dosimetry using thermoluminescence Dosimeters and real-time dosimetry. Personal dosimetry is a very reliable tool to measure personal dose but suffers from the fact that the operator gets the dose information with a time delay of weeks or sometimes even months. Real-time dosimetry is less accurate but provides real-time dose data. Thus, the operator gets immediate feedback on dose rate and how the dose rate changes if certain protective measures are put in place. Real-time dosimetry is, therefore, very important for individual radiation protection and optimisation. Occupational exposure arises mainly from scattered radiation from the patient and the angiographic Equipment. Scattered Radiation is undirected. Thus, radiation protection equipment has to be used to protect the operator. The most important tools are aprons, neck collars, lead glass shields and curtains as well as lead glass goggles. Operators have to be trained how to apply these protective measures most effectively and that they have to be used in every procedure. In addition, decreasing dose to the patient using dose optimised angiographic protocols is another important step to decrease dose to the operator.

Learning Objectives:

1. To learn which technical factors contribute to occupational exposures from interventional radiology procedures.
2. To appreciate that optimisation of a patient's exposure is a way to also reduce occupational exposure.
3. To understand additional means to reduce the occupational exposures.

A-0547 09:30

Selection and usage of personal protective equipment in the fluoroscopy and interventional radiology operating room

M. Brambilla; Novara/IT (marco.brambilla@maggioreosp.novara.it)

Workers can be exposed to significant scatter radiation during fluoroscopically guided interventions. Radiation-attenuating personal protective equipment (PPE) includes aprons to protect radiosensitive body organs, glasses to prevent cataract development, thyroid collars to protect a radiosensitive organ, lead equivalent surgical gloves and caps to reduce hands and head exposure. PPE can afford very different degrees of protection of different parts of the body during fluoroscopy and interventional radiology procedures. The concept of dose reduction factors (DRFs), equal to the ratio of the dose to the part of the body with no PPE, divided by that when PPE are worn will be introduced. The typical DRFs provided by the different PPE (Body, Thyroid, Eye lenses, Head, Extremities) will be reviewed. The need of wearing specific PPE will be discussed for the interventionalists, nurses and radiographers. Each worker involved in fluoroscopically guided interventions should wear garments that are appropriately protective for that individual's practice. Review of past personal dosimetry results and consultation with a medical physicist should guide this choice.

Learning Objectives:

1. To learn which personal protective equipment is needed for specific radiological practices.

2. To become familiar with occupational dose reduction provided by personal protective equipment.
3. To understand that a correct selection, use and periodic check of personal protective equipment are needed to ensure radiation protection of healthcare personnel.

09:50

Lung nodule management in 2019

A-0548 08:30

Chairperson's introduction

A. [Devaraj](#); London/UK

An overview of recent developments in lung nodule characterisation and management will be provided. Tips on optimal nodule characterisation and measurement will be provided; including how to avoid false positives and false negatives; as well as a brief overview of the appropriate use of lung nodule management guidelines in 2019.

Session Objectives:

1. To avoid common errors in nodule categorisation or measurement.
2. To summarise the recent knowledge about nodule management.
3. To understand the place of risk prediction models.

A-0549 08:35

A. Radiological assessment

T. [Frauenfelder](#); Zurich/CH (thomas.frauenfelder@usz.ch)

Lung nodules are common radiological findings in the clinical practice, and the majority of them remain indeterminate at imaging. Determination of lung nodule malignancy is pivotal because the early diagnosis of lung cancer could provide a curative intervention. Therefore the correct interpretation and management of a lung nodule represent relevant issues for radiologists. The probability of nodule malignancy depends on patient risk factors and nodule characteristics (size, morphology, attenuation, growth). In addition, management is substantially influenced by the nodule size, attenuation (solid, ground-glass, part-solid) and growth rate. But in daily life we often struggle by the question: is this a real nodule? And more often: what type of nodule is it, especially if there is a slightly blurry rim? Furthermore, although knowing that periferous nodules are known to be benign, there are clear definitions what this means. Nevertheless, also here there is no clear black or white. Following the guidelines and definitions, we will establish the characteristics of the different types of nodules.

Learning Objectives:

1. To learn how to recognise false nodules.
2. To learn how to classify lung nodules as solid, part solid or non-solid.
3. To be aware of the typical and atypical characteristics of periferous opacities.

A-0550 08:58

B. Computer-aided diagnosis and AI perspective

A.R. [Larici](#); Rome/IT (annarita.larici@unicatt.it)

Machine learning (ML) describes a subfield of artificial intelligence (AI) in which algorithms are trained to perform tasks by learning patterns from digital data. In classic ML approach, as the ones used in CAD algorithms, programmers define the features that appear distinctive of a disease and mathematic models are trained to identify such features. Newer ML techniques, as deep learning (DL), are focused on a particular outcome (e.g. nodule characterisation), and the distinctive features are identified through a training learning process. ML uses computational models and algorithms that imitate the architecture of the brain (artificial neural networks-ANNs). AI has the potential to replace the tasks of lung nodule detection and characterisation on images, currently performed by radiologists, with the advantage to overcome the subjectivity of human work in a quicker and standardised fashion. AI system also has the potential to automatically integrate multidisciplinary clinical data in the above-described processes and has been applied in the Radiomics analysis. Newer AI approach will increase the accuracy of CAD in lung nodule detection, especially decreasing false-positive results. Using recent CNNs 90% accuracy-one false positive detection per scan has been reported. Until recently only classical CAD-ML approaches were used for nodule characterisation. A recent experience integrating both classic ML and DL systems demonstrated a 0,99 AUC value in the lung nodule malignancy prediction. In this presentation, the

most relevant applications of CAD and AI on lung nodule diagnosis and management will be reviewed.

Learning Objectives:

1. To review the capabilities and limitation of CAD for the detection of lung nodules.
2. To learn about the performance of AI in the detection and characterisation of lung nodules.
3. To understand the basic concepts of machine learning as applied to imaging.
4. To summarise currently available machine learning techniques in radiology.

A-0551 09:21

C. Management guidelines

A.A. [Bankier](#); Boston, MA/US (abankier@bidmc.harvard.edu)

Pulmonary nodules detected on chest CT examinations often pose a substantial management problem. This presentation will review current guidelines designed to approach this problem. The presentation will also address models for evaluating the risk of a pulmonary nodule to be malignant. Finally, the presentation will discuss the fundamental differences between screening-detected and incidental pulmonary nodules.

Learning Objectives:

1. To review the incidentally-found nodule management guidelines.
2. To become familiar with the LungRADS classification of screen-detected nodules.
3. To learn about Brock and Herder and other prediction models for evaluating the malignancy risk.

Radiomics+: prediction model using convergent data

A. [Leimgruber](#); Lausanne/CH (antoine.leimgruber@hopitalrivierachablais.ch)

Medical Imaging generates large amounts of data commonly assessed visually using scientific evidence and expert knowledge combined with clinical patient-specific information. Quantitative methods have also been developed in today's multi-modality environment, providing morphologic, functional and biological information. Recent advances in data mining of quantitative image features together with powerful image analytic tools have led to what is known today as "radiomics". Naturally, radiomics analytic techniques have been welcomed with both enthusiasm and scepticism. The process used in radiomics involves the identification of vast arrays of quantitative parameters within digital images. The major challenge is to integrate radiomics data with clinical, pathological, and genomic information to decode the different types of tissue biology and specificities of the disease within a patient in a new paradigm that we introduce in this talk as "radiomics+". Imaging is indeed not the only field roaming the uncharted territory of large medical datasets. Pathology, liquid biopsy techniques or genetic analyses all provide an increasing number of molecular biomarkers. Oncology is the large port of entry of this trend given the need to tailor an increasingly diverse array of targeted therapies to the specificities of each patient and the history of each cancer within each individual. Many institutions are in the process of developing analytic personalised oncology programs (APOs). Through this prism and early local and wider APO experience, this talk will endeavour to give credit to both the traditional expert visual assessment and the radiomics approach and analyse the challenges ahead.

Learning Objectives:

1. To discuss the omics revolution and the different techniques used in radiomics and radiomics+.
2. To present trends in radiomics.
3. To understand personalised medicine initiatives by the example: where does radiomics+ fit in?

A-0553 08:50

AI and Holomics: predicting the truth from hybrid imaging and non-imaging data

I. [Buvat](mailto:irene.buvat@u-psud.fr); Orsay/FR (irene.buvat@u-psud.fr)

Hybrid imaging lends itself to the measurement of a large number of radiomic features. These include so-called handcrafted features and deep features derived either from the native images or from parametric images. This wealth of image-based information has a great potential for decision making using modern AI approaches. Yet, it is likely that if images are necessary for in vivo probing of biological mechanisms, they are not sufficient for accurate prediction of the patient outcome that depends on a number of other parameters. This is why radiomic data have to be enriched with other relevant omic or clinical data, yielding the concept of holomics. The integration of that huge diversity of data into accurate and robust models for guiding precision medicine raises a number of new challenges that will be presented and illustrated. Addressing these challenges may actually need rethinking the way we conduct research in imaging as will be discussed. In addition, the overwhelming trend towards AI-based data analysis should not hide the crucial importance of both the quality and the relevance of the input data, whatever they are. Only a clever and thorough use of sensitive and specific images reflecting biological mechanisms in an understandable way and combined with other data that also express phenomena to be accounted for will allow us to approach the truth. In that respect, AI has to be combined with human intelligence to make the most of imaging and non-imaging data in the context of precision medicine.

Learning Objectives:

1. To get an overview about shallow and deep learning.
2. To appreciate supervised, unsupervised and reinforcement learning with examples.
3. To learn about Holomics: a holistic approach for precision medicine, concept and examples.

A-0554 09:10

Sharing is caring: on the need for open research data

O. [Ratib](mailto:ratib@unige.ch); Geneva/CH

The developments of imaging biobanks and cloud-based data storage services have radically changed the way we deal with communication and data management in our daily life. On-line storage of medical images is not new; several vendors have offered such services for decades already as part of their commercial solutions. What has really changed these recent years is the emergence of such services for the wide public offering very attractive solutions at a very low cost. In medical applications, however, such systems must comply with strict regulations and guidelines geared toward protecting patient confidentiality and data security. Medical imaging is becoming a major component of the data required in every medical decision in diagnostic, assessment of treatment response, follow-up of disease recurrence and in support for therapeutic and surgical interventions. The wealth of data acquired in clinical routine these days is overwhelming and has not been apprehended yet. The main limiting factor of the development of these new analysis techniques is the lack of sufficiently large sets of structured and well-documented imaging data. There are also major difficulties in the ability to collect these large sets of imaging data due to restrictive regulatory constraints and data protection rules that prevent the usage and exploitation of medical data without formal patient approval. Our presentation will focus on the specific issue of gathering and collecting medical images for the development of large Big-Data repositories for scientific research and review the current challenges that prevent their wide development today.

Learning Objectives:

1. To give an introduction to new concepts of Open Research Databases and Big-Data repository and their impact on development of new paradigm of data-driven patient management and personalised healthcare.
2. To understand the underlying challenges and requirements as well as the ethical and legal framework that regulates the setup and usage of large collection of patient data for open research.
3. To review of potential applications in molecular imaging and in support of multi-centric clinical trials.

Captain's dashboard

A-0555 08:30

Chairperson's introduction

S. [Morozov](mailto:spmoroz@gmail.com); Moscow/RU (spmoroz@gmail.com)

A plethora of dashboard's concepts are thoroughly developed for the general management applications. A basic principle beyond dashboards states that only measurable things can be managed. Hospitals and healthcare systems around the world have developed or purchased and customised dashboards for tracking their patients' and hospitals' parameters. Being a captain in a radiology department requires a set of management skills which can be learnt and developed through a career. This session calls together experienced leaders, entrepreneurs and managers who are going to share their insights and practical examples of utilising managerial skills. Basic and advanced techniques to run radiology and healthcare projects through will be presented, including MBO, delegation, PDCA, BSC, KPIs, waterfall, agile, etc.

A-0556 08:36

A. Fundamentals of imaging management and administration

B. [Bijan](mailto:drbijanbijan@gmail.com); Sacramento, CA/US (drbijanbijan@gmail.com)

Functioning efficiently, at the level of director/chairperson/executive/chief, requires certain knowledge, skills and experience. Traditionally, the need for such managerial training was less crucial however in today's rapidly growing imaging universe, having formal training in such areas has become mainstream. Many chairpersons are actively trying to get formal training in management, attending hi-yield management and leadership courses and actively trying to broaden their knowledge, learn new skills and obtain experience. For the sake of time, here at ECR-2019, I will focus my presentation on the crucial areas of the art of building an efficient team, usage of the "Imaging informatics" technology to the max, to understand imaging economy and finance, to understand the concept of "system efficiency", communication and interaction protocols as well as risk management and the feedback system in place including dashboard monitoring.

Learning Objectives:

1. Strategy for a radiologist in a changing healthcare landscape.
2. How to leverage a physician's role by learning managerial skills.
3. Setting a goal, making it doable, prioritising, focusing and choosing what not to do.

A-0557 09:04

B. Being in a driver's seat and managing by objectives

Y. [Menu](mailto:yves.menu@sat.aphp.fr); Paris/FR (yves.menu@sat.aphp.fr)

For medical, technical, regulatory, networking and behavioural reasons, the challenge for managers is to adapt to a rapidly evolving environment. The initial analysis is achieved by different formal or informal tools including interviews, risk mapping and Lean 6 Sigma methods. It identifies gaps between performance and strategic goals, chosen as useful, shared and reachable objectives. Key Performance Indicators (KPIs) are powerful tools that will allow the follow-up of action. They are measuring tools. They are usually related to structure, process or outcome. They follow the SMART method (Specific, Measurable, Assignable, Realistic, Time-related) and measure specific services, like the best use of a CT platform, or Patient wait time. They include and quantify the objective, define the handling person, method of sampling and criteria for success. Balanced scorecards are syntheses aimed at sharing information easily and visually. They summarise KPIs. It is the manager's preferred dashboard. Balanced scorecards can also be used as a hierarchical presentation of information, with the possibility to access to a "clickable" detailed and analytic level. PDCA (Plan, Do, Check, Act) is a more global tool for management as it highlights strategy (Plan), production (Do), monitoring (Check) and improvement (Act). It helps to classify all management initiatives in a global plan. It is commonly used for certification of a department. Whatever the tool, the manager is still in charge of kick-off initiatives and final decisions. Tools will help him driving the projects and sharing it in and outside the team, but will never be a substitute.

Learning Objectives:

1. Definition of a workflow, roles and results.
2. Balanced scorecard, KPIs, dashboard and PDCA instruments for a radiology department.
3. IT solutions for automating and increasing efficiency.

C. Challenging the status quo and making new things happen

P.M.A. [van Ooijen](mailto:van.Ooijen@umcg.nl); Groningen/NL (p.m.a.van.ooijen@umcg.nl)

Radiology is at the brink of change because of all new developments are shown in Medical Imaging Informatics. For a radiology department to keep up with all developments, quick changes and adaptability of the staff and workflow models is an absolute requirement. Not only for radiologists, but also for radiographers, clinical physicists and other employees. Furthermore, new professional experts will enter the radiology domain such as medical computer scientists, data scientists and technical physicians. All these developments mean that the status quo is heavily challenged and radiology should be prepared to make new things happen. For leaders in radiology, this means that they have to be able to lead those changes against the wind by implementing change management. Furthermore, instruments already common in IT development such as Scrum and Agile will start entering the radiology domain and should be understood by radiology leaders. The overall observed change is that radiology should move (or already moves) into a value-based service using new developments to get to a more patient-centric workflow with extensive integration of the imaging in the patient workflow throughout the health process.

Learning Objectives:

1. Leading the changes against the wind: principles of change management.
2. Project management and new instruments, including Scrum, Agile.
3. Value-based service: new frontiers in medical imaging.

Foetal and neonatal imaging pearls

A-0559 08:30

Chairperson's introduction

E. [Vázquez](mailto:evazquez@vhebron.net); Barcelona/ES (evazquez@vhebron.net)

Fetal MRI has acquired an important role in the diagnostic workup of fetal abnormalities suspected on ultrasound study. Radiologists and clinicians involved in this task should be aware of the uses and limitations of fetal MRI. Suspected CNS disease continues to be the most common clinical indication for this imaging technique. Congenital malformations such as corpus callosum anomalies are among the most common requests, in which MRI can rule out other associated abnormalities, such as sulcation abnormalities or grey matter heterotopia, with high diagnostic accuracy when compared to postnatal findings. In acquired brain damage, the previously normal tissue is destroyed by diverse mechanisms, such as hypoxia, infection, metabolic disease, and even space-occupying lesions. The effect of these insults can be precisely detected with MRI and correlated with postnatal features. This technique can also be of help for evaluating fetal abdominal conditions. For example, ultrasound visualisation of some genitourinary abnormalities may be difficult because of associated oligohydramnios. MRI can accurately delineate the anatomy and identify normal renal parenchyma and cysts. In addition, newer sequences, such as diffusion-weighted imaging, are useful for assessing the normal functional kidney. This course will provide an educational overview of the main techniques and recent technological advances in fetal MRI, applicable in both CNS and body examinations. Finally, a panel discussion will be conducted, focused on overcoming certain challenges in fetal MRI performed for routine and research purposes, including technical and safety concerns.

Session Objectives:

1. To learn about the advanced techniques in foetal MRI.
2. To understand some useful applications in brain malformations or acquired injuries.
3. To discuss the main limitations and challenges of foetal MRI.

A-0560 08:35

A. Foetal MRI advanced technics

G. [Kasprian](mailto:gregor.kasprian@meduniwien.ac.at); Vienna/AT (gregor.kasprian@meduniwien.ac.at)

A human foetus can be considered as the most "uncooperative" patient. Thus, any "advanced" foetal MR imaging technique has to deal with the problem of unpredictable fetal motion. Since the beginnings of foetal MRI in the 1980ies, the most promising strategy in addressing the problem of foetal motion was shortening the acquisition time of MR sequences. This strategy has been successful for those sequences, which are nowadays regarded as "standard": T2-TSE, T1SE, SSFP, EPI/T2* and DWI sequences. After shortening Diffusion Tensor Imaging (DTI) sequences to a maximum acquisition time of 2 minutes, it has been possible to reconstruct main sensorimotor and commissural pathways in normal and pathological cases. Postmortem histo-tensor and postnatal DTI studies have recently validated these results. Thus, DTI -

commonly regarded as "experimental" in fetal MRI - can even provide clinically important data for our understanding of fetal brain pathologies. If fetal "resting state" BOLD MRI data are processed with meticulous motion, slice timing, bias field and noise correction, connectivity profiles of the fetal brain or the placenta can be generated even in single subjects. Adjusted single voxel spectroscopy sequences can be applied prenatally and may complement standard fetal MRI providing valuable insights into fetal or placental metabolism. Although interpreting the results of advanced fetal MRI techniques may have its uncertainties and risks, careful incorporation of these methods into clinical fetal MRI protocols further strengthens the position of fetal MRI as an important complement to ultrasound in the assessment of fetal pathologies.

Learning Objectives:

1. To learn about the principles for advanced techniques in foetal MRI.
2. To understand the potential for their use.
3. To discuss the limitations and disadvantages of these techniques.

Author Disclosure:

G. [Kasprian](mailto:kasprian@meduniwien.ac.at): Consultant; Bellaria Diagnose. Grant Recipient; Austrian Science Research fund, Nr. I 3925. Speaker; Shire, Biogen.

A-0561 08:53

B. Corpus callosum anomalies: pre- and postnatal correlation

C. [Garel](mailto:catherine.garel@aphp.fr); Paris/FR (catherine.garel@aphp.fr)

Corpus callosum (CC) malformations include complete and partial CC agenesis, short CC and CC dysgenesis. They can be isolated or observed in the setting of numerous syndromes. Moreover, pericallosal lipomas or interhemispheric cysts may also be observed in association with CC malformations. The diagnostic contribution of prenatal MRI ranges between 0 and 20% according to the sonographer's skill and the conditions of the US examination. In about 22.5% of cases, MRI can detect additional abnormalities. The presence of such abnormalities may have a prognostic impact. Disagreement between pre- and postnatal imaging with the postnatal identification of associated cerebral anomalies considered as having a prognostic impact, is observed in about 9%. The prognosis of CC malformations associated with a curvilinear lipoma or with an interhemispheric cyst without cortical anomalies is very good. Except for these two entities, associated CC agenesis usually carries a poorer prognosis than an isolated one. Identification of genes mutations observed in children presenting with CC agenesis with or without intellectual deficiency is currently under development.

Learning Objectives:

1. To evaluate the diagnostic accuracy of foetal MRI for diagnosis.
2. To compare pre- and postnatal MRI data.
3. To ascertain the outcome in cases of isolated complete or partial agenesis.

A-0562 09:11

C. Foetal MR imaging of acquired brain pathology

P.D. [Griffiths](mailto:p.griffiths@sheffield.ac.uk); Sheffield/UK (p.griffiths@sheffield.ac.uk)

MR imaging of the unborn baby's brain has become an established method of detecting brain pathology ante-natally. Most structural brain abnormalities shown on fetal MR are developmental in nature (e.g. agenesis of the corpus callosum, Dandy-Walker malformation) but there is increasing recognition that some brain abnormalities are 'acquired' that is occurring in a brain that was otherwise developing normally (e.g. stroke, trans-placental infections). In this presentation, I will review the types of pathology that can lead to brain injury acquired in utero and present data from the MERIDIAN study that shows the prevalence and range of such abnormalities.

Learning Objectives:

1. To learn about the various types of acquired brain pathology in the foetus.
2. To understand the limitations in the comprehension of the underlying cause.
3. To discuss about the best estimates of the prevalence of acquired brain pathology.

A-0563 09:29

D. Pre- and postnatal congenital cystic renal diseases

M. [Cassart](mailto:mcassart@his-izz.be); Brussels/BE (mcassart@his-izz.be)

The finding of hyperechoic kidneys in foetuses and children is a challenge for radiologists. It can be simply a normal variant with further resolution or an early sign of congenital renal cystic disease. These renal diseases can be uni or bilateral, isolated or part of polymalformative syndromes. Various entities can be encountered in this context: obstructive uropathies if associated with dilatation of the collecting system, multicystic kidney disease if macrocysts are present. Inherited renal cystic diseases should also be considered: recessive polycystic kidney disease in bilateral undifferentiated enlarged kidneys, dominant polycystic kidney diseases in slightly enlarged well-differentiated kidneys with cortical cysts or renal diseases associated with TCF2 mutations that can have many different aspects. The contribution of imaging can be optimised by the knowledge of the normal sonographic appearance of the kidneys at various ages and the typical patterns of different inherited renal diseases. Syndromes should be suspected in typical renal patterns associated with extrarenal anomalies (central nervous system, limb...) like for example in

Friday

Meckel Gruber or Bardet Biedl syndromes. The imaging data should also always be integrated into the familial context (consanguinity) and obstetrical history in case of recurrence. It most frequently allows approaching the specific diagnosis or at least orient the genetic testing to precise the diagnosis and establishes a prognosis.

Learning Objectives:

1. To learn about differential diagnosis of hyperechoic kidneys in fetuses and children.
2. To become familiar with the latest classification of inherited renal cystic diseases.
3. To discuss the limitations of the imaging methods for diagnosis.

Chronic obstructive pulmonary disease (COPD)

A-0564 08:30

Chairperson's introduction

D. Litmanovich; Boston, MA/US

A-0565 08:36

A. CT phenotyping and visual assessment

P.A. Grenier; Paris/FR (philippe.grenier@aphp.fr)

COPD is a slowly obstructive airway disorder resulting from an exaggerated inflammatory response to cigarette smoking and air pollution that ultimately destroys lung parenchyma and induces an irreversible reduction in calibre and number of small airways. Both phenomena (emphysema and small airway disease [SAD]) are responsible for airflow limitation. Because often SAD precedes lung destruction, patients having equal impairment of lung function may present different morphologic appearances on CT scans. Although quantitative CT is useful for identifying and sequentially evaluating the extent of emphysematous lung destruction, changes in airway walls and expiratory air trapping, visual assessment of CT scans is important to describe patterns of altered lung structures in COPD. Emphysema is classified as centrilobular (subclassified as trace, mild, moderate, confluent and advanced destructive emphysema), panlobular and paraseptal (subclassified as mild or substantial). Airway disease is commonly found with all forms of emphysema but also commonly occurs in the absence of emphysema as a predominant expression of COPD. The CT features of the bronchial disease include thickening of the walls of segmental and subsegmental airways. CT features of SAD include peripheral centrilobular micronodular opacities (inflammatory SAD) and gas trapping on expiratory CT (obstructive SAD). Associated features may be seen on large airway disease (tracheobronchomalacia, sabre sheath trachea, tracheobronchial outpouching/diverticula). Interstitial lung abnormalities include patchy ground-glass abnormality and/or mid subpleural reticular abnormality. Other associated features include pulmonary arterial enlargement suggesting pulmonary hypertension, and bronchiectasis.

Learning Objectives:

1. To learn about imaging-based phenotypes.
2. To understand the limitations of visual assessment.

P.A. Grenier: Speaker; oxyvie.

A-0566 09:04

B. Quantitative imaging biomarkers

J.B. Seo; Seoul/US (seojb@amc.seoul.kr)

A biomarker is defined as an indicator of a biological state that is objectively measured and evaluated. Biological state includes including, normal biological processes, pathogenic processes, or pharmacologic responses to a therapeutic intervention. Imaging modality can also be used to extract biomarkers. In recent studies on COPD, CT has been accepted as one of the important research tools in evaluating disease severity and characteristics. The extent of low attenuation area and bronchial wall thickening at a segmental and distal level on volumetric CT scan acquired at suspended inspiration state are commonly used as useful imaging markers for evaluating the severity of emphysema and airway wall inflammation, respectively. The clinical values of these two imaging biomarkers are as follows: 1) Many recent studies have proved that the extent of emphysema and bronchial wall thickening are independently related with the degree of airflow limitation, 2) The extent of

emphysema is correlated with other clinical parameters such as osteoporosis, exercise capacity, respiratory symptoms and most importantly with BODE index, which is known to be one of the best predictors of mortality, 3) Both parameters may be useful in subgrouping/phenotyping of patients, prediction of treatment response, and prediction of disease progression 4) Both parameters are related to frequency of exacerbation. Furthermore, many additional potential imaging biomarkers have been proposed. They include; (1) assessment of air trapping by direct anatomical matching of inspiration and expiration CT, (2) assessment of peripheral vascular changes in COPD, and so on.

Learning Objectives:

1. To understand the role of quantitative imaging in identifying COPD phenotypes.
2. To appreciate the recent development of quantitative imaging methods.

A-0567 09:32

C. Is there a role for MRI?

M.O. Wielpütz; Heidelberg/DE (wielpuetz@uni-heidelberg.de)

Magnetic resonance imaging (MRI) has emerged as a new modality for lung imaging only recently, with airway diseases being the most accepted indications for clinical routine imaging. Beyond being a substitute for X-ray and computed tomography (CT), MRI combines morphologic and functional information more consequentially than any other technologies. Morphological sequences for proton MRI suitable for airways disease will be introduced, but the focus will be on functional techniques that have been introduced into clinical routine imaging or are most advanced in scientific studies. These are dynamic contrast-enhanced perfusion MRI, T1-mapping with inhalative oxygen, and non-contrast Fourier-decomposition MRI, which allow for a regional analysis of lung function. Further, noble and fluorinated gas MRI will be discussed as advanced scientific methods to study regional lung ventilation. It has been shown that MRI may sensitively detect changes in lung morphology related to large airways diseases such as airway wall thickening, bronchiectasis, mucus plugging or tracheobronchomalacia with lower resolution than CT, but with similar clinical impact. Ventilation abnormalities attributable to small airways disease are closely linked to subsequent perfusion changes, which can be sensitively detected by dynamic contrast-enhanced perfusion MRI. By a combination of morphological with functional techniques, MRI has the potential to specifically differentiate reversible from irreversible lung changes especially in airway diseases such as COPD and cystic fibrosis. This makes MRI an important modality for non-irradiating regional disease monitoring and therapy follow-up. Subsequently, it has now been used as an endpoint in pioneer clinical trials, which will be presented briefly.

Learning Objectives:

1. To learn about the morphological and functional evaluation achievable with MRI.
2. To learn about the recent developments in lung MRI.

Head and Neck

RC 908

Head and neck imaging: when does it become abnormal?

Moderator:

N. Thieme; Berlin/DE

A-0568 08:30

A. Normative measures in the temporal bone

F. Veillon; Strasbourg/FR (Francis.Veillon@chru-strasbourg.fr)

The normal size of certain parts of temporal bone structures is important to be known for the CT diagnosis of the very frequent minor malformations of the inner ear, the increased thickness of the footplate (chronic inflammation otosclerosis) or the abnormal enlarged facial nerve canal (malformations, tumours). The knowledge of the normal size of the saccule in MRI permits to diagnose its dilation. In CT, the round window (normal width: 1.5 mm in the axial and coronal planes, small from 1.3 mm), the oval window (normal height: 1.5 mm-1.9 mm in the coronal plane, small from 1.3 mm), the normal thickness of the footplate in recent machines: 0.3 mm, increased: 0.5 mm, the normal central islet (surface circumscribed by the lateral semicircular canal in the axial plane, 7-10 mm², small from 6 mm²), the medial part of the lateral semicircular canal in the axial plane (normal minimum: 1.7 mm, enlarged from 1.8 mm), the

modiolus (normal width: 2 mm in the axial plane, small from 1.3 mm, enlarged from 3 mm), the normal aqueduct of vestibule (in the axial plane: 1.5 mm, enlarged: 1.7 mm). The inferior part of the basal turn of the cochlea (normal length: 9 mm, small from 7.3 mm), the geniculate ganglion fossa (3 mm on average, normal limits: 1.8-4.5 mm). The normal saccule in MR coronal view (normal maximal height: 1.6 mm, 1.3 mm on average, normal width: 1.4 mm). You can easily use these measurements in your daily practice.

Learning Objectives:

1. To learn about the appearance of the bone in the normal population.
2. To understand the changes in size and shape due to aging.
3. To show some examples of structures which are too large or too small.

A-0569 09:00

B. Normative measures in the orbit

R. [Kohler](#); *Sion/CH*

In the daily routine, it is not infrequent that the radiologist does not know if his/her observations of the orbit and eye at CT and MRI are in the normal range or a true pathology. Normative measures are objective data that help the radiologist for the diagnosis of many issues but also are useful for the follow-up of some pathologies. A selection of normative measures but also some changes of shape and anatomic variations will be discussed in this presentation according to five main chapters based on the anatomy: Bony orbit: how to define and grade exophthalmos and how to determine hyper-/hypotelorism? Eye: a review of main shape abnormalities. For example, coloboma, microphthalmia and axial myopia will be discussed. Optic nerve and optic nerve sheath: what is their normal size? Hypertrophy, atrophy and tortuosity of the nerve as well as dilatation of the nerve sheath will be exposed. Attention will also be given to two special applications of measurement of the optic nerve: variations in size in case of intracranial hypertension and diffusion-weighted imaging. Extraocular muscles: how to measure them, especially in case of thyroid orbitopathy? Miscellaneous: a short review of abnormalities of the size of the superior ophthalmic vein and lacrimal gland. The normative data covered during this lecture should make the interpretation of cross-sectional imaging of the orbit and eye easier and more confident by giving radiologists a useful "rigid frame" of interpretation.

Learning Objectives:

1. To understand differences in the size and shape of the eye.
2. To learn about the normal appearance and anatomic variations of the optic nerve.
3. To discuss normative measures of the soft tissue structures in the orbit.

A-0570 09:30

C. Anatomical variations in the face and neck

E. [Vassallo](#); *Msida/MT (edithvassallo@gmail.com)*

The head and neck is an anatomical compartment of the body that is fascinating as it is complex. This complexity may, at times, render radiological interpretation daunting. In addition to this, many anatomical variations may be encountered in the head and neck which, unless identified and clearly documented by the radiologist, may lead to undesired (and sometimes catastrophic) outcomes. In this discussion, we present a number of such non-pathological entities, outlining how they may present as pseudolesions or pose added risks of iatrogenic injury at surgery.

Learning Objectives:

1. To gain insight into the great variability of head and neck anatomy.
2. To be able to recognise pseudo lesions.

RC 907

Imaging strategies in renal tumours

A-0571 08:30

Chairperson's introduction

B. [Brkljačić](#); *Zagreb/HR (boris@brkljacic.com)*

Renal tumours are an important cause of mortality, and timely and accurate diagnosis is crucial for optimal treatment. The session will deal with optimal protocol and medication for CT, CEUS and MRI of renal tumours, with differences at the diagnosis, with the optimal staging protocols and with organ-preserving strategies.

Session Objectives:

1. To become familiar with current and emerging renal imaging modalities.
2. To learn about the capabilities of renal imaging in diagnosis and staging of renal tumours.

A-0572 08:35

A. CT, contrast-enhanced ultrasound (CEUS) and MRI: the best out of them

M. [Bertolotto](#); *Trieste/IT (bertolot@units.it)*

CT is the imaging modality of choice for evaluation of renal masses. The advantages of CT are its widespread availability, high speed of acquisition, high spatial resolution and isotropic imaging. MRI can be a powerful problem-solving tool for lesion characterisation, especially if a small amount of intralésional fat is suspected. The highest contrast resolution provided by MRI and CEUS allows characterisation of lesions with indeterminate enhancement at CT. Like CT, MRI provides excellent anatomic information. Moreover, advanced MRI techniques can provide information about tissue structure and function. The disadvantage of MRI compared to CT is the longer examination time and lesser panoramic view. CEUS lacks panoramic view and suffers from the same technical limitations of conventional US modes. Optimal MDCT protocol for renal masses includes a non-contrast phase followed by postcontrast acquisitions with corticomedullary, nephrographic and delayed phases of enhancement. The nephrographic phase is acquired for assessing the presence of a renal lesion and its enhancement, and is therefore sufficient for detection and characterisation of renal lesions. Corticomedullary and urographic phases are often performed to provide additional information for presurgical planning. Optimal MRI protocol for renal mass evaluation includes TSE T2-weighted imaging, TSE T1-weighted imaging with and without fat suppression, T1-weighted opposed-phase imaging (with in-phase and out-of-phase sequences) for the detection of microscopic fat, DWI, fat-suppressed 3D T1-weighted gradient-echo acquisition before and after administration of intravenous gadolinium-based contrast in corticomedullary, nephrographic and urographic phases, and subtraction imaging.

Learning Objectives:

1. To become familiar with the optimal CT and MRI protocols for renal imaging.
2. To understand the best choice of CT, CEUS or MRI according to the clinical need.
3. To illustrate the advantages and disadvantages of CT, CEUS and MRI.

A-0573 08:58

B. Differential diagnosis of renal masses

N. [Grenier](#); *Bordeaux/FR (nicolas.grenier@chu-bordeaux.fr)*

Imaging is the main source of detection of renal masses. Differentiation between complex cystic and solid masses is not always straightforward and may require several contrast-enhanced methods and DCE-MRI and CEUS are more sensitive for that purpose. Considering cystic masses, Bosniak classification is required. Considering solid masses, characterisation of fat-rich angiomyolipomas is based on plain CT, but fat-poor AMLs can be distinguished from carcinomas by multiparametric MRI only. Multiparametric MRI includes chemical shift gradient echo (GRE) sequences, signal intensity on T2-weighted images, DCE sequences, diffusion-weighted sequences and late contrast-enhanced images. Using different combinations of two or several parameters, now makes it possible to clearly distinguish some renal tumours such as fat-poor AMLs, papillary carcinomas and clear cell carcinomas the later being difficult to separate from oncocytoma when a central scar is absent. A larger validation of all these combinations is still necessary to define those having a clinical significance for routine practice. Percutaneous biopsy remains mandatory before such a validation, as soon as the pathological result is supposed to have an impact on tumour management.

Learning Objectives:

1. To learn about the histologic spectrum of renal tumours.
2. To understand the capabilities of imaging for renal tumour characterisation.
3. To become familiar with functional techniques applied to characterise renal tumours.

A-0574 09:21

C. Staging and organ-preserving strategies

P. [Asbach](#); *Berlin/DE (patrick.asbach@charite.de)*

Accurate CT- or MRI-based staging of the two most common malignant neoplasms involving the kidneys, renal cell carcinoma (RCC) and transitional cell carcinoma (TCC), is an important prerequisite for surgical decision making, especially in early stages of the disease. The TNM staging system is particularly different between RCC and TCC regarding the T-stage. Tumour size and invasion of the perirenal fat are important criteria for local staging of RCC, whereas invasion of the muscular layer of the renal collecting system and invasion into the renal parenchyma are important criteria for staging TCC. Different organ-preserving strategies are evolving especially for treatment of RCC (e.g. local excision versus local ablation). Also, important additional information such as detailed vascular anatomy is needed by the surgeon, which has an impact on the respective preoperative imaging protocol.

Postgraduate Educational Programme

Learning Objectives:

1. To understand the TNM-staging system for renal tumours.
2. To become familiar with optimal staging protocols and imaging findings in the staging of renal tumours.
3. To learn about actual organ-preserving strategies.

Introduction: Radiology in Italy

C. Bibbolino; Rome/IT (corrado.bibbolino@gmail.com)

The Italian Society of Medical Radiology (SIRM) counts about 11,000 members. It is Italy's largest scientific society and one of the largest in Europe. Its members include nearly all the radiologists working in Italian hospitals and public or privately owned health facilities, self-employed, residents and retirees. It is organised in twenty regional groups and twenty subspecialty sections. According to the OECD data, Italian Radiology runs more than 2,000 CT scanners and 1,715 MRI scanners, of which only 30% are less than five years old. A recent SIRM census showed that approx. 120,000,000 X-ray, US, CT and MRI examinations are performed every year. Many of the examinations mentioned above are not included in the figures published by the OECD and the Italian Ministry of Health. However, they cause problems of appropriateness and overdiagnosis. Many regional health services have general radiological archiving systems creating important databases. In Italy US investigations are performed by physicians: CT examinations are thus fewer than in countries where US scannings are performed by ultrasound technicians. Mammographic screening covers >70% of the female population between 50 and 70 years whereas screening of the lung and colon is routinely carried out only in some regions. In negotiations with the government and the owners of health facilities, the National Union of Radiologists counting more than 3,500 members represents the Italian radiologists. In 2016, SIRM supported Choosing Wisely by hosting the 3rd World Meeting in its Training Center in via del Cardello 24, Rome, near the Colosseum.

Session Objectives:

1. To describe the most important features of Italian radiology.
2. To reflect on new developments of imaging in Italy and Europe.
3. To discuss the role and function of a systemic vision of a radiological society.

A-0580 10:35

Italian emergency network

V. Miele; Florence/IT (vmiele@sirm.org)

Italy's healthcare system is a regionally organised National Health Service that provides universal coverage largely free of charge for Italian citizens. The request for emergency diagnostic and therapeutic services is constantly growing, due to both clinical and epidemiological factors, such as the increasing amount of traumatic events and non-traumatic clinical emergencies. Moreover, there is an overcrowding of the Emergency system, due to the fact that patients with minor health problems are also taken into care, in case of lack of immediate response in the territorial health system. In the care of emergency patients, diagnostic imaging has a very important role, so the majority of patients accessing the Emergency Department performs at least one diagnostic examination, mandatory to decide the care path (immediate treatment, hospitalisation or discharge). The availability of Department of Radiology staffed on a 24-hours a day for emergencies greatly influences the diagnostic performance. Generally, the regional emergency service is organised in specialised centres ("hub"), which are equipped and staffed to provide care for patients suffering from major traumatic and non-traumatic emergencies. In traumatic emergencies, Major Trauma Centers (MTCs) are directly connected with peripherals, radially diffused, trauma units ("spokes") that don't provide major trauma care but still play an essential role in less severely injured patients. Despite the longer transport times, this involves, triage of major trauma patients to an MTC results in a 30% decrease in mortality in the first 48 h compared with transport to a non-MTC, which may be the closest medical facility.

Learning Objectives:

1. To review the organisation of the emergency system.
2. To highlight the strengths and weaknesses of the emergency network regarding epidemiological factors, topographic features and territorial distribution of resources.
3. To define the possible areas of clinical improvement and organisational effectiveness of the emergency health system.

Interlude: The sirens: myth or reality?

R. Grassi; Naples/IT

A-0582 11:00

Emergency interventional radiology: brain and body

G. Carratiello; Varese/IT (gcarraat@gmail.com)

The demand for all types of radiological imaging and intervention on a 24-hour, seven days a week basis has increased significantly in recent years. The term '24-hour radiological imaging services' applies equally to elective and acute services. Interventional techniques are now at the forefront of management of many life-threatening emergencies. Stopping haemorrhage (eg, trauma, gastrointestinal (GI) bleeding, post-partum haemorrhage), thoracic-abdominal aortic aneurysm, traumatic dissection and the complications of Type B dissection, ruptured peripheral aneurysms, acute peripheral and visceral ischaemia, managing sepsis secondary to upper urinary tract and biliary obstruction (often urgent though rarely an emergency), image-guided intervention in subarachnoid haemorrhage and stroke, are the situations where urgent or emergency interventional radiology is indicated. Formal arrangements to secure provision of elective and emergency interventional radiology services are guaranteed in less than 10% of hospitals. These hospitals must be the reference for traumatic patients and stroke. Remnant hospitals should have contacts with closer interventional radiology services.

Learning Objectives:

1. To learn about indications.
2. To learn about techniques.
3. To discuss literature and personal experiences.

A-0584 11:25

La Radiologia Medica: the role of the journal in an international setting

A. Giovagnoni; Ancona/IT (a.giovagnoni@univpm.it)

La Radiologia Medica is the official Scientific Journal of SIRM founded in 1914 that has inaugurated a new publishing season with the scope of becoming a reference point in the panorama of the major international Journal and a tool for constant and timely updating for members. Starting from January 2014, one hundred years after its foundation, the Journal has renewed its editorial model, equating it with that of major international journals with a monthly frequency in a version online in the English language. The new publishing model, has entered into full acceptance of the SIRM Members and has allowed a series of positive practical repercussions: the reduction of production costs, increase of foreign authorship a greater visibility and penetration within the international scientific / radiological community; greater citability with a consequent positive effect on the value of the IF. The contribution of foreign authors which amounted to 62% of the total submitted manuscripts. The selection of manuscripts is accurate and the percentage of rejection rate, in progressive growth, has reached a value of 67% with a constant increase of the IF which has reached the value of about 1.9. La Radiologia Medica represents one of the most important assets of the SIRM.

Learning Objectives:

1. To learn about the organisation of the journal as the official organ of the SIRM.
2. To discuss the strengths and weaknesses of an international, general radiology scientific journal.
3. To consolidate knowledge and to explore future prospects in the international editorial scenario.

Clinical audit: how to deal with the legal and professional requirements

Moderator:

G. McGinty; New York, NY/US

A-0585 10:30

Chairperson's introduction

D.C. [Howlett](mailto:david.howlett@nhs.net); Eastbourne/UK (david.howlett@nhs.net)

This session examines clinical audit and its relationship with the legal and professional requirements of radiological practice, with particular reference to the BSSD, its uptake and what the BSSD and inspection mean for radiology departments. A review and update are provided of currently available audit tools and how they can be used to help implement or enhance audit pathways. A North American perspective is provided discussing peer review, with discussion also of IT and artificial intelligence developments supporting both clinical audit and quality improvement pathways-the potential benefits of peer review and artificial intelligence in the support and enhancement of effective clinical audit programmes are highlighted.

Session Objectives:

1. To appreciate the various tools available to facilitate effective clinical audit.
2. To understand the aims and scope of the BSS.
3. To appreciate the potential of peer review and IT/AI to improve quality in radiology now and in the future.

A-0586 10:36

ESR's concept and tools for clinical audit

K. [Drinkwater](mailto:karl_drinkwater@rcr.ac.uk); London/UK (karl_drinkwater@rcr.ac.uk)

The European Society of Radiology's (ESR) concept for clinical audit is a "process of assessing one's practice against defined standards, altering practice if necessary to meet standards, and re-assessing following changes to confirm improvement." The ESR's tool for clinical audit (Esperanto) is designed to facilitate local clinical audit in line with this concept by providing a set of principles, a collection of audit templates and pointers to sources for further information. An effective audit requires repeated cycles, appropriate methodology and an intention from the outset to document the extent of change against standards and resulting health impacts. Such documentation constitutes evidence of safe practice for departments undergoing inspection by regulatory authorities. The audit pathway comprises preparation and planning, measuring performance, implementing change, and sustaining improvement. A wide range of tools have been identified with potential for improving the effectiveness of clinical audit; each of which can be applied at one or more of these stages. Individual tools are used to best effect in combination, guided by a structured framework, and within a team working arrangement. However, knowledge gaps and conflicting evidence make it difficult to predict what works best and when.

Learning Objectives:

1. To understand the potential for improving the effectiveness of clinical audit using audit tools.
2. To learn when certain audit tools may be most effective within the audit pathway.
3. To appreciate the differing audit tools currently available.

A-0587 10:52

Overview on adoption of BSS throughout Europe

A. [Brady](mailto:adrianbrady@me.com); Cork/IE (adrianbrady@me.com)

The Basic Safety Standard (BSS) which took effect throughout EU member countries in February 2018 imposes certain new practice requirements on radiology departments in the field of radiation safety, and re-emphasises other activities, including the obligation to engage in clinical audit, according to the stipulations of national legislation in each member country. This talk will describe the specific audit-related activities required by the BSS. Information which has been collated by the ESR Audit & Standards Subcommittee and Eurosafe Imaging on BSS adoption, standards already met and audit structures and supports in place will be discussed. The role of the ESR Esperanto Audit support tool in assisting individual departments in meeting their obligations under the BSS will be explained.

Learning Objectives:

1. To learn about the legislative requirement in Europe to engage in clinical audit.
2. To appreciate the variations in how this is implemented in different European countries.
3. To understand how this requirement impacts each individual radiology department.

A-0588 11:08

Peer review as key for quality improvement: the US experience

G. [McGinty](mailto:geraldinmcginty@gmail.com); New York, NY/US (geraldinmcginty@gmail.com)

In response to the IOM report, "To Err is Human", which reported that medical errors accounted for nearly 100,000 preventable deaths each year in the United States alone, the ACR developed the RADPEER program in 2002 on the premise that whenever a radiologist interprets a new imaging study in conjunction with a preceding comparative examination, there is an opportunity to assess the accuracy of the original interpretation. RADPEER is a simple, cost-effective performance tool. The program has evolved both in its operations as well as in the scoring and categories used for reporting. RADPEER is currently the leading method for peer review in the United States. RADPEER is an accepted practice quality improvement method by the American Board of Radiology and can also satisfy hospital and Joint Commission credentialing requirements. Audit systems such as RADPEER have been criticised for not providing opportunities for learning or consideration of contributors to errors. The ACR is currently developing an expanded platform called RADLEARN that will receive images from participants into a registry and will deliver feedback. The anonymised cases submitted can be used for self-study, for teaching and remedial purposes, and to provide content to support internal department reviews especially for smaller practices which might not otherwise encounter such cases.

Learning Objectives:

1. To learn about the path to implement peer review.
2. To appreciate the positive effects of peer review.
3. To understand the implications for quality improvements.

A-0589 11:24

Can newer IT-developments including artificial intelligence (AI) help to improve quality in radiology?

J. [Schillebeeckx](mailto:jan@schillebeeckx.com); Knokke/BE (jan@schillebeeckx.com)

Quality in radiology becomes a dominant topic with the impact of the European Directive 2013/59/Euratom and voluntary accreditation platforms like Joint Commission International, Qmentum and others. The compliance with obligatory or voluntary quality standards is often challenged by the search for the up-to-date set of documents and the smooth, flawless integration of processes on the floor. Consequently, the correct documentation often remains hidden, unstructured, incomplete and leads to a non-uniform application on the floor. The interplay between an intelligent "Knowledge" and "Compliance" Management System using artificial intelligence allows hospitals to save time and efforts to link compliance criteria with their specific clinical practice. Smart algorithms are developed to detect key elements in individual accreditation criteria (step I) and in documents ("knowledge", step II) that were initially centralised. Parts of this "knowledge" were automatically retrieved from radiation dose monitoring software (e.g. scheduled/unscheduled maintenance time reports); other parts were detected by the algorithms (e.g. patient identification procedure). A final algorithm enables the matching between found tags per document and individual accreditation questions (such as equipment downtime, available procedures, etc.). An adequate matching process returns a clear overview in the CMS on the accreditation requirements that were met and with which accuracy. In conclusion, artificial intelligence will reduce efforts to detect compliance gaps and, accordingly, will highlight how quality in the radiology department can be improved.

Learning Objectives:

1. To learn about basic-concepts for IT requirements for clinical audit.
2. To appreciate the value of IT-support for quality improvement processes.
3. To understand the potential of big-data and artificial intelligence for quality initiatives.

Dream team

A-0594 10:30

Chairperson's introduction

L. [Martí-Bonmatí](mailto:marti_lui@gva.es); Valencia/ES (marti_lui@gva.es)

The "Dream Team" term was used for the 1992 USA men's Olympic basketball team, the first American Olympic team to feature active professional players from the National Basketball Association. Even some years before it was used for a group of superheroes in the Marvel Comics universe with different magical energies, surprising powers and marvellous skills. In professional and business developments, great teams are hard to come by. Great team members need to be selected and empowered. To keep abreast of the visionary projects and agreements that keep your radiology department growing and prosperous, there are a number of skills each team member needs to have. From excellent communication skills to expert negotiating tactics, they need to be able to work together to bring in more development and innovative business. Positions to be considered in this Dream Team are Research and Clinical Trials, Education and Certification, Clinical Service and Innovation, IT and Artificial Intelligence, Workflow and Quality, Patient safety and Patient experience, New business and Integrated Diagnosis (radiology, pathology, genetics).

A-0595 10:36

A. How to find the best people and make them a part of a long-time success

J.H. [Thrall](mailto:thrall.james@mgh.harvard.edu); Boston, MA/US (thrall.james@mgh.harvard.edu)

Long-term success starts with establishing a favourable culture and work environment and, for radiology, a well-equipped department that will attract the best people. Hiring decisions should balance the desire for the highest intrinsic abilities with good personality traits. After people are hired, they should be mentored and provided regular feedback on professional progress. Further feedback must also include assessment of their behaviours from direct observation (360-degree assessment) and possibly through personality assessment tools such as the Myers-Briggs Type Indicator (MBTI), Enneagram or Hogan Personality Inventory to strengthen their understanding of themselves and their impact on co-workers. Elimination of adverse behaviour-remediation or separation- is critical to achieving a conducive working environment. To maximise and sustain good performance, each person should know his/her roles and responsibilities and those of others. In this regard, the Responsibility Assignment Matrix (aka RACI) approach or variants are useful for unambiguously defining tasks and responsibilities, especially for new initiatives. As people advance in their careers through mentorship and experience, the progressive delegation of responsibilities and leadership opportunities to people with the demonstrated ability is crucial. This creates a stimulus for them, increases departmental bandwidth to get work done and sets the stage for long-term growth. Success in establishing a repeatable virtuous cycle of recruitment, mentorship, feedback, achievement of personal and professional growth and delegation of responsibility with sharing and then the transition of leadership is the key to sustained excellence.

Learning Objectives:

1. Defining roles and responsibilities in a team: RACI tool.
2. To know who you are and whom you need (MBTI, enneagram, Hogan).
3. How to delegate without losing quality and time.

A-0596 11:04

B. Leadership in radiology

M. [Forsting](mailto:forsting@essen.de); Essen/DE

"no abstract submitted"

Learning Objectives:

1. Radiologist: a ratio of a manager and a specialist.
2. Psychological aspects of leadership (EQ, enthusiasm, energy, sport, hobby).
3. Tools for organising a team's work, delegating and managing virtual/distributed teams.

A-0597 11:32

C. Leading quality improvement projects

B. [Baeßler](mailto:bettina.baessler@uk-koeln.de); Mannheim/DE (bettina.baessler@uk-koeln.de)

Initiating and participating in quality improvement projects often allow to achieve incremental and measurable changes, which make a real difference to patients' experience in a hospital or medical students' learning success. The

Model for Improvement helps define what should be accomplished, what change should be made, and what is being measured to know that any change has led to an improvement. Having a clear vision and objectives is of crucial importance, and SMART goals (which are specific, measurable, achievable, relevant, time-bound) will help in achieving continuous improvement. This talk focuses on the basic principles of leading quality improvement projects and shows personal experiences from a quality improvement project in medical education.

Learning Objectives:

1. Measuring and managing errors.
2. Peer review and continuous learning.
3. Effective feedback, basics of tutoring and coaching.

E³ 1022

Lung cancer in the era of molecular oncology and immune therapy

A-0598 10:30

Chairperson's introduction

H. [Prosch](mailto:helmut.prosch@meduniwien.ac.at); Vienna/AT (helmut.prosch@meduniwien.ac.at)

Lung cancer is the most common cause of cancer-related death in Western countries. In the last several years, a number of new drugs have revolutionised systemic therapy in lung cancer. These new therapies can be divided into two major groups, the targeted therapies and the immunotherapies. Targeted therapies, such as EGFR tyrosine kinase inhibitors, or ALK inhibitors, are a class of drugs that specifically target a well-defined molecular pathway. They have been shown to be more effective than classic chemotherapies in patients who harbour the specific mutation and are associated with fewer toxicities. As these drugs target molecules with a specific mutation, patients who harbour this specific mutation need to be identified. In addition to bronchoscopy, image-guided biopsies are the main modality for obtaining tissue for molecular analysis. Imaging may have a potential role in identifying tumours that harbour a specific mutation, and thus, in guiding further pathologic and genetic work-up. Immunotherapy, however, targets immunological pathways to induce an immunological response against tumours. Immunotherapy has been shown to be a very effective treatment in a subset of patients with non-small cell cancer. Imaging plays a major role in the follow-up evaluation of patients undergoing immunotherapy, as immune reactions must be differentiated from disease progression.

A-0599 10:36

A. Lung adenocarcinomas with EGFR mutations

M. [Lederlin](mailto:Mathieu.LEDERLIN@chu-rennes.fr); Rennes/FR (Mathieu.LEDERLIN@chu-rennes.fr)

Adenocarcinoma is the most prevalent type of lung cancer, showing a large spectrum of genetics, histologic subtype, CT appearance and prognosis. Activating mutations of EGFR are found in 30%-50% of lung adenocarcinomas in East Asian patients and approximately 15% in Caucasian patients. EGFR mutation status is correlated with nonsmoking status, female sex, lepidic subtype, and a high response rate to EGFR tyrosine kinase inhibitors (TKI). Some CT findings have shown to be associated with EGFR mutation such as nonsolid or mixed ground-glass opacity, air bronchogram, smaller and peripheral tumours. Furthermore, never-smoking patients presenting with diffuse military metastatic disease at diagnosis may be diagnosed with adenocarcinoma harbouring EGFR mutation and may show a dramatic response to EGFR-TKI. The most common resistance mechanism to EGFR-TKI is the T790M mutation, against which new irreversible TKIs have been found to be clinically effective, thus increasing demand for rebiopsy in progressive NSCLC to analyse mutational status. Rebiopsies are feasible and informative in most of the patients with acceptable rates of complications. Furthermore, continued EGFR-TKI therapy may be indicated beyond RECIST progression because these tumours grow slowly and some tumour cells remain sensitive to EGFR-TKI. Radiologists should also be aware of the risk of class-effect toxicity of EGFR-TKI, in particular, pneumonitis with an incidence rate of 4-5% in the Japanese population. Finally, European radiologists should keep in mind that a majority of studies dealing with EGFR mutations in adenocarcinomas arise from Asian countries with results that might not be transposable to Caucasian populations.

Learning Objectives:

1. To be aware of the importance of detecting epidermal growth factor receptor (EGFR) mutation.
2. To learn about demographic and CT features suggestive of EGFR mutation.
3. To learn about the various initial and follow-up CT features.

Friday

A-0600 11:04

B. PD-L1 positive lung tumours

O.L. [Sedlaczek](mailto:sedlaczek@web.de); Heidelberg/DE (sedlaczek@web.de)

Immune checkpoint inhibitors are effective in the treatment of many cancers, de-blocking immune pathways; they play an increasing role in the first-line treatment of lung-cancers. This is particularly true when there is evidence for a significant pretreatment tumour lymphocytic infiltration and/or the tumour shows a high expression for PD-L1. As checkpoint inhibitors work through a different mode of action compared to cytotoxic agents, there is a good reason to use therapy response criteria other than RECIST. In contrast to classical chemotherapies anti-tumour response in immunotherapy may take longer, and in the initial phase the response to immune therapies can manifest in a morphologic "progressive disease", therefore, called "pseudoprogression". In this situation, early discontinuation of the treatment could be inappropriate, unless PD is confirmed. An initially tolerable PD may even include the detection of new lesions ("unconfirmed progression", iUPD) that may not lead immediately to a discontinuation of the oncologic regimen and has to be reevaluated (iCPD, iSD). The disinhibition of mechanisms normally protecting from autoimmunity and prolonged immunoreactions leads not only to unusual tumour response patterns but also produces atypical toxicities including a broad spectrum of autoimmune diseases. Imaging characteristics of frequent and serious immune-related adverse events will be discussed.

Learning Objectives:

1. To know about the impact of programmed death ligand 1 (PD-L1) positivity.
2. To know how to evaluate the tumour response after immunotherapeutics.
3. To be aware of the imaging features of immune therapy complications.

A-0601 11:32

C. ALK-rearranged and other mutations of lung adenocarcinomas

M. [Silva](mailto:mariosilvamed@gmail.com); Parma/IT (mariosilvamed@gmail.com)

In the last decade, huge improvements in prognosis and quality of life have been granted by molecular characterisation of non-small cell lung cancer (NSCLC). In particular, Anaplastic Lymphoma Kinase (ALK) and ROS1-positive tumours can now be treated by oral tyrosine kinase inhibitors (TKIs), which allow survival outcomes far beyond it could be expected until a decade ago. Notably, these oncogenes are mostly found in adenocarcinoma histology and in never-smokers (about 60% of all ALK-rearranged NSCLC). Target therapy by TKI improves progression-free survival (PFS) compared with previous reference chemotherapy. In the face of a better disease control by TKI, however, it happens that ALK-positive tumours are prone to driver mutation with resistance to first-line TKI, in the first months of therapy. In clinical practice, diagnostic imaging, notably computed tomography (CT), has a high yield in the management of patients under target therapy. The CT evidence of disease progression, either local or systemic (note: brain metastases are relatively common because first-line TKIs have low trespassing coefficient through the hematoencephalic barrier) is paramount for timely adaptation of therapy. Rapid radiologic progression demands prompt TKI swap towards second-line (e.g. ceritinib, brigatinib, or alectinib) or third-line target therapy (e.g. lorlatinib) or otherwise. Re-biopsy is suggested to pitch the optimal second (or further) line therapy by continuous molecular testing. Adverse events occur in a minority of patients under TKI (1% incidence of lung toxicity). Therapy discontinuation is usually sufficient to reduce toxic effects, with only 3-6% of cases lingering after therapy withdrawal.

Learning Objectives:

1. To learn about clinicopathologic features characterising anaplastic lymphoma kinase (ALK)-rearrangement.
2. To learn about other mutations and their implications for management.
3. To see some illustrative cases.

Systemic effects of image guided tumour therapy: have we opened Pandora's box or found the Holy Grail?

S.N. [Goldberg](mailto:sgoldber@bidmc.harvard.edu); Jerusalem/IL (sgoldber@bidmc.harvard.edu)

Image-guided cancer therapies have matured and gained sufficient clinical acceptance to the point that the relatively new discipline of interventional oncology has joined surgery, radiation, and chemotherapy as the fourth pillar of cancer care. Percutaneous thermal ablation using energy sources, including radiofrequency and microwave to produce heat and cryoablation to produce freezing, is a prominent interventional oncologic technique commonly used to treat a wide range of focal primary and metastatic tumours in the liver, kidney, lung, bone, and elsewhere. Although it has been asserted that tumour ablation is a local therapy, recent research suggests that it can induce systemic effects largely via cytokines and other growth factors. On the one hand, these factors can produce potentially unwanted "off-target" tumorigenesis that, in some cases, may lead to unintended increased cancer progression. Such human-made iatrogenesis could be viewed as an opening of Pandora's Box. On the other hand, there is ever increasing research documenting that ablation can activate the immune system to induce widespread distant anti-tumoral effects. Leveraging these "abscopal" effects to achieve synergy in combination with recently developed immuno-oncologic therapeutics can be viewed as a Holy Grail. Given this potential double-edged sword, further molecular biologic research is necessary to better understand the mechanisms behind these processes. This will afford better insight as to which pathways are activated in individual patients and ultimately allow us to develop rational strategies to accentuate and more consistently induce positive immune effects, while simultaneously eliminating negative tumorigenic effects to benefit our patients and discipline.

Learning Objectives:

1. To appreciate the extent of potentially beneficial and harmful systemic effects of "focal" interventional oncologic therapy.
2. To gain awareness of the molecular mechanisms that cause such systemic effects with an eye toward potentiating them for clinical benefit.
3. To learn how immuno-oncologic techniques can be combined with both percutaneous and transcatheter interventional oncologic therapies to potentially achieve better clinical outcomes.

Intraductal papillary neoplasms

S. [Skehan](mailto:stephenskehan@me.com); Dublin/IE (stephenskehan@me.com)

Most pancreatic neoplasms with a predominantly intraductal growth pattern are intrapancreatic mucinous neoplasms (IPMNs), which can be classified according to the involvement of the main pancreatic duct or its side branches. There are also much less common solid intraductal tubulovillous neoplasms. IPMNs are characterised by intraductal proliferation of mucin-producing cells arranged in papillary formations. Duct dilatation due to mucin production is the pathological and radiological hallmark. IPMNs demonstrate varying degrees of dysplasia and varying cellular differentiation, with a recognised adenoma-carcinoma sequence. Pancreatic, intestinal and oncocytic cell types are mostly seen in main duct IPMNs, which have a much higher risk of invasive carcinoma than the more common branch duct IPMN, which are usually of gastric differentiation. Branch duct IPMNs are the most common cause of incidental

Postgraduate Educational Programme

pancreatic cysts. Imaging features such as luminal communication with the main pancreatic duct and pathological/biochemical analysis of cyst fluid can help to distinguish branch duct IPMNs from other causes of pancreatic cysts. Because of the risk of malignant transformation, prolonged imaging surveillance is recommended for individuals with branch duct IPMNs who would be potential candidates for pancreatic surgery. Worrisome features on surveillance include the development of solid or nodular enhancing components, interval enlargement of cysts and dilatation of the main pancreatic duct or common bile duct.

Learning Objectives:

1. To learn about classification of cystic pancreatic neoplasms.
2. To appreciate the classification of IPMNs.
3. To understand the diagnostic imaging findings of IPMNs.

Spinal trauma: how to get it right

A. Leone; Rome/IT (a.leonemd@tiscali.it)

Spinal trauma is an extremely complex event, whose effects and related appropriate treatment choice and timing are classically based on the evidence of the lesions, their anatomic landmarks and mechanisms of injury at diagnostic imaging. The primary aim of this lecture was to describe: 1) range of injuries resulting from high-energy trauma in patients of all ages; 2) indications to the different diagnostic imaging modalities; and 3) imaging findings which have to be looked for in spinal trauma patients, in order to adopt a pattern-based approach for efficient imaging interpretation and communication with all specialists involved in spinal trauma. Radiography and, above all, CT provides most of the information needed for the diagnostic workup; therefore, CT is the preferred imaging modality. MR imaging can provide additional information on the state of paraspinal soft tissues thanks to the high contrast resolution allowing oedema detection; moreover, it is needed to determine the integrity of the discoligamentous complex, contributing to a better evaluation of spine stability, and is thus mandatory in all cases of neurological compromise. In conclusion, the appropriate use of radiography, CT and MR imaging has the potential of correctly identifying the injured spine, allowing early treatment while minimising the risk of a delayed diagnosis.

Learning Objectives:

1. To become familiar with imaging features of cervical, thoracolumbar and sacral trauma.
2. To understand the importance of mechanism of injury in the setting of spinal trauma.
3. To appreciate the usefulness of radiography, CT and MR imaging in the detection and evaluation of spinal trauma.

EFRS meets Denmark

EM 4

EFRS meets Denmark

Presiding:

J. McNulty; Dublin/IE

H. Precht; Odense/DK

A-0619 14:00

Session introduction

J. McNulty; Dublin/IE (jonathan.mcnulty@ucd.ie)

Introduced for the first time for ECR 2013, the 'EFRS meets' sessions follow the tradition of the 'ESR meets' sessions and give the European Federation of Radiographer Societies (EFRS) the opportunity to highlight the contribution of one of their member societies to the profession of radiography each year. Having met with Spain in the first of these sessions in 2013, the EFRS has gone on to meet with societies and radiographers from Russia, Germany, Sweden, Belgium, Portugal, and Switzerland. The Danish Society of Radiographers, Radiograf Rådet, is a founding member of the EFRS and have been an active member of the EFRS throughout our ten-year history. University College Lillebelt is currently the only Danish educational institution within the Educational Wing of the EFRS and joined in 2009. The Danish Society of Radiographers is extremely active in promoting our profession, advancing education and training opportunities, encouraging radiographers to undertake research at the highest level, and in lobbying for their radiographers. Danish radiographers are currently involved in the EFRS leadership and across a number of our active working groups.

A-0620 14:05

Introduction: Across Denmark

C. Graungaard Falkvard; Copenhagen/DK (charlotte@radiograf.dk)

You will be presented to Denmark as a country with a focus on the good Danish life, Danish culture and the Danish radiography profession. The presentation will also have a focus on the possibilities and struggles in the profession and how to work politically for the profession in Denmark.

Learning Objectives:

1. To introduce the EFRS meets session and the involvement of Denmark in the EFRS.
2. To introduce the country of Denmark, Danish life and culture and the Danish radiography profession.

A-0621 14:10

Machine learning: a new aspect of radiography

L.M. Pehrson; Copenhagen/DK (Lea.marie.pehrson@gmail.com)

Machine learning (ML) and deep learning (DL) are becoming established disciplines in the broad field of applying artificial intelligence in analysing and utilising patterns in data sets. As the complexity - as well as the sheer amount of - data increases, applying these patterns to the benefit of, e.g. clinical decision making, becomes increasingly nontrivial. Extraordinary advancements in areas of technology such as high-performance computing have made it possible to attempt solving these problems algorithmically. The purpose of various ML and DL algorithms may be to improve quality, consistency and/or capacity of data interpretation in diagnostics, thus improving diagnostics and treatment decisions to the benefit of clinical outcomes. Considering the implications this may have for the practice of medicine / healthcare. It is important to engage in this area of research from many perspectives. ML is already being applied to the practice of radiology, and the systems being developed today are showing to be robust to real-world conditions. In this discussion, the general concept of AI methods, together with an overview of early results in the field of medical imaging will be introduced. Furthermore, aspects of implementation and its impact will be discussed.

Learning Objectives:

1. To recognise Machine learning as a tool for medical image analysis.
2. To learn about the opportunities within machine learning, the challenges and new directions in clinical practice.
3. To acknowledge the potential impact for the patient, radiographer and radiologist.

A-0622 14:27

Improvements in healthcare

P. Blackburn Andersen; Kolding/DK (picaandersen@yahoo.dk)

The number of patients in Danish hospitals increased by 50.000 during the years 2015-2017 while the number of hospital staff increased by 4 in the same period. Furthermore, today's patients expect a higher level of individualised

Friday

Postgraduate Educational Programme

treatment and care whilst most hospitals struggle with hospital infections, stressed staff and medical mistakes. As we see how time-consuming and expensive medical mistakes are we also recognise improvements that need to happen to increase patient safety, satisfaction and quality of hospital care. Patient involvement and shared decision making have been shown to increase patient satisfaction and safety whilst decreasing medical mistakes. Consequently, patient involvement is fundamental to a continuous and successful improvement process. As radiographers, we encounter a large number of hospitalised patients every day. Naturally, we also see inefficiencies of the hospitalised patients journey to the radiology department. At times we even recognise actual errors made prior to the patient's arrival at Department of Radiology, and this is where radiographers have two choices - do we ignore these errors and inefficiencies because they do not occur in our department, or do we think "patient first" and address the problem to the involved departments? Could we perhaps take it a step further and think "how can we contribute"? By presenting some improvement cases from Kolding hospital, we will see how resourceful and valuable radiographers are to patient safety and satisfaction when improvements are created systematically, vertically and in collaboration with other staff and patients.

Learning Objectives:

1. To understand the need for improvement in Danish healthcare (and perhaps European healthcare).
2. To appreciate how radiographers can contribute beyond the radiology department.
3. To acknowledge the need for patient and staff involvement to create improvements.

A-0623 14:44

Technologically mediated patient and radiographer experience

S. [Holm](#); *Faaborg/DK (suho@ucl.dk)*

The Danish healthcare system has a great focus on patient-centred care in all elements of a patient trajectory. In diagnostic imaging settings, previous qualitative research into patient's experienced care generally investigates verbal and non-verbal communication in the relation between the patients and professionals. The effects that imaging technologies have on these experiences and relations are nonetheless seldom investigated. Yet technological devices and systems play a significant role in shaping human experience, communication and relations in these settings and needs to be addressed. To explore how technologies mediate experience in diagnostic imaging practice, I turn to a particular philosophy of technology, as a theoretical and analytical framework, for studying human and technology relations. Applying concepts developed within this position provides theoretical and methodological means to explore embodied and perceptual lived experience. In particular, postphenomenology reflects on how technological mediation transforms our perceptual experience of our world. This talk suggests that by applying this approach in the unfolding of the specific human dimension of Radiography, we are able to identify important issues that can help professionals to perform improved patient-centred care.

Learning Objectives:

1. To understand what is meant by technological mediation.
2. To learn about embodied perception.
3. To explore how technologies mediate experience in radiographic practice.

A-0624 15:01

MR safety

A.D. [Blankholm](#); *Aarhus/DK (anneblan@rm.dk)*

MR safety is a hot topic amongst MR professionals. Incidents related to MR are rare but can be dangerous. MR safety is related to the three types of fields: main magnetic field, gradient field and the radio frequency (RF) field. The main magnetic field accounts for the projectile effect, torque/rotation and translational forces. The gradient field accounts for the noise and peripheral nerve stimulation. The RF-field accounts for heating. Most MR incidents can be avoided. The key to avoiding MR related incidents is correct planning of the site, awareness about MR safety and MR safety education of internal and external staff. The fact that no databases containing information about the type of implants patients have exists. Often such information in the patient record is inadequate, and the information from the manufacturer is not standardised and can be inadequate. Furthermore, control forms with missing or wrong information is a challenge. A search in a national database reflected few reported incidents but that incidents and near-incidents are happening. A national questionnaire amongst MR operators reflected that more than half of the respondents had been involved in an MR related incident, that was reported to the national database, but one forth had been involved an MR related incident that was not reported. Sixty-one per cent of the respondents indicated that guests in the MR environment are a safety risk. Recommendations for MR safety education of MR safety -officers, -experts and -directors have been published and supported by several organisations and authorities.

Learning Objectives:

1. To understand the challenges of MR safety.
2. To appreciate MR safety from the Danish radiographer's perspective.
3. To become familiar with recommendations for MR safety education.

Professional issues for radiology departments to enable research

Moderator:

J.K. Bell; *Manchester/UK*

A-0625 14:00

Chairperson's introduction

O. [Clément](#); *Paris/FR (olivier.clement@aphp.fr)*

One of the major issue for academic radiology is to attract the young generation to our discipline in a time of big potential changes in the way we practice with artificial intelligence and the necessity to be visible to the patient. The aim of this session is to explore how research is the main way to follow.

Session Objectives:

1. To learn about research in imaging or imaging for clinical research.
2. To appreciate how to attract residents in research.
3. To learn about examples of implementing AI research in radiology.

Author Disclosure:

O. Clément: Advisory Board; Bayer. Speaker; Bracco, Guerbet.

A-0626 14:06

How to attract residents to research

H.-U. [Kauczor](#); *Heidelberg/DE (Hans-Ulrich.Kauczor@med.uni-heidelberg.de)*

In the era of fast technological advances in medical imaging, high-quality research plays an essential role in advancing radiology as an independent speciality with its sustained development and radiologists remaining leaders in the field of biomedical imaging. Identifying young radiology residents interested in research, encouraging and supporting them to become a proficient and competitive academic radiologist is an important task for every academic radiology department. It is important that the residents' subspecialty interests are identified early and considered by department chairs for the clinical training and scientific career. In times of ever increasing clinical responsibilities, protected research time for research for residents is crucial. Empowering young residents with an optimal research environment consisting of qualified mentoring, training courses on clinical research methods, study design, biostatistics, human, infrastructure and financial resources and last but not least administrative grant support is of utmost importance. Since the speciality of radiology is tremendously influenced by developments in artificial intelligence, deep learning and other technological advancements, multidisciplinary and integrative research approaches are indispensable. There is no doubt that residents exposed to research will gain experience in critical thinking and leadership in order to pursue a successful career either in academia or many other fields.

Learning Objectives:

1. To learn basic concepts for research options for residents.
2. To appreciate the value of research activities in the professional career.
3. To understand the requirements for research environments for residents.

A-0627 14:22

How to organise an imaging department for clinical research

L.S. [Fournier](#); *Paris/FR (laure.fournier@aphp.fr)*

Radiology and nuclear medicine imaging provide independent and complementary information from clinical examination and biological explorations, such as drug development and validation. In these cases, imaging is not the object of the research but a tool to measure outcomes, therefore its quality must be assured to guarantee the quality of the overall research data. This clinical research occurs on imaging platforms in public or private structures, most of which are part of clinical departments organised to deal with clinical care. There are several challenges to integrate a research among a clinical workflow. First, the volume of imaging dedicated to clinical research is steadily increasing, as imaging is recognised as giving useful biomarkers of disease and drug efficacy. Second, the quality assurance and quality control required are also becoming more stringent. However, there has

Postgraduate Educational Programme

not been a proportional investment in departments in terms of material and personnel resources. Departments need to organise imaging research units embedded in clinical departments, for quality control, archiving and processing. For this, dedicated personnel needs to be identified, including imaging CRAs and radiographers with training in clinical research, and financial self-sufficiency needs to be reached by including specific overcosts for imaging.

Learning Objectives:

1. To learn about concepts for research facilities.
2. To appreciate how to implement quality approaches.
3. To understand the financial background.

A-0628 14:38

How to deal with legal requirements in research activities

P.M.A. [van Ooijen](mailto:p.m.a.van.ooijen@umcg.nl); Groningen/NL (p.m.a.van.ooijen@umcg.nl)

One of the major challenges nowadays when performing research is how to comply with the legal requirements that are posed upon the researcher based on the General Data Protection Regulation (GDPR) in Europe. Through the GDPR the rights of the patients or participants in your research are protected, but how to work within this framework and still be able to get your research done might be a challenge. Especially since the GDPR not only restricts the use of prospective data but also retrospective data and the ability to link a number of databases into a new research database. On the other side, open science is gaining interest, and the question is how to make your database open when all these restrictions are in place. In this lecture, we will look into the GDPR and how it affects prospective and retrospective research. Furthermore, we'll discuss how multi-centre studies could be set up with multiple participants from different European countries. Finally, we'll look at some of the concepts and tools that are available to ensure data protection and data security.

Learning Objectives:

1. To learn about the relevance of legal framework for research.
2. To appreciate the European perspective for multi-centre projects.
3. To become familiar with best practice concepts for data-protection and data-security.

Author Disclosure:

P.M.A. van Ooijen: Advisory Board; MedicalPHIT. Board Member; EuSoMII.

A-0629 14:54

How to implement research on artificial intelligence in radiology

K.J. [Dreyer](mailto:K.J.Dreyer@boston.ma.us); Boston, MA/US

"no abstract submitted"

Learning Objectives:

1. To learn about the key-concepts of AI and the challenge for radiology.
2. To appreciate the opportunities for radiologists active in AI-research.
3. To become familiar with new concepts for supporting research on AI in radiology.

14:00 - 15:30

Room E1

Joint Session of the ESR and BBMRI-ERIC

ESR/BBMRI-ERIC

Will the General Data Protection Regulation (GDPR) hamper the secondary use of clinical imaging data for research?

Moderators:

E. Steinfeldt; Graz/AT

A. van der Lugt; Rotterdam/NL

A-0630 14:00

Why is secondary use of existing imaging data important for research progress?

E. [Steinfeldt](mailto:erik.steinfeldt@bbmri-eric.eu); Graz/AT (erik.steinfeldt@bbmri-eric.eu)

There is no medical innovation without biobanking, and there is no biobanking without patients and their consent. In this context, the question of secondary use of samples and data is a very relevant one. BBMRI-ERIC, the world largest biobanking directory, is collaborating with more than 90 public and private health research organisations to provide guidance on how to use the GDPR to both protect patients' rights to privacy and empower medical research. The result of the collaboration will be a Code of Conduct for Health Research, a soft law instrument that research organisations and EU countries can use to better implement the GDPR. One of the main risks is that a piecemeal implementation of the GDPR might affect the European Research Area and

obstruct collaboration among European and international research groups, slowing down innovation. Another risk is that the GDPR will negatively impact on the total amount of samples and data shared by biobanks. We know that around 5-10% of samples stored in BBMRI-ERIC biobanks is shared for research purposes. While BBMRI-ERIC is developing a new strategy to increase access, the GDPR can pose new obstacles that will make our final objective, "making new treatment possible", more time- and resource-consuming.

Learning Objectives:

1. To learn about Biobanking and BioMolecular resources Research Infrastructure (BBMRI).
2. To learn what BBMRI can do for you in the GDPR era.
3. To learn about the importance of existing imaging data for research in imaging biomarkers, radiomics and artificial intelligence.

A-0631 14:15

Can I reuse, share or give open access to existing imaging data for research?

M.T. [Mayrhofer](mailto:michaela.th.mayrhofer@bbmri-eric.eu); Graz/AT (michaela.th.mayrhofer@bbmri-eric.eu)

This presentation will give an overview of the EU General Data Protection Regulation, focusing on imaging data for research. It will discuss privacy principles and concerns of privacy breaches and contextualise it within the policy goal of open access and open science. Thereafter, it will turn to data reuse and data sharing, which are standard practices for research that pose complex challenges upon researchers and research participants alike and include, among others, data security, privacy and good scientific practice: How can data reuse be simplified? How can compliance be demonstrated by controllers and processors towards the regulation? How can open access help to ensure trust by the research participants?

Learning Objectives:

1. To learn what you can do with imaging data in the PACS and observational research studies.
2. To learn what you can do with data from investigator initiated or industry sponsored RCTs.
3. To learn how to prevent future problems with re-use of clinical data.

A-0632 14:40

Can I sell or licence imaging data to industry or spin-off companies?

J.A. [Bovenberg](mailto:jabovenberg@xs4all.nl); Aerdenhout/NL (jabovenberg@xs4all.nl)

My talk will discuss whether and, if so, how medical imaging data can be shared with commercial partners or used by spin off companies. To that end, we will map the various rights vested in these data and examine the various legal bases for sharing. Taking a case based approach, we will specifically explore the various mechanisms to share imaging data with commercial partners outside the EU.

Learning Objectives:

1. To understand the issues of sharing data with industry.
2. To learn about proper informed consent for sharing data with industry.
3. To learn whether data can be shared outside the European Union.

A-0633 15:05

How to anonymise imaging data for research?

B. [Gibaud](mailto:bernard.gibaud@univ-rennes1.fr), E. Cordonnier, G. Pasquier; Rennes/FR (bernard.gibaud@univ-rennes1.fr)

Secondary use of clinical imaging data is becoming a major topic, especially in the context of the growing needs of training and testing Artificial Intelligence (AI) algorithms. The General Data Protection Regulation (GDPR) which entered in application in Europe in May 2018 enforces strict constraints regarding protection of personal data, especially for sensitive data such as medical images. As a general rule, de-identification is needed to ensure patient confidentiality and can be achieved through anonymisation or pseudonymisation. This presentation will focus on the de-identification of DICOM data. Therefore, the basic principles of DICOM syntax will be recalled, as well as the general organisation of image metadata and pixel data. Then, the principles of DICOM de-identification and re-identification will be introduced (DICOM Part 15 Security and system management profiles). The need for Confidentiality Profiles will be explained, as a means to address the balance between the removal of any information that might directly or indirectly lead to patient identification, and the need to retain information so that the DICOM data remain useful for its intended purpose in the context of secondary use. Examples of such DICOM Confidentiality Profiles will be shown and explained. Several tools implementing DICOM de-identification will be briefly introduced. A concrete use case will be presented to illustrate the use of de-identification / re-identification.

Learning Objectives:

1. To learn the difference between anonymisation and pseudonymisation.
2. To become familiar with tools for pseudonymisation.
3. To understand the secrets of the DICOM header.

Investment strategies

A-0634 14:00

Chairperson's introduction

E. [Kotter](mailto:elmar.kotter@uniklinik-freiburg.de); Freiburg/DE (elmar.kotter@uniklinik-freiburg.de)

Investment strategies are key to successfully running both a private practice and a radiology department. This session will give insights into the principles of investment strategies for radiology. Participants will be given the keys to understanding how to consider a radiology unit from an economic point of view. The focus will be on the return of investment.

A-0635 14:06

A. Budget: all these numbers

A. [Giovagnoni](mailto:a.giovagnoni@univpm.it); Ancona/IT (a.giovagnoni@univpm.it)

In simple terms, an operating budget is a projection or a snapshot of the results a practice hopes to achieve or believes it will achieve. The words "hope" and "believe" are used because budgeting is an intuitive process that can be employed for different purposes and executed in various ways. Mapping out a strategic plan involves goal setting, a plan of action to achieve the goals, and monitoring systems to measure the efforts intended to achieve those goals. Operating budgets can tangibly show the results of numerous decisions that have been made and often act as a report card on the success of any given strategy. While hospitals tend to be steeped in the budgeting process, in many radiology practices, budgets are often wrongly considered unimportant or unnecessary. A general feeling that the clinical side of practice lacks control over the business aspects of revenues and expenses can lead to the mindset that there is no reason to project them. While a budget does not define how effective an operation is, without one, operating results are left to chance with no real measure of success or failure. Good budgeting includes both science and intuition in making projections. Practices working with budgets control their destiny better and operate less blindly. This presentation intends to define and illustrate the necessary components that radiology practices must consider as they carve out a budget.

Learning Objectives:

1. Why to be aware of financial literacy.
2. Major financial indicators for radiology: to dig into numbers with profit.
3. How to make all these boring numbers work for you and do more with fewer resources.

A-0636 14:34

B. Value-based imaging

M.G.M. [Hunink](mailto:mariefaruch@hotmail.com); Rotterdam/NL

Value-based imaging is in vogue. But how do we measure value? For the patient, quality of life and length of life are fundamental. Most of the conveniently-measured patient outcomes are proxies or intermediate outcomes. The value of medical imaging performed for screening, surveillance, diagnosis, or prognosis is a function of pre-test probability of disease, sensitivity and specificity of the imaging test, risk and burden of the imaging test, the gains if the disease is identified, the harms if a non-diseased patient is inadvertently labelled as diseased. The expected value of imaging is largest when the pre-test probability of disease is at the treatment threshold. In treatment planning, the added value of imaging is determined by the net reclassification to a different treatment plan and the net gains from the change in treatment plan. In treatment guidance, the added value of imaging comes from reduced risk and increased effectiveness of the treatment. From the healthcare system perspective, costs are included and should consider not only the imaging tests but also costs of treatment and long-term costs of events during follow-up. From the societal perspective, additionally, productivity gains and losses are important to elucidate in order to fully quantify

the value of imaging. Finally, investing in the health, happiness, and skills of our employees is crucial in order to provide value-based care since a competent resilient workforce translates into patient safety and quality of care.

Learning Objectives:

1. To understand the value of what we do in radiology.
2. To understand how cost-effectiveness analysis can demonstrate the value in imaging.
3. To recognise how investing in our employees increases the value of what we do.

A-0637 15:02

C. Start-up in radiology

A. [Alberich-Bayarri](mailto:alberich_ang@gva.es); Valencia/ES (alberich_ang@gva.es)

The main steps when creating a new start-up company in the field of radiology are presented, including the do's and don'ts from the experience in creating a start-up dedicated to Imaging Biomarkers quantification and artificial intelligence. The topics include bringing to market the developments in research, how to raise funds from zero, deal with investment funds and regulatory aspects. Start-ups must be focused on value, and for that, the hypothesis for the value proposition of the company must be validated from the very beginning. After that validation, the company must dedicate the efforts to be able to demonstrate some traction among stakeholders and potential customers. In parallel, there must be an intense progress in regulatory aspects to reach the clinical market.

Learning Objectives:

1. Understanding successful investments: which number you really need to take care of.
2. Designing a standalone imaging centre.
3. Investments: how to find money for new projects in imaging informatics.

Author Disclosure:

Advances in musculoskeletal techniques: whole-body MR

A-0646 16:00

A. Oncologic application

F.E. [Lecouvet](mailto:lecouvet@brussels.be); Brussels/BE

This interactive session will illustrate the wide range of indications of whole-body MRI in oncology, the protocols and technical requirements, the contribution of anatomic and functional diffusion sequences and their respective strengths and pitfalls. Latest technical refinements and efforts to decrease examination duration and tailor sequences to the targeted disease will be presented. Simple and more complex cases will highlight how the technique extends the exploration of the body beyond the musculoskeletal system to lymph nodes and visceral metastases screening. Specific cases will show how WB-MRI has become a modality of choice for detecting bone metastases from many cancers and bone marrow involvement by multiple myeloma or lymphoma. The comparison will be provided with bone scintigraphy, CT and PET by the time of lesion detection and for assessment of the response to treatment.

Learning Objectives:

1. To become familiar with the technical aspects of whole-body MR.
2. To learn the role of whole-body MR in the management of oncologic patients.

A-0647 16:45

B. Non-oncologic applications

M. [Faruch](mailto:mariefaruch@hotmail.com); Toulouse/FR (mariefaruch@hotmail.com)

Thanks to the improvement in technique as the shortening of examination durations, whole-body MR imaging can now be feasible for use in routine clinical practice in numerous skeletal and neuromuscular disorders as the seronegative rheumatologic disease, multifocal ischemic lesions, multifocal eosinophilic granulomas and inflammatory myopathies. Whole-body MR could

be helpful for early diagnosis, evaluation of the extent and activity of the disease, and evaluation of therapeutic response. Current MRI protocols usually include anatomic sequences as T1-weighted and water-sensitive sequences as STIR, but could also provide functional DWI sequences.

Learning Objectives:

1. To become familiar with the indications for whole-body MR in non-oncologic patients.
2. To learn the role of whole-body MR in the management of non-oncologic musculoskeletal disorders.

GI Tract

RC 1201

Imaging the acute abdomen: new insights

Moderator:

D.E. Malone; Dublin/IE

A-0648 16:00

A. Acute mesenteric ischaemia

M. Ronot; Clichy/FR (maxime.ronot@aphp.fr)

Acute mesenteric ischemia is defined as inadequate blood supply to the gastrointestinal tract resulting in an ischemic and inflammatory injury that may progress to necrosis of the bowel wall. Prognosis is poor with a mortality rate greater than 95% without treatment, dropping to around 70% when surgical treatment is performed. Contrast-enhanced computed tomography (CT) has become the cornerstone of the diagnosis by showing features of vascular disorders (occlusion and/or insufficient blood supply) and features of intestinal ischemic injury. CT should be performed as rapidly as possible. Imaging-based patient management is required, and multimodal and multidisciplinary management should be introduced. The treatment involves multidisciplinary management by gastroenterologists, vascular and digestive surgeons, cardiologists, intensivists, and diagnostic and interventional radiologists. Based on our experience at a dedicated mesenteric stroke centre, this article gives an overview of the diagnosis of acute mesenteric ischemia. The goal of this presentation is to improve the understanding of the imaging-based diagnosis to further improve the management of this life-threatening condition.

Learning Objectives:

1. To learn about the different types and clinical conditions in which acute mesenteric ischaemia occurs.
2. To understand how the imaging features are related to the underlying pathophysiology.
3. To appreciate the role of endovascular interventional procedures in the management of acute mesenteric ischaemia.

A-0649 16:30

B. Low-dose abdominal CT for evaluating suspected appendicitis

K.H. Lee; Seoul/US (khleeemail@gmail.com)

Evaluation of suspected appendicitis in adolescents and young adults is one of few LDCT applications which were validated to be safe and effective regarding clinical outcomes through large randomised clinical trials. As summarised in recent systematic reviews, high-level evidence has been accumulated for the use of LDCT (down to 2 mSv) in diagnosing appendicitis. However, the adoption of LDCT is disappointingly slow. Given the evidence level, there is no reasonable basis to insist on using radiation dose of multi-purpose abdomen CT for the diagnosis of appendicitis, particularly in adolescents and young adults.

Learning Objectives:

1. To emphasise the need for reducing radiation exposure in adolescents and young adults with suspected appendicitis.
2. To critically review published evidence indicating that LDCT is comparable with normal-dose CT for diagnostic performance and clinical outcome.
3. To review LDCT imaging techniques and other practical issues for the successful implementation of LDCT in practice.

A-0650 17:00

C. Acute colonic diverticulitis

S. Schmidt Kobbe; Lausanne/CH (sabine.schmidt@chuv.ch)

Acute colonic diverticulitis (ACD) frequently occurs in the Western worlds, and the severity ranges from mild, simple inflammation to complicated disease with pericolic abscesses or perforation with feculent peritonitis. Only about 25% of

patients show complications during the first acute presentation. Imaging plays a crucial role in the initial diagnosis of colonic diverticulitis as well as for excluding the various differential diagnoses. Depending mainly on the location the latter include epiploic appendagitis, acute appendicitis, ischemic, inflammatory, or infectious colitis, gynaecological diseases, such as tuboovarian abscesses, and infarction of the great omentum. Computed tomography (CT) is the most commonly performed imaging modality in an emergency to detect and to confirm ACD although false negative results may occur in 2-21% of cases. Ultrasonography has been known for a high specificity for ACD, but results remain very operator-dependent. Magnetic resonance imaging is still not a first-line emergency modality, but very sensitive for fistulous complications. The most specific imaging finding is the inflamed diverticulum (arrowhead sign), often with pericolic stranding and colonic wall thickening. Complications of ACD may be regional, such as adjacent abscesses and fistulae, or distant, such as thrombophlebitis or organ abscesses, ideally demonstrated by CT with intravenous contrast medium injection. Treatment of colonic diverticulitis has evolved away from immediate surgery towards more conservative and minimally invasive strategies. Today, small abscesses are managed conservatively, while abscesses of >3-4cm require percutaneous drainage, often conducted by radiologists. Surgery has become less and less straightforward but considered as second-line treatment after previous imaging-guided intervention.

Learning Objectives:

1. To review the typical and atypical imaging features of acute colonic diverticulitis and their influence on patients' management.
2. To become familiar with the complications and the most important differential diagnoses of acute colonic diverticulitis.
3. To understand the importance of imaging-guided interventions for the management of complicated acute colonic diverticulitis.

Radiographers' challenges offering imaging services in Africa

Presiding:

D. Newman; Fargo, ND/US

P. Gerson; Paris/FR

A-0651/A-0652 16:00

Chairpersons' introduction

D. Newman; Fargo, ND/US

P. Gerson; Paris/FR (philippe.gerson@htd.aphp.fr)

This paper is about ISRRT involvement in Africa for the past 24 years in more than 10 countries. Beginning in 1994 in Tanzania. ISRRT has organised several workshops and congresses in this continent especially in French-speaking African countries. The involvement has contributed to help countries to set up associations and establish a huge network in Africa.

Session Objectives:

1. To recognise the demographics and patient accessibility to health services of a particular African country.
2. To understand the infrastructure of the imaging health services and their contribution to the primary and hospital health services to sustain the population and individual health.
3. To appreciate the radiographers' effort to keep up to date with evidence-based practice in imaging services.
4. To become familiar with the radiology education system and lifelong learning opportunities for radiographers practicing in Africa.

A-0653 16:08

Nigeria. Healthcare services in Nigeria: the radiographers' opportunities and challenges

E. Olasunkanmi Balogun; Lagos/NG (kanmibalo@yahoo.com)

Radiography is an art and science of the application of both ionising and non-ionising radiation in diagnostics and treatment of diseases when medically indicated. The study of radiography dates back in Nigeria, first as hospital-based training after which foreign examinations were taken. These examinations were conducted by the college of radiographers, London, United Kingdom. The certificates evolved from MSR, DSR, to DCR. In the year 1965 the first indigenous school was established in Lagos (Circa) and then another in Ibadan in the year 1972. The bachelors of Science (BSc) in Radiography started in the year 1983 and has spread over the years with seven universities offering radiography at a first-degree level and three at postgraduate levels. Training of manpower is the bedrock of better practice, therefore, the increase in training schools brought about an increase in manpower and translated to

Postgraduate Educational Programme

better practice across the country. The status of being a developing Nation as well as a Small non-influential market brought great challenges to the availability and maintenance of infrastructure. Recently the Nigerian government introduced the public, private, partnership (PPP) model of funding which has helped with increasing access to very expensive but needed equipment. There are a few challenges with the Scope of practice, hands-on training and limitations by government policies. Radiography training and practice in Nigeria is progressing and still an arrowhead even in Africa as a continent. However, Research funding opportunities are required.

Learning Objectives:

1. To recognise the demographics and patient accessibility to healthcare services in a densely populated country as Nigeria.
2. To understand the infrastructure of the imaging health services and their contribution to the primary and hospital health services to sustain the population and individual health.
3. To appreciate the radiographers' effort to keep up to date with evidence-based practice in imaging services.
4. To become familiar with the radiography education system and lifelong learning opportunities for radiographers practicing in Nigeria and its environs.
5. To look at the challenges of team work/professional rivalry/nomenclature even in the face of infrastructural challenges.

A-0654 16:26

South Africa. The South African radiographer: button pusher or creative thinker?

H. [Friedrich-Nel](#); Bloemfontein/ZA (hfried@cut.ac.za)

In 2014 two of the Universities of Technology in South Africa implemented four-year degrees in radiography. The Health Professions Council of South Africa (HPCSA) and specifically the Professional board for Radiography and Clinical Technology (RCT) guided this process. Previously the education and training model was a two-year hospital-based diploma and a three-year bachelor's degree or diploma. Six years after the first universities implemented the revised education and training model, the question lingers: Do universities deliver radiography graduates with the ability to work independently, think critically and creatively? Recently the HPCSA updated the scope of practice of a radiographer to align this with the four-year bachelor's degree education and training model to offer expanded opportunities to the radiographer who wishes to engage in lifelong learning opportunities. In South Africa, it is a statutory requirement for a health care practitioner to register with the HPCSA. To maintain his or her HPCSA registration each registered healthcare practitioner (radiographer) must pay a yearly registration fee and earn 30 continuing education units (CEUs). Five CEUs must be collected in the category ethics, patient-centred care and patient rights.

Learning Objectives:

1. To learn about the radiography education models in South Africa.
2. To become familiar with continuing education requirements and registration.
3. To share the revised scope of practice.

A-0655 16:44

Côte d'Ivoire. Professional practice of radiology and imaging in Africa: radiographers for more commitment and responsibility in patients' safety

K.B. [Yao](#); Abidjan/CI (kwame_boniface@yahoo.fr)

Radiology is the pathway to clinical settings and Diagnostic Imaging. It is a powerful tool in medicine, and its influence is expected to increase for years to come. Besides, the growth of modern imaging depends on advances in technologies, and the professional practice includes the development of radiographers' skills as well as the implementation of radiation safety culture. However, in Africa, hundreds of hospitals and institutions do not have the possibilities to perform the most fundamental imaging procedures, for lack of appropriate technologies, and skills. Moreover, setting a careful balance between the benefits and the risks related to patients' exposure is a challenge. Despite the recurrent shortage, African Technologists keep on struggling to bridge the gap. The methodology of approach consists in covering the state of art of professional practice and safety, revealing the main gaps and actions carried out to bridge them up and, the perspective and operational plan for a better view on the future. As deliverable outcomes, different projects carried out by radiographers and results are presented, and their impact on professional practice and safety discussed. They are essentially made up by the development of homemade equipment for professional practice purpose, training project to strengthen radiographers' skills. The global situation of practice is characterised by a gap between international standards and local settings. Therefore, radiographers are urged to demonstrate more commitment and responsibility in the management of their activities. Besides, ISRR's support is very much appreciated and exchange between technologists, through international congress is strongly encouraged.

Learning Objectives:

1. To reveal the challenges faced by African radiographers in practicing their profession.
2. To learn about the different actions carried out by radiographers for

radiographers within Africa, in seeking alternatively affordable means of practicing their profession.

3. To appreciate the ISRR's initiatives and capacity building projects to provide sustainable support to radiographers in Africa.

4. To understand the clues set up by ISRR regional officers' to improve patient care.

A-0656 17:02

Kenya. Discovering Kenyan radiographers: past, present and future

C. [Muchuki](#); Nairobi/KE (cmuchuki@gmail.com)

Kenya is a country in East Africa with a coastline on the Indian Ocean with a population of 49 Million. It's a home to wildlife and Maasai Mara Reserve known for its annual wildebeest migrations. The Kenyan radiographers are governed by Society of Radiography in Kenya (SORK) a registered professional body whose overall aim is to promote, support, regulate the professional standards of practice, conduct, and ethics of radiographers. Currently, they are 1200 registered radiographers and 300 radiologists in the country. Kenya medical training college offers Diploma in imaging courses for three years. Additional training is Bachelor of Radiography program an integrated academic and clinical course of 4 years duration. The Kenyan radiological system is continuously innovating. Previously, radiographers would process the films in a darkroom, now we have jumped into a new era. The workflow is greatly facilitated by automatic machine-facilitated workflow processes, and Patients receive digital imaging. Kenya's health care system is structured in a step-wise manner so that complicated cases are referred to a higher level. Gaps in the system are filled by private and church-run units. There are three major national hospitals in Kenya, where Kenyatta National Hospital is the largest Referral Hospital in Kenya and the entire East and Central Africa. It caters for 80,000 in-patients, >500,000 out-patients annually with a bed capacity of 1800. It offers diagnostic imaging service to >300 patients daily. Concerning radiation safety, AFROSAFE campaign addresses issues arising from radiation protection in medicine in Africa.

Learning Objectives:

1. To understand the current situation and trend of radiographers in Kenya.
2. To understand the Kenyan health system.
3. To become familiar with Kenyan radiation safety issues; Afro safe Kenyan chapter.

Improving radiation protection in medical imaging in low- and middle-income countries: past actions and future directions

A-0657/A-0658 16:00

Chairpersons' introduction

L. [Donoso](#); Barcelona/ES (ldonoso@clinic.ub.es)

M.M. [Rehani](#); Boston, MA/US (madan.rehani@gmail.com)

The international professional societies have the mandate and responsibilities to extend outreach to low and middle-income (LMI) countries. In this respect, both the International Organization for Medical Physics (IOMP) and International Society of Radiology (ISR) join hands to assess and improve the situation of radiation protection in medical applications of radiation. This session involves important stakeholders like the International Atomic Energy Agency (IAEA), World Health Organization (WHO) and representative of an important region-Africa. The session will deliberate not only on actions taken, result achieved but also on a vision for the future. There have been important developments through IAEA in LMI countries with the support of WHO, IOMP and ISR such that reasonable information is available on radiation doses to patients in various imaging procedures dominantly in CT and interventional procedures and diagnostic reference levels (DRLs) are available from some of the LMI countries. There are few situations where patient doses are on higher side. However, the information comes largely from few major centres in each country (lacking in breadth), and depth of penetration of radiation protection actions is lacking. The session will identify actions that can be taken to improve the situation to cover the breadth and depth in LMI countries.

Postgraduate Educational Programme

Session Objectives:

1. To learn about the situation of medical imaging and radiation protection in low- and middle-income countries.
2. To understand the past challenges and possibly future ones in the area of radiation protection in medical imaging in low- and middle-income countries.
3. To learn about the activities of worldwide organisations to support low- and middle-income countries.

A-0659 16:05

The International Society of Radiology's (ISR) vision

G. [Frija](mailto:guy.frija@aphp.fr); Paris/FR (guy.frija@aphp.fr)

Universal health coverage includes health promotion, preventive services, diagnostics, and medicines for communicable and non-communicable diseases. Regarding diagnostics, a global plan for imaging is needed, covering equipment, manpower, and regional governance. Quality and safety need to be addressed in each aspect. The Quality and Safety Alliance of the International Society of Radiology (ISRQSA) is working closely with the WHO and IAEA to improve radiation protection in low-, and middle-income countries (LMICs). It acts as a convener of radiation safety campaigns across the globe and encourages campaign creation in regions where none currently exist. Following the need for a multi-stakeholder approach to radiation protection, the ISRQSA seeks collaboration with related international organisations, including IOMP and ISRRRT. The ISR recently defined its forthcoming work plan with the WHO, which will focus, among others, on the following areas: advocating the development of a global plan for equipment and manpower, also in LMICs; awareness raising and advocacy activities towards the implementation of the International Radiation Basic Safety Standards (BSS) and Bonn Call for Action; facilitating access to imaging referral guidelines and providing expertise to support implementation particularly in LMICs; fostering teamwork approaches and risk communication; and safety and quality in the medical use of non-ionizing radiation. In addition, the ISR is involved in the Lancet Oncology Commission on medical imaging and nuclear medicine with the aim of increasing global awareness of the importance of cancer imaging and improving access to imaging.

Learning Objectives:

1. To learn about the ISR's radiation protection policy.
2. To appreciate actions which are currently developed.
3. To understand the challenges of low- and middle-income countries to improve radiation protection.

A-0660 16:20

Patient doses in large part of the LMI countries and way forward: The International Organization for Medical Physics' (IOMP) vision

M.M. [Rehani](mailto:madan.rehani@gmail.com); Boston, MA/US (madan.rehani@gmail.com)

The radiation doses to patients in diagnostic imaging examinations and optimisation of dose with image quality is something akin to medical physicists. Medical physicists have published hundreds of papers covering data from more than 80 LMI countries. IOMP collated the data and information on patient doses pertains to computed tomography (CT) dominantly, but also for interventional procedures, mammography and other radiographic imaging. The patient dose information from Eastern European countries is more than other regions like Asia, Africa and Latin America, primarily because of Euratom. The past challenges pertained to crossing the threshold of dose assessment, shift from machine focus to patient focus, whereas future challenges pertain to creating focus on the protection of the individual patient. A large part of the data from LMI countries comes through the work of the IAEA. IOMP plays a role in creating agenda; organising training events; motivating professionals to work, produce results and publish them; disseminating the work; act as an expert for international organisations and provide leadership in creating and propagating outreach programs. Further, IOMP identifies the changing scenario and create a vision for professional colleagues with an emphasis on LMI countries. IOMP works with international organisations like IAEA and WHO and professional bodies.

Learning Objectives:

1. To learn about the current situation of patient doses in a large part of the world.
2. To appreciate the challenges and needs based on experience gained.
3. To understand the needs that will impact future actions.

A-0661 16:35

The International Atomic Energy Agency's (IAEA) approach

D. [Gilley](mailto:D.Gilley@IAEA.org); Vienna/AT (D.Gilley@IAEA.org)

The International Atomic Energy Agency's mission is to assist its Member States, in the context of social and economic goals, in planning for and using nuclear science and technology for various peaceful purposes and facilitates the transfer of such technology and knowledge in a sustainable manner to developing the Member States. Challenges in low and middle income have been identified, and the IAEA is achieving positive results in radiation protection with the support of local radiology professionals. The IAEA, through

the radiation protection of the patient's unit and technical cooperation, have seen improvements in patient safety activities at the local, national and regional levels. The success of these efforts would not be possible without the strong commitment of local radiology professionals who support the IAEA goal of bringing the beneficial and safe uses of nuclear and radiology technology to all of society.

Learning Objectives:

1. To learn about regional challenges in radiation protection in healthcare.
2. To appreciate the efforts professionals are demonstrating in achieving progress in radiation protection in a resource-limited region with the help of the IAEA.
3. To understand the effects this has on the overall improvement of radiation protection of patients and workers.

A-0662 16:50

The World Health Organization's (WHO) approach

M.d.R. [Perez](mailto:perez@who.int); Geneva/CH (perez@who.int)

The UN Member States made a commitment towards 17 Sustainable Development Goals (SDGs) by 2030: the SDG #3 aspires to "ensure healthy lives and promote well-being for all at all ages". Half the world lacks access to essential health services. Many countries have adopted national commitments to achieve universal health coverage (UHC), which means ensuring that all people have access to quality essential health services they need for their health and well-being without incurring financial hardship. This presents a unique opportunity for joining global efforts towards achieving UHC and, in this context, ensuring safety and quality in medical imaging services will be central to the success of these efforts. Indeed, both diagnostic radiology and image-guided interventions are linked to health promotion, preventive services, diagnosis, treatment, follow-up, rehabilitation and palliative care. A culture of radiation safety and quality can be embedded into policies, processes and institutions as the health care systems grow and develop as it is the case in low and middle-income countries. This represents at the same time a challenge and an opportunity and requires strong leadership, robust planning and strategic investment. This presentation will summarise WHO's views on the importance of safety and quality in medical imaging for globally advancing patient care, describe the roles and responsibilities of different stakeholders in strengthening radiation protection in health care and identify challenges and opportunities for enhancing radiation protection in medical imaging in low- and middle-income countries.

Learning Objectives:

1. To learn about WHO's views on the importance of safety and quality in medical imaging for globally advancing patient care.
2. To identify challenges and opportunities for enhancing radiation protection in medical imaging in low- and middle-income countries.
3. To understand the role and responsibilities of different stakeholders in strengthening radiation protection in health care.

A-0663 17:05

Africa's vision to improve radiation protection

B. [Mansouri](mailto:boudjema.mansouri@gmail.com); Algiers/DZ (boudjema.mansouri@gmail.com)

Radiation protection: Needs and challenges in Africa The burden from communicable and non-communicable diseases, including the socio-economic impact of these, has adversely affected development in Africa due to a poor or absent legislative and regulatory framework for radiation protection in many countries, an inadequate awareness of the radiology safety policies an insufficient awareness about radiation doses and the associated risks in the other health professions, an inequitable distribution of radiation facilities, equipment and skilled personnel, and the financial and political constraints. The continent's health care system faces big challenges to match health workforce supply and demand. Contemporary discussions in radiation protection entail a systematic articulation of the African health system as well as an explanation of how the professionals apprehend reality and interpret their experiences. To avoid to be left behind the progress and the international actions for safety is recommended, to provide an efficient response for a good medical practice, ensuring that the benefits outweigh risks in all radiological medical procedures using customized systems adapted to the heterogeneous African context. The establishment and implementation of regulations to standardize with the development of policies, guidelines the practice of radiation is required and need to be adapted to the specific status of the health system in Africa. It is requested to all the stakeholders and the international organisations to develop national and regional action plan constructed from current discussions about conceptions in African thought and realities ensuring Africa's patients the same quality and safety.

Learning Objectives:

1. To understand the African gaps and to identify the challenges with the existing opportunities.
2. To learn about the implementation of a safety culture in medical radiation protection in Africa and the support provided by international organisations, like IAEA and WHO, and professional societies, like ISR and ESR.

3. To learn about the Afrosafe campaign, in particular about the lessons from the past and the envisaged programme for the next three years 2019-2021.

A-0664 16:00

A. The role of intra-procedural perfusion assessment in peripheral arterial disease

J.A. Reekers; Amsterdam/NL (j.a.reekers@amc.uva.nl)

Non-invasive measurement of blood vessel flow can be performed in many ways. The most used modalities to measure flow are Doppler flow imaging and MRA. The restriction of these flow measurements is that only intravascular flow can be measured while more than 80% of the organ perfusion flows through the microcirculation. To investigate the perfusion of an organ we need to know the total blood flow through that organ and the tissue volume because perfusion is the volume of blood flowing through certain mass (or volume) of tissue per unit time. If we measure true perfusion in a volume of tissue, we measure foremost the flow through the microcirculation of the tissue. With specially designed DSA 2D perfusion acquisition software on the X-ray system, the DSA data are processed instantaneously, allowing for immediate evaluation and comparison. The time taken for contrast to pass through the arterial vasculature and to enter into the venous system is the duration of the maximal analysis possible on the tool. Improvement of tissue perfusion after revascularisation could be a parameter for success and might be a predictor for outcome. Several competing mechanisms play a role in the final interpretation of the perfusion data. The value of each mechanism depends on the clinical situation and the intervention performed. The value of intra-procedural perfusion assessment will be discussed.

Learning Objectives:

1. To understand the technique of intra-procedural perfusion assessment.
2. To learn how to target peripheral revascularization therapy based on perfusion assessment.
3. To discuss the value of using intra-procedural perfusion assessment on the outcome of endovascular therapy for peripheral artery disease.

A-0665 16:30

B. CT 4D imaging after (T)EVAR

R. Scherthaner; Vienna/AT (Ruediger.scherthaner@meduniwien.ac.at)

Endovascular Aortic Repair (EVAR) has evolved into a successful treatment option for aortic aneurysms and dissections; however, the possibility of remaining endoleaks after the procedure requires continuous imaging follow-up of these patients. However, the reliable classification of different endoleak types is sometimes challenging, especially in patients with complex, customised stent-graft designs. By adding time as the 4th dimension, 4D CT angiography allows the visualisation of blood flow within the aorta and its branches. Thus, 4D CT angiography facilitates a more detailed analysis of endoleaks and their underlying cause. However, 4D CT angiography requires thorough planning by a vascular radiologist before and during the examination to achieve optimal visualisation at the lowest possible exposure to ionising radiation and contrast material following the ALARA principle. In addition, it is important to understand that 4D CT angiography cannot replace regular imaging follow-up, but should only be used as a supplemental technique in uncertain cases.

Learning Objectives:

1. To understand the challenges of imaging follow up after (T)EVAR.
2. To become familiar with the technique of 4D CT.
3. To learn how to establish treatment recommendations based on 4D CT results after (T)EVAR.

C. How cone-beam CT can change your practice in interventional radiology

R. Uberoi; Oxford (Raman.Uberoi@ouh.nhs.uk)

C-arm cone-beam computed tomography (CBCT) is a new imaging technology that enables acquisition of cross-sectional imaging with modern angiographic systems equipped with a flat panel detector. Volumetric tomographic images can be combined and co-displayed with conventional 2D angiographic imaging and dedicated software used to plan treatment, navigate/position the catheter or device, monitor the treatment, and assess the final result or verify margins. This technique has the potential to improve outcomes in a wide range of IR treatments. An excellent example of the huge potential benefits of CBCT is in the field of interventional oncology. CBCT with its 3D nature, soft tissue contrast, and with the post-processing software is superior to DSA in lesion detection and tumour-feeding vessel identification. In addition Dual Phase CBCT, where a bi-phasic CBCT is acquired using a single contrast injection allows increased tumour detection versus single phase CBCT alone comparable to gold standard contrast-enhanced MDCT and MRI in lesion detection and in predicting therapy response. Similarly, for Selective internal radiation therapy (SIRT) CBCT also has several potential advantages. Angiographic work-up is required to identify hepatoenteric arteries, originating from the hepatic arteries, defining the vascular territory of all targeted hepatic arteries; and identifying the tumoral lesions within these vascular territories. CBCT can demonstrate extrahepatic contrast enhancement in 52 % of cases, in 33 % of cases these additional CBCT observation scan lead to additional coil embolisation and/or change in catheter position.

Learning Objectives:

1. To understand the technique of cone-beam CT.
2. To learn about the role and applications of the cone-beam in the angio suite.
3. To discuss the influence on daily clinical practice in interventional radiology.

A-0667 16:00

Doppler imaging

F. Calliada; Pavia/IT (fabrizio.calliada@gmail.com)

Doppler, it's undoubtedly a not new imaging technique, but an adequate knowledge of the basic physics and the scanner tuning's it's essential to avoid errors and misunderstanding. In the first part, the presentation will cover the principal sources of error that should be avoided during a Doppler examination and the major tuning tricks needed for an optimal and successful examination. In the second part, we will try to become familiar with new Doppler imaging techniques dedicated both to very low-velocity microvascular flow and to high-velocity complex flow representation.

Learning Objectives:

1. To learn about actual indications and applications of Doppler imaging.
2. To show better parameter settings for optimal technical results.
3. To illustrate tips and tricks for technical and clinical successful examinations.
4. To become familiar with the new Doppler imaging techniques and applications.

CEUS

M. D'Onofrio; Verona/IT (mirko.donofrio@univr.it)

Contrast-enhanced ultrasonography (CEUS) is a safe and accurate imaging method to evaluate the vascularity of abdominal organs. CEUS improve the ultrasound characterisation of tumoral masses. CEUS should be performed when possible immediately after the US detection of indeterminate mass in abdominal organs. CEUS is accurate in the characterisation of neoplastic lesions such as liver metastases and pancreatic ductal adenocarcinoma. The use of CEUS in studying focal liver and pancreatic lesions found at the US, especially in the same session of ultrasound examination is, therefore,

recommendable to promote faster diagnosis. In particular, liver metastases detection could be improved by the use of contrast-enhanced ultrasound in respect to basal examination. Actual indications and applications of CEUS are presented in official published guidelines. Every CEUS examinations should be performed with better parameter settings for optimal technical results.

Learning Objectives:

1. To learn about actual indications and applications of contrast-enhanced US (CEUS).
2. To show better parameter settings for optimal technical results.
3. To illustrate tips and tricks for technical and clinical successful examinations.
4. To become familiar with the new CEUS techniques and applications.

Elastography

D.A. [Clevert](mailto:Dirk.Clevert@med.uni-muenchen.de); Munich/DE (Dirk.Clevert@med.uni-muenchen.de)

In the daily clinical routine characterisation of focal lesions using native B-mode ultrasound and colour-Doppler can be difficult or insufficient. Therefore, additional diagnostic information must be taken into consideration, using ultrasound-elastography it is possible to evaluate and characterise tissue properties and focal lesions regarding their stiffness to gather additional information on a non-invasive basis. Regarding the liver, elastography techniques can also be used for the evaluation of fibrosis/cirrhosis. Nowadays, elastography has been implemented into every modern ultrasound system and has been established as a supplementary examination technique to the conventional ultrasound techniques.

Learning Objectives:

1. To learn about actual indications and applications of elastography.
2. To show better parameter settings for optimal technical results.
3. To illustrate tips and tricks for technical and clinical successful examinations.
4. To become familiar with the new elastography techniques and applications.

Fusion imaging

C. [Ewertsen](mailto:caroline.ewertsen@dadlnet.dk); Copenhagen/DK (caroline.ewertsen@dadlnet.dk)

Image fusion software is available on most high-end ultrasound systems, and several publications for different clinical applications are available. Ultrasound images can be fused with images from CT, MRI or PET/CT, which enables the user to target biopsies or verify the nature of inconspicuous lesions. In order to fuse the images, a co-registration or alignment must be made. This can be done manually, by choosing common points or planes in the different datasets, or automatically by the system by recognition of pixel intensities in the images. This applies for some systems, but not for all modalities. The theory behind these different co-registration methods will be covered as well as their accuracy. Furthermore, examples of clinical applications will be demonstrated. The technique is more time consuming than conventional B-mode ultrasound, but time spent decreases with increasing user experience. Depending on the body size of the patient and the organ of interest patient positioning should be identical to when the previously recorded data set was recorded, but this is not mandatory. However, for liver applications, accuracy of the co-registration may improve if this is taken into account. Also identical in- or expiration may improve accuracy. Real-time image fusion enables real-time assessment of lesions in several anatomical regions.

Learning Objectives:

1. To learn about actual indications and applications of fusion imaging.
2. To show better parameter settings for optimal technical results.
3. To illustrate tips and tricks for technical and clinical successful examinations.
4. To become familiar with the new fusion imaging techniques and applications.

Minimally-invasive local treatment of breast cancer: the time is now

A-0671 16:00

Chairperson's introduction

A. [Athanasiou](mailto:aathanasiou@mitera.gr); Athens/GR (aathanasiou@mitera.gr)

Breast cancer management is evolving towards "less-is-more". Image-guided percutaneous biopsies provide accurate histologic diagnosis thus replacing open surgical biopsies in more than 90% of cases. Breast conservation therapy is the standard treatment for early-stage breast cancer. Sentinel lymph node biopsy has replaced axillary lymph node dissection in many cases. Is treating early breast cancer without surgery the next challenge? For liver metastases, treatment by means of ablative techniques has widely replaced surgery. Is there any place for minimally invasive treatment of early breast cancer? During this course, three main procedures will be presented, and current indications, advantages and disadvantages will be discussed. They include radiofrequency ablation, high intensity focused ultrasound ablation, and cryotherapy ablation. They may offer effective tumour management in selected cases (small < 2cm tumours, elderly patients) and provide treatment options that are oncologically safe and cosmetically acceptable. By means of excessive local heating or freezing under imaging guidance, these procedures can cause cell death and tumour destruction. Surgical excision remains the standard local treatment of breast cancer. However, these procedures may represent an interesting alternative of successful treatment in selected cases. Large prospective trials should evaluate the efficacy, cost-effectiveness, cosmetic results and long-term outcome of minimally, imaging-guided local treatment compared with the traditional surgical approach.

Session Objectives:

1. To learn about HIFU, radiofrequency ablation and cryotherapy that challenge traditional surgical excision in the management of breast cancer.
2. To become familiar with the role of imaging in using these new technologies.
3. To understand the potential advantages and disadvantages for each of these techniques.

A-0672 16:05

A. High-intensity focused ultrasound (HIFU) therapy

F. [Pediconi](mailto:federica.pediconi@uniroma1.it); Rome/IT (federica.pediconi@uniroma1.it)

Surgical treatment of breast cancer has changed over time, evolving from radical mastectomy to more conservative approaches. This has been possible thanks to technical advantages in the field of diagnostic imaging that allowed the early diagnosis of breast cancers with very small dimensions. Mini-invasive technologies (radiofrequency ablation, cryoablation, etc.) can preserve the original breast volume avoiding glandular resections and surgical scars and ensuring at the same time complete tumour ablation. Ablation with high-intensity focused ultrasound (HIFU) is based on the use of an extra-corporeal ultrasound transducer that selectively destroys target tissue avoiding thermal damages to surrounding structures. The technique can be performed under ultrasound or magnetic resonance (MR) guidance. MR guidance offers several advantages that improve the safety and efficacy of the procedure: a visualization of the planned US beam during each phase of the procedure, a real-time monitoring of the progressive temperature increase within the target tissue and surrounding tissues, an accurate treatment planning, an evaluation of the treatment efficacy thanks to the use of intravenous gadolinium-based contrast agent. HIFU ablation of breast cancer is a new and promising technique that deserves large interest in the field of clinical research in order of its potential application in the clinical practice.

Learning Objectives:

1. To learn about the basics of HIFU therapy.
2. To become familiar with the different types of imaging guidance.
3. To appreciate its role in treating benign and malignant lesions.

A-0673 16:30

B. Radiofrequency ablation therapy

B. [Brkljacic](mailto:boris@brkljacic.com); Zagreb/HR (boris@brkljacic.com)

Radiofrequency ablation (RFA) is promising, but quite rarely used minimally invasive modality to treat small breast cancer in patients in whom general anaesthesia is contraindicated or who refuse surgery. In most studies, cancers were surgically excised shortly after RFA. In very few studies, RFA was used as the only treatment modality, instead of surgery. The procedure is most conveniently performed under ultrasound guidance, in local analgesia, which allows constant contact with the patient during the procedure. Precise

preprocedural imaging is crucial and should include contrast-enhanced MRI in addition to mammography and ultrasound. Preprocedural core biopsy is mandatory, with precise assessment of the tumour type, grade, and immunohistochemical features. Typical US findings of hyperechogenicity of ablated mass are noted during the procedure. Postprocedural mammographic and MRI findings are characteristic and will be presented. The complete ablation can be achieved in small T1-2 NO MO breast cancers that present as masses of maximum 2-3 cm in diameter, with the sufficient distance from the skin and pectoral muscle to avoid the thermal lesion of these tissues. In larger lesions, only partial ablation may be achieved. Only solitary, unicentric, invasive ductal cancers, preferably ER/PR positive should be treated. Invasive lobular cancers should not be treated with RFA. Our results will be presented in a small group of patients who were treated with RFA, and who refused surgery, had a contraindication to general anaesthesia and opted for RFA. The technique, preprocedural, intraprocedural and postprocedural imaging findings, as well as the long-term result will be presented.

Learning Objectives:

1. To learn about how radiofrequency works.
2. To become familiar with its use in clinical practice.
3. To appreciate the advantages and disadvantages.

A-0674 16:55

C. Cryotherapy

M.H. Fuchsjäger; Graz/AT (michael.fuchsjaeager@medunigraz.at)

Cryotherapy is a new, minimal-invasive image-guided treatment option for breast tumours. A specific 12-17G probe is applied into a tumour. Argon gas making use of the Joule-Thomson effect cools down the needle tip to minus 187 degrees centigrade. An ice ball covering lesion and an adequate safety margin is formed. Coagulative necrosis of the tumour cells after two freezing cycles is the result. Cryoablation for breast tumours can be performed under US, CT or MRI guidance. Several studies showed an overall success rate of more than 90%. Indications for cryotherapy are small tumours, contraindications to general anaesthesia or increased risk of complications, support of standard therapies and palliative approach. Cryotherapy can be performed under local anaesthesia on an out-patient basis with a potential better cosmetic outcome than standard surgical therapies. Minimal-invasive therapies ask for a paradigm-shift as the eradicated tumour is left in situ and resection with clear margins will not be proven histopathologically, but functionally by MR imaging. It is important to emphasise that radiology is not aiming to take over therapy of breast cancer patients but to help with innovative, less invasive treatment options as a member of a multidisciplinary team. Close cooperation with our clinical partners (surgery, gynaecology, oncology, radiation therapy, etc.) is the key to success and avoidance of turf battles. The goal for the future should be minimal-invasive ablation therapy for breast cancer as a valid therapeutic option.

Learning Objectives:

1. To learn about the cryotherapy technique.
2. To become familiar with its use in clinical practice.
3. To appreciate its role in treating benign and malignant lesions.

17:20

Panel discussion: Will we still need surgery for local therapy of breast cancer in the future?

Inflammatory and infectious CNS pathology

A-0675 16:00

Chairperson's introduction

E.T. Tali; Ankara/TR (turgut.tali@gmail.com)

Modern life, particularly the influence of globalisation, immigration and expanding tourism, facilitating transportation between the continents, thereby increasing the social-personal relationship that may be the cause of increased infections. The brain has some unique peculiarities like the absence of lymphatics, lack of capillaries in the subarachnoid space, and presence of cerebral spinal fluid (CSF), which is an excellent culture medium for dissemination of infectious processes, in the subarachnoid space and into the ventricular system. Infections of the central nervous system (CNS) frequently present diagnostic and therapeutic challenges. CNS infections are not frequent when encountered, require prompt diagnosis and initiation of specific treatment often are necessary to allow the best chance of recovery without sequelae.

The prognosis depends on rapid identification of the site of the inflammation and pathogen. Most CNS infections can be treated successfully as long as they are detected early. Delayed diagnosis remains a major cause of disability. It is particularly unfortunate if a rapidly progressive but treatable disease remains undetected until irreversible damage is caused. Improvements in diagnostic imaging, in particular, computed tomography (CT) and magnetic resonance imaging (MRI) have greatly facilitated the diagnosis and treatment of intracranial and spinal infections.

Session Objectives:

1. To understand the role of imaging in the diagnosis and monitoring of inflammatory and infectious diseases of the central nervous system.
2. To learn basic principles of the use of imaging in neuroinfection and neuroinflammation.
3. To appreciate the added value of imaging in addition to the clinical findings and laboratory tests including CSF analysis.

A-0676 16:05

A. Autoimmune encephalitis

P. Demaerel; Leuven/BE (philippe.demaerel@uzleuven.be)

Autoimmune Encephalitis (AE) is emerging as a more common cause of encephalopathy than previously thought. AE remains a difficult diagnosis. The presence of antibodies (Ab) in the CSF confirms the diagnosis, but it can take several weeks before the results become available and a negative result does not exclude AE. Therefore, MR plays an important role in these patients, who often present with nonspecific neurological symptoms. Subacute encephalopathy, new onset seizures or psychiatric symptoms should raise the suspicion of a possible AE. AE consists of a large number of Ab-related diseases. Neuromyelitis Optica and ADEM are typical examples of AE with anti-glial Ab. The diseases with anti-neuronal Ab are usually divided into three groups: (1) Ab to cell-surface antigens, (2) Ab to intracellular synaptic proteins and (3) Ab to intracellular antigens. The imaging-related findings will be reviewed in this course. The most common imaging finding consists of uni- or bilateral FLAIR hypersignal in the hippocampus and/or amygdala. It is important to emphasise that these signal changes can be very subtle. Extratemporal lesions in the cerebral cortex, the grey nuclei, the cerebellum and the brainstem have been reported too and can support the clinical suspicion of AE. Brain MR can also remain normal, and FDG-PET is certainly recommended in these patients. Finally, central nervous system involvement can be observed in several autoimmune diseases. The MR findings can sometimes be very specific. This will be illustrated in, e.g. Susac syndrome, Rasmussen encephalitis, granulomatous angiitis and neurosarcoidosis.

Learning Objectives:

1. To learn about the imaging pattern of autoimmune encephalitis.
2. To understand the limited role of conventional MRI and the need for advanced imaging techniques in the diagnostic process and for follow-up purposes.
3. To appreciate the role of imaging in a multidisciplinary and multimodal approach.

A-0677 16:28

B. Infectious encephalitis

A. Zimny; Wroclaw/PL (abernac@wp.pl)

Infectious encephalitis is an inflammation of the brain which can be caused by different pathogens. Majority of them are viruses, less frequently bacteria, fungi and parasites. Immunocompromised patients or people travelling to endemic regions may develop encephalitis due to less frequent pathogens. Adult patients with encephalitis present with acute onset of fever, headache, confusion, and sometimes seizures. Encephalitis may be accompanied with the involvement of meninges (meningoencephalitis) or spinal cord (encephalomyelitis). It is a life-threatening condition, and prompt diagnosis is crucial. Diagnosis may be very challenging and is typically based on symptoms and supported by blood tests, analysis of cerebrospinal fluid and imaging. Brain CT is often a first line imaging method in acute settings, but MRI is a method of choice in the initial diagnosis and follow-up of patients with encephalitis. MR imaging is also used to rule out other important differential diagnoses (vascular, tumoral, inflammatory). The role of different MR sequences including DWI, SWI, perfusion, spectroscopy and post-contrast images will be discussed as well as a significance of a good knowledge of the MRI patterns of brain involvement which can be helpful in suspecting a particular pathogen. Infectious encephalitis is a heterogeneous entity which requires a comprehensive and multidisciplinary approach that takes into account individual clinical, microbiological, and radiological features of each patient.

Learning Objectives:

1. To learn about the correct choice of imaging modalities and image acquisition parameters for the detection and monitoring of infectious diseases of the central nervous system.
2. To understand the benefits and challenges of image pattern recognition for diagnostic purposes.

Postgraduate Educational Programme

3. To appreciate the heterogeneity of the disease spectrum and challenges to interpret imaging findings in the context of the clinical presentation and possible comorbidities.

A-0678 16:51

C. Inflammatory and infectious myelitis

M.M. Thurnher; Vienna/AT (majda.thurnher@meduniwien.ac.at)

Transverse myelitis (TM) is an "umbrella term" used to describe an inflammatory disorder of the spinal cord that can be idiopathic or associated with the central nervous system (CNS) autoimmune inflammatory diseases, connective tissue autoimmune diseases, or post-infectious neurological syndromes. Myelitis can present either as monophasic or recurrent disease. The most common monophasic diseases causing TM are idiopathic transverse myelitis and acute disseminated encephalomyelitis (ADEM), whereas recurrent disorders include multiple sclerosis (MS), neuromyelitis optica spectrum disorder (NMOSD), vasculitis (Behcet disease, SLE, Sjögren syndrome) and neurosarcoidosis. The recent discovery of multiple novel neural-specific autoantibodies accompanying autoimmune and demyelinating disease has improved the current understanding and classifications. This lecture will provide an overview of radiological, clinical, serological, and prognostic differences of inflammatory and infectious spinal cord diseases.

Learning Objectives:

1. To learn about the spectrum of infectious diseases of the spinal cord level and their most characteristic imaging features.
2. To understand the difficulties in image acquisition and image interpretation.
3. To appreciate the clinical relevance of early diagnosis and therapeutic intervention.

17:14

Panel discussion: Ask the expert: is imaging the key diagnostic modality for an early and specific diagnosis of infectious diseases, leading to a better functional outcome?

16:00 - 17:30

Paediatric oncology

Moderator:

L.-S. Ording Müller; Oslo/NO

A-0679 16:00

The most common brain tumours

E. Vázquez; Barcelona/ES (evazquez@vhebron.net)

Brain tumours are the most common group of solid tumours in the paediatric age. Clinical onset commonly includes signs and symptoms related to increased intracranial pressure, gait disorders, or cranial nerve deficits. Although usually insidious, acute presentations due to stroke or obstruction of cerebrospinal fluid flow can occur. Certain previous histological classifications, such as that of medulloblastoma, are being replaced by new classifications based on genetic characteristics, which enable better prediction of tumour aggressiveness and help to better guide therapy according to the specific tumour type. Magnetic resonance (MR) imaging has an important role in tumour characterisation, surgical planning and follow-up, but structural or anatomic brain MRI is often limited. Advanced MR techniques, including diffusion-weighted imaging, diffusion tensor imaging, functional MRI, perfusion imaging, and spectroscopy, help to improve the accuracy on tumour malignancy and risk in initial diagnosis and to facilitate therapy effectiveness monitoring and diagnosis of possible recurrence during tumour follow-up. The main imaging clues of the most common brain tumours (astrocytoma, ependymoma, and medulloblastoma) in children will be presented in a didactic manner in this talk, together with the updated MR imaging protocols for diagnostic approach and therapeutic monitoring.

Learning Objectives:

1. To present current imaging techniques and describe the typical features of astrocytomas.
2. To present current imaging techniques and describe the typical features of medulloblastomas.
3. To present current imaging techniques and describe the typical features of ependymomas.

A-0680 16:30

The most common chest tumours

A.S. Littooi; Utrecht/NL (alittooi@hotmail.com)

Malignant thoracic tumours may arise from the chest wall, pleura, lung parenchyma or mediastinum. When a chest mass is discovered on a conventional chest X-ray, cross-sectional imaging is often required to accurately localise and characterise the mass in order to narrow the differential diagnosis. Magnetic resonance imaging is preferred for mediastinal and chest wall lesions, whereas CT is commonly used for imaging of pulmonary lesions. The location of the lesion is important in determining the differential diagnosis: Mediastinum: tumours in the mediastinum are best characterised by the compartment in which they arise. Tumours arising from the anterior mediastinum are most commonly due to lymphoma or leukaemia followed by germ cell tumours. Lesions in the middle mediastinum are usually seen in association with anterior mediastinal lesions. The tumours of the posterior mediastinum are usually of neurogenic origin with neuroblastoma being the most common. Lung: in children, most pulmonary malignancies are metastatic in nature. Primary pulmonary malignant neoplasms are rare in children. The majority of pulmonary lesions are congenital or inflammatory lesions. Chest wall: the most common malignant chest wall tumours include Ewing's sarcoma and rhabdomyosarcoma and occur in children older than seven years. Ewing's sarcoma classically causes a permeative lytic expansive lesion of the rib with bone destruction, periosteal reaction and soft tissue mass. When the soft tissue component is massive, bone involvement may be very subtle. This lecture will highlight the most common malignant thoracic tumours with emphasis on those with characteristic imaging features.

Learning Objectives:

1. To present current imaging techniques and describe the typical features of malignant mediastinal tumours.
2. To present current imaging techniques and describe the typical features of pulmonary tumours.
3. To present current imaging techniques and describe the typical features of chest wall malignancies.

A-0681 17:00

The most common abdominal tumours

S. Franchi-Abella; Le Kremlin-Bicêtre/FR (stephanie.franchi@bct.aphp.fr)

Wilms Tumor or Nephroblastoma is the second most common abdominal and renal paediatric tumour. The aims of imaging are to establish the local tumour extension, the lymph nodes involvement, the presence of bilateral disease, the vascular invasion and the presence of metastases (mostly in the lungs). Both MR and CT can be performed for the abdominal extension. CT is standard for pulmonary metastases. US-Doppler can be helpful for the assessment of vascular extension in addition to CT or MR. Lymphoma is the third most common paediatric neoplasm. Non-Hodgkin lymphoma (NHL) commonly involves extra-nodal sites. Patients typically present with widespread disease. CT and MRI are used for staging. FDG-PET/CT plays a role to evaluate the extension of the disease and the response to the treatment. Neuroblastoma is the most common abdominal paediatric solid tumour accounting. The adrenal gland is the most common site of origin (50 %). The aim of imaging is the tumour staging prior to surgery and chemotherapy. The International Neuroblastoma Risk Group staging system is now based on the presence of "image-defined risk factors" (IDRFs) which allow children to be assigned to specific risk groups at the time of diagnosis. IDRFs include vascular invasion, invasion of adjacent solid organs, soft-tissue structures and extension into the spinal canal. CT and MRI are used. MRI is more sensitive for characterising bone marrow involvement, extension to the central nervous system. MIBG scintigraphy or SPECT/CT allows identification of both primary tumours and metastatic disease including bone marrow.

Learning Objectives:

1. To present current imaging techniques and describe the typical features of Wilms' tumour.
2. To present current imaging techniques and describe the typical features of non-Hodgkin's lymphomas.
3. To present current imaging techniques and describe the typical features of neuroblastomas.

Emergency Imaging

RC 1217

Why do I miss fractures in emergency?

A-0682 16:00

Chairperson's introduction

S. [Wirth](mailto:wirth@med.uni-muenchen.de); Munich/DE (stefan.wirth@med.uni-muenchen.de)

Fractures are the most common type of missed injuries, especially at the lower extremity and in particular, the foot. Although there are limitations, Radiography is the imaging standard for fracture detection. Typical reasons for overlooking fractures are missed soft tissue signs, insufficient imaging parameters or views, satisfaction of search, small fracture extent or missing displacement of fragments. Appropriate strategies to reduce the number of missed fractures are the correlation of findings with clinical features, knowledge of difficult regions and technical limitations, re-assessment in cases of ongoing pain or disability- if necessary by using cross-sectional imaging, checklists, appropriate communication/ information flow.

Session Objectives:

1. To learn the typical constellations and findings of missed fractures.
2. To understand the potential complications resulting from missing fractures.
3. To appreciate direct and indirect fracture signs with different imaging modalities.

A-0683 16:05

A. Missed fractures in children

K.J. [Johnson](mailto:johnson@bch.nhs.uk); Birmingham/UK (karl.johnson@bch.nhs.uk)

Traumatic injury and subsequent fracturing are one of the commonest reasons that children attend hospital and undergo some form of imaging. While the majority of injuries are easily detected, in some instances, a fracture may be missed. Broadly speaking, missed fractures occur in children for three reasons, namely; Perception - the fracture was not seen Interpretation - an abnormality was seen but reported as something else Occult injuries - the fracture is present but not visible on the imaging. The fact that the paediatric skeleton is developing and not fully ossified can lead to confusion between normal development and pathological changes. In addition, the plastic nature of a child's bones and the presence of growth plates means that the fracture patterns are seen different from those in adults. This presentation will discuss the commonly missed fractures that occur in childhood. There will be a discussion on how to avoid perception errors. There will be a review of those anatomical areas in which interpretation errors commonly occur, such as the elbow and wrist, typically due to confusion with normal variations in the growing skeleton. It will highlight those occult injuries in which additional or follow up imaging is useful.

Learning Objectives:

1. To become familiar with the commonly missed fractures in childhood.
2. To understand the choice of the best-suited imaging modality.
3. To learn about atypical imaging findings in different clinical scenarios.

A-0684 16:30

B. Missed fractures in adults

S. [Döring](mailto:doring@uzbrussel.be); Brussels/BE (seema.doring@uzbrussel.be)

Missed fractures are a common problem in the emergency department. Poor X-ray exposure factors, improper positioning, an inadequate number of views are common technical reasons for missed fractures. Subtle non-displaced fractures, inadequate experience, misinterpretation as normal variants, difficulty in the visualisation of fractures due to severe arthrosis or osteopenia, satisfaction of search (SOS) and working under duress in the emergency are important contributory factors. Commonly missed fractures in upper extremity include posterior shoulder dislocation, non-displaced greater humeral tuberosity, radial head, non-displaced radial styloid, scaphoid and hook of hamate fractures. In the lower extremity, femoral neck, Segond, osteochondral fracture of talar dome, lateral and posterior talar process, anterior calcaneal process, Lisfranc dislocation, or peroneus fractures can be easily missed. Apart from long-term pain and morbidity, missed fractures can lead to serious consequences such as osteoarthritis, non-union, delayed union, malunion, avascular necrosis and heterotopic ossifications. Reduction in misdiagnosis of fractures can be achieved by continued education of technical staff to improve X-ray quality. Similarly, continued education and supervision of younger less experienced radiologists can be very helpful. Systematic evaluation of the X-rays, avoiding SOS, knowledge of injury mechanisms and corresponding expected fracture patterns, knowledge of indirect signs of fractures, requesting complementary CT/MRI in negative X-rays with a high degree of suspicion and follow-up repeat X-rays when required are important measures that experienced radiologists employ to decrease misdiagnosis of fractures.

Learning Objectives:

1. To become familiar with the most commonly missed fractures in adult patients.
2. To understand which additional information will influence the choice of imaging modality.
3. To learn about atypical imaging findings in adult patients after trauma.

A-0685 16:55

C. Missed musculoskeletal injuries in whole-body trauma CT

A. [Platon](mailto:platon@hcuge.ch); Geneva/CH (alexandra.platon@hcuge.ch)

Whole-body usually consists in an initial unenhanced cerebral CT, followed by a helical, single-step continuous acquisition from the vertex to the symphysis pubis, after iv contrast injection. The rate of missed injuries at initial CT reading, reported in the literature, ranges between 2.4% and 47%; more than 50% of them involve the musculoskeletal system. The majority of missed musculoskeletal lesions involve the spine, followed by the skull, shoulder girdle, ribs and pelvic ring. Missed injuries are usually subtle, are frequently located close to other well identified major lesions, and their rate is correlated to the severity of trauma. Based on the literature data, the wide majority of missed musculoskeletal lesions have no impact on the patients' mortality. However, they may have functional consequences on the outcome of the patients. Multiplanar reconstructions must be systematically obtained to detect subtle fractures and, in the spine, to demonstrate a fracture extension into the posterior vertebral elements, which will turn a stable compression fracture into an unstable lesion. The rate of subtle missed musculoskeletal injuries can be reduced by searching associated indirect CT signs. For instance, pneumocephalus or fluid content in paranasal sinuses are indirect signs of skull (or face) fracture; vocal cord hematoma may suggest the presence of a laryngeal injury and a thickening of the prevertebral stripe a vertebral fracture; the widening of the discal space, an interspinous widening or a misalignment of articular facets at CT will mandate an MRI to look for ligamentous injuries.

Learning Objectives:

1. To become familiar with the most commonly missed musculoskeletal injuries in patients after polytrauma.
2. To understand the clinical impact of missed subtle injuries on clinical outcome of trauma victims.
3. To be familiar with less typical imaging findings in musculoskeletal injuries.

Clinical dilemmas in radiography: what graduates need to know

A-0686 16:00

Chairperson's introduction: What are the current issues in radiography?

J. [Santos](mailto:joanasantos@estescoimbra.pt); Coimbra/PT (joanasantos@estescoimbra.pt)

Technology evolution plays a central role in medical imaging diagnosis and treatment. Different imaging modalities, hybrid technologies, new image detectors, high computing capabilities, new image processing tools are being developed daily. Radiographers are integral members of medical imaging and radiotherapy teams delivering high-quality clinical care. Radiographer's knowledge skills and competencies (KSC) are defined in guidelines. However, radiography courses have different models across Europe, and the definition of professional expertise levels varies per country. Essential tools must be obtained during the graduation. The development of the critical thinking skills of students is mandatory to meet the challenges of daily clinical practice. To be updated radiographers must undertake Continuing Professional Development (CPD) appropriate to their practice. CPD is crucial to preserve and demonstrate continuing competence with autonomy and responsibility. Radiographers developed their clinical practice in a variety of complex procedures improving outcomes for patients without neglecting patient care. The challenge is to obtain proper education and training to effectively link graduation and clinical daily practice.

Session Objectives:

1. To understand the current issues facing new graduates.
2. To consider the development needed to become an effective practitioner.
3. To appreciate the changing face of radiographic practice.

Postgraduate Educational Programme

A-0687 16:05

Issues surrounding consent

E. [Dodd](mailto:emma.dodd@boltonft.nhs.uk); Bolton/UK (emma.dodd@boltonft.nhs.uk)

The potential for a patient centred approach to all diagnostic imaging begins from the moment a patient arrives within the Radiology department. The prime opportunity for attaining the required trust and rapport with the patient is during the consent process. The complexities of gaining such consent can be influenced by a wide range of varying factors including age, gender, culture and capacity all of which require a very different approach to ensure that informed consent is definitively attained. The presentation of challenges associated with consent may be overt or have the potential to be relatively subtle, and so the radiographer must be aware of both the values of the individual patient and also the requirements of the radiographic examination in order to meet the delicate balance that these potentially opposing concepts present. The increasing pace, expectations and evolution of the role of the radiographer lead to this perpetual dilemma which must be sensitively and adequately broached to avoid the potential for litigation and overall patient dissatisfaction. Student and qualified radiographers alike must ensure that informed consent is achieved by employing a systematic approach alongside appropriate problem solving and open discussion to allow for transparency and candour during every patient encounter.

Learning Objectives:

1. To understand the current issues surrounding consent within radiographic practice.
2. To become familiar with methods needed to ensure correct consent for radiographic procedures.
3. To discuss the changing role of the radiographer with regards to patient consent.

A-0688 16:28

Communication and compliance difficulties in imaging

S. [Kada](mailto:sundaran.kada@hvl.no); Bergen/NO (sundaran.kada@hvl.no)

Compliance with advice and instructions in the medical imaging department is important because we frequently use ionising radiation in our daily work and have long waiting lists for specialist examinations. Not adhering to instructions may result in repeating of the examination, thereby, increased waiting times for other patients and an additional radiation dose for the patient. Noncompliance can occur at any stage of the medical process - for example, failure to attend for outpatient appointments is regarded as a specific form of noncompliance. Knowledge and understanding of the various types of non-compliance would allow the formation of strategies to tackle them effectively. It is important to understand why patients do not comply with the information they are asked to follow. Compliance is generally seen to improve when patients are given more information about their state of health, investigations and treatment. Studies have shown that increasing the amount of information for the patient not only improves satisfaction but also empowers the patient and increases compliance. Affective and cognitive empathetic communication styles have a significant positive relationship with both patient satisfaction and compliance. However, providing information to certain groups of patients (people with dementia) is a challenge for healthcare professionals. Due to the projected increase in the percentage of the population suffering from dementia, who are frequently referred to imaging departments, it is suggested a CPD program (with theoretical knowledge and practical training of dementia) be provided to all radiographers.

Learning Objectives:

1. To be aware of communication and compliance issues within radiology.
2. To discuss methods for improving communication and compliance.
3. To appreciate the need for CPD in areas such as dementia, obesity.

A-0689 16:51

Professionalism in an era of social media (part 1)

R. [García Gorga](mailto:rodriggog@hotmail.es); Sabadell/ES (rodriggog@hotmail.es)

Social media has become a useful tool for health professionals. The most frequent advantage of using social media is receiving news and updated information about research, and new technologies. However, professionals are getting more involved in other ways of using social media; for instance, for getting in touch with other colleagues and for sharing opinions about different topics related to our profession. These discussions, often motivated by some publication, are an excellent intellectual exercise that helps us stay updated and in touch. Many radiographers have taken a step forward. Social media has served to narrow the gap between professionals and patients, which is an excellent way to provide first-hand information. The close contact with individual patients and patient's associations has another utility; make our profession visible and showing the valuable role of radiographers. In order to use social media with these objectives, it is necessary to identify ourselves adequately using a clear profile. In our opinion, it is mandatory to review the quality of the content we share and maintain a proactive and generous attitude. In our experience, the benefits far outweigh the efforts. It is also a work that can be done as a team. As a result, we identify ourselves more intensively with

our profession and contribute to generating a public profile of it. Social networks should be seen as a meeting point between people. It is at this point that we understand the relevance of these tools for those of us who must be health agents.

Learning Objectives:

1. To learn about professionalism in social media by showing activity models of radiography professionals in social media.
2. To appreciate the impact of digital information on the profession of radiography.
3. To understand professionalism in social media through the proposal of quantitative and qualitative research models.

A-0690 17:02

Professionalism in an era of social media (part 2)

M.A. [de la Camara](mailto:de_la_Camara@Talarrubias/ES); Talarrubias/ES

Professionalism in Social Media implies using digital tools to innovate processes and products and keep up with the digital development. One of the keys to professionalism in Social Media is to incorporate the evidence-based radiology resource in order to evaluate the behavioural impact (qualitative and quantitative). This is done by mastering a specific metric and its research with tools provided by Digital Marketing on each of the Social Networks and Digital Platforms used. Examples of shared and connected knowledge of professional practices in various Social Networks and platforms will be presented, and the case of the creation of audio-visual content in Spanish (videos on YouTube) that, through digital narrative, the informative and formative context, and the measurement of quantitative and qualitative data, we can identify better non-clinical communicative practices in the performance of CT and MRI tests, addressing the problem of claustrophobia, and improving the professionalism of the radiographer before the patient in radiology.

Learning Objectives:

1. To learn about professionalism in social media by showing activity models of radiography professionals in social media.
2. To appreciate the impact of digital information on the profession of radiography.
3. To understand professionalism in social media through the proposal of quantitative and qualitative research models.

The radiological investigation of musculoskeletal tumours

A-0691 16:00

Chairperson's introduction

F.M.H.M. [Vanhoenacker](mailto:Vanhoenacker@telenet.be); Antwerp/BE (filip.vanhoenacker@telenet.be)

Plain films are generally the initial imaging modality in the detection and characterisation of bone tumours, as they accurately depict matrix, cortical permeation or disruption, and periosteal reaction. However, the sensitivity of this technique for the detection of small lesions is limited. CT can be used for characterisation in anatomically complex areas, such as the spine, pelvis and skull. The CT appearance is similar to plain radiographs. Due to radiation restraints, CT is not recommended in children nor for evaluation of the appendicular skeleton in adults. Conventional MRI may be of additional help in narrowing the differential diagnosis of bone tumours. Soft Tissue Tumours (STT) based on imaging remains even more limited, and histology is usually required for a definitive diagnosis. Ultrasound is mostly nonspecific but may be used for superficially located cystic STT. On MRI, analysis of multiple parameters (shape, the presence of signal voids, fluid-fluid levels, SI, intratumoral necrosis, multiplicity, pattern/degree of enhancement) yields the best results. The highest confidence is reached in benign lesions, such as lipomas, vascular lesions, benign neural tumours, peritumoural cysts, hematomas, PVNS, GCTTS, and abscesses. The major role of MRI consists - however - of local tumour staging and monitoring of treatment. Recently, the European Society of Musculoskeletal Radiology (ESSR) has published guidelines for detection, characterisation, and referral pathway of musculoskeletal tumours based on conventional imaging. The specific aim of this session is to discuss the role of recent advances in ultrasound technology, advanced CT and MR techniques and hybrid imaging in the imaging evaluation of musculoskeletal tumours.

Friday

Postgraduate Educational Programme

Session Objectives:

1. To describe how to differentiate tumours from other non-tumoural pathological conditions.
2. To discuss the value of imaging modalities in this field.
3. To explain how to determine resectability and extension of the tumour.

A-0692 16:05

A. Radiographs and ultrasound

L.M. [Sconfienza](mailto:io@lucascnfienza.it); Milan/IT (io@lucascnfienza.it)

Besides advanced techniques, such as computed tomography and magnetic resonance imaging which are important in the workup of musculoskeletal tumours, plain films and ultrasound still play a crucial role. Plain films represent the cornerstone in the evaluation of bone tumours, as they allow for detecting the presence of a bone lesion and giving important information about characterization of the lesion such as the presence and type of periosteal reaction, the pattern of bone destruction, the lytic or sclerotic appearance of lesion, the presence of soft tissue involvement or associated findings such as pathological fractures. However, plain films have limitations in particularly complex anatomical locations (e.g., spine and pelvis) and in the evaluation of soft tissue tumours not involving the bone. Ultrasound has limitations in the evaluation of bone tumours, as the ultrasound beam can minimally cross the bony cortex. However, ultrasound may detect the presence of a periosteal reaction in early stages and may be used to assess the involvement of surrounding soft tissues and neurovascular bundles by bone tumours. On the other hand, ultrasound is accurate in the detection and evaluation of soft tissue tumours, being able to correctly evaluate the size and the relationship of the mass with the surrounding structures. The use of supplementary tools, such as power Doppler, contrast-enhanced ultrasound, and elastography has been proved to be useful in increasing the diagnostic performance of ultrasound in certain conditions. However, ultrasound may be limited by low contrast resolution, small field of view, and deep lesions.

Learning Objectives:

1. To discuss the value of radiography and US in the diagnostic work-up of MSK tumours.
2. To explain the most recent advances and trends in the development of US technology, including contrast-enhanced US and elastography.

A-0693 16:28

B. MRI and whole-body MRI

S.L.J. [James](mailto:stevenjames@nhs.net); Birmingham/UK (stevenjames@nhs.net)

This presentation aims to review a number of aspects of MR imaging related to primary bone tumours. Initially, a review of a basic MR protocol will be performed to establish a minimum requirement to adequately image this type of pathology. The role of some more advanced techniques including chemical shift imaging, diffusion-weighted imaging, MR spectroscopy and perfusion MR imaging will also be discussed. Finally, the role of whole-body MRI will be described. It should be noted that the focus of this talk will be on primary bone tumours and not on the use of these techniques in metastatic disease, myeloma or lymphoma.

Learning Objectives:

1. To describe how to perform an advanced clinical MR protocol for MSK tumours.
2. To explain the potential of new MR techniques.
3. To discuss the impact of MR imaging and whole-body techniques in MSK tumour imaging.

A-0694 16:51

C. CT and hybrid imaging

T. [Bäuerle](mailto:tobias.baeuerle@uk-erlangen.de); Erlangen/DE (tobias.baeuerle@uk-erlangen.de)

For diagnosis, staging and follow-up of musculoskeletal tumours, CT and the hybrid techniques PET/CT and PET/MRI offer a broad spectrum of methods. On the morphologic level, bone destruction ranging from osteolytic to -blastic lesions and adjacent soft tissue tumours, e.g. in Ewing sarcoma or lytic bone metastases, are captured by CT. Beyond morphology, PET radiopharmaceuticals including [18F]-fluorodeoxyglucose ([18F]-FDG) or [18F]-sodium fluoride ([18F]-NaF) display tumor and bone metabolism, respectively. Whereas the soft tissue tumours of rhabdomyosarcoma or bone marrow involvement in multiple myeloma is assessed by [18F]-FDG, osteoblastic activity is captured using [18F]-NaF for example in sclerotic metastases. Due to the excellent sensitivity of PET, information on the molecular level is available when administering tumour-specific radiotracers such as the [68Ga]- or [18F]-labeled prostate specific membrane antigen (PSMA) ligands for prostate cancer bone metastases. This lecture will summarise the use of CT and the hybrid imaging techniques PET/CT and PET/MRI in primary and secondary musculoskeletal tumours as well as in hematologic disease affecting bone. Current state-of-the-art techniques on the morphologic, metabolic and

molecular level will be reviewed, including an outlook on future developments, particularly for hybrid imaging.

Learning Objectives:

1. To discuss the role of CT and hybrid imaging in the evaluation of MSK tumours.
2. To describe how hybrid imaging allows the intrinsic combination of functional and anatomical image information.
3. To explain how future developments of novel PET tracers and integrated PET/CT and PET/MRI may impact the management of MSK tumours.

IT-security and GDPR

Moderator:

O. Ratib; Geneva/CH

A-0695 16:00

Chairperson's introduction

E. [Kotter](mailto:elmar.kotter@uniklinik-freiburg.de); Freiburg/DE (elmar.kotter@uniklinik-freiburg.de)

The introduction of the GDPR has raised many questions among radiologists and hospital administrators. Standard procedures of data management had to be modified, and IT systems had to be modified to adopt. This session will give an overview of GDPR, will summarise the practical aspects of GDPR and patient consent and highlight the special aspects of using mobile devices.

Session Objectives:

1. To give an overview on the GDPR and patient consent.
2. To understand practical aspects of GDPR and patient consent.
3. To know security aspects specific to mobile devices and social media.

Author Disclosure:

E. Kotter: Advisory Board; Agfa.

A-0696 16:05

Understanding the key points of GDPR

C.D. [Becker](mailto:Becker@Geneva/CH); Geneva/CH

The General Data Protection Regulation implies several new rules for the protection of the confidentiality of patient data, access of data for patients, processing, as well as technical and organisational safeguards. Explicit informed consent is necessary prior to processing and communication of imaging data. Patients have the right to access their image data and to obtain copies of their data ("data portability"). Data must be rectified in case of errors, and the patient and/ or supervising authority must be informed in the case of inadvertent or voluntary inappropriate disclosure of patient data ("data breach"). Derogations may be defined for special purposes, including research or public health, and special guidelines may be defined by national law.

Learning Objectives:

1. To give an overview of the GDPR.
2. To understand the key points of GDPR.
3. To review what is important for radiological practice.

A-0697 16:28

Issues related to patient consent to allow access to the data

O. [Ratib](mailto:Ratib@Geneva/CH); Geneva/CH

The developments of imaging biobanks for research and development of analysis tools and machine learning techniques must comply with strict regulations and guidelines geared toward protecting patient confidentiality and data security. The recent legal frameworks and regulatory data protection rules prevent the usage and exploitation of medical data without formal patient approval. Traditional informed consent principles used in medical research require that the patient is informed of the purpose and goals of the research performed with the data collected. This defeats the basic principle of deep learning and Big-Data analytics which looks for random patterns and correlations without a specific pre-established hypothesis. To overcome this dilemma, regulatory bodies, government agencies and academic experts in ethics have promoted new concepts of innovative legal frameworks that will allow and regulate the ability of each individual to contribute to the development of Big-Data collections of images while complying with fundamental ethical principles and regulatory directives. Our presentation will focus on the different technical and practical issues of implementing adequate patient consent and data protection strategies for the development of imaging biobanks repositories for scientific research and data mining.

Learning Objectives:

1. To understand the difference between general consent and informed consent.
2. To learn how to manage patient consent.
3. To understand special aspects of data access in the context of scientific data.

A-0698 16:51

Security aspects when using mobile devices and/or social media

E.R. [Ranschaert](#); *Tilburg/NL* (ranschaert@telenet.be)

Medical specialists and radiologists are using mobile devices to share and exchange medical information and images with other healthcare professionals. Usually, they need advice regarding a diagnosis or treatment, sometimes in an acute setting. Popular messaging services such as WhatsApp are frequently used for such purpose. Transmission of patient data with mobile devices and messaging services, however, does have several risks and limitations, mostly related to the security and privacy of patients, but also from an ethical and legal point of view. Some questions need to be answered: is this type of communication unsafe and/or illegal, and if yes, why? Is this type of communication compliant with the GDPR legislation? What safe and secure options are available for sharing patient information on mobile devices and with messaging services? In this session, these issues will be discussed in more detail.

Learning Objectives:

1. To understand the vulnerability of data on mobile devices and in social media.
2. To learn how to protect data on mobile devices.
3. To learn how to protect data and identity in social media.

17:14

Panel discussion: Data protection: benefit or burden?

16:00 - 17:30

Fibrotic lung diseases

A-0699 16:00

Chairperson's introduction

S.R. [Desai](#); *London/UK*

Session Objectives:

1. To understand the implications of diagnosing UIP.
2. To be aware of the various fibrotic entities prognosis.
3. To re-evaluate the links between smoking and fibrosis.

A-0700 16:05

A. Idiopathic pulmonary fibrosis

N. [Sverzellati](#); *Parma/IT*

Idiopathic pulmonary fibrosis (IPF) is the most common and lethal form of idiopathic interstitial pneumonia. Two guidance documents for the diagnosis of IPF have been recently published by international experts representing major respiratory and radiological societies. The documents have reached similar conclusions and recommendations, with only a few differences. The critical role of high-resolution computed tomography (HRCT) has been emphasised, proposing new HRCT diagnostic criteria. In particular, the role of HRCT has been expanded to permit diagnosis of IPF without surgical lung biopsy in select cases when HRCT shows a classic or probable UIP pattern. Additional investigations, including surgical lung biopsy, should be considered in patients with either clinical or HRCT findings that are indeterminate for IPF. A multidisciplinary approach is particularly important when deciding to perform additional diagnostic assessments, integrating biopsy results with clinical and CT features, and establishing a working diagnosis of IPF if lung tissue is not available.

Learning Objectives:

1. To learn about the updated criteria for IPF diagnosis.
2. To understand the implication for patient management.
3. To review illustrative cases with pathological assessment.

A-0701 16:28

B. Lung fibrosis in connective tissue and granulomatous diseases

P.-Y. [Brillet](#); *Bobigny/FR* (pybrillet@yahoo.fr)

The objective of the course is to review the main CT features of connective tissue diseases and sarcoidosis. The role of the radiologist in case of pulmonary fibrosis will be discussed (evaluation of severity, progression of disease, diagnosis of complications). Connective tissue diseases are a diverse

group of immunologically mediated systemic disorders that includes systemic sclerosis and antisynthetase syndrome. Involvement of the respiratory system is common in connective tissue diseases and can affect every part of the lung: pleura, alveoli, interstitium, vessels, lymphatic tissue, and large and/or small airways. Interstitial lung disease (mainly nonspecific interstitial pneumonia, but also usual interstitial pneumonia, organising pneumonia and lymphoid interstitial pneumonia) and pulmonary arterial hypertension are the main causes of mortality and morbidity. Sarcoidosis is a systemic disease of unknown cause that is characterised by the formation of immune granulomas in various organs, mainly the lungs and the lymphatic system. In up to 20%, patients develop fibrotic lung disease, which can be associated with potentially life-threatening manifestations. Three main CT patterns can be observed: bronchial distortion with or without fibrotic masses, Hilo-peripheral lines and honeycombing. Complications of fibrotic pulmonary sarcoidosis include pulmonary hypertension and chronic Aspergillus disease, with hemoptysis.

Learning Objectives:

1. To review the CT features of systemic sclerosis.
2. To learn about CT manifestations of antisynthetase syndrome.
3. To learn about lung fibrosis characteristics in sarcoidosis.

A-0702 16:51

C. Other causes of lung fibrosis

C.P. [Heussel](#); *Heidelberg/DE*

Drug-induced lung disease is an underestimated cause of morbidity in 5-10% of drugs like Amiodarone, Bleomycin, Busulfan, Methotrexate. Other drugs with potential lung toxicity include Cytarabine, Etoposide, NSAR, Azathioprine, Nitrofurantoin, Amphotericin B, Sulfonamide, Sulfasalazin, Statins, TNF- α -Blockers, anti-CD20, INF- α , Cetuximab, Bevacizumab, Alemtuzumab, Trastuzumab, Tacrolimus, Everolimus, Sirolimus. A suspected drug can be checked at www.pneumotox.com and sum up to >450 drugs. Risk factors include rheumatoid arthritis and chronic inflammatory bowel disease, and previous irradiation. Lung toxicity becomes more frequent nowadays in tumour therapy using recent biologicals that might cause autoimmune diseases. Pneumonitis has resulted therein in 5%. Time-point of pulmonary affection is extremely variable between days and several years after exposure. Patterns include alveolitis, COP, and NSIP. Radiation toxicity is related to the irradiation field, however, COP patterns typically occur adjacently to this field. Time-point varies between 6 weeks after the end of irradiation and might be later than 1 year thereafter. Patterns include alveolitis, COP, and NSIP. Smoking-related lung disease include, besides of emphysema, the mainly or partially reversible respiratory-bronchiolitis interstitial lung disease (rb-ILD), desquamate interstitial lung disease (DIP), Langerhanscell histiocytosis (LHC), and in combination of lung fibrosis and emphysema the respective irreversible syndrome (CPFE) which suffers from a worse prognosis than emphysema alone.

Learning Objectives:

1. To learn about drug-induced lung fibrosis.
2. To review CT features of post-radiation fibrosis.
3. To learn about smoking-related lung fibrosis.

Translating functional and molecular imaging in oncology

A-0703 16:00

Chairperson's introduction

R.J. Méndez; Madrid/ES (ramiro.mendez@outlook.com)

Different functional imaging techniques are currently able to in vivo assay many biological features of cancer, and they can be used in the detection, characterisation and follow-up of neoplasms. The non-invasive monitoring of the molecular and physiologic changes offers clear advantages for preclinical studies of the disease and the development and analysis of new therapies. Many of these functional imaging techniques and imaging biomarkers even being proved useful in cellular or animal cancer models, will never be brought into a clinical scenario for diagnosing cancer patients, for therapy tailoring or follow-up. To cross this translational gap the imaging technique must be reproducible; it has to be available using clinical equipment, the imaging biomarker should prove its validity for cancer detection, characterisation, prognosis or monitoring. Then, cost-effectiveness would also be considered. All these steps are part of a long road for translating functional and molecular imaging techniques from laboratory research to the comprehensive clinical management of cancer patients. In this session three different functional/molecular imaging techniques used in oncology will be presented, describing biological processes that can be assessed with each technique and analysing how to translate this basic knowledge to benefit cancer patients in a standard clinical practice.

Session Objectives:

1. To understand the basic concepts of functional and molecular imaging methods in oncology.
2. To appreciate the challenges in translating novel functional and molecular imaging methods.
3. To learn approaches to enhance clinical translation of functional and molecular imaging methods.

A-0704 16:05

A. Functional cancer imaging with MRI

S. Gatidis; Tübingen/DE

Medical imaging plays an increasingly important role in diagnosis, risk stratification and response assessment in oncology. While morphological assessment of tumour size and localisation is a prerequisite for oncologic imaging, the concept of personalised and precise medicine demands further information on tumour biology for the guidance of the therapeutic decision. MRI is the most versatile clinical imaging modality providing both, morphologic and functional information about tissues and organs in vivo and is thus an effective method for functional cancer imaging. This presentation will give an overview of MR-based methods of functional cancer imaging and their technical principles. Clinical applications of MR-based functional cancer imaging will be summarised, and methods for advanced analysis of complex imaging data will be discussed.

Learning Objectives:

1. To learn the basic principles of functional cancer imaging with MRI.
2. To understand the biological process that can be assessed using functional MRI.
3. To learn about clinical applications of functional MRI in oncology.

A-0705 16:28

B. New PET tracers in oncology

M. Herranz; Santiago de Compostela/ES (michel.herranz.carnero@sergas.es)

Advances in imaging modalities both anatomical (MRI, CT, US) and functional (PET, SPECT, fMRI) has provided with a new tool for earlier and more accurate diagnoses, and for personalised treatments follow-up. Positron Emission Tomography (PET), currently always combined with an underlying anatomical technique such as CT or MR, is a noninvasive molecular imaging technique that enables visualisation, measurement and quantification of metabolic events by detecting the distribution of molecules (targeting agent) bound to a positron-emitting compound, chemical complex known as a radiotracer. Development of new specific and sensitive radiotracers, nowadays, targeting practically any biological process (transporter, receptor, nucleic acid, enzymes, and many other molecular targets), is generating huge scientific and clinical interest. Currently, not only cancer but multiple pathologies including cardiovascular and neurodegenerative, are being visualised with specific radiotracers. The huge variability of the chemistry

behind the synthesis, the different radionuclides (positrons-emitting-compounds beyond 18F: 11C, 13N, 15O, 68Ga, 62Rb, 89Zr) allow almost infinite combinations for the majority of the processes that occur into the cell, getting closer and closer to a more specific, and more personalised medicine. Here we review the biological bases of different pathological processes and the way they can be visualised with different radiotracers, their clinical utility and future developments.

Learning Objectives:

1. To learn the basic concepts in the development of new PET tracers.
2. To understand the biological process that can be assessed using novel PET tracers.
3. To learn about clinical applications of new PET tracers in oncology.

A-0706 16:51

C. Optical imaging in cancer

D. Razansky; Zurich/CH (daniel.razansky@uzh.ch)

Microscopy has been a major optical imaging tool since the seventeenth century. Optical imaging is still a rapidly emerging field with remarkable new approaches continuously emerging to improve on the capabilities and application potential; ultimately impacting biological discovery and healthcare. A significant role in these developments has played the discovery, development and propagation of fluorescent proteins and probes, as well as bioluminescence, to in-vivo imaging applications. Linked to this progress is the ability to visualise disease features and biomarkers with high versatility. The recently introduced multi-spectral optoacoustic tomography methods are poised to revolutionise optical imaging by delivering high-resolution visualisation of structural, functional, metabolic and molecular information deep from optically opaque living tissues. These modalities are uniquely endowed with rich and label-free hemodynamic contrast, excellent spatial and temporal resolution, centimetre-scale penetration into living tissues, and versatile exogenous contrast approaches. State-of-the-art handheld and intraoperative imaging solutions are further transforming medical diagnostics by offering a new level of precision in non-invasive clinical observations of patients, demonstrating high diagnostic efficacy in a number of indications, including skin and breast lesions, cardiovascular and inflammatory diseases and metastatic lymph node detection.

Learning Objectives:

1. To learn the basic concepts of optical imaging in oncology.
2. To understand the biological process that can be assessed by optical imaging.
3. To learn about clinical applications of optical imaging in oncology.

E³ 1218

Secrets of radiology communications with patients and referring physicians

A-0707 16:00

Chairperson's introduction

M. Fatehi; Tehran/IR (fatehi@irsr.org)

While the referring physicians are looking for a detailed but concise description of patient's problem enriched by recommendations for the next step or action, the patients and their loved ones, look for an ordinary explanation of the situation in daily life language. The effectiveness of a professional report is based on not only the imaging aspect of the procedure including anatomy, pathology and physical principles of image acquisition but also mechanisms of decision making in the clinical discipline of the referring physician. In other words, the knowledge requirements of the successful radiology reports are not limited to medical imaging but to the subspecialty profession of the physician. It is not possible to ask patients to avoid reading their professional radiology interpretation but obviously, the report may increase their anxiety. So we need new tools and channels of communicating with patients. The major challenge is to find the best way to inform patient without additional workload and without breaking principles of the medical discipline.

Postgraduate Educational Programme

A-0708 16:06

A. Communication is all that really matters

J.A. [Verschakelen](mailto:verschakelen@uz.kuleuven.ac.be); *Leuven/BE (johny.verschakelen@uz.kuleuven.ac.be)*

A fluid transfer of information among radiologists, referring physicians and patients is essential for timely care, patient satisfaction and optimal health outcomes. As radiology practices become larger and more specialised, communication should be efficient and streamlined. While the introduction of sophisticated systems like computerised order entry, voice dictation systems and picture archiving and communication systems have certainly improved the information transfer, they may come at the expense of personal interaction with patients, referring physicians and medical colleagues. As the practice of radiology is evolving to become more patient-oriented and more multidisciplinary with the radiologist having an important clinical value in the care team, it is obvious that adequate personal communication is essential. Each person has a style of communication that is unique and refers to the choices made when communicating with others. Differences in communication style can be a barrier to effective communication. So it is important to identify its own personal communication style, to identify the barriers one might face when communicating with other styles and learn to enhance communication with others no matter what communication style they have.

Learning Objectives:

1. Patients, patients' organisations and referring physicians: "know your client" in radiology.
2. Communications styles for building trust and the role of informed consent
3. Psychology tips and tricks for effective communications and negotiations.

A-0709 16:34

B. Marketing channels for radiology promotion

D. [Pinto dos Santos](mailto:pinto.dos.santos@uk-koeln.de); *Cologne/DE (daniel.pinto-dos-santos@uk-koeln.de)*

As radiologists (or any other physician) we are constantly marketing ourselves and our practices, whether we are aware of it or not. In this talk, an overview is given about the various channels by which we are already marketing radiology and how to improve those. Also, some channels that traditionally receive less attention are discussed. The 5 P's mnemonic of marketing (product, price, placement, promotion and people) will be introduced to further explain some fundamentals of marketing. These fundamentals naturally have some overlap with the five dimensions of service quality (reliability, assurance, tangibles, empathy and responsiveness) as proposed by Parasuraman et al. which will also be reviewed. To conclude, potential implications on current clinical practice will be discussed, with a special focus on how feedback from patients and referring physicians can be gathered as well as how the radiological report (especially structured reports and lay-language reports) can contribute to improving the perception of radiology.

Learning Objectives:

1. Traditional and new marketing channels in healthcare.
2. Multi-media, multifaceted and lay-language reporting: is there a way to change the format of radiology reports?
3. Referring physicians' and patients' feedback as a driver of quality improvement.

A-0710 17:02

C. Personal-branding and promotion for a radiologist

S. [Morozov](mailto:spmoroz@gmail.com); *Moscow/RU (spmoroz@gmail.com)*

Current social media channels provide unparalleled possibilities for a wide promotion of healthcare services and professional expertise. Potential favourable outcomes include continuous communications within and outside a professional community, wider promotion of new medical technologies, and quicker distribution of professional news. Relatively low signal-to-noise ratio is a significant limitation of social media's effectiveness. Moreover, care should be taken to avoid misinterpretation of the superficial and brief information. A promotion and communication activity allows to achieve the expected result if it follows a pre-defined plan with an agile modification as it is realised. The major definitions to be preliminary made are the following: mission, executive strategy, target audience, key messages, tools and tactics, metrics, budget, schedule and amendments. The expected SMART result is a major differentiator of leisure social activities from a coordinated art of actions. Careful planning and execution do not exclude a personal touch in the communications. Moreover, a combination of personal and professional messages allows to effectively reach out to a wider audience. Recommendations on the content: at least 20% of personal messages, at least 20% of videos, description, hashtags, geo-tags, and face-tags. Publications about events, meetings with interesting people, resumes of books, teamwork reports, and personal motivations sources are the most attractive. Although social activities are attractive and joyful, their amount should be limited to less than 5% of daily working time. Core professional activities including clinical, research, administrative, teaching, and writing are the most valuable.

Learning Objectives:

1. A personal touch in healthcare marketing and challenges of "Group Practice" in developing a brand.
2. The best recipe for building a radiologist's personal brand to be known internationally.
3. Radiologist's role in an early diagnostics promotion and education of patients.

Oncologic Imaging

RC 1216

Oncological imaging: where are we now?

A-0711 16:00

Chairperson's introduction: What are the problems of morphologic evaluation

E. [De Kerviler](mailto:eric.de-kerviler@sls.aphp.fr); *Paris/FR (eric.de-kerviler@sls.aphp.fr)*

Since the 1980s, there have been many criteria to assess response of cytotoxic agents in solid tumours: WHO, SWOG, RECIST... These various response criteria have evolved over a period of time to establish their consistency in the assessment of efficacy in various solid tumours. Using these criteria, the primary endpoint is a significant decrease in the overall tumour burden, with thresholds for a response depending on the method used. For years, the main debate was therefore around the use of unidimensional versus bidimensional measurement of target lesions, the number of target lesions, and the assessment of non-target lesions. In the era of precision oncology, there has been a marked growth of targeted therapies and immunotherapies. Now there is evidence that single morphological response criteria may not be good enough. Evaluating early responses to precision therapy is essential for "go" vs. "no-go" decisions for these expensive molecularly targeted drugs. In the near future, it is clear that CT perfusion, functional MRI and molecular imaging will offer new perspectives in the assessment of the therapeutic response of non-cytotoxic drugs. More than ever before, imaging will play a prominent role in the management of cancer patients.

A-0712 16:05

A. CT perfusion techniques

H. [Schöllnast](mailto:helmut.schoellnast@medunigraz.at); *Graz/AT (helmut.schoellnast@medunigraz.at)*

CT-Perfusion imaging is a functional imaging tool which enables qualitative and quantitative evaluation of tumour perfusion and, therefore, assessment of tumour-related angiogenesis. Clinical applications for CT-perfusion imaging have mainly evolved to include lesion characterisation, prediction of prognosis, prediction of response to therapy and assessment of response to local or systemic therapies. Perfusion values have shown significant differences when comparing normal tissue with tumours and between benign and malignant lesions, although there is overlap between benign and malignant lesions. The degree of tumour perfusion is potentially associated with tumour aggressiveness as tumour-related angiogenesis determines the ability of tumours to metastasise and, therefore, affects prognosis. On the other hand, hypoxia within a tumour reflected by restricted perfusion limits the effect of chemotherapy and radiotherapy, potentially allowing for prediction of response. Both conventional chemotherapy and targeted therapies such as angiogenesis inhibitors may affect tumour vascularisation. In contrast to conventional chemotherapy, which mainly shows a cytotoxic effect on the tumour, angiogenesis inhibitors show rather a cytostatic effect. Traditional tumour size-based response criteria may underestimate the response to angiogenesis inhibitors in the early course of treatment due to stable tumour size despite effective therapy. In contrast, CT-perfusion imaging allows detection of a decrease in tumour perfusion which precedes decrease in size. Use of different models for Perfusion calculation such as compartmental model and deconvolution model, use of different CT-perfusion protocols including contrast media injection protocols and inter- and intraobserver variability when using Perfusion software limit use of CT-perfusion imaging in clinical Routine.

Learning Objectives:

1. To learn about current approaches for CT perfusion.
2. To understand the basic principles behind each technique.
3. To discuss radiation exposure from CT perfusion techniques.
4. To appreciate the clinical usefulness of these techniques in routine clinical practice.

Friday

A-0713 16:28

B. Functional MRI techniques

V.J. Goh; London/UK (vicky.goh@kcl.ac.uk)

It is recognised that cancer is a biologically heterogeneous disease. Thus a 'one size fits all' management approach may not bring about the best outcome for the individual patient. Oncologic therapies have evolved substantially over the last two decades providing cancer patients with a greater opportunity for a cure. This personalised approach has also required a paradigm shift in oncologic imaging to capture this biological heterogeneity and improve patient triage. MRI provides a unique opportunity to combine high contrast and spatial resolution imaging of tumour morphology with physiological imaging of water diffusion, vascularisation and oxygenation status. At initial diagnosis and staging this may allow tumours to be phenotyped better and during therapy, for tumours to be assessed more comprehensively, particularly where therapy is cytostatic and will not result in significant size change. In this lecture, the different functional imaging techniques that can be applied in clinical practice will be discussed, and evidence for practice highlighted. The potential of integrated PET/MRI will also be considered.

Learning Objectives:

1. To learn about different functional MR techniques such as diffusion and perfusion.
2. To understand the basic principles behind each technique.
3. To appreciate the clinical usefulness of these techniques in routine clinical practice.

Author Disclosure:

V.J. Goh: Research/Grant Support; Siemens Healthcare.

A-0714 16:51

C. Assessment by molecular imaging

J. Grimm; New York, NY/US (grimmj@mskcc.org)

Functional imaging in oncology-beyond-morphology basically describes molecular imaging - i.e. imaging and measurements of biological processes at the cellular and molecular level. This means predominantly clinical PET imaging with FDG. However, a multitude of other tracers allows for the detection of additional structural or functional entities, e.g. the imaging of PSMA in prostate cancer to detect disease; or the imaging with amino acids, reflecting higher amino acid metabolism in brain tumours. However, existing tracers can also be used to explore new signatures, such as positron lymphography with 18F-FDG to characterise sentinel lymph nodes. While most of the clinical molecular imaging is done using Pet (or SPECT) imaging, newer modalities are becoming more prominent, such as optoacoustic imaging or optical imaging. Optoacoustic imaging describes "listening to the light", i.e. the detection of absorbers of light with ultrasound. This can be used, e.g. to detect melanoma metastases. Optical imaging uses either fluorescently labelled agents (requiring excitation light) or radiotracers for Cerenkov luminescence imaging, the optical imaging of radiotracers, which does require radiotracers but no incident excitation light.

Learning Objectives:

1. To learn about the basic concepts in molecular imaging.
2. To understand how molecular imaging might be integrated into patient care.
3. To discuss clinical examples of where molecular imaging is already established in clinical practice.

The heart between the lungs

A-0715 16:00

Chairperson's introduction

J.E. Wildberger; Maastricht/NL (j.wildberger@mumc.nl)

Modern high-end CT scanners with faster scan acquisition times allow for routine assessment of cardiac pathologies, even on a standard chest CT. Relevant information regarding the heart can be retrieved, and incidental cardiac findings will play a major role for patient management in the future. Plain CT allows for fat distribution as well as for coronary calcium analysis. On contrast-enhanced scans, coronary arteries and myocardial changes can be

assessed. During this session, three esteemed speakers will present an overview of the diagnostics and the clinical impact of various cardiac pathologies on standard thoracic CT scans.

A-0716 16:06

A. Cardiomyopathies

D.J. Murphy; Dublin/IE (murphy.84@gmail.com)

Cardiomyopathies are a heterogeneous, important group of diseases with significant morbidity and mortality, and can be classified into five major subtypes based on morphology (hypertrophic, dilated, restrictive, arrhythmogenic and unclassified). Diagnosis is based on a composite of clinical history and examination, laboratory and genetic testing, electrocardiography and cardiac imaging. Echocardiography is the first-line imaging test for the evaluation of cardiac structure and function, with cardiac magnetic resonance imaging (CMR) the gold standard. The computerised tomography (CT) has a growing role in this area. ECG-gated cardiac CT is a well-established test for coronary artery imaging, but it also allows an excellent opportunity to assess for structural cardiac abnormalities, such as asymmetric septal hypertrophy in hypertrophic cardiomyopathy, or left ventricular dilatation in dilated cardiomyopathy. The CT features of the common cardiomyopathies will be reviewed with a comparison to CMR, along with a revision of normal cardiac chamber anatomy. The improved temporal resolution of modern CT scanners has reduced the deleterious effect of cardiac motion artefact on routine non-ECG gated chest CT, allowing an opportunity for the detection of cardiac structural abnormalities. Standard non-ECG gated chest CT has a reported sensitivity of 68% in the detection of cardiomyopathies, and the most reliable imaging features of cardiomyopathies on standard chest CT, as well as potential pitfalls, will be reviewed.

Learning Objectives:

1. To review the normal anatomy on standard chest CT.
2. To learn about the CT signs of various cardiomyopathies.
3. To learn about CT performance for the diagnosis of cardiomyopathy.

A-0717 16:34

B. Coronary artery disease

M. Williams; Edinburgh/UK

The heart and coronary arteries can be identified on imaging performed specifically to assess the heart and also on imaging of the chest performed for other reasons. Normal imaging coronary artery anatomy will be reviewed. Coronary artery calcification (CAC) is a marker of atherosclerotic plaque burden. CAC identified on electrocardiogram-gated computed tomography (CT) is associated with an increased risk of cardiovascular morbidity and mortality. Randomised controlled trials have shown that management guided by CT coronary angiography can improve outcomes for patients with suspected coronary artery disease. CAC can also be identified on non-gated CT performed for other reasons. Calcium scoring or ordinal assessment of CAC on non-gated CT correlates with results from gated imaging. CAC on non-gated CT is associated with increased mortality in a variety of diseases, including patients with respiratory diseases. Evidence of previous myocardial infarction can also be identified on non-gated CT with features including mural thinning, fatty infiltration and complications such as aneurysms.

Learning Objectives:

1. To review the normal coronary artery anatomy.
2. To learn about calcium scoring on non-gated CT.
3. To learn about the CT signs of healed myocardial infarction.

Author Disclosure:

M. Williams: Consultant; GE Healthcare.

A-0718 17:02

C. Fat and calcium in the heart

F. Pontana; Lille/FR (Francois.pontana@chru-lille.fr)

Population ageing and other risk factors are not only associated with calcification of coronary arteries but are also likely to induce changes in the cardiac structure. These changes can be evaluated on a standard chest CT without cardiac synchronisation. Calcifications of the cardiac valves may be a sign of valvulopathy. Aortic valve calcium scoring by CT is useful to estimate aortic stenosis severity when echocardiography is not feasible or not conclusive. Myocardial calcification may be due to abnormalities of calcium homeostasis or calcium accumulation in necrotised cardiac myocytes. Pericardial calcification is a sign of constrictive pericarditis. Physiological age-related fat deposits within the myocardium or the atrial septum are frequent and must not be misreported as pathological. Benign or more rarely malignant cardiac tumours may present fatty component. More recently epicardial adipose tissue seems to be a new cardiac risk factor quantifiable by imaging.

Learning Objectives:

1. To learn about physiologic changes.
2. To review the main causes of fat and calcium.
3. To learn how to differentiate pathologic from physiologic images.

Room M 5

Head and Neck

RC 1208

Post-treatment imaging of the head and neck

A-0719 16:00

Chairperson's introduction

H.B. Eggesbø; Oslo/NO (h.b.eggesbo@medisin.uio.no)

Head and neck cancer in the Western countries accounts for 3-4% of all cancers. Worldwide incidence is estimated to 500,000, and in Europe to 250,000. There are three times as many men as women that are affected. Squamous cell carcinoma constitutes for more than 80%. At the time of the diagnosis, one-third is staged I/II, and two-thirds staged III/IV. The recurrence rates for stage I/II is relatively low, and 5-year-survival is 70-90%. Hence, the risk of a secondary primary cancer after radiation therapy (RT) may be higher than the risk of recurrence. For stage III/IV, the local recurrence rates vary from 25 to 80%, and metastases from 10 to 30% and the 5-year-survival is 10-55%. Main treatment options for stage I/II are surgery and/or RT and for stage III/IV chemo- and RT. Regardless of choice of treatment, all tissues undergo major changes that challenge the post-treatment imaging interpretation for all modalities. This session will focus on expected changes after RT and the most frequent surgical procedures. Then, when and how to perform post-treatment imaging, in order to depict early cancer recurrence.

Session Objectives:

1. To become familiar with different methods of treatment.
2. To understand post-surgical and post-RT complications.
3. To know how to follow-up with patients in order to depict early recurrence.

A-0720 16:05

A. Normal findings after radiotherapy

R. Hermans; Leuven/BE (Robert.Hermans@uzleuven.be)

After radiotherapy, imaging may be used to monitor tumour response, and to detect recurrent or persistent disease before it becomes clinically evident. Early tumour recurrence may be difficult to distinguish from treatment-induced tissue changes. Therefore, the expected imaging changes after radiotherapy of head and neck cancer should be well known. These tissue changes depend on the radiation dose, the irradiated volume, and the time elapsed since treatment. Reticulation of fat layers, retropharyngeal space oedema, postirradiation sialadenitis, lymphatic tissue atrophy, and thickening of the pharyngeal and laryngeal structures may be seen. These expected tissue changes often appear symmetrical, unless asymmetric radiation portals were used. However, at the site of a bulky tumour, scar tissue may cause an asymmetric appearance also after successful treatment. Therefore, obtaining a baseline CT or MR study after therapy for a neoplasm with high risk for recurrence is recommended, best 3-6 months post-treatment. By comparing subsequent studies with this baseline study, tumour recurrences or treatment complications can be detected with more confidence. Some recommend PET-CT as the initial baseline study, as this technique has a high negative predictive value; the positive predictive value is lower, as therapy-induced inflammatory changes may cause false-positive results. Tissue necrosis is a rare complication of radiotherapy in the head and neck region, usually appearing late after treatment. Both soft tissue, cartilage and bone necrosis may be encountered; differentiation from tumour recurrence at an early stage may be difficult. Other long-term complications may occur, such as the development of a secondary tumour.

Learning Objectives:

1. To get acquainted with changes in tissues during and after radiotherapy.
2. To understand expected changes after radiotherapy in CT and MR imaging.
3. To recognise treatment complications from expected tissue changes after radiotherapy.

A-0721 16:28

B. Normal findings after surgery

A. Trojanowska; Lublin/PL (agnieszka30@yahoo.com)

Nowadays, the management of head and neck cancer involves multidisciplinary evaluation and treatment, which usually includes surgery, radiation therapy and chemotherapy. The various approaches to surgical resection and tissue reconstruction, the types of neck dissection, different radiation therapy techniques and the addition of concurrent and neoadjuvant chemotherapy regimens may complicate imaging findings. Differentiating post-treatment changes from tumour recurrence with the use of different imaging modalities is challenging because of the presence of altered anatomy secondary to resection, flap reconstructions, oedema, inflammation and the

presence of scar tissue. Therefore, it is essential to be familiar with normal findings after surgery and radiotherapy, to distinguish these characteristics from tumour recurrence and treatment-related complications.

Learning Objectives:

1. To get acquainted with the most frequent surgical procedures in the head and neck.
2. To understand how to evaluate post-surgical patients.
3. To learn how to assess microvascular flaps.

A-0722 16:51

C. Treatment monitoring for early detection of recurrence

A.D. King; Hong Kong/CN

Head and neck tumour recurrence occurs in 15-50% of patients with squamous cell carcinoma treated by chemoradiotherapy, the majority are in-field and detected either on the post-treatment assessment or within 2-3 years. MRI and CT aim to identify recurrence and also avoid unnecessary biopsy or surgery. Size criteria for recurrence include a primary focal mass or node (short axis) ≥ 1 cm, or $< 75\%$ -90% reduction in nodal size, but size has limitations especially in the assessment of HPV+ nodal disease. The main advantages of MRI over CT are the T2 weighted and diffusion-weighted images (DWI). Tumour recurrence tends to show T2 intermediate signal intensity and restricted diffusion (b-1000 high + ADC map low signal intensity), compared to inflammation (high signal intensity) or mature scar tissue (low signal intensity) on the T2 images and ADC maps. Contrast-enhancement tends to be moderate in recurrence compared to mature scar tissue (mild/absent) and granulation tissue/inflammation (marked), while DCE-MRI parameters show earlier and more intense contrast-enhancement in recurrence compared with benign posttreatment change. DWI is complementary to FDG-PET, helping to reduce the FDG-PET false positive results for recurrence caused by inflammation. False negative findings arise from microscopic disease such as that found at tumour margins or in pre-treatment occult nodal metastases, and also from small/infiltrating tumours mixed with benign post-treatment change. False positive findings arise from post-treatment changes, especially granulation tissue/inflammation, a sterile component of necrotic node (ADC map low signal intensity) and complications such as radionecrosis, radiation-induced tumours and granulomatous polyps.

Learning Objectives:

1. To get acquainted with the problem of recurrence in imaging studies.
2. To understand how to estimate signs of recurrence in CT and MRI.
3. To learn about false positive and false negative findings.

Contrast media guidelines

A-0723 16:00

Chairperson's introduction

H.S. Thomsen; Herlev/DK (henrik.thomsen@regionh.dk)

The document "summary of product characteristics (SPC)" is the legal document that directs the use of drugs, including contrast agents. It is approved by the European Medicines Agency (EMA) and/or the national authorities. It tells us for which examination that you may use the agent/medium based on the studies which the Marketing Authorization Holder (MAH) did prior to the application. Generally, the SPC for gadolinium-based agents are much detailed than that for iodine- or barium based media. However, no SPC cover all aspects. It is here where we need guidelines. Clinical practice guidelines are a key component for medicine, as they provide evidence-based recommendations for physicians and other health care professionals about the management of care for patients with diseases or other clinical conditions. However, all aspects of radiology are not covered by evidence-based knowledge. This applies also to contrast media/agents. Despite the first case of post-contrast acute kidney injury (PCAKI) was reported in 1954, the majority of recommendations dealing with PCAKI is not evidence-based, but eminence based. Generally, despite the fact that contrast agents/media are very safe drugs, adverse reactions occur. They may be acute, late and very late. Through guidelines we want reduce the rate of all adverse reactions. This session is devoted to the most recent developments with regard to 1) PC-AKI, 2) Contrast media and myeloma and 3) non-renal acute adverse reactions.

Session Objectives:

1. To learn about emergent issues regarding safe use of contrast media.
2. To understand the mechanisms underlying acute reactions and renal function deterioration after contrast media injection.
3. To provide evidence-based recommendations for safe use of contrast media and for the management of acute reactions.

A-0724 16:05

A. Post-contrast acute kidney injury (PC-AKI)

A.J. van der Molen; Leiden/NL (molen@lumc.nl)

The prevalence of Contrast-Induced Nephropathy, or more appropriately termed Post-Contrast Acute Kidney Injury (PC-AKI), has in recent times been the topic of intensive research. For intravenous CM administration large propensity score based studies showed a much lower frequency than was previously taught. Therefore, the Contrast Media Safety Committee of ESUR has recently systematically reviewed the existing literature and updated their guideline on Prevention of PC-AKI. The recommendations of this update will be explored. Also, results of a follow-up survey study among ESUR members into the barriers and facilitators of the implementation of this guideline in practice will be briefly shown.

Learning Objectives:

1. To understand the definition of PC-AKI.
2. To learn about the possible causes for PC-AKI.
3. To review current evidence regarding PC-AKI.

Author Disclosure:

A.J. van der Molen: Author; Incidental, ESUR CMSC Safety Book. Speaker; Incidental, Guerbet and Canon Medical Systems in past.

A-0725 16:30

B. Iodine-based contrast media in myeloma patients

F. Stacul; Trieste/IT (fulvio.stacul@aots.sanita.fvg.it)

Many radiologists and clinicians still consider multiple myeloma (MM) and monoclonal gammopathies (MG) a contraindication for using iodine-based contrast media. The ESUR Contrast Media Safety Committee performed a systematic review of the incidence of post-contrast acute kidney injury (PC-AKI) in these patients. A systematic search in Medline and Scopus databases was performed for renal function deterioration studies in patients with MM or MG following administration of iodine-based contrast media. Data collection and analysis were performed according to the PRISMA statement 2009. Eligibility criteria and methods of analysis were specified in advance. Cohort and case-control studies reporting changes in renal function were included. Thirteen studies were selected that reported 824 iodine-based contrast medium administrations in 642 patients with MM or MG, in which 12 unconfounded cases of PC-AKI were found (1.6%). The majority of patients had intravenous urography with high osmolality ionic contrast media after preparatory dehydration and purgation. In conclusion, MM and MG alone are not risk factors for PC-AKI. However, the risk of PC-AKI may become significant in dehydrated patients with impaired renal function. Hypercalcaemia may increase the risk of kidney damage and should be corrected before contrast medium administration. Assessment for Bence-Jones proteinuria is not necessary.

Learning Objectives:

1. To learn about the relationships between iodine-based contrast media and myeloma.
2. To understand the mechanisms of AKI in myeloma patients.
3. To review current evidence regarding risk of PC-AKI in myeloma patients.

Author Disclosure:

F. Stacul: Consultant; Bracco International.

A-0726 16:45

C. Ongoing evidence for acute adverse reactions

O. Clément; Paris/FR (olivier.clement@aphp.fr)

Contrast media (CM) use may lead to immediate hypersensitivity (IH) reactions, which should be distinguished from other adverse effects (pain, the sensation of heat, altered taste) and numerous pretreatment protocols have been implemented, but with uncertain efficacy. Different mechanisms were hypothesised to account for this until new diagnostic tests demonstrated an allergic mechanism in some patients through elevated tryptase and histamine concentrations and positive skin tests. Differentiating allergic from non-allergic IH is crucial, as allergy means immune memory and systematic recurrence at re-administration of the responsible or related agents (cross-reactivity), whereas non-allergic IH depends on direct toxicity. Numerous studies have been published over the last few years demonstrating these new pathophysiological pathways, both for iodinated and gadolinium-based agents, originating from European and Asian investigators. As a result, a clear modification of the clinical guidelines on hypersensitivity reactions is being witnessed, with an emphasis on skin testing for patients having presented immediate or delayed reactions. American (ACR Manual on Contrast Media Version 10.2), and European guidelines (ESUR, French, Spanish, British,

German) are going to be compared on different aspects of hypersensitivity to contrast media : -pathophysiology - risk factors - skin testing - biological testing (histamine, tryptase and other mediators) - provocation tests. The practical implications in terms of department organisation and medical responsibilities will be discussed.

Learning Objectives:

1. To learn about the acute adverse reactions for contrast media.
2. To understand the current evidence regarding risk factors.
3. To illustrate the first-line treatment of acute adverse reactions.

A. Lung nodule: managing uncertainty

M. Prokop; Nijmegen/NL (mathias.prokop@radboudumc.nl)

"no abstract submitted"

Learning Objectives:

1. To identify the key imaging findings.
2. To become familiar with the new Fleischner guidelines.

A-0733 09:15

B. Interstitial lung disease: searching for clarity

N. Sverzellati; Parma/IT

Diffuse interstitial lung diseases (DILDs) are an important but difficult group of disorders. High-resolution computed tomography (HRCT) is at the centre of the assessment of patients who have a suspected DILD. The term DILD comprises more than 200 separate disease entities. However, their pathological and HRCT patterns are relatively restricted compared to their number. This is an essential concept for understanding either the basics of the interpretation of HRCT scans or the need for a multidisciplinary discussion for securing the correct diagnosis. Having an organised approach is important for the efficient and accurate interpretation of HRCT scans. An example of this approach is a systematic sequential analysis of all the anatomical compartments of the thorax (e.g. airways, followed by the lung parenchyma, the pleura itself, and the mediastinum). Each finding should be further described concerning size, shape, location within the lungs, and relationship to any normal surrounding structures. Radiologists are to recognise basic HRCT patterns and key HRCT signs that may link abnormal imaging patterns to lung diseases. Some of these are specific to a disease, whereas others help narrow the differential diagnosis. Recognising these imaging patterns and HRCT scan signs are thus very important for the differential diagnosis.

Learning Objectives:

1. To become familiar with the differential diagnosis.
2. To identify the key imaging findings.

Radiology and pathology: will we ever be (digitally) married?

A-0734 08:30

Chairperson's introduction

L. Donoso; Barcelona/ES (ldonoso@clinic.ub.es)

Pathology and radiology are the core for clinical diagnosis, yet the workflows of both specialities remain in separate "silos," with no direct linkage between their reporting systems, even when both departments belong to the same host institution. Because both radiologists' and pathologists' data are essential to making correct diagnoses and appropriate patient management and treatment decisions, this isolation of radiology and pathology workflows can be detrimental to the quality and outcomes of patient care. With the information technologies advances currently occurring in healthcare, there is a clear opportunity to develop an integrated diagnostic reporting system that supports both specialities and, therefore, improves the overall quality of patient care. In this session, we will review the potential benefits of merging both specialisations and the most relevant technical and organisational factors involved in the integration process.

Session Objectives:

1. To learn about digital pathology.
2. To understand the differences with digital radiology.
3. To appreciate the opportunities of a possible integration.

A-0735 08:34

Are digital pathology and AI the definitive factors for the merging?

P.J. van Diest; Utrecht/NL

"no abstract submitted"

Learning Objectives:

1. To learn about key aspects in the implementation of digital pathology.
2. To understand the AI impact in pathology.
3. To appreciate the opportunities of a common workflow in the imaging domain.

A-0736 08:58

How would the integration work? (Part 1)

P.J. van Diest; Utrecht/NL (P.J.vanDiest@umcutrecht.nl)

Where radiology has been digital for decades, pathology is at the brink of the digital revolution. Around the world, several labs have turned to full digital diagnostics, and many more labs are working on it. This offers new possibilities for integration of radiological and pathological diagnostics, as the first step towards integrated diagnostics. Both specialities will benefit from seamless access to each other's images. This presentation will provide a visionary overview of such benefits, as well as the first impressions from the integration of digital radiology and digital pathology at the University Medical Center Utrecht.

Learning Objectives:

1. To understand the difficulties of the professional integration.
2. To become familiar with the common workflow.
3. To appreciate the disease-specific needs for radiology-pathology integration.

Author Disclosure:

P.J. van Diest; Advisory Board; Sectra and Philips.

A-0737 09:10

How would the integration work? (Part 2)

W.B. Veldhuis; Utrecht/NL

"no abstract submitted"

Learning Objectives:

1. To understand the difficulties of the professional integration.
2. To become familiar with the common workflow.
3. To appreciate the disease-specific needs for radiology-pathology integration.

A-0738/A-0739 09:22

What difference would there be for patients?

R. Palmqvist; Umea/SE (richard.palmqvist@umu.se)

K. Riklund; Umea/SE (katrine.riklund@umu.se)

Diagnosis, staging, treatment evaluation and follow up is managed with a combination of patient information sources. Imaging with radiology and nuclear medicine and pathology are the main contributor of information during the entire lifespan of a disease. The already done digital transformation of radiology has meant higher availability to the examinations. The images are accessible when and where they are needed. The consequence of this has been an increased exposure of images to the patients, to the treating clinician and others. The conversion to digital pathology will have the same positive consequences but also with another added value - the combination of digital radiology and pathology in the multidisciplinary meeting room, when meeting the patient, for teaching and evaluation - all information accessible when and where needed. Radiology is often used to determine the site for biopsy or cytologic examination, but the radiologist does not routinely receive the results. The opposite counts for the pathologist that rarely take part in the radiology findings. The novel possibility to have accessibility to both radiology and pathology will be an important base not only for more accurate interpretations but also for continuous education. Examples of how radiologists and pathologists can make use of the digital development in radiology and pathology to make the best for the patients will be discussed at the session.

Learning Objectives:

1. To learn about clinical efficiency improvement.
2. To understand the impact on research and innovation.
3. To appreciate the improvement in patient care.

Working in radiology: burnout and bore-out or engaged and passionate?

A-0740 08:30

Chairperson's introduction (part 1)

M.G.M. Hunink; Rotterdam/NL (m.hunink@erasmusmc.nl)

Symptoms of chronic stress and burnout occur in approximately half of all healthcare professionals leading not only to diminished health and quality of life among the professionals themselves but also to concerns about patient safety, quality of care, patient outcomes, professionalism, and sustainability of our healthcare systems. Radiologists rank in the top 10 of medical specialists with burnout, and they are among the most unhappy physicians. Key symptoms of burnout are emotional exhaustion, a detached, callous, cynical attitude, and a feeling of personal inadequacy. Chronic stress and burnout are due to an imbalance between stressors and resources. Stressors include ambition, perfectionism, self-criticism, lack of self-care, 24/7 electronic connectivity, interpersonal conflicts, employer demands, litigation, digitalisation, the complexity of care, and financial concerns. Resources include resilience training, healthy lifestyle, social support, meaningful activities, effective communication, and efficient work processes. To combat burnout among radiologists and radiographers, and thereby improve the quality of care, effective interventions are needed at both the organisational and individual level. In this session we will discuss the signs and symptoms of chronic stress and burnout, the factors that lead to the problem, and preventive measures that can be taken that will lead to active work engagement, meaningful work, and well-being among professionals working in radiology.

Session Objectives:

1. To learn to recognise the symptoms of chronic stress and burnout.
2. To understand what factors contribute to chronic stress and burnout among radiologists and radiographers.
3. To learn what preventive measures can be taken to prevent chronic stress and burnout among radiologists and radiographers.
4. To appreciate what is needed to achieve work engagement, meaningful work and well-being among radiology staff.

Author Disclosure:

M.G.M. Hunink; Advisory Board; EIBIR. Author; Textbook: Decision Making in Health and Medicine. Research/Grant Support; American Diabetes Association.

A-0741 08:33

Chairperson's introduction (part 2)

E. Metsala; Helsinki/FI (eija.metsala@metropolia.fi)

Work wellbeing is essential to keep on working in fast developing professions such as radiology. Most of the factors contributing work well-being and job-tenure and vice versa to burnout and willingness to change workplace are the same for all the healthcare staff. However, there are differences amongst professional groups. In the light of the current studies work autonomy, job design, leadership and possibilities for professional development as well as possibility to fluently combine family life, hobbies and work e.g. by the means of autonomous work time planning seem to be associated with low levels of stress, work satisfaction and commitment to ones' workplace amongst radiographers. Commitment to ones' workplace predicts job tenure. Having low pay, too little time for patients, working under tensed circumstances. Insufficient resources and amount of employees, as well as administrative pressures, cause stress and dissatisfaction amongst radiographers. Also, one big issue affecting all healthcare staff work circumstances if technological development, e.g. fast coming of Artificial Intelligence coming as a part of our work environment. About all these, we hear more in the upcoming session.

Session Objectives:

1. To learn to recognise the symptoms of chronic stress and burnout.
2. To understand what factors contribute to chronic stress and burnout among radiologists and radiographers.
3. To learn what preventive measures can be taken to prevent chronic stress and burnout among radiologists and radiographers.
4. To appreciate what is needed to achieve work engagement, meaningful work and well-being among radiology staff.

A-0742 08:35

A personal story

M.F. Berger; Nottwil/CH (markus.berger@paraplegie.ch)

In this talk, I shall present my episode of burnout that I experienced about seven years ago, from a first-person point of view: early warning signs, failed attempts at self-help, sudden break-out of symptoms, medical workup, interventions and, finally, resolution and consequences. Mindfulness played a major role in my recovery. I shall describe my personal experience with mindfulness and explain how the practice not only can help you cope with stress in your private and professional life but how it may actually make you a better radiologist.

Learning Objectives:

1. To learn to recognise the early symptoms of burnout in oneself.
2. To understand how life events and work stress in radiology contribute to burnout.
3. To appreciate the challenges in dealing with burnout.
4. To understand what is needed to prevent chronic stress and burnout.
5. To appreciate the value of mindfulness in being a better radiologist/radiographer.

A-0743 08:53

The role of technology in the job satisfaction and well-being of radiology workers

S. Aarts; Eindhoven/NL (s.aarts@fontys.nl)

The rate of the pace at which technological developments are introduced in healthcare is enormous; especially people working in technology-driven professions are confronted continuously with technological innovations. Unfortunately, technological developments are not always positively perceived by healthcare professionals. For example, the occurrence of 'power supply issues' and lack of knowledge of the technology at hand, can make health professionals sceptical about using new technology. For a technological application to be adequately implemented, health care professionals need to see the benefits of such an application and should feel competent to use it. To date, the role technology plays in the work of health professionals is intensively studied. Research shows that aspects such as 'responsibility' and 'privacy' are important for healthcare professionals when technology is involved: they feel it as their responsibility to safely, efficiently and effectively use the available technological devices and applications. They expressed the need to understand the background and principles of the technological applications they use, rather than 'push a button'. Hence, technology affects multiple aspects of the day-to-day profession of radiology workers, which, in turn, affects job satisfaction and well-being. We will discuss how the role of technology is perceived by health care professionals, especially by radiographers, nuclear medicine technologists and radiation therapist. In addition, several barriers to the implementation of new technological developments will be brought forward during this talk. Moreover, possible solutions for these barriers will be discussed to maintain high job satisfaction and well-being.

Learning Objectives:

1. To understand how technology is perceived by radiographers, nuclear medicine technologists and radiation therapists.
2. To learn about the role of technology in the well-being of these healthcare professionals.
3. To learn which factors should be addressed if a new technology is introduced on the work floor in order to acquire/maintain a high job satisfaction and well-being.
4. To understand how the role of technology in the future is perceived by these healthcare professionals and how these ideas/opinions may influence their work, job satisfaction and well-being.

A-0744 09:11

Dealing with daily battles: factors that lead to chronic stress and burnout

A. Montgomery; Thessaloniki/GR (antmont@uom.gr)

Today all evidence in regard to causal factors associated with burnout points to the direction that burnout is an organisational, rather than an individual problem, rooted in issues related to the working environment and organisational culture. Burnout should be viewed as an obvious outcome of systems that are developed within medical education and fostered all through the career of physicians. Burnout, in terms of exhaustion, cynicism, and inefficacy, are experienced by individuals, but this focus on the individual can cause us to forget that it's a shared experience in response to common job stressors meaning that we should frame it as a systems problem, and not simply as an individual one. Thus, we need to move the focus away from a physician-centric approach towards what can be done for the modern healthcare setting to enhance the ability of doctors to thrive. In other words, it is time to move from the burnt out physician to the resilient health care organisation.

Saturday

Learning Objectives:

1. To learn about factors that lead to chronic stress and burnout among healthcare professionals.
2. To appreciate that preventive intervention should be setting-specific and context-dependent.
3. To become familiar with possible interventions at the organisational and individual level.

Advanced clinical dosimetry in interventional radiology

A-0746 08:30

Chairpersons' introduction (part 1)

W.R. Jaschke; Innsbruck/AT (werner.jaschke@i-med.ac.at)

The term "clinical dosimetry" in scientific literature was until recently, mainly used for radiotherapy, but is now also applied to diagnostic and interventional procedures although the term "dosimetry for imaging in clinical practice" including patient and staff dosimetry would be more appropriate. Several publications of the International Commission on Radiological Protection (ICRP) recommend that patient protection and occupational protection be managed in an integrated approach. First, interventional radiologists have to learn which parameters of the DICOM dose report are reliable indicators for patient dose. Second, they have to understand that occupational dose is mainly due to scattered Radiation originating mainly from the patient. Thus, patient dose and occupational dose are somewhat related to each other, especially in fluoroscopy guided interventional procedures. New electronic personal dosimeters and automatic registry systems for patient and staff doses allow access to detailed information on doses derived from all the radiation events (fluoroscopy, cine, DSA and CBCT runs). Real-time information on occupational doses (and dose rates) during interventional procedures inside the catheterisation rooms are also available in addition to the patient dose information and skin dose maps. Such information allows active optimisation strategies during and after the interventional procedures. The new interventionalists should be trained on the basic dosimetry aspects to properly use the information available inside the catheterisation room during the procedures, and apply it to improve their clinical practice and the radiation safety aspects. Medical physics experts should be an integral part of the optimisation process.

Session Objectives:

1. To learn about the clinical value of dosimetry.
2. To understand the technique of dosimetry and the implementation of real time personal dosimetry.
3. To appreciate the impact of dosimetry for dose management in interventional radiology.

A-0747 08:33

Chairpersons' introduction (part 2)

E. Vaño; Madrid/ES (eliseov@med.ucm.es)

The term "clinical dosimetry" in scientific literature was until recently, mainly used for radiotherapy, but is now also applied to diagnostic and interventional procedures although the term "dosimetry for imaging in clinical practice" including patient and staff dosimetry would be more appropriate. Several publications of the International Commission on Radiological Protection (ICRP) recommend that patient protection and occupational protection be managed in an integrated approach. This approach, especially relevant in fluoroscopy guided interventional procedures, has also been included in the recent European Directive on Basic Safety Standards. New electronic personal

dosimeters and automatic registry systems for patient and staff doses allow access to detailed information on doses derived from all the radiation events (fluoroscopy, cine, DSA and CBCT runs). Real-time information on occupational doses (and dose rates) during interventional procedures inside the catheterisation rooms are also available in addition to the patient dose information and skin dose maps. Such information allows active optimisation strategies during and after the interventional procedures. The new interventionalists should be trained on the basic dosimetry aspects to properly use the information available inside the catheterisation room during the procedures, and apply it to improve their clinical practice and the radiation safety aspects. Continuous comparison of the current patient doses with diagnostic reference levels is now possible. The introduction of automatic patient dose registries (with proper validation of the dosimetric data) will help optimise radiation protection and support to decide which patients could require a clinical follow-up for potential radiation skin injuries.

Session Objectives:

1. To learn about the clinical value of dosimetry.
2. To understand the technique of dosimetry and the implementation of real time personal dosimetry.
3. To appreciate the impact of dosimetry for dose management in interventional radiology.

A-0748 08:35

The basis of clinical dosimetry in interventional radiology

K. Bacher; Ghent/BE (Klaus.bacher@ugent.be)

Interventional radiology procedures can be linked to high patient radiation exposures. In order to be able to avoid deterministic (skin) effects and to evaluate the potential risks for radiation-induced cancer and genetic effects, accurate dosimetry is needed. First of all, dosimetric indexes such as dose area product and kerma at reference point are important quantities as they are measures during the fluoroscopy procedures and stored in a DICOM Radiation Dose Structured Report format. These dosimetric indexes are a useful tool for optimisation and the generation of diagnostic reference levels, but they don't describe the actual patient dose. Skin dose can be directly measured by means of small dosimeters, but the latter technique is cumbersome and time-consuming. The generation of skin dose maps, to identify peak skin doses during/after the procedure can overcome these issues. Accurate patient-specific dosimetry requires detailed information concerning patient characteristics and all irradiation events. Nowadays, modern systems allow for the collection of most of the required data. In this lecture, an overview of various dosimetric quantities will be presented, together with their use in clinical dosimetry and optimisation.

Learning Objectives:

1. To learn how to assess dose to patients and staff.
2. To appreciate the importance of dosimetry for optimisation.
3. To understand the potential pitfalls in clinical dosimetry.

A-0749 08:45

Real time staff dose monitoring

F. Vanhavere; Mol/BE (fvanhavere@SCKCEN.BE)

Staff working in interventional procedures are classified as occupationally exposed workers. Their doses need to be monitored by personal dosimetry. This dosimetric monitoring is done mostly by passive dosimeters. These have to be sent back after a wearing period of mostly one month so that the results are normally only available to the staff weeks or even months after the exposure. Using active dosimeters would be beneficial to the workers because they can get immediate feedback from their exposure and thus apply better the ALARA principle. Several types of active dosimeters can be used in interventional procedures. But when using active devices, it is important to verify that their characteristics are good enough for use in the specific hospital fields. Especially the low energies, high angles and the pulsed aspect of the X-ray fields can give problems for many active dosimeters. A series of tests in realistic hospital fields have been done within the EURADOS WG12, and the results of these tests and the limitations of the active dosimeters will be reported. But not only active dosimeters are being further developed and used, but also computational methods are more and more used to visualise the radiation fields around the patient. If this can be made available to the workers in real time, this will also be a good ALARA tool. It is possible to go even a step further and determine the doses to the staff with purely computational methods.

Learning Objectives:

1. To understand how on-line dosimetry can help in radiation protection of medical staff in interventional procedures.
2. To learn how the ALARA principle (as low as reasonably achievable) can be applied for medical staff in interventional procedures.
3. To learn about the current status of real-time dosimetry.
4. To become familiar with the tools, which are available for radiation protection of medical staff in interventional procedures.

A-0750 09:05

Real time patient dose monitoring

R.M. [Sánchez Casanueva](#); Madrid/ES
(robertomariano.sanchez@salud.madrid.org)

Some interventional procedures may require large fluoroscopy times, many DSA images and/or several procedures on the same patient to address complex lesions. In such cases, the radiation dose to patients' skin has to be monitored in real time and in case of high radiation doses, to propose a follow-up for potential skin injuries. In the case of repeated procedures, information about the radiation received in previous interventions may be necessary to manage the radiation dose and avoid potential skin injuries. The management of radiation dose will need several physical quantities as fluoroscopy time, number of images, air kerma at the patient entrance reference point, kerma area product and peak skin dose. An overview of the relevance of those quantities and their units will be provided. Modern C-arms offer some tools to monitor patient doses, from the simplest consisting in an indicator of fluoroscopy time and number acquired images, through the amount of radiation delivered by the X-ray tube, to the most complex skin dose calculators that provide quite accurate dose maps in patients' skin in real time or at the end of the procedures.

Learning Objectives:

1. To learn about the motivation for real-time patient dosimetry.
2. To understand quantities and units to monitor patient dose.
3. To learn about prototypes and systems currently available.

A-0751 09:25

Dose management of patients and staff in interventional radiology

J. [Damilakis](#); Iraklion/GR (damilaki@med.uoc.gr)

Fluoroscopically-guided interventional procedures are associated with the relatively high patient and occupational doses mainly due to high utilisation, long fluoroscopy time and a large number of cine acquisitions. Optimisation of protection is essential to reduce patient dose while keeping image quality at acceptable levels. Advanced dosimetry methods will be presented and discussed. Optimising patient dose will result in a decrease in scatter radiation to the staff. To decrease the patient dose, operators should increase the distance of the X-ray tube from the patient as much as practicable and decrease the distance of the imaging detector. To avoid radiation overexposure accidents in interventional suites, interventional radiologists in cooperation with medical physicists should establish standard clinical protocols for each specific type of procedure performed. Cumulative absorbed dose to the skin should be limited to the minimum necessary for the clinical task. To decrease occupational radiation doses, exposed personnel must use protective garments, i.e. a lead apron to protect body trunk, leaded gloves, radio-protective glasses and a thyroid shield. Interventional radiologists should keep hands outside the primary beam. If hands are inside the beam, the automatic exposure control will increase exposure parameters and, therefore, radiation doses to both patient and staff will increase. Radiation dose to staff is reduced drastically when ceiling-suspended protective lead shielding or mobile floor shielding is used.

Learning Objectives:

1. To learn about radiation doses and risks associated with fluoroscopically-guided procedures.
2. To describe the actions that should be taken to enhance patient and staff safety during interventional radiology procedures.
3. To learn parameters that can be modified to decrease patient dose without compromising image quality.

A. Abdominal aorta

D.A. [Clevvert](#); Munich/DE (Dirk.Clevvert@med.uni-muenchen.de)

Abnormalities of the abdominal aorta may represent a diagnostic challenge in patients both with acute and chronic clinical symptoms. In addition to the examination using colour-coded duplex ultrasound, contrast-enhanced ultrasound (CEUS) with low-mechanical-index (low MI) may contribute to achieving a precise diagnosis. CEUS is a new and promising method in the

diagnosis and follows up of aortic and visceral artery lesions. Colour code duplex ultrasound and CEUS with SonoVue® allow for rapid and noninvasive diagnosis, especially in critically ill patients since these methods can readily be applied bedside. In this RC, the contribution of colour-coded duplex ultrasound and CEUS as compared to Multi-Slice Computed Tomography Angiography (MS-CTA) in various pathologies of the abdominal aorta will be addressed.

Learning Objectives:

1. To learn how to perform the examination and its role in diagnostic assessment.
2. To learn about US findings in AAA treatment planning and post-treatment evaluation.
3. To appreciate the role of CEUS and technological innovations in routine practice.

A-0753 09:00

B. Upper and lower limb: arterial district

B. [Brkljačić](#); Zagreb/HR (boris@brkljacic.com)

B-mode ultrasound enables evaluation of arterial anatomy and of the vessel wall, detects early atherosclerotic changes, and allows detection of stenosis and occlusions, but tends to overestimate the degree of stenosis and should not be used for stenosis grading. Colour duplex Doppler ultrasound (CDUS) enables fast visualisation of the vessel to be examined. It demonstrates haemodynamic changes, including velocity increase. Underestimation of disease is likely if only colour is used and the precise assessment of haemodynamic disturbances is impossible without a spectral analysis. In general, CDUS has a high diagnostic accuracy, it is cheap and widely available, and there is no exposure to ionising radiation and no contrast media injection. However, the examination is time-consuming and requires high operator dependence. The thorough understanding of haemodynamics and physics is needed for adequate interpretation of Doppler findings. The factors influencing spectral morphology will be discussed in the lecture and the different types of spectra presented. Waveform changes will be presented in stenosis and occlusion. The typical findings of pseudoaneurysms and arteriovenous fistulas will be presented. Findings in acute occlusion and collateral flow will be discussed, both for native arteries and bypass grafts. The role of ultrasound in endovascular recanalisations will be discussed, both in planning and performing of the procedure and in the follow-up. Several clinical examples will be presented.

Learning Objectives:

1. To understand how to perform the examination and its role in diagnostic assessment.
2. To understand US findings for diagnosis and follow-up.
3. To underline tips and tricks to start your activity.

A-0754 09:30

C. Ultrasound as guidance for vascular interventions

W.K. [Matzek](#); Vienna/AT (Wolfgang.Matzek@meduniwien.ac.at)

While there is a long tradition of blind puncture of arterial vessels which works quite well in many cases, ultrasound-guided puncture might be advantageous in certain situations. The main reasons for ultrasound-guided puncture are, e.g. unusual puncture site, severely calcified wall, avoidance of double-wall puncture, non-palpable vessel, or small vessel diameter. Eventually, ultrasound-guided arterial puncture can aid the less experienced interventionist at finding appropriate access to the vessel. Vascular malformations are congenital anomalies of veins, arteries, capillaries, lymphatic vessels, or a combination of these. These lesions become clinically apparent at almost any age, starting with newborns. Most of the venous, arteriovenous, and lymphatic lesions, simple or combined, can be treated using interventional techniques and ultrasound guidance contributes significantly to the success of this treatment. A couple of selected cases and treatment options will be presented. Varicose veins can be treated using different strategies. Ultrasound-guided foam sclerotherapy will be discussed, as well as endogenous ablation therapy using radiofrequency and laser ablation.

Learning Objectives:

1. To understand the value of ultrasound guidance for arterial puncture.
2. To learn about the possibilities of ultrasonographic guided therapy of AVMs.
3. To become familiar with endovenous treatment of varices.

Cutting edge imaging and minimally invasive interventions of the spine

A-0755 08:30

Chairperson's introduction

J. Van Goethem; Antwerp/BE (johan.vangoethem@uantwerpen.be)

This session will present the latest developments in spine imaging. The topics that have been chosen cover a wide range of frequently occurring spinal pathology. The best and most renowned speakers will bring you up-to-date on the newest developments in the field. These will be presented in a way to make it easy to implement them in your daily practice.

Session Objectives:

1. To become familiar with state-of-the-art spinal imaging and minimally invasive spine interventions.
2. To learn about advanced imaging of the spine.
3. To learn how to improve on spinal imaging.

A-0756 08:35

Imaging strategies in spine and spinal cord trauma

P.C. Maly Sundgren; Lund/SE (Plia.Sundgren@med.lu.se)

Spinal injuries to the spinal column or spinal cord are devastating for the patient, their family and costly for the society. Depending on the degree of trauma, the age and condition of the patient, clinical, and neurological symptoms different imaging strategies are suggested. Different imaging rules and schemes have been suggested where the degree of trauma and the patients symptoms play an important role in the imaging decision making. The presentation aims to focus on when and how to image and present the differences that can be seen in injuries between the pediatric and the adult population.

Learning Objectives:

1. To review the imaging strategy in spinal trauma.
2. To know the most optimal imaging techniques in spinal trauma.
3. To learn about new developments in imaging spinal trauma.

A-0757 08:53

Advanced imaging of spinal cord lesions: do we need DWI, perfusion and spectroscopy?

M.M. Thurnher; Vienna/AT (majda.thurnher@meduniwien.ac.at)

Despite its high sensitivity but low specificity, magnetic resonance imaging (MRI) is the modality of choice for diagnosis of spinal cord diseases. Spinal cord examination is one of the most challenging MR examinations from a technical, interpretative, and differential diagnostic standpoint. In practice, there are no satisfactory ways to distinguish among different forms of myelitis and neoplastic conditions when conventional MR sequences are used. In the last decade, several indications for diffusion-weighted MR imaging (DWI) and diffusion tensor imaging (DTI) in the spine have been reported. DTI could provide reliable postoperative evaluation and analysis for cervical spondylotic myelopathy patients. DTI has been proven useful for differentiation of ependymoma and astrocytoma of the spinal cord. This lecture will review advantages and disadvantages of the advanced MR sequences (such as DWI, DTI, Perfusion) when used for the spine. Possible pitfalls, helpful clinical information, and recognition patterns will be discussed.

Learning Objectives:

1. To understand the indications for advanced imaging in spinal cord lesions.
2. To differentiate spinal cord lesions.
3. To learn the different imaging patterns of spinal cord lesions.

A-0758 09:11

Spinal CSF leaks: the precise "roadmap" for clinicians

J.S. Ross; Phoenix, AZ/US (Ross.Jeffrey1@mayo.edu)

Spontaneous intracranial hypotension caused by spinal CSF leaks can be a frustrating diagnosis from both diagnostic and therapeutic standpoints. While the classic finding is an orthostatic headache which may be exacerbated with a cough, sneezing or valsalva, a wide variety of other symptoms can be attributed to the disorder including photophobia, imbalance, hearing abnormalities and mental status change. Underlying etiologies may be a dural tear from osseous spur or disc, meningeal diverticulum or CSF-venous fistula. Up to 1/3 of patients may have no aetiology defined. The workup of these patients may vary widely and can include multiple imaging modalities and strategies ranging from nuclear medicine, CT, MR, and myelography. Our workup includes an initial evaluation with contrast-enhanced brain MR and

epidural blood patch X2. If the blood patch fails, then a complete spine MR is performed looking for an epidural fluid collection (fast leak). If a fast leak is discovered, then additional dynamic imaging is performed (either dynamic myelography or dynamic CT myelography). If no extradural fluid is identified (presumed slow leak), then routine CT myelography is performed. If this routine study is negative, then MR myelography is performed with attention to defining a CSF-venous fistula.

Learning Objectives:

1. To review the most optimal imaging strategy in spinal CSF leaks.
2. To interpret different imaging studies in spinal CSF leaks.
3. To learn the value of different imaging techniques in detecting spinal CSF leaks.

A-0759 09:29

Cutting edge minimally invasive spine interventions

L. Manfrè; Catania/IT (Imanfre@me.com)

During the last decade, we attended an incredible improvement in spine biomechanics knowledge and powerful diagnostic tools, as well as the development of a new generation of "minimally invasive" devices and "covert surgery" procedures, that changed our mind about who, when and how to treat a patient affected by spine disease. The use of X-ray and/or CT-guided procedures give Radiologists a wide range of new possibilities in treating the spine, reducing the risk of side effects and complications in comparison to conventional "open" surgery, lowering the economic costs of the procedures as well as rehab time, avoiding the risk of general anesthesia, as the most of the procedures can be performed in mild sedation. Last, but not least, CT-X ray guided procedures allows significant cost reduction for the Health Care System, as smaller medical staff is needed, with no operating room occupation as well as beds/patients rate reduction, a must in our money-saving critic times. Interventional Radiology, however, cannot progress without an advanced knowledge of Diagnostic Radiology of the Spine, that is fundamental when a decisional route must be proposed to the patient. We will analyse all the most recent CT-guided technique in the treatment of tumours, degenerative and traumatic disease of the Spine, treated with fully CT-guided techniques in simple analogue-sedation.

Learning Objectives:

1. To review the current state-of-the-art in minimally invasive spine interventions.
2. To learn how to choose an optimal minimally invasive treatment in low back pain.
3. To learn about new interventional spine techniques available in low back pain.

New mammography: digital breast tomosynthesis and future techniques

A-0760 08:30

Chairperson's introduction

E.M. Fallenberg; Munich/DE

Early detection of breast cancer through X-ray mammography (MG) has been shown to reduce mortality; however, the method is limited by a decreased sensitivity and specificity particularly in young patients and women with radiographically dense breasts due to tissue overlying and masking tumours or architectural distortions. The introduction of full-field digital mammography gave the possibility to develop further technical methods, to overcome these limitations. Some of these are tomosynthesis, contrast-enhanced mammography and contrast-enhanced tomosynthesis as well as most recently also breast CT. In this talk will be presented the background of 2D mammography, tomosynthesis and contrast-enhanced mammography techniques and breast CT. Potential advantages and disadvantages will be indicated, and a sample of clinical cases will be presented to illustrate how the different techniques contribute to the detection of lesions.

Session Objectives:

1. To learn about 2D mammography and digital breast tomosynthesis.
2. To recognise the advantages and disadvantages of digital breast tomosynthesis compared to 2D mammography.
3. To understand the future potential of new breast imaging techniques in lesion assessment.

A. Should we abandon 2D mammography?

S. [Zackrisson](mailto:sophia.zackrisson@med.lu.se); Malmö/SE (sophia.zackrisson@med.lu.se)

Full-field digital mammography (FFDM), also called 2D mammography, with flat panel detectors, has been broadly used in clinical routine for about a decade. Even if there has been advances in the technical development of the digital detectors, the detectors are not the main limiting factor in breast imaging; the challenge is the anatomical noise, i.e. dense breast tissue in the optimisation of breast cancer detection. FFDM is a 2-dimensional modality and inherent in that is that dense breast tissue may cause overprojection and hide or simulate the presence of a tumour on these images even if several views are acquired. Digital breast tomosynthesis, DBT is a 3D mammography technique that, to a large extent, can suppress the confounding effect of the overlapping tissue. DBT is a strong competitor to 2D mammography both for screening and clinical examinations. This presentation will cover 2D mammography in terms of technical background and optimisation of image quality. Furthermore, it will discuss the advantages and disadvantages of 2D mammography compared to DBT and evaluate if there are situations where 2D mammography still could be the preferred method if DBT is transitioned into screening and clinical practice.

Learning Objectives:

1. To understand the technique of 2D mammography and what the limits could be.
2. To learn if there are ways to improve the image quality of 2D mammography.
3. To understand when 2D mammography is better than digital breast tomosynthesis.

Author Disclosure:

B. Clinical validation of digital breast tomosynthesis and results in the last 10 years: where do we stand?

P. [Skaane](mailto:per.skaane@outlook.com); Oslo/NO (per.skaane@outlook.com)

Digital breast tomosynthesis (DBT), an advanced mammographic technique, has the potential to improve two inherent limitations of conventional digital mammography (DM): The poor sensitivity in women with dense breasts (caused by superimposed parenchyma, "masking effect") and the low specificity (caused by parenchyma simulating masses, "pseudotumors"). In the diagnostic setting, DBT can replace supplemental views for evaluation of indeterminate noncalcified lesions, "downgrade" indeterminate (BI-RADS 3) lesions, and "upgrade" other equivocal masses indicating the need for biopsy. Evaluation of cancer extent and multifocality is better demonstrated, and preoperative staging is improved. Retrospective US screening studies comparing DM versus DM+DBT have shown significantly lower recall rates for DBT and often increased cancer detection rates. Lack of increased cancer detection in some US studies might have been caused by study design and lack of power. Prospective European screening trials comparing DM versus DM+DBT have all demonstrated a significantly higher cancer detection rates for DBT. Challenges regarding the implementation of DBT in screening include a number of projections, reading time, and women with very dense breasts. The increased radiation dose problem using DM+DBT is solved by synthesised two-dimensional images (SM), created by summing and filtering the reconstructed tomosynthesis slices. Several studies have shown that SM+DBT have comparable results with DM+DBT regarding the recall and cancer detection rates, and SM will replace conventional DM in screening. Studies on cost-effectiveness, potential overdiagnosis, and subsequent interval cancer rates may be required to determine long-term benefits of DBT screening.

Learning Objectives:

1. To become familiar with the technique of digital breast tomosynthesis.
2. To understand the results of digital breast tomosynthesis in the screening and diagnostics settings.
3. To know the evolution of digital breast tomosynthesis in screening organisation.

C. Contrast-enhanced mammography and other developing techniques

E. [Giannotti](mailto:Elisabetta.Giannotti@nuh.nhs.uk); Nottingham/UK (Elisabetta.Giannotti@nuh.nhs.uk)

Switching from analogical to digital technology has lead breast imaging to a new era where it has been possible to develop and introduce in the clinical practice new techniques such as tomosynthesis, CT mammography, contrast-enhanced spectral mammography (CESM), CAD and, eventually, advanced

breast biopsy techniques, blurring the lines between diagnosis and treatment. CESM combines a iodinate contrast agent with the standard mammographic technique providing not only a morphological but also a functional examination of the breast, being able, in a similar fashion as MRI does, of depicting the enhancement related to the neoangiogenesis of tumour growth. CESM has been shown from literature studies to be a valuable tool in diagnosis and staging of primary breast cancer with a better diagnostic accuracy compared to conventional mammography, especially in women with dense breasts. It is also being explored the potential value of CESM as a screening tool. Further development of digital techniques is ready to be developed and implemented in breast imaging. In the near future, the introduction of Artificial Intelligence (AI) could let mammogram to become a tool of precision medicine. In fact, mammography could be used not only in a diagnostic setting but also as image-driven risk assessment tool and tumour biomarkers in order to move to a personalised screening approach and personalised treatment.

Learning Objectives:

1. To become familiar with further developments in digital mammography, such as contrast-enhanced mammography and contrast-enhanced digital breast tomosynthesis.
2. To understand the role of these new techniques in detection and characterisation of breast lesions.
3. To learn about the new potential of combining mammography with molecular imaging, optical imaging and texture analysis.

Chairperson's introduction

M.A. [Van Buchem](mailto:VanBuchem@leiden.nl); Leiden/NL

Session Objectives:

1. To learn about the complex spectrum disease entities presenting with cognitive decline.
2. To understand the role of standardised imaging and reporting in the context of diagnosis and monitoring of patients with neurocognitive disorders.
3. To appreciate importance of multimodal imaging approaches in the diagnosis of neurocognitive disorders.

A-0765 08:35

A. MRI in the diagnosis of cerebral amyloid angiopathy (CAA)

J. [Linn](mailto:Jennifer.Linn@uniklinikum-dresden.de); Dresden/DE (Jennifer.Linn@uniklinikum-dresden.de)

Cerebral amyloid angiopathy (CAA) is defined as the deposition of β -amyloid in the walls of cortical and leptomeningeal cerebral vessels. It is very common in the elderly population with prevalence rates up to 60% and associated with Alzheimer's disease. Intracerebral lobar microhemorrhages (ICH) are the most devastating presentation of CAA and the main cause of morbidity and mortality. However, in addition, CAA patients can also suffer from transient neurological symptoms and/or progressive cognitive impairment ultimately resulting in dementia. Besides ICH, typical MRI signs of CAA include multiple cerebral microbleeds in a cortical-subcortical localisation, focal subarachnoid haemorrhage, cortical superficial siderosis (cSS), silent cortical infarcts, white matter hyperintensities, and enlarged perivascular spaces. Evidence of previous ICHs and/or (disseminated) cSS represents an important risk factor for recurrence of CAA-related intracranial haemorrhages. To date, there exist no diagnostic test that allows the definite diagnosis of CAA related haemorrhage during life. The "classic" and the "modified" Boston criteria estimate the likelihood of the presence of CAA in vivo based on the pattern of intracranial hemorrhagic lesions on neuroimaging studies.

Learning Objectives:

1. To recognise cerebral amyloid angiopathy in imaging studies.
2. To understand the pathophysiology of the disease.
3. To know the clinical consequences of the diagnosis.

B. Imaging in an altered mental state

J. Boban; Novi Sad/RS (jasmina.konstantinovic@gmail.com)

Altered mental state (AMS) represents a group of clinical symptoms associated with different degrees of mental functioning disorder, including cognitive, attention, arousal disorders and decreased level of consciousness. Clinical entities that are endorsed by this term are divided into brain death, coma, vegetative state/unresponsive wakefulness state, minimally conscious state, acute confusional state and Locked-in syndrome. A separate entity included in the definition is dementia from the point of mild cognitive impairment to manifest dementia. Aetiology of these conditions is different and varies greatly, including trauma, infectious diseases, metabolic disorders, psychiatric diseases, psychoactive substances and other, less common causes. The diagnosis of AMS is based on clinical observation and standardised neurobehavioral assessments. A focused clinical examination remains essential in distinguishing between separate entities, including testing of sleep-wake cycles, awareness, motor skills, auditory function, visual function, communication and emotional integrity. Since the rate of misdiagnosis reaches 40%, imaging studies are a complementary tool. Classic diagnostic modalities were computed tomography (CT) and magnetic resonance imaging (MRI), especially useful in the setting of trauma, infection and metabolic disorders. However, emerging new techniques, such as functional MRI and PET scan show promising results in defining etiological factor and neuropathological substrate in AMS. The aim of this lecture would be to present the main differential diagnosis in AMS and to summarise current diagnostic possibilities in different clinical settings.

Learning Objectives:

1. To learn about the role of imaging in the diagnosis of neurocognitive diseases: from the exclusionary approach to the inclusionary approach.
2. To understand the challenges when diagnosing neurocognitive disease in a very early stage using imaging.
3. To appreciate the complexity of differential diagnosis of neuroimaging in cognitively affected individuals and the crucial need for other biomarkers to support the clinical diagnosis.

A-0767 09:21

C. MRI in the diagnosis of Alzheimer's disease

M. Vernooij; Rotterdam/NL (m.vernooij@erasmusmc.nl)

This lecture will discuss the use of magnetic resonance imaging in current clinical practice for the diagnosis of Alzheimer's disease. It will tap into characteristic imaging features of AD on MRI, as well as most important differential diagnoses (depending on patient characteristics). Furthermore, future developments in imaging that may alter clinical practice, such as the use of volumetry, are discussed.

Learning Objectives:

1. To learn about the imaging features and possible comorbidities of Alzheimer's dementia.
2. To understand the complexity of differential diagnosis.
3. To appreciate the crucial, and so far unmet, medical need to use quantitative MRI techniques in the diagnosis of Alzheimer's disease.

Gastrointestinal and abdominal

A-0768 08:30

Chairperson's introduction

C. Stoupis; Männedorf/CH (c.stoupis@spitalmaennedorf.ch)

One of the most important focus of current abdominal imaging is not only to detect abnormalities but being able as well to characterise lesions in the parenchymal organs, facilitating the final diagnosis, noninvasively. Knowledge of anatomy, embryology, physiology and pathology of the liver, pancreas and spleen is essential to understand, diagnose and differentiate congenital, inflammatory, neoplastic and other miscellaneous lesions of those upper abdominal organs. Similar issues apply to the gastrointestinal tract, specifically with regard to pathologies affecting not only the lumen but the wall also and beyond, areas not accessible by endoscopy. In this session, the role of multimodality imaging will be discussed (including hybrid imaging), in order to demonstrate the radiological features of common abdominal diseases,

including emergency situations, targeting to the specific diagnosis in acute and chronic abnormalities and displaying the crucial role of radiology in the personalised management of each patient, facilitating on this way not only the diagnosis but enabling as well an efficient and specific therapy.

Session Objectives:

1. To understand the typical imaging features of benign and malignant lesions of the hepatobiliary system.
2. To learn the typical imaging features of benign and malignant lesions of the pancreas and spleen.
3. To become familiar with the methodological basis and to differentiate typical features in imaging examinations of the gastrointestinal tract.
4. To understand the role of different imaging modalities including hybrid imaging in diagnosing and staging neoplasms, gastrointestinal and abdominal organ systems.

A-0769 08:36

A. Hepatobiliary system

I. Santiago; Lisbon/PT (ines_agp_santiago@hotmail.com)

An overview of the anatomy, normal variants and congenital disorders of the hepatobiliary system will be provided, followed by the discussion of the imaging features of the most relevant benign and malignant diseases of the biliary tract. Primary and secondary imaging features of acute and chronic diffuse liver diseases will be briefly discussed. The underlying causes and imaging features of the most frequent and relevant benign and malignant focal liver lesions, including cysts, haemangiomas, adenomas, focal nodular hyperplasia, hepatocellular carcinomas and metastases will also be addressed.

Learning Objectives:

1. To learn the anatomy, normal variants and congenital disorders of the hepatobiliary system.
2. To become familiar with the primary and secondary imaging features of acute and chronic diffuse liver diseases.
3. To understand the causes and imaging features of benign and malignant focal liver lesions, including cysts, haemangiomas, adenomas, focal nodular hyperplasia, hepatocellular carcinomas and metastases.
4. To learn the various causes and imaging features of benign and malignant diseases of the biliary tract and gallbladder.

A-0770 09:04

B. Pancreas and spleen

W. Schima; Vienna/AT (wolfgang.schima@khgh.at)

In general, contrast-enhanced MDCT is the primary tool of pancreatic imaging, and MRCP is very valuable for assessment of the ductal system. Important anatomic variants and anomalies of the pancreas include pancreas divisum, and annular pancreas is, which are the result of either failure of fusion or rotation of the pancreas anlagen during the fetal period. Both anomalies may result in significant morbidity. Ductal adenocarcinoma is by far the most common malignant tumour of the pancreas, with approximately 80% of patients having non-resectable (advanced) disease at the time of diagnosis. In patients with equivocal CT findings, contrast-enhanced MRI is the technique of choice for visualisation of small tumours. A wide differential diagnosis exists for cystic masses: from (non-neoplastic) benign pseudocysts to benign, borderline and invasive malignant neoplasms. Contrast-enhanced MRI is the best modality for characterisation of lesions and to guide follow-up in patients. Acute pancreatitis is classified as interstitial edematous or necrotising pancreatitis according to the revised Atlanta classification, which has brought consistent terminology for fluid collections and complications of the disease. Imaging of splenic masses is one of the less esteemed tasks in abdominal imaging. Imaging appearances of many splenic lesions are non-specific and may overlap, which makes non-invasive characterisation quite challenging. However, imaging findings of the most important benign lesions such as hemangiomas, hamartomas, and abscesses should be familiar. If the noninvasive characterisation of focal splenic lesions is not possible, US-guided core needle biopsy may be helpful, which can be performed with low risk of complications.

Learning Objectives:

1. To understand the anatomy, normal variants and congenital disorders of the pancreas.
2. To become familiar with the causes and imaging features of benign and malignant pancreatic tumours.
3. To understand the imaging features of acute and chronic pancreatitis and its potential complications.
4. To learn the causes and imaging features of focal and diffuse splenic abnormalities.

C. Imaging of the gastrointestinal tract

D.M. [Lambregts](mailto:Amsterdam/NL); [Amsterdam/NL \(doenja.lambregts@gmail.com\)](mailto:doenja.lambregts@gmail.com)

In this session, a brief overview will be provided of the main imaging anatomy and imaging manifestations of the most important pathologies of the gastrointestinal tract, including acute and chronic inflammatory conditions, bowel obstruction and ischemia and the most important GI tumours. This session serves as a preparation for the European Diploma.

Learning Objectives:

1. To become familiar with the anatomy, normal variants and congenital disorders of the oesophagus, stomach, duodenum, small bowel, colon, rectum and anal canal.
2. To understand the imaging features of appendicitis, diverticulitis, tumour stenosis, ileocolic intussusception, colonic fistula, paracolic abscess, epiploic appendagitis, intraperitoneal fluid collection, colonic pneumatosis and pneumoperitoneum.
3. To learn typical radiological manifestations of inflammatory bowel diseases, infection, bowel obstruction and bowel ischaemia.
4. To become familiar with the staging of tumours of the gastrointestinal tract, including features that indicate nonresectability, and to understand the role of different imaging modalities including hybrid imaging in diagnosing and staging.

Cardiac: recalling the forgotten structures

A-0772 08:30

Chairperson's introduction

C. [Peebles](mailto:Southampton/UK); [Southampton/UK \(Charles.Peebles@suht.swest.nhs.uk\)](mailto:Charles.Peebles@suht.swest.nhs.uk)

Cardiac imaging techniques tend to focus on the Left ventricle, coronary arteries and cardiac valves, particularly in the adult patient. This reflects the prevalence and significance of disease affecting these structures in the general population. This session will focus on areas of anatomy, and their functional significance, that is often forgotten in the primary cardiac analysis yet may be the cause of significant pathology. This introduction will provide an overview of the imaging techniques available.

Session Objectives:

1. To become familiar with normal cardiac anatomy and variants outside the cardiac chambers.
2. To understand the important interactions between ventricular chambers and their adjacent structures.
3. To learn what findings are significant and when to report them.
4. To appreciate the strengths and weaknesses of cross sectional imaging techniques when applied to the structures below.

A-0773 08:35

Hide and seek: the pericardium

A. [Nchimi Longang](mailto:Luxemburg/LU); [Luxemburg/LU \(alainnchimi@gmail.com\)](mailto:alainnchimi@gmail.com)

Pericardial diseases encompass a broad spectrum for which delayed diagnosis and inappropriate management are associated with high morbidity and mortality, whereas appropriate treatment may dramatically relieve patient symptoms. Imaging is often necessary to evaluate pericardial fluid collections, calcifications, thickening, hyperemia, masses and constriction. The current presentation will emphasize the definition of the pericardial syndromes and the specific advantages and weaknesses of CT and MRI in evaluating pericardial diseases and differentiating normal from abnormal findings.

Learning Objectives:

1. To learn the normal appearances of the pericardium on CT and MRI.
2. To understand the basic spectrum of disease process that affect the pericardium.
3. To be aware of the physiological effects of pericardial disease on cardiac function.

A-0774 08:52

Lost chamber: the right ventricle

G. [Bastarrika](mailto:Pamplona/ES); [Pamplona/ES \(bastarrika@unav.es\)](mailto:bastarrika@unav.es)

Even if traditionally the right ventricle (RV) has been the neglected side of the heart, the role of this cardiac chamber in evaluating different cardiovascular, as well as pulmonary diseases, is being increasingly recognized, including pulmonary arterial hypertension, ischemic heart disease, chronic obstructive pulmonary disease, arrhythmogenic RV cardiomyopathy and congenital heart disease. Currently, echocardiography and magnetic resonance imaging (MRI)

are the imaging modalities of choice to assess RV morphology and function. Recently, the added value of multidetector computed tomography (MDCT) with its latest advances, i.e. spectral imaging, is being emphasised. In this lecture, the complementary role of different imaging modalities to appraise the RV and pulmonary circulation will be underlined. Further, imaging features of most common diseases involving the RV as well as prognostic markers related to the RV will be reviewed.

Learning Objectives:

1. To learn the normal appearances of the right ventricle on CT and MRI.
2. To differentiate the appearances and physiology of RV volume loading and RV pressure loading.
3. To be aware of adverse prognostic markers related to the RV.

Author Disclosure:

G. Bastarrika: Grant Recipient; Guerbet. Speaker; General Electric, Siemens.

A-0775 09:09

Friend or enemy: epicardial fat

K. [Gruszczynska](mailto:Katowice/PL); [Katowice/PL \(kgruszczynska@poczta.onet.pl\)](mailto:Katowice/PL (kgruszczynska@poczta.onet.pl)

Epicardial Fat Tissue (EFT) is the layer of adipose tissue located within the visceral pericardium, directly on the myocardium, around coronary vessels. Paracardial Adipose Tissue (PAT), is located outside the parietal epicardium, in the mediastinum. EFT is metabolically active visceral fat. Under physiological conditions, its function includes myocardial energy supply, lipid-storage, thermoregulation and endocrines secretion. There has been growing interest among researchers in EFT recently, as cardiovascular disease remains the main cause of death in the developed world and due to the epidemic of obesity. The evidence shows the association between EFT and cardiovascular risk factors: obesity, metabolic syndrome, hypercholesterolemia and also coronary atherosclerosis burden. Studies are suggesting that EFT can act as an independent predictor of CAD risk or for adverse coronary events. Traditionally, EFT thickness has been measured by ECHO. However, CT and MRI offer the possibility of the non-invasive quantification of EFT, and the dedicated software already exists. Although EFT is subject to research in diagnostic imaging, it is also useful to recognise its anatomical variants as they could mimic the disease. To sum up, the presentation will give the possibility get to know current opinions on the role of EFT in asymptomatic and symptomatic population and present its anatomy, variants and methods of measurement to practising radiologists.

Learning Objectives:

1. To understand the difference between epicardial and pericardial fat.
2. To learn the methods of quantifying epicardial fat.
3. To be aware of the up-to-date evidence relating to cardiovascular risk and the extent of epicardial fat.

A-0776 09:26

Wrong ways: anomalies of cardiac veins and venae cavae

M. [Hrabak Paar](mailto:Zagreb/HR); [Zagreb/HR \(maja.hrabak.paar@mef.hr\)](mailto:Zagreb/HR (maja.hrabak.paar@mef.hr)

The normal venous anatomy includes drainage of the superior and inferior caval veins and coronary sinus (CS) into the right atrium (RA), and drainage of all pulmonary veins into the left atrium (LA). The most common anomaly of superior vena cava (SVC) is persistent left SVC that usually drains into the CS and can make detection of central venous catheter position more difficult. Rarely the persistent left SVC drains into the LA causing the right-to-left shunt. Most common anomalies of the inferior vena cava (IVC) include left or double IVC, less commonly azygos continuation of the IVC can be observed. Anomalous pulmonary venous return (APVR) is commonly partial with one or two pulmonary veins draining into the SVC, IVC or RA; it can be asymptomatic and is frequently incidentally found during thoracic imaging. Partial right-sided APVR can be associated with a sinus venosus atrial septal defect (ASD). Total APVR is cyanotic congenital heart disease with all pulmonary veins draining into systemic veins, RA or CS, and can be divided into supracardiac, cardiac and infracardiac types. The depiction of pulmonary venous anatomy using CT or MRI is commonly performed for the planning of pulmonary vein isolation in patients with atrial fibrillation. CT mapping of the cardiac venous system is especially important for planning of left ventricular pacing in cardiac resynchronisation therapy. Unroofed CS is a rare form of ASD with a communication between CS and LA. Understanding of venous anomalies is essential for their optimal interpretation and avoidance of diagnostic pitfalls.

Learning Objectives:

1. To learn the normal anatomy of pulmonary venous drainage, common anomalies and their clinical significance.
2. To learn about the normal anatomy of systemic venous drainage, common anomalies and their clinical significance.
3. To learn the normal anatomy of coronary venous drainage, common anomalies and their clinical significance.

Radiography research: a "how to" guide

A-0777 08:30

Chairperson's introduction: Why is radiography research important?
D. O'Leary; Newcastle/UK (desiree.lemiereoleary@gmail.com)

Radiography as a profession is a young entity, and indeed, in some countries, radiography is not yet recognised as a professional vocation. With the professional registration of radiographers comes the requirement to ensure that we as radiographers are evidence-based practitioners. It is essential in our profession that we strive to ensure that our practice in this extremely technological area of para-medicine, is continually investigated for the benefit of the operators, the public and the most of all, the patient. In the United Kingdom, the number of active research radiographers is low with only around 0.1% of all registered radiographers with doctoral level education. The number of research-active radiographers worldwide is less established but is thought to be lower than 0.1% of practitioners. The number of radiographer published research is increasing; however, the number of authors for these publications are not, again showing that the number of active research radiographers is low. Indeed, the number of radiographer abstracts being presented for this Congress are increasing annually, but these appear to be from a small number of researchers in multiple areas. It is past time that radiographers, radiology managers, and educators take research in radiography more seriously and ensure that this profession thrives on evidence-based practice.

Session Objectives:

1. To become familiar with common ethical issues arising in radiography research.
2. To understand the value of undertaking research in radiography.
3. To identify good practices for developing and presenting radiography research studies.

A-0778 08:35

How to avoid ethical issues

P. Bezzina; Msida/MT (Paul.bezzina@um.edu.mt)

As professionals, ethical codes guide on how we should behave in our practice and as individuals in the society that we live in. The first modern code governing ethics in research was developed during the Nuremberg trials in response to the abuse performed during medical experimentation. Various published reports about abuses were the motivating factors that led to the development of legislation on ethical principles and regulations when conducting research. These regulations may be seen as the boundaries that direct us in specific situations to help us make decisions and guide our behaviour while conducting research. Policies and procedures are also generally linked to cultural values and may be explicit to a particular time and are subject to change as attitudes and values evolve in today's society. Conflicts may arise while performing research and these have to be addressed while being respectful to the participants at all times. It is crucial for researchers to be knowledgeable of any pitfalls that may inhibit the undertaking of the study. Research ethics committees have been set up to ensure that researchers follow procedures during the collection of data so that participants willingly consent to take part and are aware, and know of the associated risks and benefits. These committees also need to ensure that legislation is being respected and adhered to. If integrity is not maintained, public confidence and belief in findings will be lost. Therefore, it is important to be transparent, competent, and follow ethical procedures when conducting research.

Learning Objectives:

1. To understand the importance of ethics in medical research and the role of research ethics committees.
2. To become familiar with common ethical pitfalls in imaging research.
3. To appreciate strategies for avoiding ethical problems in imaging research.

A-0779 08:53

How to critically appraise a research article

J. Thompson; Salford/UK (j.d.thompson@salford.ac.uk)

When planning a research project, it is vital that a good appreciation of the existing literature is gained. Performing a literature search prior to beginning your research enables you to realise trends, understand the gaps in the existing literature, and limitations in the existing knowledge base. Article critique is a core skill for evidence-based practice and it is important to have the skills and knowledge to successfully critique research articles. The different elements of a research paper will be discussed, helping you understand what

information you should expect to find, and which aspects of a research paper require close inspection. Good critique should always be positive and negative, and this session will help you understand the implications of positive and negative aspects of a research article on the overall outcomes and meaning of the research.

Learning Objectives:

1. To appreciate the role of the literature review in the research process.
2. To identify strengths and weaknesses in each section of a research report.
3. To critically appraise the overall value of a research report.

A-0780 09:11

How to write a good scientific abstract

L. Ribeiro; Faro/PT (lpribeiro@ualg.pt)

The abstract is the "door" to your scientific publication, and when written in the right way, will open the desire of the reader to continue reading your full work. Although the main objective for the author is that the number of persons who read the publication will be all interested by the scientific topic, he must write the abstract as the "big picture" in 250 words in order to sell his work. To achieve this goal, it is needed to choose the words that are capable of creating a desire of continue reading, but also with scientific content and respecting the format covenanted by the rigours scientific community, in other words, sell the work within the rules. In this talk, we will try to use the precise and right words to "How to write a good scientific abstract" according to a scientific structure and with the right message of your work. The measure of the success of your abstract is given by the equivalent number of readers of the full work. To conclude we hope to see you all at this talk, and at the end of that fulfil your expectations, because it is the most important!

Learning Objectives:

1. To understand general qualities of good scientific abstracts.
2. To be aware of typical formats of scientific abstracts.
3. To consider tips for success.

A-0781 09:29

How to produce a high-quality scientific or educational poster

C. Malamateniou; London/UK (christina.malamateniou@kcl.ac.uk)

Communication and dissemination of research in an ethical and systematised manner is as important as the research itself. One of the most common, most direct and commonly encountered ways to share data is the scientific poster. There are specific rules about the structure, the format, the presentation devised each time by the respective scientific event at which the poster is submitted and presented. However, there are also some generic rules universally applicable about structure, content and presentation of scientific posters that this talk will delve into. Once these rules adhere to the poster can fulfil its aim, which is to communicate the findings of research and stimulate discussion. Many research collaborations have started from a well-organised poster, and it is considered the predecessor of scientific presentations and research papers. It remains one of the most versatile means of disseminating evidence-based practice.

Learning Objectives:

1. To become familiar with poster formats and layouts.
2. To consider good practices in poster design.
3. To appreciate important considerations when designing a poster.

Imaging of forgotten small joints

Moderator:

R. Sutter; Zurich/CH

A-0782 08:30

A. Sterno-clavicular joints: from trauma to inflammation

A.-G. Jurik; Aarhus/DK

The sternoclavicular joints (SCJs) are the only synovial joints between the upper extremities and the body. They accompany arm movements and move slightly during respiration, resulting in an almost continuous strain on the joints. The SCJ surfaces are incongruent, consisting of a relatively small area of the medial clavicle articulating with the manubrium sterni and the adjacent cartilage of the first rib, but the joint space contains a stabilising intraarticular disc. Furthermore, the SCJ is stabilised by strong surrounding ligaments. Due to the SCJ anatomy, traumatic joint dislocations can occur in connection with shoulder or chest trauma. It is especially important to detect posterior clavicular

Saturday

displacement, which can potentially cause vascular damage. Lesion of the intraarticular disc may be common, but difficult to detect without high-resolution MRI. The stabilising ligaments surrounding the SCJ imply that the sternoclavicular region contains many areas of fibrous tissue inserting into bones (entheses), areas which may be involved by inflammatory disorders, predominantly seronegative spondyloarthritides. Most other joint disorders can also occur in the SCJ, predominantly osteoarthritis due to the joint strain. Detection of SCJ infection is particularly important due to a potential spread to the mediastinum. The SCJs are difficult to visualise by radiography; cross-sectional imaging by ultrasonography, CT, MR or radionuclide imaging is needed for appropriate visualisation. The lecture will encompass illustrations of characteristic imaging features of the most frequent SCJ disorders applying appropriate imaging strategies depending on the suspected disorder.

Learning Objectives:

1. To explain the pathologic conditions that involve the sterno-clavicular joints.
2. To describe the imaging findings of abnormalities that involve the sterno-clavicular joints.

A-0783 09:00

B. Symphysis pubis and its surroundings

A. [Kassarjian](#); *Pozuelo De Alarcón/ES*

The symphysis pubis and its surroundings are a common source of groin pain in athletes. This presentation will discuss the complex anatomy of the symphysis and the para-symphyseal region with an emphasis on MR anatomy. Furthermore, common causes of symphyseal and para-symphyseal groin pain in athletes will be illustrated.

Learning Objectives:

1. To explain the pathologic conditions that involve the symphysis pubis and its surroundings.
2. To describe the imaging findings of abnormalities that involve the symphysis pubis and its surroundings.

A-0784 09:30

C. Proximal tibio-fibular joint: a cause for lateral knee pain

A. [Cotten](#); *Lille/FR (anne.cotten@chru-lille.fr)*

Although rare, various disorders of the proximal tibiofibular joint have been reported. They should be kept in mind in the evaluation of lateral knee pain. They include traumatic subluxation or dislocation, atraumatic instability, congenital or acquired synostosis, osteoarthritis, rheumatic disease, ganglion or synovial cysts, synovial chondromatosis, pigmented villonodular synovitis and hypomobility of the joint. The peroneal nerve can be at risk with pathologies of this joint, either by compressive effect or formation of an intra-neural ganglion. After a reminder of the normal anatomy of this joint, emphasis will be put on the imaging features allowing depiction and assessment of the various disorders affecting this joint, which should not be forgotten any more.

Learning Objectives:

1. To explain the pathologic conditions that involve the proximal tibio-fibular joint.
2. To describe the imaging findings of abnormalities that involve the proximal tibio-fibular joint.

Dose management in paediatric radiology

A-0785 08:30

Chairperson's introduction

C. [Saidléar](#); *Dublin/IE (colm.saidlear@cuh.ie)*

The important concept of dose management, specifically in paediatric radiology, is now mainstream following two decades of campaigns by various stakeholder organisations and advocacy groups championed by radiologists, radiographers and medical physicists. The initial drive was to tackle high dose procedures such as CT and interventional radiology. This has now expanded into all diagnostic modalities that use ionising radiation. The IAEA Safety Report No. 71 (2012) highlights and requires the ICRP (2007) concepts of justification, optimisation and risk to be addressed in paediatric radiography, interventional radiology, CT and neonatal imaging, the focus of this refresher session. This report was a tipping point for dose management in paediatric radiology and has led to a significant body of work to implement these concepts in radiology departments and practices across the world. Audit and dose tracking mechanisms are key to this process. Recent initiatives and publications such as the 'The Gentle Way' by the IDoR (2015), RP 185 (European Guidelines on Diagnostic Reference Levels for Paediatric Imaging) by the European Commission (2018), along with enactment into law in member

states of the strict requirements in the Council Directive 2013/59/Euratom (Basic Safety Standards) for DRL's and the tracking of same, is timely for the next steps. They provide guidelines, benchmarking tools, meaningful processes and data, which are required to assist all stakeholders, including manufacturers, to obtain the best possible outcome for paediatric patients, that is, diagnostic quality images from a paediatric optimised modality at the appropriate dose.

Session Objectives:

1. To become familiar with modern dose management methods in paediatric radiology.
2. To understand the important aspects of paediatric dose management.
3. To appreciate the current trends and limitations.

A-0786 08:35

A. The special case of the paediatric patient: risks and justification

C. [Owens](#); *London/UK (owensc@gosh.nhs.uk)*

Advances in imaging technology have revolutionised our ability to produce exquisite images in children. We have a huge potential armamentarium and hence a duty of care to the child and parents to choose the correct examination which answers the posed clinical question, with the least exposure to radiation. Choice of the correct modality and optimisation of the machinery for use in children to obtain the best image quality is paramount, especially when using CT scanning, which has the relatively highest radiation burden. We will illustrate with examples comparing older and newer models of CT to compare doses with image quality.

Learning Objectives:

1. To learn about risks and justification techniques in paediatric radiology.
2. To understand how these methods are applied in a clinical setting.
3. To appreciate the benefits of new information and the current limitations.

A-0787 08:58

B. Optimisation and technology in paediatric projection radiography, interventional and CT scanning

V. [Tsapaki](#); *Athens/GR (virginia@otenet.gr)*

Radiological imaging has added incredible value in paediatric patient clinical diagnosis and treatment especially in the last decades with the help of digital technology, multidetector-row computed tomography (CT) and the use of angiography systems. The latest United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR) 2008 report states that approximately 180 million radiological examinations are performed on children and of these 18 million are CT exams. At the same time, all data show that the steadily increasing use of ionising radiation examinations and specifically the high dose procedures such as CT and interventional techniques) over the last years, result in progressively increasing of population radiation dose. Various studies in the recent literature have reflected a lack of attention to the potential hazards for children or to the need for reducing dose according to the body size of a small patient. It is well known that children are more sensitive to radiation than adults due to longer life expectancy and due to developing and growing tissues. They consequently have more years in which cancerous changes might occur. For all the above reasons continuous need for dose optimisation is needed. The lecture will present a summary of practical ways for radiation dose optimisation in projection radiography, interventional and CT scanning together with the latest trends in technology.

Learning Objectives:

1. To learn about the optimisation of techniques in paediatric radiology.
2. To understand how these methods are applied in a clinical setting.
3. To understand the new information that is available and the current limitations.

A-0788 09:21

C. Optimisation in the neonate

H. [Delis](#); *Vienna/AT (hdelis@gmail.com)*

"Neonates are not little children" one could say paraphrasing the quote "Children are not little adults", that is frequently used to highlight the special attention required in paediatric medicine. With birth weight often even below 1 kg for premature babies, and with a number of examination that can sometimes reach to tens, neonates are a very sensitive group of patients and their particularities and needs in terms of medical imaging are such that deserve a more scrutinised approach to optimisation. Although computed tomography is also used for neonates, it is the traditional radiographic projection imaging that is leading the list of examinations. Radiographs are not typically obtained for the healthy and full-term infant, but they are used for newborns with a spectrum of conditions and especially in the neonatal intensive care unit. Modern tools, such as the utilisation of dose management systems, to extensively review local practices, and iterative reconstruction algorithms that can limit the dose in CT, can provide a very good platform for optimisation. However, traditional optimisation methods, such as tube voltage, filtration and collimation, are of paramount importance to make sure that little patients are handled with the respective care needed.

Learning Objectives:

1. To learn about dose management techniques in neonatal radiology.
2. To understand how these methods are applied in a clinical setting.
3. To understand the new information that is available and the current limitations.

09:44

Panel discussion: Paediatric dose management: are we doing enough for the next generation?

08:30 - 10:00

Joint Session of the ESR and EORTC

ESR/EORTC

Imaging in oncological trials

Moderator:

M. Smits; Rotterdam/NL

A-0789 08:30

Chairperson's introduction

N.M. [deSouza](#); Sutton/UK

This educational session of imaging in oncological trials will explore the role of imaging biomarkers as end-points in oncology trials. It will underline the importance of joint organisational working and collaboration for a successful outcome. Designing trials that assess the validity and utility of imaging biomarkers will be discussed using treatment of oligometastatic disease as an exemplar. The use of imaging biomarkers specific to immunotherapy and derivation of quantitative biomarkers from radiomics platforms will be addressed.

Session Objectives:

1. To highlight the collaboration between EIBALL and the EORTC imaging group.
2. To introduce the need for radiologists to learn about oncological trials beyond RCTs and how such knowledge can be used to initiate and advance oncological imaging research.
3. To appreciate the impact imaging has on patient stratification and response assessment.
4. To learn about the requirements for and potential of radiomics in oncological imaging research.

Author Disclosure:

N.M. deSouza: Grant Recipient; Cancer Research UK, EU Framework 7.

A-0790 08:35

Trial design and imaging end-points

L. [Collette](#); Brussels/BE (Laurence.collette@eortc.org)

Nowadays the trial designs that are used for the evaluation of anti-cancer treatments range from the simplest, the traditional single-arm or 2-arm randomized designs addressing a specific histology, to much more complex designs that either address multiple (targeted) treatments for a given cancer type ("umbrella trials") or assess treatments across histopathological tumour types ("basket trials"). We will discuss the use and characteristics of these designs. Images play an important role in the assessment of the treatment effect through either qualitative or quantitative measures of change over time. We will discuss some quality requirements that need to be met to ensure that the information they convey results in an accurate evaluation of the trial endpoints. Finally, we will give some thoughts on how the images collected for the study may be exploited to meet additional research objectives.

Learning Objectives:

1. To learn about the several types of trial design, including RCT, umbrella and basket trials.
2. To appreciate the different requirements of imaging end-points for different trials and phases.
3. To understand how imaging data acquired in the context of different trials can be used for additional research questions.

A-0791 08:55

Modern imaging-based trials: focus on oligometastatic disease and evaluation of metastatic directed therapies

F.E. [Lecouvet](#); Brussels/BE

Patients with oligometastatic disease (OMD) have controllable symptoms, and cures are theoretically possible. Technical improvements in surgery and radiotherapy have introduced the option of metastasis-directed therapies (MDT) as an adjunct or alternative to the standard of care systemic therapies. Standard imaging methods recommended by current guidelines often have insufficient diagnostic accuracy for a reliable diagnosis of OMD. Modern imaging methods using positron emission tomography /computed tomography

(PET/CT) with a tumour specific radiotracers, and increasingly whole-body magnetic resonance imaging (WB-MRI) with diffusion-weighted imaging (DWI), allow an earlier and more precise identification of metastases. This lecture discusses the evidence and offers recommendations for the implementation of standard-of-care (Response Evaluation Criteria in Solid Tumours measurements on CT, MRI and bone scintigraphy) and advanced imaging modalities for identifying and following patients with OMD in the most frequent cancers. The presentation suggests clinical algorithms for integrating modern imaging methods in the care pathway at the various stages of these cancers in order to identify OMD. Clinical trials utilising modern imaging methods are proposed for evaluating the needs for a reliable identification of OMD and the benefits of metastasis-directed therapies.

Learning Objectives:

1. To understand how imaging modalities may affect patient selection.
2. To appreciate how imaging modalities may affect response assessment.
3. To learn how to design a trial evaluating the best imaging strategy according to the objective.

Assessing treatment response in the era of immunotherapy

C. [Caramella](#); Villejuif/FR (Caroline.CARAMELLA@gustaveroussy.fr)

Immunotherapy has rapidly and profoundly changed the management of many cancer patients. The high level of disease control rate has led to multiple approvals around different types of cancers, mainly in the metastatic situation, but is going to also win new indications in neoadjuvant and adjuvant therapy. The radiological evaluation of patients under immunotherapy is challenging because of the random occurrence of a new pattern of response named "pseudoprogression", that is (mis)classified by RECIST 1.1 as a progression. Consequently, iRECIST new guidelines were proposed by the RECIST working group in order to clarify and standardise how progressions in trials investigating immunotherapies should be assessed. In particular, a disease described as progressive by RECIST rules, should be named as an immune unconfirmed progressive disease (iUPD) and therefore require a subsequent evaluation in order to confirm -or not- the progression.

Learning Objectives:

1. To learn about new immunotherapies.
2. To appreciate new patterns of response and progression observed under immunotherapy.
3. To learn about the specific criteria derived from RECIST (iRECIST), harmonising data collection in clinical trials.
4. To learn about future functional imaging techniques which could help to better understand effects of immunotherapies.

Radiomics in oncology trials

P. [Kickingereder](#); Heidelberg/DE

(philipp.kickingereder@med.uni-heidelberg.de)

Magnetic resonance imaging plays a key role for diagnosis and treatment monitoring of brain tumours and novel imaging techniques that specifically interrogate aspects of underlying tumour biology and biochemical pathways, have great potential in neuro-oncology. This presentation focuses on the emerging role of radiomics and radiogenomics in establishing the diagnosis, for monitoring treatment response and for predicting prognosis in brain tumour patients.

Learning Objectives:

1. To become familiar with the radiomics process.
2. To learn what is important in data collection and curation for radiomics.
3. To understand how radiomics can lead to a new biomarker discovery.

A-0794 08:30

A. Conventional radiography: still a helpful method?

S.C. [Shelmerdine](#); London/UK (susie_c_s@yahoo.co.uk)

Juvenile Idiopathic Arthritis (JIA) is a chronic, rheumatic illness that is associated with a high risk of long-term physical disabilities. Radiography can help identify changes related to JIA, which are primarily those of chronic, destructive changes seen in late disease, but it can also provide indirect information on soft tissue inflammation (such as peri-articular increased soft tissue density or the presence of a joint effusion). In the initial assessment of a child with joint pain, radiography is also useful to rule out other differential diagnoses such as neoplasms, posttraumatic changes and developmental defects. In this lecture, we will focus on the typical findings of joint inflammation and destruction seen in a variety of commonly affected joints. We will also touch upon common pitfalls and how such features may overlap with normal findings of skeletal maturation. We conclude by reviewing benefits and drawbacks of using radiography as a follow-up imaging tool and how this modality compares to other radiology techniques for JIA imaging.

Learning Objectives:

1. To learn about the features of joint inflammation on plain radiographs.
2. To understand the role of this technique in the diagnosis and follow-up of children with JIA.
3. To appreciate the strengths and limitations of conventional radiography compared to other modalities in JIA.

A-0795 09:00

B. Ultrasound for detecting and grading of inflammation in JIA

L. [Tanturri de Horatio](#); Rome/IT

"no abstract submitted"

Learning Objectives:

1. To learn about normal features vs pathology on ultrasound of joints in children.
2. To understand the role of ultrasound in diagnosing and grading of joint inflammation.
3. To appreciate the research-based evidence of ultrasound.

A-0796 09:30

C. MRI and role of contrast in the assessment of synovitis

L.-S. [Ording Müller](#); Oslo/NO (lilsofie.ording@googlemail.com)

MRI scanning is the current gold standard modality for imaging synovitis and tenosynovitis in patients with Juvenile idiopathic arthritis. Enhancement of the synovium after gadolinium injection is traditionally regarded as mandatory in the assessment of synovitis, both for diagnosis and grading, and to distinguish between active and inactive disease. There have been huge advances in medical treatment of JIA over the last two decades, and disease remission is now the ultimate goal for all patients. This increases the role of imaging to detect early signs of disease or relapse and subtle response to treatment. Several research groups work on establishing scoring systems to create objective imaging measures of disease activity in JIA. However, repeatability in the differentiation between normal synovial enhancement and inflammation and of the grading of contrast enhancement in early disease is rather poor. The timing of imaging post contrast injection has shown to play an important role in the assessment and grading of synovitis, and dynamic contrast-enhanced might be a better method to improve quantification of synovitis. New focus on potentially harmful effects of Gd-injection forces us to search for alternative methods in synovitis imaging. The diffusion-weighted imaging (DWI)-derived apparent diffusion coefficient (ADC) seems to be higher in active JIA and may serve as a non-invasive imaging biomarker for JIA in the future. In this lecture, current knowledge on the role of contrast in synovitis assessment, challenges in the standardisation of imaging, potential alternative methods for detection and grading of inflammation in JIA will be presented.

Differential diagnoses you don't want to miss

Moderator:

E. Arkin; Reykjavik/IS

A-0797 08:30

A. Differential diagnoses of nose and paranasal sinus lesions

S. [Connor](#); London/UK (sejconnor@gmail.com)

Sinonasal pathologies will be categorised and discussed as inflammatory/infectious processes, benign tumours, malignant tumours and miscellaneous sinonasal lesions. CT is the initial imaging study performed for an inflammatory disease to establish the extent and to provide an anatomical road-map for surgery. Important anatomical variants should be reported as they are predictive of disease patterns and impact on surgical approaches. "Red flag" imaging features such as isolated polyps, bony erosion, extra sinus extension and skull base defects should be sought on paranasal sinus CT, as these will indicate further evaluation with MRI or endoscopic correlation. Additional inflammatory processes such as polyps, retention cysts, mucocoeles, silent sinus syndrome, rhinolith and odontogenic sinusitis may be recognised on CT. Potential extra-sinus extension of sinonasal infection, including that resulting from invasive fungal disease, requires additional evaluation with MRI to demonstrate orbital, intracranial and deep face involvement. Benign tumours such as inverted papilloma, odontogenic lesions and juvenile angiofibroma may present with typical and sometimes pathognomonic appearances on CT and MRI, but imaging also provides useful information on the extent of the abnormality. MRI and CT are complementary in the assessment of sinonasal malignant lesions. MRI, in particular, is vital, to assess for direct skull base, perineural, orbital and deep facial extension. Optimised MRI protocols enable delineation of a tumour, and the most useful MRI sequences will be discussed. Miscellaneous entities such as developmental sinonasal abnormalities and destructive midline pathologies also require pattern recognition on CT and MRI for their differential diagnosis.

Learning Objectives:

1. To describe disease patterns in nose and paranasal sinus CT.
2. To learn when additional imaging is mandatory.
3. To provide tools to narrow down the list of differential diagnoses in sinonasal MR studies.

A-0798 09:00

B. Differential diagnoses of paediatric neck lesions

P.A. [Caruso](#); Boston, MA/US (pcaruso@partners.org)

We will review those pediatric head and neck lesions, neoplastic, malformative, and inflammatory where consideration of the differential diagnosis is key to avoid missing critical pathology. As we review these lesions, we will see how taking the time to consider the differential diagnoses particular to the pediatric population can inform our search strategies, protocols, and interpretation. We will review the pertinent embryologic and anatomical considerations as well for each case.

Learning Objectives:

1. To become familiar with the normal development of facial and neck structures.
2. To discuss which imaging modality to use: US, CT or MRI?
3. To understand the typical imaging appearance of congenital neck lesions.

A-0799 09:30

C. Differential diagnoses of soft tissue masses in adults

D. [Farina](#); Brescia/IT (davide.farina@unibs.it)

Soft tissue masses of the supra and infrahyoid neck are a rather heterogeneous group of tumours, classified by WHO in nine categories, based on their histologic differentiation: adipocytic, fibroblastic or myofibroblastic, fibrohistiocytic, smooth muscle, skeletal muscle, vascular, pericytic, and chondro-osseous tumours, and tumours of uncertain differentiation. Based on their clinical behaviour and history such tumours may be described as benign, malignant or intermediate, the latter further subclassified as locally invasive or metastasizing at distant sites. The US is generally the first imaging step in infrahyoid neck lesions; MDCT or MRI are mandatory in suprahyoid masses but are also needed to better define the deep extent and anatomic relationships of infrahyoid tumours. In many cases, imaging findings are overlapping and insufficient for tumour characterisation; nonetheless, some specific clues may orient the differential diagnosis. The site of origin of the lesion is probably the first brick in the wall. Therefore knowledge of the space-

based neck anatomy is an essential prerequisite. Patient's age, size and number of lesions, presence and pattern of calcifications are useful additional details. Some specific density or signal intensity patterns may cut the list of differentials, whereas the potential role of the additional information provided by DWI-MRI or dual-energy CT is far from being fully elucidated. However, it is clearly assumed that imaging diagnosis does not replace pathologic assessment, which in a significant number of cases can be accurately obtained with FNA.

Learning Objectives:

1. To become familiar with the anatomy.
2. To learn which imaging technique to use.
3. To understand the typical imaging appearance of soft tissue masses.

Pleural neoplasms

A-0800 08:30

Chairperson's introduction

F. Gleeson; Oxford/UK (fgleeson@mac.com)

Pleural disease is a common manifestation of both intra- and extrathoracic disease and may be either benign or malignant. Although pleural effusions are common, pleural malignancy is less common and often diagnosed late. This session will discuss both primary pleural malignancy - mesothelioma, and metastatic disease, most commonly adenocarcinoma, and benign pleural tumours, including pleural fibromas. We will discuss their presentation, the use of different imaging modalities including PET/CT and the methods available to obtain a tissue diagnosis. The session will start with a case presentation which will illustrate the importance of considering a pleural aetiology in the differential diagnosis of patients presenting with an abnormal CXR.

A-0801 08:36

A. Malignant mesothelioma

I. Hartmann; Rotterdam/NL (i.j.c.hartmann@gmail.com)

Malignant pleural mesothelioma (MPM) is the most common primary malignant tumour of the pleura and the second most common pleural malignancy after metastatic disease. MPM has a poor prognosis and limited treatment options. Imaging plays a central role in the detection, diagnosis, staging, and response assessment of MPM. Although multimodality imaging, especially PET/CT, is increasingly used, contrast-enhanced CT alone is often sufficient. MPM has a unique morphology and growth pattern, making the image interpretation frequently a challenge. The aim of the presentation is to provide an overview of the most common and less frequent imaging findings of MPM, staging of MPM according to the 8th TNM classification, the role of PET/CT in the management of MPM, and the revised, modified RECIST 1.1 guidelines for MPM response assessment.

Learning Objectives:

1. To learn about the various presentation of malignant mesotheliomas.
2. To learn about the role of PET/CT.
3. To learn about the modified RECIST criteria.

A-0802 09:04

B. Pleural carcinomatosis of thoracic and extra thoracic origin

C. Beigelman; Lausanne/CH

Pleural metastases are the most common malignant pleural tumours, usually originating from an adenocarcinoma of the lung, breast, ovary, and stomach. Pleural malignancy may also be related to lymphoma, a thymoma or may be of unknown origin. Typical features of malignancy include circumferential thickening, nodular thickening, thickness greater than 1 cm, and involvement of the mediastinal pleura. A pleural effusion is commonly seen, sometimes without any associated pleural thickening. Multiple pleural-based nodules or focal pleural thickenings, as well as a solitary mass, may also be observed. Focal pleural thickenings (PT) should not be confused with normal structures, typical pleural plaques, PT related to previous tuberculosis, silicosis, or other rarer conditions. Importantly, in case of known or suspected malignancy, the presence of postero-basal PT in supine examination requires an additional low dose acquisition on prone position. Indeed, such thickenings may be reversible, therefore excluding pleural metastasis. Any atypical shape, location or change of a PT should suggest a pleural metastasis in a context of malignancy. In all cases, a careful analysis of other CT findings, previous imaging studies and clinical history are determinant for the final diagnosis of pleural metastasis. Beside contrast-enhanced MDCT, the major imaging modality in this setting, there is an undeniable role of PET imaging. In particular, by using the latest equipment allowing a spatial resolution of 3 mm,

a high metabolic activity in the absence of prior thoracocentesis may help to strongly suggest malignancy faced with minor or subtle anomalies. Illustrative cases will be reviewed.

Learning Objectives:

1. To review the CT signs of pleural carcinomatosis.
2. To become familiar with the signs of dry pleural dissemination.
3. To review illustrative cases.

Author Disclosure:

A-0803 09:32

C. Other pleural and juxta pleural malignancies

A. Snoeckx; Antwerp/BE (annemie.snoeckx@uza.be)

Pleural malignancies, other than mesothelioma and metastases, are very rare. According to the latest World Health Organization Classification, these tumours can be further divided into lymphoproliferative disorders and mesenchymal tumours. The latter includes malignant solitary fibrous tumour, desmoid-type fibromatosis, sarcomas, desmoplastic round cell tumour,... Pleural lymphoma can be primary or secondary. Primary lymphoma is a very rare entity that can be seen in the setting of HIV with primary effusion lymphoma or associated with pyothorax. Imaging findings are nonspecific, but an isolated pleural lesion is unlikely to represent lymphoma. Secondary pleural lymphoma is most commonly non-Hodgkin lymphoma and mainly seen in association with other types of thoracic involvement. Pleural solitary fibrous tumours are malignant in up to one-third of cases. On CT these well circumscribed pedunculated large masses are heterogeneous. Calcifications and associated pleural effusion are less common. Desmoid tumours appear as well-defined isodense to hypodense masses on CT. Contrast enhancement is variable and central necrosis is usually absent. Whereas chest radiographs can be the initial study for detection, Computed Tomography remains the imaging modality of choice for primary assessment of pleural masses. Magnetic Resonance Imaging and Positron emission tomography may have a role in further characterisation, defining local tumour extension and staging.

Learning Objectives:

1. To learn about the CT features of solitary fibrous tumours.
2. To know when to suspect a desmoid tumour.
3. To learn about pleural lymphoma.

Shoulder sports injuries and postoperative MRI

Moderators:

L.W. Bancroft; Orlando, FL/US

A.J. Grainger; Leeds/UK

A-0804 08:30

A. Shoulder injuries in the throwing athlete

L. Steinbach; San Francisco, CA/US

Overhead throwing athletes acquire adaptations to the extremes of motion in the dominant shoulder. These changes may aid in pitching, throwing or serving velocity, however for some athletes they might eventually result in an inability to throw with the same velocity. These injuries and adaptations involve capsule, labrum, rotator cuff and biceps tendons, muscles, nerves, and bones. This presentation will review the biomechanics of throwing forces as they relate to the shoulder using baseball as an example. The MR imaging characteristics of the resultant changes in the rotator cuff, superior labrum and osseous structures will also be highlighted.

Learning Objectives:

1. To understand the biomechanics of throwing forces as they relate to the shoulder.
2. To become familiar with rotator cuff and labroligamentous injury patterns caused by overhead sports.

A-0805 09:00

B. Postoperative shoulder MRI after instability surgery

L.W. Bancroft; Orlando, FL/US (laura.bancroft.md@flhosp.org)

Purpose: To become familiar with the expected and abnormal MR imaging findings after labral repair, capsular shift/capsulorrhaphy, remplissage and Latarjet/Bristow procedures. Methods and Materials: MR imaging will be used

to demonstrate the various normal and abnormal imaging appearances after shoulder instability surgery. Results/Conclusion: Labral re-tear will be evident as contrast or joint fluid extension into linear or complex tear cleft, absent/truncated/fragmented labrum, or labral displacement from an anatomic location. Capsular shift results in smaller capacity joint and sometimes irregular capsular nodularity. Complications of capsulorrhaphy include capsular tears and subluxation of the humeral head. Postoperative MR imaging can evaluate healing after combined remplissage and Bankart repair for moderate size, engaging Hill-Sachs lesions. Laserjet and Bristow procedures may be performed in patients with recurrent dislocations and glenoid deficiency. Incorporated bone will yield non-anatomic glenoid configuration, and complications include non-union, fatty degeneration of subscapularis muscle, and osteoarthritis.

Learning Objectives:

1. To become familiar with the expected and abnormal MR imaging findings after labral repair.
2. To learn about the postoperative imaging features after capsular shift/capsulorrhaphy.
3. To appreciate normal imaging and complications after remplissage and Laterjet/Bristow procedures.

Author Disclosure:

L.W. Bancroft: Author; Lipipincott. Speaker; World Class CME.

A-0806 09:30

C. Interactive case discussion (Part 1)

L. [Steinbach](mailto:lynnesteinbach1@gmail.com); San Francisco, CA/US

This interactive session will showcase that relate to the shoulder in the throwing adolescent. This age group has additional problems related to the stress of throwing. These abnormalities were not discussed in the lecture on the throwing shoulder of the adult. Many of the cases relate to stress on the physical plates around the shoulder.

Learning Objectives:

1. To appreciate pathologic and normal developmental changes in skeletally immature throwing athletes.
2. To learn how to differentiate normal and failed labral repairs with MRI.
3. To consolidate the knowledge gained from the session with interactive cases of pre- and postoperative shoulder MRI.

A-0807 09:45

C. Interactive case discussion (Part 2)

L.W. [Bancroft](mailto:laura.bancroft.md@flhosp.org); Orlando, FL/US

To engage in interactive case discussions with the expected and abnormal MR imaging findings after labral repair, capsular shift/capsulorrhaphy, remplissage and Laterjet/Bristow procedures. An interactive case discussion will be used to demonstrate the various normal and abnormal imaging appearances after shoulder instability surgery. Labral re-tear will be evident as contrast or joint fluid extension into linear or complex tear cleft, absent/truncated/fragmented labrum, or labral displacement from the anatomic location. Capsular shift results in smaller capacity joint and sometimes irregular capsular nodularity. Complications of capsulorrhaphy include capsular tears and subluxation of the humeral head. Postoperative MR imaging can evaluate healing after combined remplissage and Bankart repair for moderate size, engaging Hill-Sachs lesions. Laterjet and Bristow procedures may be performed in patients with recurrent dislocations and lenoid deficiency. Incorporated bone will yield non-anatomic glenoid configuration, and complications include non-union, fatty degeneration of subscapularis muscle, and osteoarthritis.

Learning Objectives:

1. To appreciate common patterns of athletic injury in the shoulder.
2. To learn how to differentiate normal and failed labral repairs with MRI.
3. To consolidate the knowledge gained from the session with interactive cases of pre- and postoperative shoulder MRI.

Imaging in pregnancy

A-0808 08:30

Chairperson's introduction

G. [Masselli](mailto:gabriele.masselli@uniroma1.it); Rome/IT

Modalities that do not use ionising radiation, such as US and MR imaging, should be the preferred examinations for evaluating a pregnant patient. Ultrasound is currently the standard approach for the initial evaluation of fetal

anatomy and maternal conditions during pregnancy since it allows a real-time examination and is widely available and cost-effective. Magnetic resonance imaging, due to its morphological and functional capabilities, can greatly improve the diagnostic performance of US during pregnancy. Determining the cause of acute abdominal and pelvic pain in pregnant women can be difficult because of the multiple confounding factors found in normal pregnancy. Pelvic ultrasound may be of limited value due to the altered body habitus, a small field of view and the presence of interfering overlying structures. MR imaging is extremely accurate in identifying both obstetric and non-obstetric causes and should be used when ultrasound findings are nondiagnostic or equivocal. Imaging of the placenta can have a profound impact on patient management, owing to the morbidity and mortality associated with various placental conditions. Placental conditions affecting the mother and fetus include molar pregnancies, placental hematoma, abruption, previa, accreta, vasa previa, chorioangioma, and retained products of conception. Although uncommon, abnormalities of the placenta are important to recognise owing to the potential for maternal and fetal morbidity and mortality.

Session Objectives:

1. To understand how to safely perform imaging procedures in pregnant women.
3. To become familiar with the most relevant pathological conditions in pregnancy.
2. To learn about the indications of imaging procedures in pregnancy.

A-0809 08:35

A. Safety issues in pregnancy: what radiologists need to know

C. [Bourgioti](mailto:charisbourgjoti@yahoo.com); Athens/GR

Imaging of the pregnant patient is challenging as it involves both the mother and the fetus. A number of medical, ethical or legal issues is likely to be raised. Potentially, all available imaging modalities may be applied to the evaluation of the pregnant patient; however, confusion regarding the safety of the mother and the fetus often results in unnecessary avoidance of useful diagnostic tests, especially those using ionising radiation. Sonography is the frontline imaging method for gravid patients, and its use for diagnostic reasons practically lacks any adverse effects. In the case of equivocal sonography, MRI (3T or less) can be used judiciously, regardless of gestational age, providing that the information gained is likely to offer medical benefit. When sonography or MRI are not feasible or less suitable, including cases with severe trauma or suspected pulmonary emboli, ionising radiation studies can be performed after a careful risk-benefit assessment, always keeping the radiation dose to the fetus as low as reasonably achievable (ALARA principle). The absorbed doses for diagnostic purposes are usually less than 50mGy and considered safe for the fetus; however, when CT is to be performed, implementation of dose reduction techniques or abdominal shielding is advised. Administration of iodinated contrast media intravenously is recommended only under special circumstances, and neonatal thyroid function should be checked soon after birth. Currently, paramagnetic contrast injection is strongly discouraged, unless the potential benefit for the mother overcomes the potential risks of long-term exposure of the developing fetus to gadolinium.

Learning Objectives:

1. To learn about safe radiology practices and procedures in pregnant women.
2. To understand how to minimize the radiation burden in pregnant women.
3. To learn how and when to use contrast media in pregnancy.

A-0810 08:58

B. Imaging acute abdomen in pregnancy

M. [Weston](mailto:michael.weston2@nhs.net); Leeds/UK

There are causes of pain that are specific to pregnancy and causes of pain in other organs that may present during pregnancy. Pregnancy-related pain may relate to ectopic pregnancy, fibroid degeneration, placental abruption or uterine dehiscence. Acute conditions may occur in any other organ during pregnancy just as they may in the non-pregnant patient, but commonly seen conditions are appendicitis, pyelonephritis, renal colic and adnexal torsion. Complications post delivery primarily relate to either bleeding or sepsis. Ultrasound and MR form the mainstay of imaging in the pregnant patient, and the talk will concentrate on the appearances in these modalities. However, sometimes it can be better to use a test such as CT, with which the radiologist is familiar despite the perceived risks of ionising radiation, as the risk of misdiagnosis is reduced.

Learning Objectives:

1. To become familiar with the different causes of acute abdominal pain in pregnancy.
2. To learn about imaging features of the different causes of acute abdominal pain in pregnancy.
3. To learn how to use different imaging modalities in the setting of acute abdominal pain in pregnancy.

Postgraduate Educational Programme

A-0811 09:21

C. Imaging the placenta

P. Sover; Paris/FR

The placenta can be imaged with ultrasound and MRI for routine assessment, computed tomography for acute complication such as placental abruption, and angiography, should further embolisation be considered for hemorrhagic complication. The placenta can be involved by physiological and morphological abnormalities and may have an abnormal location. Rarely, the placenta can be involved by gestational trophoblastic diseases (hydatidiform mole, invasive mole and choriocarcinoma). Retained products of conception are rarely diagnosed with imaging because obstetricians systematically perform a uterine revision. In vivo assessment of placental vascularisation is routinely performed with Doppler ultrasound but 3D imaging and functional MRI can be used to scrutinise placental functions. Decreased maternal blood to the placenta is associated with preeclampsia and intrauterine growth restriction. Each imaging technique has intrinsic advantages that are counterbalanced by limitations. Placental location is best depicted with MRI. Regarding abnormally invasive placenta (AIP), MRI is used as a second line examination and several MRI findings are associated with AIP with various degrees of sensitivity and specificities, but the added value of MRI by comparison with ultrasound alone is not well established. Functional MRI (arterial spin labelling, blood oxygen level-dependent and oxygen-enhanced, diffusion-weighted MRI) helps estimate the placental function that are related to vascularisation, oxygenation, and metabolism. Current evidence does not support the use of gadolinium-based contrast agent.

Learning Objectives:

1. To understand the appearance of the placenta with different imaging modalities.
2. To become familiar with the imaging appearance of the commonest pathological conditions of the placenta.
3. To discuss the added value of cross-sectional imaging in the evaluation of placental abnormalities.

Genitourinary radiology for the general radiologist

A-0820 10:30

A. Cystic pelvic masses: differential diagnosis and management

O. Nikolic; Novi Sad/RS (nikolic.olivera@gmail.com)

Cystic pelvic masses are frequent in women and are related to the female reproductive system (gynecologic lesions-usually of ovarian origin). Genital fluid masses in men are less frequent. Moreover, a variety of fluid-filled lesions unrelated to the genital organs may be seen in both sexes, normally associated with the urinary system, gastrointestinal system or miscellaneous group of lesions. The aim of this talk is to present the imaging features of different cystic pelvic entities and their differential diagnoses and to learn the practical workflow in everyday clinical practice. Different types of cystic pelvic masses may have similar imaging characteristics, and therefore radiologic evaluation may be of limited diagnostic use. To avoid misdiagnosis, it is very important to understand the relationship of a mass with its anatomic location, to identify the ovaries at imaging in female patients and correlate imaging findings to the clinical history and laboratory findings.

Learning Objectives:

1. To learn the imaging characteristics of the different entities.
2. To become familiar with the practical workflow in everyday clinical practice.

A-0821 11:15

B. Gynaecological emergencies

M. Weston; Leeds/UK (michael.weston2@nhs.net)

Gynaecological emergencies may present with abdominal distension, pain, bleeding or sepsis. Normal physiological changes that might mimic disease are discussed. This presentation will show the common imaging features of ectopic pregnancy, ovarian cyst accidents, hyperstimulation, adnexal torsion, fibroid degeneration, and pelvic inflammatory disease. The appropriate use of US, CT and MR scans will be discussed.

Learning Objectives:

1. To become familiar with the differential diagnosis.
2. To identify the key imaging findings.

ESR Patient Advisory Group (ESR-PAG)

PA 1

Communicating the role of the radiologist: best practices to manage patient expectations

A-0822/A-0823 10:30

Chairpersons' introduction

N. Bedlington; Vienna/AT

N.I. Traykova; Plovdiv/BG (nikoletatraikova@gmail.com)

The relationship between the radiologist and patient representative groups is of paramount importance to ESR. A radiologist's visibility is far too often insufficient to patients due to lack of communication, as a result of understaffed departments, overworked radiologists and not enough time for them to properly communicate with patients. ESR is committed to cooperating with ESR PAG to improve radiologists' communication skills, to effectively promote their role to the patients and to make the former better understand and appreciate patients' needs. ESR is also committed to maintaining and improving all aspects of patients-radiologist relationships in the modern high tech radiology department.

Session Objectives:

1. To explain to radiologists how to effectively communicate their roles to their patients.
2. To identify room for improvement in patient communication based on experience reports by patient representatives.
3. To discuss approaches on how to maintain a good patient-health professional relationship in the high-tech radiology department.

A-0824 10:40

Explaining the radiologist's role to patients

A. Brady; Cork/IE (adrianbrady@me.com)

Historically, radiologists have often worked, "undercover". The perception has been created that radiologists are often "the doctors' doctor", and that we have little or no engagement directly with patients. This is neither desirable nor true. Nonetheless, patients often do not know if they've engaged with a radiologist, and may not understand our role and responsibilities. Conversely, radiologists may not understand the main concerns of patients with whom we interact, given that most of the information provided to us to assist us in caring for patients is delivered from a third party, the referrer. One of the responsibilities of a radiologist which is often underfulfilled is that of communicating with patients. This takes many forms, including explaining the reason for an investigation, what a patient will experience, what will happen after the investigation, and what the findings mean. This talk will explore how these pieces of information may be communicated, and how mutual understanding between patients and radiologists may be improved, for the benefit of all.

Learning Objectives:

1. To outline the role of the radiologist in patient care.
2. To consider how best to explain the radiologist's input in diagnosis and care to patients.
3. To understand how radiologists and patients may communicate for the benefit of patients.

A-0825 11:00

The patient perspective: sharing expectations and experiences (part 1)

B. Bauer; Abensberg/DE (birgit.bauer@manufaktur-fuer-antworten.de)

People diagnosed with a disease like MS or other chronic conditions experience a lot of different exams. One of those is an MRI. I will talk about the information given to patients and what they need and what they have to understand when they sign the information leaflet. With my own story and a lot of research, I will bring up the patient perspective about the needs in information and understandability.

Learning Objectives:

1. To understand language used within the radiology department and patients' needs to effectively communicate with the radiologist.
2. To learn about programmes that help patients to better understand the illness and medical imaging procedures used in the hospital.
3. To understand both the patient and radiologist's perspective in order to further empower the patient.

The patient perspective: sharing expectations and experiences (part 2)

E. [Briers](mailto:erikbriers@telenet.be); Hasselt/BE (erikbriers@telenet.be)

The patient entering the "Medical imaging - radiology department" normally has some knowledge on the way he is there. He has been referred by another clinician for some imaging procedure. This referring clinician may or may not have taken the time to inform the patient on the upcoming procedure. Because of the "may or may not" it would be prudent for the department to ask the patient: "Do you know why you are here?" this could be the starting point of supplementary information. It is possible that the clinician explained that the procedure would help come to a final diagnosis or on the success or progress of treatment. It is not certain that the patient is also informed on the procedure sensu stricto, entering the confined space of a CT or MRI equipment, the use of contrast and much more. There is almost always extra information needed. At the moment the patient enters the department, the moment to choose is over, but if choices can be made it is important that the patient is involved in this decision. Due to time constraints in the department, the waiting time before the actual procedure seems to be the moment when patients could be given extra information, in print or on dedicated screens. If the intervention is special (biopsies) the information should be given to the patient while he is receptive and before any anaesthesia is applied. Any-way the provided information should be adapted to the personal learning capabilities of the patient(s).

Learning Objectives:

1. To outline patient expectations in terms of communication and radiology procedures within the hospital department.
2. To learn about practical solutions in hospital departments to meet patients' demands for involvement in decision-making regarding the care pathway.
3. To understand how to effectively communicate with patients through face-to-face interaction and online reports.

Best practices: tools to optimise communication with patients

L. [Robinson](mailto:lesliero10@gmail.com); Gatley/UK (lesliero10@gmail.com)

This presentation will consider an effective communication from the standpoint of partnership working; that is partnerships between patients, the public and practitioners. Historically, communication in radiography has been predicated on a paternalistic model; i.e. the practitioner determines what it is that the patient needs to know. This is at odds with current health policy on partnership working and shared decision-making where there should be "no decision about me without me". In 2018, the UK Society and College of Radiographers convened a group of patients and practitioners to address this mismatch. The outcome was a set of Guiding Principles, written in the patient voice, which establishes what patients perceive to be effective communication and partnership working within diagnostic imaging and radiotherapy services. The presentation will discuss these Guiding Principles focusing in on what patients have told us they want in terms of effective communication.

Learning Objectives:

1. To learn about effective communication and useful information for patients.
2. To learn that an overload of information is equally detrimental to a safe feeling as no information.
3. To understand how patient summaries and online reports can empower patients and contribute to shared decision-making.

Neuro

A-0828 10:30

Chairperson's introduction

C. Calli; Izmir/TR

Session Objectives:

1. To learn relevant imaging and interventional algorithms and important imaging features of neurovascular disorders of the brain and spine.
2. To understand imaging features and prognostic implications of tumours of the brain and spine.
3. To become familiar with the role of different imaging modalities including hybrid imaging in diagnosing disorders of the central nervous system.

A-0829 10:36

A. Congenital and white matter disorders of the brain

A. Rossi; Genoa/IT (andrearossi@gaslini.org)

In this lecture I will review the basic concepts about brain maturation and myelination, and how to set up a baseline MR study of the brain in the pediatric age group. I will also examine some frequent pitfalls in pediatric neuroimaging, focussing on a frequent finding: pineal gland cysts. Then, I will address the main congenital malformations of the brain, highlighting the role of MR with diffusion tensor imaging (DTI) in their understanding and classification. I will also examine the principal neurocutaneous syndromes, such as Neurofibromatosis type 1 and 2, tuberous sclerosis, Sturge-Weber syndrome, and von Hippel-Lindau disease. Finally, I will elucidate a few basic concepts about leukodystrophies, focusing on pattern recognition based on MR, and understanding how to differentiate them from acquired white matter disorders, notably acute disseminated encephalomyelitis.

Learning Objectives:

1. To understand the development, normal anatomy and normal variants of the brain.
2. To become familiar with common congenital disorders of the brain and neurocutaneous syndromes.
3. To learn imaging features and differential diagnoses of white matter disease, inflammation and neurodegeneration.

A-0830 11:04

B. Neurovascular disorders and trauma of the brain

M. Vernooij; Rotterdam/NL (m.vernooij@erasmusmc.nl)

This lecture is part of a series of lectures aimed at preparation for the neuroradiology part of the EDiR examination.

Learning Objectives:

1. To become familiar with the normal anatomy and normal variants of the craniocervical arterial and venous system.
2. To learn the causes and imaging features of stroke, haemorrhage and other common vascular lesions of the brain and their relevance to interventional neuroradiology.
3. To understand the imaging features of traumatic injury to the brain.

A-0831 11:32

C. Tumours of the brain and spine

M.M. Thurnher; Vienna/AT (majda.thurnher@meduniwien.ac.at)

The fifth edition (2016) of the WHO Classification of Tumors of the CNS is the worldwide standard for classifying and grading brain neoplasms. Standardised MR brain tumour protocol is crucial for the preoperative evaluation and interpretation of postoperative changes. Brain tumour imaging objectives include the diagnosis of a brain tumour and the ability to distinguish it from non-tumoral lesions, assessment of histological grade of the tumour, delineation of the tumour borders and extension, differentiation between a tumour and peritumoral oedema, and finally the evaluation of possible recurrence and therapy-induced phenomena. In this lecture, two major issues will be discussed: the value of different conventional and advanced MRI techniques in evaluation of CNS tumours; most common spine tumours not to miss.

Learning Objectives:

1. To understand the normal anatomy and normal variants of the spine, spinal cord and nerve roots.
2. To learn imaging features of benign and malignant tumours of the neurocranium.
3. To become familiar with the imaging features of benign and malignant tumours of the spine.

Spinal emergencies: a look beyond trauma

D. [Ivanova](mailto:dari.ivanova@gmail.com); Varna/BG (dari.ivanova@gmail.com)

Nontraumatic spinal emergencies present a wide range of conditions resulting in acute and/or rapid development of neurological symptoms from the spinal cord. The clinical presentation can be very unspecific, and imaging plays a pivotal role in getting the right diagnosis. The causes of nontraumatic spinal emergencies can roughly be classified into two major groups. The group of intrinsic and non-compressive causes, such as spinal cord ischemia and myelitis, and the group of extrinsic and compressive causes, such as spontaneous extramedullary haemorrhages, spondylodiscitis and epidural abscess, metastatic and malignant entities etc. Most of the cases of compressive spinal cord damage present neurosurgical emergencies and their outcome depend heavily on the timely and correct diagnosis and treatment. MRI is the preferred modality for evaluation of patients with nontraumatic spinal emergencies, and an appropriately tailored and timesaving protocol is always crucial. As an adjunct to MRI, CT and conventional X-ray are very helpful when bone and calcium-containing structures have to be assessed, and ultrasound has a special role in establishing the diagnosis in small children.

Learning Objectives:

1. To learn about the various causes, both compressive and non-compressive, of non-traumatic spinal emergencies.
2. To become familiar with the imaging features of different non-traumatic spinal emergencies.
3. To appreciate the role of different imaging modalities in the diagnosis and differential diagnosis of non-traumatic spinal emergencies and the importance of choosing the right imaging protocol.

A-0833 11:00

Acute aortic syndrome: intimate knowledge through intimate case

G.I. [Kirova-Nedialkova](mailto:gal.kirova@gmail.com); Sofia/BG (gal.kirova@gmail.com)

Acute Aortic Syndrome (AAS) is a highly lethal disease responsible for a wide range of clinical manifestations. In any given patient, the particular outcomes effects are related to the pattern and extent of the aortic wall injury, and, in the long term, the ability of the aorta to compensate circulatory pressure forces. It is therefore essential for radiologists to understand the characteristic appearance of the different aspects of AAS while recognising and reporting relevant imaging features, which would affect the patient's management. Using a case-based approach, the lecture will provide essential knowledge in evaluating, diagnosing, reporting and therapeutic planning of patients with signs and symptoms of the acute aortic syndrome.

Learning Objectives:

1. To focus on the appropriate imaging technique in case of acute chest pain.
2. To guide radiologists through an assessment of the characteristics of acute aortic dissection, penetrating atherosclerotic ulcer and intramural haematoma.
3. To focus on some details that could influence the selection of a therapeutic approach.
4. To foster a critical thinking approach based on specific features of the disease process.

A-0834 11:30

Getting it right: how to report an imaging study before the interventional radiology procedure

R. [Dezman](mailto:rok.dezman@gmail.com); Ljubljana/SI (rok.dezman@gmail.com)

Interventional radiology is a medical speciality which provides minimally invasive image-guided treatment of disease. The rapid development and of the speciality has led to the growth of the number and complexity of the procedures, and a consequent subspecialization of interventional radiologists was a logical result. Diagnostic radiologists, however, need to be aware of interventional radiology procedures, know their basic principles, indications and importance of diagnostic follow-up. This lecture will present the importance of a quality report of imaging studies prior to the interventional procedure. The most common interventional procedures that diagnostic radiologists encounter will be presented with focus emergency interventional procedures. Pearls and pitfalls of reporting prior to the intervention and the follow-up studies will be presented. The importance of follow up imaging of the common elective procedures will also be presented.

Learning Objectives:

1. To present core procedures of interventional radiology.
2. To provide tips for reporting imaging studies before potential interventional radiologic procedures.
3. To appreciate the importance of collaboration between diagnostic radiology and interventional radiology.

Pros & Cons Session

PS 1427

US before CT in the acute abdomen?

A-0835 10:30

Chairperson's introduction

J. [Stoker](mailto:j.stoker@amc.uva.nl); Amsterdam/NL (j.stoker@amc.uva.nl)

Acute abdominal pain can be caused by a myriad of diseases. Clinical history and physical examination have substantial limitations in differentiating between urgent and non-urgent conditions and even more in making an accurate diagnosis. Ultrasound and computed tomography are therefore mainstays in the diagnostic workup of these patients. Magnetic resonance imaging is used to a more limited extent. There are different approaches to using ultrasound and computed tomography, taking advantage of each technique's strength. A conditional diagnostic strategy with ultrasound in all patients and computed tomography only in those with negative or inconclusive ultrasound has been advocated as being the most accurate and effective approach. Others have encouraged widespread use of computed tomography as a one-stop-shop technique or have advocated a diagnostic approach tailored to the individual patient or suspected disease. The pros and cons of different diagnostic strategies will be discussed.

Session Objectives:

1. To be familiar with the role of clinical findings in the management of acute abdomen.
2. To understand the role of imaging in the management of acute abdomen.

A-0836 10:35

A. Acute abdomen: US first!

J.B.C.M. [Puylaert](mailto:dr.jbcmputylaert@wxs.nl); The Hague/NL (dr.jbcmputylaert@wxs.nl)

CT advantages over US in the diagnosis of the acute abdomen: CT is extremely rapid, the actual costs of CT are probably lower than a time-consuming US examination, CT images are not disturbed by gas and bone, while obesity is even an advantage; producing the CT images is not operator-dependent and CT can be reviewed at a later point in time and also from a distance by means of teleradiology. Finally, CT images are easier understood and accepted by clinicians than US images are. US advantages over CT: US has an image definition in the loose range which is much higher. US is more interactive: patient's history, as well as painful area or palpable mass, can be correlated with the US findings. The US shows peristalsis, pulsations and blood flow. The US shows the effects of respiration, Valsalva manoeuvre, gravity and compression with the probe, allowing to assess whether organs as bowel and gallbladder are soft or rigid. US allows easy puncture of intraperitoneal fluid. US in acute abdomen is performed with graded compression. US examination should be symptom-directed and requires communication with the patient. A US finding may lead to a specific question to the patient and v.v. information provided by the patient may lead to a specific US search for pathology. In patients with an acute abdomen, the entire abdomen should be examined, i.e. from the axilla to the groin. The final US report should be integrated with the clinical findings, laboratory data, CT-scan and possible other radiological examinations.

Learning Objectives:

1. To be familiar with the optimal technique and optimal application of US in acute abdomen.
2. To learn the strengths of US in common diseases causing acute abdomen.
3. To understand the arguments why US should be performed as initial imaging technique.

A-0837 11:00

B. Acute abdomen: CT of course!

M. [Laniado](mailto:michael@laniado.de); Dresden/DE (michael@laniado.de)

The acute abdomen is a potentially life-threatening situation that requires an immediate diagnosis of the underlying cause. The optimal CT technique is to use contrast-enhanced CT at least in the portal-venous (PV) phase. If vascular pathologies or haemorrhages are suspected, plain scans and arterial phase imaging are mandatory in addition to the PV phase. Oral contrast is not recommended. Considering the top ten diseases in patients presenting with an acute abdomen (i.e. acute appendicitis, acute cholecystitis, ileus,

Saturday

gynaecological diseases, acute pancreatitis, urological diseases, perforated viscus, carcinoma, diverticulitis), CT is an accurate technique to either confirm or exclude the working diagnosis of the emergency physician. The strengths of CT in common diseases causing acute abdomen is the ease with which indicative findings are shown such as calcified and even uncalcified stones, gas in the abdominal cavity, the bowel wall or mesenteric/hepatic blood vessels, peri-inflammatory tissue stranding and abscesses, the transition point from bowel distension to collapsed bowel, blood vessel occlusion and compromised organ perfusion, etc. CT should be performed as an initial imaging technique in cases of the acute abdomen because of the widespread 7/24 availability in emergency departments, the speed of image acquisition, the robustness even in uncooperative patients, the standardised imaging protocols and low operator dependence, and the reliability in the discussion of findings with referring physicians. In addition, the diagnosis of acute abdomen is increasingly made in elderly patients making radiation exposure a less significant issue. In conclusion, CT should be used first in cases of acute abdomen.

Learning Objectives:

1. To be familiar with the optimal technique and optimal application of CT in acute abdomen.
2. To learn the strengths of CT in common diseases causing acute abdomen.
3. To understand the arguments why CT should be performed as initial imaging technique.

TC 1428

Wrist and foot/ankle sports injuries

Moderators:

L.W. Bancroft; Orlando, FL/US

A.J. Grainger; Leeds/UK

A-0839 10:30

A. Soft tissue wrist injury in the athlete

C.W.A. Pfirrmann; Zurich/CH

Wrist injuries account for 5 % of sports injuries. In the young athlete, fractures are the most common injuries. The hand and wrist are the most common sites for fracture in the young athlete. Physeal injuries are typical overuse injuries in gymnasts. Chronic stress reactions with a widening of the growth plate are seen in the distal radial and less common in the ulnar growth plate. Injuries to the TFCC in the athlete occur in acute trauma and with overuse. TFCC injuries are an important cause for ulnar-sided wrist pain. The differential diagnosis includes ulnar styloid impaction syndrome, ulnar impingement syndrome and tenosynovitis of the extensor carpi ulnaris tendon. Injury to the interosseous ligaments may lead to carpal instability. Chronic injury of the intrinsic or extrinsic ligaments of the wrist may cause ganglion cyst formation.

Learning Objectives:

1. To learn about the patterns of injury seen at the wrist in athletes.
2. To understand the advantages and disadvantages of different modalities for imaging the athlete's wrist.
3. To recognise the imaging appearances of cartilage and ligamentous injury at the wrist.

A-0840 11:00

B. Multimodality imaging of foot and ankle injuries in the athlete

A.J. Grainger; Leeds/UK

Ankle injuries are common in many sports, and the complicated anatomy of the ankle joint can be challenging the reporting radiologist. The ankle joint itself is a synovial hinge joint, but the important movement for ankle function also occurs at the joints of the hind and midfoot which are also susceptible to injury. In addition to conventional radiographs, CT, MRI and ultrasound all have important roles to play in the diagnosis of foot and ankle injuries in the athlete. The ligamentous and tendon structures about the ankle are generally superficial in nature and readily amenable to assessment with ultrasound where assessment can be enhanced due to the dynamic capabilities of the technique. While MRI also demonstrates these structures, it has advantages for assessing deeper joint structures such as the chondral surfaces and bones. The complex 3d anatomy of the foot and ankle means that conventional radiographs can struggle to demonstrate bone injury which means CT also has

an important role to play. This lecture will focus on the use of these imaging modalities for the assessment of acute and chronic ligamentous and tendon injury. Emphasis will be put on the mechanisms of injury and how they determine the resultant patterns of injury and imaging appearances.

Learning Objectives:

1. To appreciate the different and often contributory roles that imaging modalities have in the foot and ankle.
2. To recognise the most common ligamentous and tendon injuries in the ankle.
3. To understand how common patterns of injury relate to the mechanisms involved.

A-0841 11:30

C. Interactive case discussion (Part 1)

C.W.A. Pfirrmann; Zurich/CH

This interactive teaching session will show various cases related to upper extremity sports injuries. Case discussion about soft tissues injuries of the wrist such as TFCC lesions and other wrist and hand injuries in athletes will be done interactively. The differential diagnosis and diagnostic challenges, as well as pitfalls, will be discussed.

Learning Objectives:

1. To become familiar with the techniques available and imaging appearances of wrist athletic injury.
2. To become familiar with the techniques available and imaging appearances of foot and ankle athletic injury.
3. To consolidate the knowledge gained from the session with interactive cases of wrist, foot and ankle athletic injury.

A-0842 11:45

C. Interactive case discussion (Part 2)

A.J. Grainger; Leeds/UK

Cases will be presented with the opportunity for audience response highlighting and consolidating ideas presented in the preceding lecture. Abstract for that Lecture: Ankle injuries are common in many sports, and the complicated anatomy of the ankle joint can be challenging the reporting radiologist. The ankle joint itself is a synovial hinge joint, but the important movement for ankle function also occurs at the joints of the hind and midfoot which are also susceptible to injury. In addition to conventional radiographs, CT, MRI and ultrasound all have important roles to play in the diagnosis of foot and ankle injuries in the athlete. The ligamentous and tendon structures about the ankle are generally superficial in nature and readily amenable to assessment with ultrasound where assessment can be enhanced due to the dynamic capabilities of the technique. While MRI also demonstrates these structures, it has advantages for assessing deeper joint structures such as the chondral surfaces and bones. The complex 3d anatomy of the foot and ankle means that conventional radiographs can struggle to demonstrate bone injury which means CT also has an important role to play. This lecture will focus on the use of these imaging modalities for the assessment of acute and chronic ligamentous and tendon injury. Emphasis will be put on the mechanisms of injury and how they determine the resultant patterns of injury and imaging appearances.

Learning Objectives:

1. To become familiar with the techniques available and imaging appearances of wrist athletic injury.
2. To become familiar with the techniques available and imaging appearances of foot and ankle athletic injury.
3. To consolidate the knowledge gained from the session with interactive cases of wrist, foot and ankle athletic injury.

Contrast enhanced ultrasound in paediatrics: ready for clinical practice?

P.S. Sidhu; London/UK (paulsidhu@btinternet.com)

Ultrasound is gentle and patient-friendly imaging technique, with the ability to image in real time, with superb resolution, and the advantage of being less expensive than other imaging techniques. An ultrasound machine is the ultimate 'plug-and-play' modality. The uniqueness of real-time, safe, portability makes this an ideal solution for imaging in children. The child is reassured by the presence of the examiner explaining, the parent comforting, and the ability

Postgraduate Educational Programme

to move and question all the time aids the child's tolerance of the imaging procedure. Many areas of the body are inaccessible to an ultrasound examination, where other imaging techniques are superior. Nevertheless, when ultrasound visualises an organ, it has the best resolution of all the techniques. This is particularly true for abdominal work in the child, where often the body habitus allows for a detailed examination. Ultrasound has long been the poor relation with respect to contrast examinations, often incorrectly a non-contrast ultrasound in the adult is compared unfavourably with the contrast-enhanced CT. Microbubble ultrasound contrast agents have been in clinical practice in adults for 20 years, most used off-licence in areas of need, revolutionising many aspects of the diagnostic capabilities of an ultrasound examination. The introduction of contrast-enhanced ultrasound (CEUS) has been led by a number of pioneers, recognising the usefulness in aiding diagnosis and management with minimal morbidity to the child. This lecture will outline the pathway of CEUS in children to the sanctioning by the FDA.

Learning Objectives:

1. To learn about the application of CEUS in children.
2. To understand the legal implications of using CEUS off-label in children.
3. To appreciate the potential of combining ultrasound with CEUS in assessing the child.
4. To become familiar with the techniques and applications of CEUS.

Solid pancreatic neoplasms

Moderator:

I. Lupescu; Bucharest/RO

A-0852 12:30

Diagnosis

M. Zins; Paris/FR (mzins@hpsj.fr)

CT remains the standard of reference technique for diagnosis and staging of pancreatic ductal adenocarcinoma (PDA). Most PDA appear as a hypodense mass at pancreatic or portal phase CT with associated dilatation of the bile ducts and/or the pancreatic ducts. Pancreatic MRI is a solving tool that helps in the diagnosis of the isodense lesion at CT and in the assessment of liver metastases. Differential diagnosis of Solid pancreatic tumours includes a Neuroendocrine tumour (NET) of the pancreas. Typical Pancreatic NETs appear as hypervascularized tumours in the arterial phase using CT or MR.

Learning Objectives:

1. To learn about diagnostic imaging findings of solid pancreatic neoplasms.
2. To understand treatment planning.
3. To appreciate differential diagnosis of solid pancreatic neoplasms.

A-0853 13:00

Staging

N. Kartalis; Stockholm/SE (nikolaos.kartalis@me.com)

Pancreatic cancer is a disease with a very dismal prognosis. The 5-year survival is around 5% and has been stable over the last decades. The only potentially curative treatment is surgical resection combined with adjuvant and/or neoadjuvant therapy. However, at diagnosis, less than 20% of patients have a resectable tumour, while the rest have tumours that are locally advanced and/or have distant metastases. In order to improve survival, there is a need to increase the number of patients that undergo surgery. However, for the surgical removal to be meaningful, the goal is to achieve complete macroscopic and microscopic removal of a tumour (R0-resection). For the identification of patients who will benefit from surgery, the so-called "resectability status" was developed. It is based on the presence and extent of tumour contact with the major peripancreatic vessels such as portomesenteric axis (PV/SMV), hepatic artery, celiac artery and superior mesenteric artery. Depending on the presence and degree of the circumferential tumour-vessel contact the tumours are classified in one of the three categories: resectable, borderline resectable and unresectable. The criteria of the various existing classification systems will be discussed and their differences outlined. Furthermore, potential areas of improvement will be analysed and, finally, the role of CT, MRI and PET-CT in the evaluation of these patients will be presented.

Learning Objectives:

1. To learn how to stage pancreatic adenocarcinoma.
2. To understand resectability criteria.
3. To appreciate the role of imaging in treatment planning.

EDiR Session

EDiR

EDiR: an instrument to develop excellence in your career

A-0848 12:15

Chairperson's introduction

L. Oleaga Zufiria; Barcelona/ES (lauraoleaga@gmail.com)

The European Diploma in Radiology (EDiR) examination is designed to test knowledge, skills and competence in anatomy, pathophysiology, imaging procedures, physics and management in general radiology. The exam is divided into three parts: a knowledge test with Multiple Response Questions (MRQs) and Short Cases (SCs) and the Clinically Oriented Reasoning Evaluation (CORE) where problem-solving skills are tested. The EDiR teaser that will be presented during the session includes examples of the three different parts of the exam simulating the real exam. The aim is to get the possible candidates to become familiar with the structure and degree of difficulty of the exam, including some tips and tricks to succeed.

Session Objectives:

1. To present the structure of the EDiR examination.
2. To describe how to prepare for the EDiR examination and the resources available.
3. To detail the CORE examination.
4. To learn the importance of structured reporting for the CORE examination.

Author Disclosure:

L. Oleaga Zufiria: Consultant; Telemedicine Clinic.

A-0849 12:20

EDiR teaser

L. Oleaga Zufiria; Barcelona/ES (lauraoleaga@gmail.com)

Objective structured Clinically Oriented Reasoning Evaluation (CORE) examination is a standard method of testing the knowledge in clinical core competencies. Web-based CORE examination represents a simulation of radiological practice in which candidates face a complete case that must be resolved in each of the areas of sub-specialisation as if they were in a real situation. It is crucial for EDiR candidates to be aware of the structure of the exam, establishing a method of reading the images in a structured way. A broad spectrum of educational materials and structured reporting products are readily available online for trainees to prepare for CORE exam. The first step, in the CORE examination, is to detect the disease. It is important to systematically review the whole picture to avoid perception errors, including "satisfaction of search errors". Next step is to create a list of the most relevant findings; it is essential to be consistent, starting from those that respond to the clinical question. The third step is to prepare a preliminary differential diagnosis, and suggest, if necessary, the most appropriate imaging modality to further study the patient, and finally define the most likely diagnosis. The practice of making structured reports with a specific script can be perfectly combined with the methodology needed to make a correct CORE exam and succeed. The systematic use of structured reports helps in the standardisation; it is a useful tool that serves as a guide for candidates facing the CORE exam.

Learning Objectives:

1. To review some practical cases: multiple response questions, short cases and CORE case.
2. To learn new online resources for the examination.
3. To answer any questions from the audience.

Author Disclosure:

L. Oleaga Zufiria: Consultant; Telemedicine Clinic.

Arthritis: an imaging approach

F. Kainberger; Vienna/AT (franz.kainberger@meduniwien.ac.at)

The current diagnostic concept is to embed imaging in the assessment systems in rheumatology. This means that imaging should contribute to the detection of early arthritis and to the quantification of abnormalities with prognostic impact. With the combinations of joint pain, laboratory indicators of inflammation and imaging features of tendovaginitis, joint effusion and/or bone marrow inflammation subforms of early arthritis may be defined. Synovitis is today regarded as part of a systemic autoimmune disease, and certain phenotypes can be classified with relation to the fibroblastic response and different interleukin expression leading to a destructive-erosive, a sclerotic-proliferative or a mixed imaging appearance. With US and radiography, followed by MRI, the patterns of arthritis and their differentiation from normal anatomic structures can be assessed and displayed in dedicated structured reporting templates. The differential diagnosis of autoimmune-mediated arthritis includes crystal-induced arthropathies, erosive osteoarthritis, posttraumatic and other forms of secondary joint inflammation.

Learning Objectives:

1. To become familiar with the current diagnostic concepts in the imaging of arthritis.
2. To understand the pathology of arthritis and its imaging phenotypes.
3. To appreciate the value of radiography, ultrasound and MRI.

A. Diagnosis and management of common ductal and nipple-areolar complex (NAC) abnormalities

S. Perez Rodrigo; Madrid/ES (drasilviap@gmail.com)

The nipple-areolar complex lesions deserve particular consideration. They are a group of entities that arise in this specific area. It may be affected by normal variations in embryologic development and breast maturation. Besides, abnormal processes can be found, and benign and malignant pathology can be seen in this region. Eczema, mastitis, abscesses, adenomas, papillomas and duct ectasia should be considered as benign processes. On the opposite, Paget disease, in situ carcinoma, invasive carcinoma and lymphoma should be included as malignant processes. The radiologist should be aware of the clinical manifestations of these entities (inversion, retraction, palpable mass, nipple discharge, skin changes etc.). We should also keep in mind the different radiological findings and their peculiarities. We should be aware of the different imaging techniques and which of them is better for reaching a specific diagnosis. Mammography, ultrasound, galactography, ductoscopy and MRI can be useful in the diagnosis of these lesions. A multimodal diagnosis is required, and a multidisciplinary approach is recommended to correct treatment.

Learning Objectives:

1. To learn about NAC and ductal anatomy, and pathology.
2. To become familiar with the practical workflow in everyday clinical practice.

B. Techniques, artefacts and pitfalls in breast MRI

R.M. Trimboli; Milan/IT (trimboli.rm@gmail.com)

Over the last three decades, magnetic resonance imaging (MRI) has dramatically entered the clinical field of detection and management of breast cancer (BC). Thanks to the introduction of contrast-enhanced (CE) sequences it gained very high sensitivity and intrinsic multiparametric nature. A modern, robust protocol is essentially composed of an unenhanced T2-weighted sequence; T1-weighted sequences acquired before and after intravenous administration of gadolinium-based contrast agent (GBCA) at a dose of 0.1 mmol/kg/body weight; and diffusion-weighted imaging (DWI). A fat suppression with fat saturation, inversion recovery or alternatively, Dixon method, should be added to T1w and/or T2w scans. Non-uniform magnetic field and patient motion may reduce image quality potentially rendering an image or study non-diagnostic. Artefacts in breast MRI may be grouped under two broad categories: patient-related such as positioning, motion, and susceptibility and technical artefacts such as wraparound, chemical shift, and misregistration. Radiologists should be aware of and identify common artefacts to minimise potential negative effects on image interpretation and patient experience. Close attention must be played to injection of contrast material, the timing of the examination, lymph node evaluation, extra-mammary findings and kinetic assessment for avoiding pitfalls that can make interpretation of breast MR images challenging and lead to misdiagnosis. Recognising pitfalls associated with breast MR imaging is necessary for appropriate and accurate interpretation. Finally, empathic patient management has been reported as the most important factor in the overall quality of the examination.

Learning Objectives:

1. To describe the basic techniques for breast MRI (including DWI).
2. To illustrate patient-related and technical artefacts, and pitfalls in breast MR.

Dual-energy CT of the abdomen: the time is now

Moderator:

J. Sosna; Jerusalem/IL

A-0857 14:00

A. Basic principles and different approaches

L.S. [Guimaraes](mailto:luis.s.guimaraes@gmail.com); Toronto, ON/CA

Dual-energy CT (DECT) refers to the use of CT data from two different energy spectra for differentiating and classifying tissue composition, in addition to displaying anatomy and pathology. DECT data can be obtained using various hardware solutions (dual source, fast kVp switching, 2-rotation fast-kV-mA switch, dual layer detector and split filter). An explanation of how each of these solutions works, as well as the advantages and disadvantages of each, will be presented. Abdominal DECT has as main advantages the ability to identify/quantify certain materials (iodine, calcium, urate, etc.), as well as to increase the possibility of performing low kV imaging in a wider range of patients, which in turn is associated with an increased conspicuity of enhancing structures and lesions. The background and reasons for each of these advantages will be reviewed. Several challenges remain for full implementation of Dual Energy CT in routine clinical abdominal practices. These challenges, including the absence of standardized post-processing (which may be time-consuming), lack of well-defined advantageous routine applications and limitations in terms of patient size/radiation dose will be discussed.

Learning Objectives:

1. To learn about the types of dual-energy scanners and principles of dual-energy CT.
2. To understand issues of radiation dose and image quality in comparison with single-energy CT.
3. To appreciate the possible advantages of this technology with its many post-processing applications.

A-0858 14:30

B. Applications for genitourinary system

H. [Ringl](mailto:helmut.ringl@meduniwien.ac.at); Vienna/AT

Dual-energy CT is increasingly becoming an important diagnostic tool for the non-invasive assessment of the genitourinary system, with a wide range of applications: The use of dual-energy CT with optimised spit-bolus protocols enables considerable dose savings by eliminating two scan phases. However, using virtual non-contrast images, this protocol provides the same information as an unenhanced, an arterial, a venous, and a urographic phase. Virtual non-contrast images and iodine maps enable better characterisation of renal cysts with dense content, which often pose a diagnostic dilemma in single-energy CT, and which might require MRI or CT follow-up examinations. The reconstruction of low kV mono-energetic images results in a higher iodine contrast, and, therefore, in better lesion conspicuity in the kidneys and the bladder wall. Dual-energy CT enables the quantification of iodine-uptake, and may, therefore, be used for therapy monitoring of cancer of the urinary tract, and the material decomposition algorithms of dual-energy CT are able to discriminate urate from non-urate stones in the case of nephrolithiasis in the clinical routine, making this method a game-changer in therapy.

Learning Objectives:

1. To learn about the role of dual-energy CT in the genitourinary system.
2. To understand the value of determination of renal stone composition with dual-energy CT.
3. To appreciate the ability of dual-energy CT to exactly quantify the iodine uptake in renal lesions.

H. Ringl: Research/Grant Support; Siemens Healthcare.

A-0859 15:00

C. Applications for abdominal organs

M. [Karcaaltincaba](mailto:karcaaltincaba@yahoo.com); Ankara/TR

Dual-energy CT (DECT) is increasingly used for abdominal applications. DECT can be performed by dual-source CT, fast kVp switching and dual-layer detector CT. The major advantage of DECT is the availability of virtual non-contrast (water) images in every patient. Spectral CT images can allow diagnosis of a low amount of fat (normally invisible on CT) within lesions similar to in-out of phase T1-weighted MR images. DECT can allow diagnosis of calcification or haemorrhage within lesions encountered during routine abdominal CT. Low kV images obtained by DECT is more sensitive to hepatic

and pancreas hypervascular lesions compared to standard kV images. DECT can also be helpful in the differentiation of colonic polyp/mass from stool detected during routine abdominal CT. In the future, all CT scanners will be most likely produced by DECT capability.

Learning Objectives:

1. To learn about the current applications of dual-energy CT in evaluating the abdominal viscera.
2. To understand the role of dual-energy CT for characterisation of incidental lesions discovered during routine abdominal CT.
3. To appreciate how dual-energy CT increases sensitivity for detecting both hypervascular and hypovascular liver and pancreatic lesions.

Radiography research: where should we be in 2030? (part 1)

L.A. [Rainford](mailto:louise.rainford@ucd.ie); Dublin/IE

The scope of medical imaging and its many sub-specialities has grown substantially over the past two decades. How medical imaging is employed by medical specialities, outside radiology has also altered the clinical use of imaging across medical centres and primary care settings internationally. Healthcare systems are developing to meet the changing needs of patients. There is a need for an evidence base of practice across all medical imaging activity to ensure optimal use. As multiple medical specialities, e.g. cardiology, rheumatology, orthopaedics, emergency medicine clinicians, to name a few, are involved in imaging on a daily basis, the scope of potential research activity is immense. Additionally, there is an increased use by other healthcare professionals such as physiotherapy and midwifery. An overview of this changing landscape will be discussed.

Learning Objectives:

1. To explore the changing landscape in medical imaging and how this might influence our research.
2. To consider the future radiography profession, what it might look like and where it might lead our research.
3. To propose some research targets for our profession to work towards over the next decade.

A-0861 14:08

Radiography research: where should we be in 2030? (part 2)

G. [Paulo](mailto:graciano@estescoimbra.pt); Coimbra/PT

There is no doubt that the only way to develop a professional field of knowledge is through research and Radiography is even more dependent on it, due to the exponential technological development of its field. In fact, we need to stop, watch and listen, to understand where these new technological roads will take us. One thing is certain: our profession will not be the same in 2030 and universities demonstrate some difficulties in anticipating what the future will bring, to be able to adapt the education models to incorporate the changes arising. Technology is taking over most of the decisions we have to make in our daily clinical practice, and therefore we have an obligation to, through research, develop new competencies in the fields where technology will never take over our role: It's "The human touch".Radiographers will have to understand that patient safety (understood in a broad concept) and communication skills are the main pillars of our profession and developing them is the only way to keep our profession alive. Therefore, there is an urgent need to bring together professional societies and universities on a global summit, to establish an international strategic research agenda for radiography, as an instrument to develop our profession, anticipating the impact of the new technological advancements in our field of knowledge.

Learning Objectives:

1. To explore the changing landscape in medical imaging and how this might influence our research.
2. To consider the future radiography profession, what it might look like and where it might lead our research.
3. To propose some research targets for our profession to work towards over the next decade.

Radiography research: where should we be in 2030? (part 3)

H. [Precht](#); *Odense/DK (hepr@ucl.dk)*

To support radiography research growth in the future different several elements require consideration. First radiography research should align with modern hospital structures and practices, with a focus on multidisciplinary cooperation to produce new knowledge. Radiography research needs to broad in activity to include, for example, cardiology, forensic medicine, midwifery, machine learning, robot technology, in addition to traditional radiography research subjects. Universities and colleges with Radiography training programmes need to support and advance research activity. Realistic targets could be that Radiography programmes are involved in research work within a specific time-frame, over the next five years to develop research networks. The OPTIMAX model demonstrates a good model for collaborative research; this can be developed nationally between colleges or on a larger scale across colleges in different countries. Staff research portfolios are important and should be public, to highlight the activity and cooperation within our profession. It is important to note that promoting radiography research is to the benefit of patients and is essential to maintain high standards of patient management.

Learning Objectives:

1. To explore the changing landscape in medical imaging and how this might influence our research.
2. To consider the future radiography profession, what it might look like and where it might lead our research.
3. To propose some research targets for our profession to work towards over the next decade.

A-0863 14:24

The clinical research radiographer: essential for our profession or facilitating the research of others?

B. [Snaith](#); *Wakefield/UK (bev.snaith@midyorks.nhs.uk)*

Radiography is developing a research community, supporting the profession to gain capability in research skills. The majority of this activity is taking place in academia, yet research is required to develop evidence-based practice. Radiographers are supporting the delivery of research projects through clinical activity, recruitment and support, but are yet to develop clinical independence in research. This presentation will consider the challenges and opportunities for the development of clinical researcher roles, skills and activities. Using case studies examples from practice will explore the challenges and identify future strategies to support personal and professional development.

Learning Objectives:

1. To understand the scope of a research radiographer in clinical practice.
2. To learn how the role can improve clinical research capacity and capability and clinical-academic collaboration.
3. To appreciate the difference between research facilitation and the radiographer as a clinical researcher.

A-0864 14:42

Turning your research idea into reality: opportunities for European funding

P. [Zolda](#); *Vienna/AT (pamela.zolda@myes.org)*

Many national funding schemes do not support a cross-border approach, which limits the scientific collaboration of European research groups. Thus researchers rely on European Union funding sources as provided by Horizon 2020, the largest EU research and innovation programme. However, the programme has become highly competitive, and often even high-quality project proposals cannot be funded. Additionally, successful projects are facing the challenge of navigating through the rules of large EU projects while simultaneously carrying out innovative research with partners from across Europe. Consequently, multidisciplinary and multinational consortia require professional support for proposal preparation and project management. The European Institute for Biomedical Imaging Research, EIBIR, is a non-profit organisation founded by the European Society of Radiology and supports researchers and industry partners in the coordination of biomedical imaging research. EIBIR offers expert advice, professional project management and coordination, as well as dissemination services for international collaborative research projects. The EIBIR services also include advice on funding opportunities and proposal writing support by an experienced team with knowledge of the European Commission's requirements. Through EIBIR's large landscape of network members, shareholder organisations, industry partners and media contacts the conducted research is widely and rapidly communicated. EIBIR is currently a partner and/or coordinator of seven Horizon 2020 projects and relieves researchers of the administrative burden, allowing them to focus on the scientific aspects and thereby ensuring the best project outcome. All services are free of charge for active EIBIR network members and can be used for a moderate annual fee.

Learning Objectives:

1. To learn about EIBIR and its services for researchers.
2. To understand project management and dissemination activities of European projects.
3. To appreciate how EIBIR can support your research project.

A-0865 15:00

Research is nothing without effective dissemination

F. [Zarb](#); *Msida/MT (francis.zarb@um.edu.mt)*

Research is the contribution to the body of knowledge in a particular area/expertise. Research findings should be disseminated, shared and made available to fellow professionals and others for these findings to have an overall beneficial effect. There are a number of ways for disseminating research findings such as through peer-reviewed publication, conference presentations, posters etc. This presentation aims to highlight the importance of research finding dissemination for both the individual researcher/practitioner and to the clinical/academic departments and countries they represent. The dissemination process may not always seem easy and straightforward, requiring a commitment and perseverance in the work it entails. However, the benefits and satisfaction associated with research dissemination outweigh the hard work involved.

Learning Objectives:

1. To explore the importance of dissemination at the local, national and international level.
2. To explore the importance of publishing for clinical and academic departments.
3. To consider the benefits and limitations of publishing in different journal formats.

Getting the balance right: radiation risk and imaging benefit in paediatric procedures

A-0871 14:00

Chairperson's introduction

C. [Owens](#); *London/UK (owensc@gosh.nhs.uk)*

This important session takes a multidisciplinary approach on team efforts to facilitate the best use of expensive medical imaging equipment. We will attempt to ask and answer questions about our role in helping to optimise CT technology for best use in children, including our role as radiologists in dose reduction and adaptation to the use of lower dose techniques and post-processing methods which assist with noise reduction.

Session Objectives:

1. To learn about risk and benefits in imaging children.
2. To understand the importance of an integrated approach from radiology and medical physics.
3. To appreciate a multidisciplinary approach to imaging optimisation and radiation protection.

A-0872 14:05

Guidelines for the use of conventional radiographs in children and adolescents

R. [Seuri](#); *Helsinki/FI (raija.seuri@hus.fi)*

Conventional radiography, usually nowadays either CR or DR is the most often used medical imaging modality. The rapid development of other modalities - some more sensitive, some without the burden of ionizing radiation - has changed the use of conventional radiography. Also, the wide postprocessing possibilities and the even more sensitive detectors have challenged our knowledge and practise in optimisation. Evidence-based information on the use of radiological modalities and different examinations, also conventional radiography, is widely available. But even when following the most recent literature we must keep in mind that adult rules do not always apply to paediatrics. The digital imaging techniques of computed radiography (CR) and direct radiography (DR) have changed optimization considerably. They give the possibility of diagnostic imaging with very low patient dose, but at the same time the dose is not any more visually seen in the image. This has created the problem of possible "dose creep". Even if the dose is transferred to the image

display, systematic dose evaluations are needed to verify and maintain the level of dose optimization. The use of pre-set protocols is usually not possible in paediatric imaging. Deep understanding of the postprocessing systems is not easily available during the optimisation process. The key point is close cooperation between professionals. Wide variation in imaging practices and the parameters used have been noticed in Europe. Lack of written guidelines means variation in both image quality and patient exposure.

Learning Objectives:

1. To learn about the current developments in conventional radiography.
2. To understand the strengths and weaknesses of each technique.

A-0873 14:25

Computed tomography: are we doing enough?

E. Castellano; London/UK (elly.castellano@rmh.nhs.uk)

Optimal CT imaging of children requires the concerted effort of manufacturers, radiologists, radiographers and physicists. Only by working together as a multidisciplinary team can images of adequate quality be produced at appropriate radiation doses. Recent developments in CT scanner technology that particularly benefit children, such as lower tube voltages, faster scanning, improved detector design and iterative reconstruction, are reviewed in this talk. The impact of technology on patient dose can be determined using dose management systems. This lecture considers how such a system, in combination with the PiDRL guidelines, can become a valuable tool for benchmarking and monitoring evolving clinical practice. Notwithstanding, dose indicators such as dose-length-product can be misleading when scanning children, so the need for better radiation risk estimates remains; recent advances in CT dosimetry will also be considered. The role of the radiologist is vital in maintaining the balance between radiation dose and image quality. Radiation dose reduction without regard to image quality poses a greater clinical risk than a radiation risk and may precipitate a backlash from clinicians. This lecture suggests ways in which the radiologist can work with radiographers and physicists to define image quality requirements and thus complete the optimisation loop.

Learning Objectives:

1. To learn about the current status of CT systems.
2. To understand the strengths and weaknesses of each CT type.
3. To appreciate the importance of dose optimisation and an active physics programme.

A-0874 14:45

Dose reduction strategies in paediatric PET/CT and PET/MR examinations

J. Schäfer; Tübingen/DE (juergen.schafer@med.uni-tuebingen.de)

High cumulative effective doses (ED) by repetitive PET/CT have been described ranging from 6-400 mSv, whereas the CT proportion is up to 80 % of the total dose. Usually, the administered tracer dose is adapted to body weight according to published recommendation (e.g., dosage card of the EANM), and therefore relatively standardised. However, the kind of CT acquisition is quite variable reaching from CT used only for attenuation correction (AC) over a reduced dose CT for anatomical allocation to whole-body contrast-enhanced diagnostic CT plus an additional CT for AC which reveals the highest radiation of all variants. According to these purposes (also as a combination), the scan-parameters must be optimised using automatic exposure control (AEC). Depending on the patient size and the CT mode, AEC achieves appropriate dose reduction up to 40% by maintaining image quality. Overall in comparison to PET/CT, PET/MRI has shown to be equivalent concerning the PET component. PET/MRI allows for a reduction in radiation dose by replacing CT with MRI making it particularly suitable for pediatric applications. A dose reduction of up to 80% has been demonstrated in individual cases. Moreover, also the administered dose of the PET tracer can be reduced due to both, the higher sensitivity of PET detectors in PET/MR scanners and the longer PET data acquisition times compared to PET/CT. Thus, ED of PET/MR below two mSv are realistic if a local PET/MR is performed (e.g., in inflammatory bowel disease) further reduction is possible.

Learning Objectives:

1. To understand the real doses involved in PET/CT and PET/MRI.
2. To appreciate relative risks of multiple examinations and highlight benefits of the different imaging protocols.

A-0875 15:05

Radiation safety in interventional procedures in children

C. Granata; Genoa/IT

Interventional Radiology (IR) encompasses a wide range of techniques, including both cardiac and non-cardiac procedures. During the last decade, there has been a significant increase in IR procedures in children, many of

them delivering high radiation doses, without any other treatment option. The few published studies in children mostly concern single centre experience and confirm the very high variation of doses among different centres due to child size, complexity of conditions, technique adopted, experience of medical staff, and available equipment. Furthermore, the underlying disease may require repeated procedures causing a higher cumulative dose. Diagnostic Reference Levels (DRLs) are excellent tools for technique optimisation. Nevertheless, due to the reasons detailed above, national DRLs have not been established in any European country for any IR procedure in children so far. Therefore, a cohesive effort is needed with the initial aim to establish local DRLs at least in the less complex procedures, characterised by a smaller number of variables. Subsequently, local DRLs from different centres should be compared and analysed to better understand the reasons of the large differences in administered doses and to be able to decide if national or even European DRLs for IR procedures in children are feasible and appropriate.

Learning Objectives:

1. To learn about current practices in interventional radiology in children.
2. To understand the range of doses across centres.
3. To appreciate the importance of a cohesive approach.

Cardiac imaging in structural heart disease

A-0876 14:00

Chairperson's introduction

L. Natale; Rome/IT (luigi.natale@unicatt.it)

Structural heart diseases refer to non-coronary cardiovascular processes and related interventions. The term was first used in 1999 Transcatheter Cardiovascular Therapeutics meeting. A huge amount of efforts have been done in last two decades, embracing recognition of disease, the underlying pathophysiologic mechanisms, the developments of imaging techniques and catheter-based techniques and devices, resulting in improvement of diagnosis and treatment of structural heart diseases. Main examples of structural heart diseases are congenital (ASD, PFO, VSD, PDA), thrombi source assessment and treatment (left atrial appendage and ventricular aneurysm closure), valvular diseases and hypertrophic obstructive cardiomyopathy. Three final considerations are mandatory: first, the need for a multidisciplinary time, due to the different expertise needed; second, the volume of procedures, that is increasing but is still much lower than coronary interventions; third, the huge technical differences in procedures with consequent further subspecialties needs.

Session Objectives:

1. To become familiar with the concept of "structural" heart disease in modern cardiovascular medicine.
2. To get an overview about the minimally invasive treatment possibilities in structural heart diseases.
3. To learn about the requirements and possibilities of modern cardiac imaging in structural heart diseases.

A-0877 14:05

A. CT-guided planning of minimally invasive procedures

R. Salgado; Antwerp/BE (rodrigo.salgado@uza.be)

Transcatheter valve replacement and repair techniques have recently enjoyed significant widespread clinical attention, offering new therapeutic options for certain patient populations with functional aortic and mitral valve disease which were previously unable to undergo surgical valve replacement. While most of the attention has focused on the treatment of severe aortic valve stenosis, intensive research is currently underway investigating the possibilities of transcatheter mitral valve repair and even replacement. While initial trials relied on echocardiography for pre-procedural assessment of the aortic root components, CT has rapidly become the imaging modality of choice for a correct anatomical evaluation. The intrinsic 3D nature of CT offers unparalleled non-invasive access to investigated anatomy, delivering the needed accurate measurements to further optimise the eligibility for and the choice of transcatheter valve best suited for a specific patient. During this lecture, we will further highlight the role of CT in this pre-procedural setting, with attention to the relevant anatomy, the scan protocol and the necessary information that has to be delivered in order to achieve maximal procedural success.

Learning Objectives:

1. To learn about the requirements prior to minimally invasive valvular repair and other diseases.
2. To outline the most appropriate imaging protocols.
3. To gain insights into future developments in devices and minimally invasive treatments.

A-0878 14:28

B. Defining the optimal time to treat valvular heart disease: role of MR

J. [Mascherbauer](#); Vienna/AT

"no abstract submitted"

Learning Objectives:

1. To outline the clinical problem and to approach treatment decision-making in valvular heart disease.
2. To become familiar with the MR derived imaging biomarkers in valvular heart disease.
3. To discuss the possible future role of MR in outcome prediction in valvular heart disease.

A-0879 14:51

C. Follow-up after minimally invasive valvular repair

H. [Alkadhi](#); Zurich/CH (hatem.alkadhi@usz.ch)

Minimally invasive valvular repair has become a well-established alternative for patients with severe valve disease being considered at high or prohibitive surgical risk. Several devices are currently under preclinical and clinical evaluation. In this lecture, the various devices are being described, along with postinterventional imaging of the devices and their complications. Main challenges and future perspectives on this emerging field are discussed.

Learning Objectives:

1. To become familiar with the appropriate imaging technique after minimally invasive valvular repair.
2. To learn about the different devices currently used in treatment of structural heart disease.
3. To become familiar with the normal outcomes and most common procedural complications.

15:14

SF 15a

Everything you always wanted to know about metabolic bone disease (but were afraid to ask)

A-0880 14:00

Chairperson's introduction

A. [Bazzocchi](#); Bologna/IT (abazzo@inwind.it)

Despite appearances, bone is a very active organ. The metabolic life of bone is frantic and fully involved in human physiology and pathophysiological processes. Cross-talks (interactions) between bone and other organs (and between bone and other MSK system tissues) allow for energy exchanges and modulation of functions. Bony structure and composition are dynamically changed, and pathological processes can result in bone healing or lead to permanent alteration and eventually dysfunction and failure. Radiologists are not always completely aware of the importance of bone metabolic conditions.

Session Objectives:

1. To become familiar and get answers to the most frequently asked questions regarding findings that could be interpreted or misinterpreted as metabolic bone disease, with a special emphasis on bone marrow patterns.
2. To become familiar with DXA-based body composition assessment and understand the potential applications of recently developed DXA-based software.
3. To become familiar with the typical and atypical features of insufficiency fractures.
4. To learn about texture analysis and its application to bone architecture assessment.

A-0881 14:05

Could "that" be metabolic?

M.P. [Aparisi Gomez](#); Valencia/ES (pilucaparis@yahoo.es)

The bone marrow is one of the largest organs in the body. Its composition varies physiologically through life, in the context of normal maturation (red to yellow conversion) and also in response to situations of need (yellow to red conversion). The bone marrow is present in the background of every MR examination performed, and sometimes its appearances can pose a challenge to interpretation. In addition to this, opportunistic diagnosis of pathology showing as changes in the bone marrow should be taken advantage of by every radiologist. In this lecture, we will start by reviewing the histology of the normal bone marrow and its expected age-related appearances. We will review the causes that trigger changes in the appearances of the bone marrow, in a first instance addressing the most common physiological and benign situations, with a rationalisation for these. We will also review the pathological conditions involving the bone marrow, and resulting imaging signs. A special emphasis will be made on changes triggered by metabolic diseases. The second half of the lecture will focus on establishing the ideal structured way to interpret appearances of bone marrow on MRI, with a review of the different additional imaging tools, mainly MRI-based, to orientate diagnosis. The radiologist should develop a rational, structured way to assess bone marrow appearances on MRI, and become familiar with bone marrow patterns and their significance, in the context of known pathology but also to raise awareness on the possibility of underlying processes and orientate diagnosis.

Learning Objectives:

1. To learn about the variety of different physiological and pathological bone marrow patterns.
2. To understand the pathophysiological mechanisms behind changes in the bone marrow and how they translate into imaging findings.
3. To become familiar with the most frequently asked questions regarding findings that could be interpreted or misinterpreted as metabolic bone disease.

A-0882 14:23

Unrevealed fractures: from missed diagnosis to opportunistic screening

C.R. [Krestan](#); Vienna/AT (christian.krestan@meduniwien.ac.at)

This lecture focuses on occurrence, imaging and differential diagnosis of insufficiency fractures. These fractures occur when normal stress is exerted on weakened bone. The morphologic features and the most common sites of insufficiency fractures and their clinical implications are discussed. A large proportion (up to 1/3 or more) of fractures are asymptomatic and do not come to clinical attention. There is a chance for opportunistic identification of insufficiency fractures including vertebral fractures from various imaging modalities including radiographs, computed tomography, magnetic resonance imaging, and PET- scans performed for other clinical indications. Fractures will often be missed on axial scans; thus midline sagittal reformatted images from computed tomography which include the spine in the field of view have the greatest potential for opportunistic detection. It may be a challenge for the radiologist to detect and diagnose insufficiency fractures as well as to differentiate them from malignant fractures. The different modalities have a broad range of sensitivity in detecting insufficiency fractures. Dual-energy Multidetector CT can depict bone marrow oedema and thus has the ability to differentiate acute from old fractures at different body sites. PET-CT and PET-MRI with hybrid-scanners combine different radiological modalities with the properties of tracers. Hybrid imaging has been the upcoming modality for the differentiation of benign from malignant fractures. The lecture also focuses on the importance of the accurate reporting of fractures to avoid underreporting, as vertebral fractures and fractures at other sites are powerful predictors of future fracture risk.

Learning Objectives:

1. To become familiar with the typical features of insufficiency fractures.
2. To understand why some types of insufficiency fractures can be missed.
3. To appreciate the value of opportunistic diagnosis and the potential implications on patient management.

A-0883 14:41

DXA: a much more powerful imaging tool than you thought

C. [Messina](#); Milan/IT (carmelomex@gmail.com)

Dual-energy X-ray absorptiometry (DXA) is the mainstay in clinical practice to evaluate bone mineral density (BMD) in patients with suspected osteoporosis. Nevertheless, DXA can be now considered a multi-parametric tool, being able to offer several other diagnostic possibilities. Among these, one of the most promising is the use of DXA body composition (BC), a technique that is able to quickly assess BC parameters such as lean and fat mass, with very low radiation dose. There is, therefore, a growing interest in DXA BC for the emerging aspects of sarcopenia and osteosarcopenia. DXA can be used for the diagnosis of prevalent and incident vertebral fractures using vertebral morphometry, which showed to be comparable to classic radiographic morphometry analysis. In addition, DXA morphometry is computer-assisted, which helps the radiologist to better fracture detection. The lecture will also

cover the clinical utility of Trabecular Bone Score (TBS), a textural index based on grey-level variations that can be obtained from the lumbar spine DXA. Studies in postmenopausal women showed that TBS is associated with vertebral, hip and major osteoporotic fracture risk, but the software also has limitations that can limit its applicability.

Learning Objectives:

1. To learn about vertebral morphometry with DXA.
2. To become familiar with DXA-based body composition.
3. To understand the applicability of a recently developed DXA-based software, the "trabecular bone score" (TBS).
4. To understand the technical principles and the clinical utility of hip structural analysis (HSA), which uses DXA data to derive measurements of bone geometric properties at the proximal femur.

The bone naked: texture analysis

C.M. [Phan](mailto:phan@sat.aphp.fr); Paris/FR (catherine.phan@sat.aphp.fr)

Texture analysis is a technique that allows quantification of the spatial arrangement of pixel intensities by using statistical evaluation of image intensities in a region of interest and can be performed with different imaging modalities. Texture analysis is able to detect distinct quantitative differences in tissues, which may not be depicted using a pure visual assessment alone. Texture analysis is an image processing that extracts texture descriptors from an image thereby allowing the mathematic detection of subtle CT attenuation or MRI signal intensity changes amongst image pixels. Most studies have used CT texture analysis in patients with neoplasms to differentiate benign from malignant lesions, to assess tumour grade, and to predict survival. In vivo bone texture analysis is a new application for the assessment of skeletal integrity in different diseases (primary or secondary osteoporosis, haematological diseases). The current features of texture analysis will be reviewed as well as the limitations of this imaging processing.

Learning Objectives:

1. To learn about texture analysis and its application to bone architecture analysis.
2. To understand how texture analysis could be used in differentiating control subjects with normal bone density from patients with osteoporosis and patients with hematological diseases such as multiple myeloma.
3. To appreciate the limitations of this imaging processing.

Imaging in Meniere's disease: what to believe and how to interpret

A-0885 14:00

Chairperson's introduction

J.W. [Casselman](mailto:casselman@azsintjan.be); Bruges/BE (jan.casselman@azsintjan.be)

For many years Meniere's disease remained a clinical diagnosis which could not be confirmed by imaging. The role of imaging was to exclude other causes like VIIIth nerve schwannoma, labyrinthitis etc. The underlying mechanism of endolymphatic hydrops was already confirmed by Harold Schuknecht on histologic sections (1965, guinea pigs). The imaging diagnosis of endolymphatic hydrops only became possible with the advent of better MR systems/techniques and after it was discovered that there was a selective enhancement of the perilymph spaces after intratympanic or intravenous gadolinium administration. Since then more and more is discovered, and we already realise that endolymphatic hydrops is not only found in patients with Meniere's disease but can be found in many other patients (e.g. BPPV, intralabyrinthine schwannomas, liquor hypotension etc.). During this Special Focus Session, the pathophysiology and clinical presentation and findings in Meniere patients will be discussed explaining why and in which patients imaging is needed. The therapeutic options will also be discussed and especially the possibilities once the imaging diagnosis is available. The state of the art imaging techniques will be shown, and the correlation of the imaging findings and clinical presentation will be presented. The today available MR classifications for endolymphatic hydrops will also be discussed. Many other lesions can mimic Meniere's disease, and many other causes of endolymphatic hydrops exist, these will also be illustrated. Finally, it is important to understand

what the clinicians can do with this information and how it will or already has changed the treatment of Meniere patients.

Session Objectives:

1. To learn about clinical presentation and treatment strategies in Meniere's disease.
2. To discuss state-of-the-art imaging for the evaluation of endolymphatic hydrops.
3. To understand how to interpret MR hydrops imaging.

Meniere's disease: the clinician's perspective

A. [Zarowski](mailto:zarowski@me.com); Antwerp/BE (andrzej.zarowski@me.com)

Menière's Disease (MD) is characterised by a specific set of symptoms comprising vertigo spells with a duration of at least 20 minutes usually accompanied by low-frequency perceptive hearing loss, tinnitus and pressure sensation in the ear. The severity and natural history of MD is highly unpredictable, with often prolonged periods without any symptoms. The fear of getting an acute vertigo spell at virtually any moment of daily activities makes MD very annoying to patients and creates significant behavioural changes. Histologically all patients with MD show an increased volume of the membranous labyrinth (endolymphatic space) that is morphologically described as an endolymphatic hydrops (EH). It is however not known if the occurrence of EH is due to endolymph overproduction, malabsorption or other disorder of endolymphatic homeostasis. Or is it merely an anatomical malformation that needs an additional trigger to become symptomatic. One of the most important problems in MD is that until now there have been no objective criteria available for precise definition of MD. Diagnosis is typically based on mere anamnestic criteria and is not accurate. In clinical practice, many different balance problems show similar symptomatology and are classified incorrectly as MD. There have been numerous endeavours to find objective methods allowing for the precise definition of the definitive MD, but they were not successful. Medical imaging was until now only used for exclusion of other pathologies. The development and availability of the specific MRI hydrops protocols initiate a whole new era in the diagnosis and treatment of MD.

Learning Objectives:

1. To discuss the pathophysiology of Meniere's disease.
2. To learn about the clinical presentation and diagnostic pitfalls.
3. To become familiar with the therapeutic options for patients with Meniere's disease.

A-0887 14:15

MR hydrops imaging: how to do it?

A. [Attye](mailto:aattye@chu-grenoble.fr); Grenoble/FR (aattye@chu-grenoble.fr)

Within the inner ear, there are two distinct compartments filled with endolymph and perilymph. The accumulation of endolymph fluid is called "endolymphatic hydrops" (EH). Two alternative routes for contrast media administration have been assessed to identify EH: intratympanic (IT) and intravenous (IV). The main advantage of an IT injection is a higher perilymphatic contrast, particularly in the basal turn of the cochlea, although previous studies suggest this method can cause local toxicity in animal models. In addition, cases of bilateral disease require a double IT injection and an MR scan waiting time of 24 h before imaging acquisition. In contrast, the intravenous method requires a shorter waiting time, which has been evaluated as optimal in the 4-6 hours interval. More recently, the effect of varying the contrast media molecule on normal inner ear structures enhancement has been evaluated, and the use of 3D-FLAIR sequences with constant flip angle proposed are more sensitive than those with a variable flip angle for the hydrops protocol. Finally, radiologists must be vigilant to other inner ear diseases, such as perilymphatic fistulae, Minor syndrome, vestibular neuritis or intralabyrinthine fistulae, which may mimic Meniere's disease symptoms.

Learning Objectives:

1. To review different MRI techniques for investigation of endolymphatic hydrops.
2. To present tips and tricks for state of the art imaging today.
3. To discuss how to exclude other pathology mimicking Meniere's disease.

Abdominal emergencies: advanced imaging in daily routine?

A-0891 14:00

Chairperson's introductionM. Scaglione; Castel Volturno/IT (scaglione.fun@gmail.com)

This special focus session focuses on new imaging developments and advanced approaches to the acute abdomen. As we all know, in the contest of emergency "time" to reach the exact diagnosis and effective management is crucial for every acutely ill patient. In this context, MDCT has deeply changed the classic clinical paradigm and currently represents an "ideal tool" regarding sensibility, specificity, and accuracy. However, the use, overuse and, in certain circumstances, abuse of MDCT mainly related to the continuously increasing number of patients coming to every emergency department, has actually led to a tremendous radiation dose exposure growth worldwide which has reasonably raised worrying levels. For this reason, it is important to know if there are valuable imaging alternatives in the radiology portfolio and to understand how and in which context these new technologies can be appropriately used.

Session Objectives:

1. To understand how new technological developments can be used in the emergency setting.
2. To learn specific applications of advanced imaging to investigate abdominal emergencies.
3. To understand how advanced imaging can help to reduce radiation exposure.

A-0892 14:05

Routine CT vs dual energy CT in acute abdominal pain: should we change our scan protocol?E. Danse, E. Coche; Brussels/BE (etienne.danse@uclouvain.be)

The objective of this presentation is to discuss the optimal scenarios when a routine CT examination requested for acute abdominal conditions is replaced by a dual energy CT acquisition. CT protocols have to be cautiously adapted regarding the clinical context. Concerning the delivered radiation, an adaptation of mAs and the use of iterative reconstructions have to be applied systematically. When renal function is impaired, the volume of contrast medium can be reduced with preservation of adequate contrast enhancement. Virtual non-contrast series, iodine maps, Zeff maps and virtual monoenergetic reconstruction images can be generated automatically and sent to the PACS, with a direct impact on the storage capacity of the system. Additionally, the radiologists have to adapt the image analysis process, because new data sets are available (low and high mono-energy images, iodine uptake measurement, Z effective values). In our daily routine, these parameters contribute to optimal imaging reporting and better care to the patients.

Learning Objectives:

1. To learn about potential dual-energy CT applications in the acute abdomen (biliary stone, bowel wall enhancement, etc.).
2. To understand how virtual non-contrast images might replace the pre-contrast phase.
3. To become familiar with the available material decomposition reconstructions, image optimisation possibilities and radiation exposure concerns.

A-0893 14:30

CT scan vs MRI in acute abdominal pain: who do we have to send to the magnet?I. Millet; Montpellier/FR (milletingrid@wanadoo.fr)

Acute abdominal pain results from a wide range of different pathologies. CT is the main imaging modality used in the emergency context due to its availability and its high diagnostic performances. However, it remains an ionising radiation procedure with a potential long-term risk of cancer, and iodinated contrast material is often required, potentially affecting renal function. MRI image quality has been greatly improved in the last few years, with sequences allowing to cover a large volume with good spatial resolution, even in freely breathing patients. MRI has a better sensitivity than CT to detect little biliary stones, a better contrast resolution to characterise the content of the peri-pancreatic collections, a better assessment of pelvic inflammatory disease complications. Moreover, MRI is obviously useful to investigate abdominal pain when CT is not recommended because of ionising radiation risk (pregnant or young patients) or iodinated contrast material allergy. Indeed, MRI can be diagnostic without exogenous contrast material. The protocol can now be tailored to cover

the enhancing scala vestibuli and scala tympani. Grade 1 cochlear hydrops is defined as a mild dilatation of the non-enhancing cochlear duct into the scala vestibuli with partial obliteration of the scala vestibuli. In grade 2 cochlear hydrops, the scala vestibuli is uniformly obstructed by the distended cochlear duct. In the vestibule -in normal cases- one can clearly discriminate the non-enhancing saccule and utricule in the enhancing vestibule. A grade 1 vestibular hydrops presents as distention of the endolymphatic space of the saccule and utricule, with the enhancing perilymphatic space still visible around it. In grade 2 vestibular hydrops, the saccule and utricule are extremely distended without any visible surrounding enhancing perilymphatic space. Other signs have been described in patients with Ménière's disease such as the more pronounced cochlear perilymphatic enhancement and the obliteration of the endolymphatic sac. In patients with definite Ménière's disease, the degree of MR morphological hydrops severity correlates significantly with impairment of hearing function and saccular function. However endolymphatic hydrops is not only seen in patients with Ménière's disease. It has also been reported in a variety of other disease entities such as sensorineural hearing loss, otospongiosis and superior semicircular canal dehiscence.

Learning Objectives:

1. To get acquainted with the imaging appearance of endolymphatic hydrops.
2. To correlate imaging findings with clinical presentation.
3. To learn about other causes of endolymphatic hydrops.

A-0889 15:05

MR hydrops imaging: what are the benefits for the surgeon and the patient?A. Zarowski; Antwerp/BE (andrzej.zarowski@me.com)

Diagnosis of Ménière's Disease (MD) significantly influences the emotional and social wellbeing of affected patients. There are different conservative and invasive treatments available for MD, but their value is still questionable. Therapeutic results show large variability and are very difficult to differentiate from placebo effects, which play an important role in the treatment of MD. Lacking objective diagnostic criteria for a precise definition of MD is one of the most important problems for validation of any particular treatment in a placebo-controlled trial. When the study group and the control group comprised patients with an incorrect diagnosis, it becomes very difficult to demonstrate any significant differences between these groups. Since the presence of the endolymphatic hydrops (EH) is the necessary underlying condition for the diagnosis of definite MD, the new MRI diagnostics have dramatically changed the clinical approach to patients with MD by an improved definition of the affected patients. This game-changer gave rise to the re-evaluation of the efficacy of the historically available therapeutic options. In spite of this revolution in MD imaging, some unanswered questions still have to be addressed in future research. Is EH acquired or is it a congenital anatomical malformation? How many patients in the general population show asymptomatic EH? Is EH the necessary and sufficient condition for the development of MD symptoms, so that all patients with a radiologically diagnosed EH will eventually develop symptoms of MD? Does the localisation or the radiological grade of EH correlate with the clinical appearance of MD?

Learning Objectives:

1. To recognise the value of endolymphatic hydrops imaging.
2. To appreciate the impact of imaging findings on therapeutic strategy.
3. To discuss patient outcome after different treatment strategies.

A-0890 15:15

Panel discussion: Did you pick up the essentials?J.W. Casselman; Bruges/BE (jan.casselmann@azsintjan.be)

The audience will be able to test their knowledge about Ménière's disease by answering multiple choice questions. They will be able to answer by using an electronic voting system (using their own smartphone/tablet/laptop). The purpose of these questions is to evaluate what the participant picked-up about the "clinical presentation of Ménière's disease, treatment options, MR technique, mimicking pathology, MR diagnosis and classification, other causes of endolymphatic hydrops and the impact of the MR diagnosis on therapeutic strategy and treatment". The answers will be analysed and discussed by the presenters.

Postgraduate Educational Programme

both the upper abdomen and the pelvis in less than 10 min. Optimised T2-weighted images with and without fat suppression are mandatory, in association with optimal T1-weighted sequences performed with Dixon techniques.

Learning Objectives:

1. To learn about the superior MRI performance in diagnosing specific pathologies such as acute biliary disease, pancreatitis and gynaecological emergencies.
2. To understand that MRI should be used as an alternative to CT for investigating abdominal pain in pregnant, paediatric or young adult patients.
3. To become familiar with new MRI sequences that allow shorter examination times.

A-0894 14:55

CEUS in abdominal inflammatory and infectious conditions (-itis and abscesses)

T. Fontanilla; Madrid/ES (fonteche@gmail.com)

Many abdominal emergencies, including abdominal inflammatory conditions, are evaluated with ultrasound. Contrast-enhanced ultrasound further improves ultrasound effectiveness in this setting. CEUS of inflammatory conditions in any location depends on the presence of liquefied component and its proportion to the phlegmonous component; in the number and thickness of the septa and in the thickness of the wall also. Phlegmonous component enhances in the arterial phase and washes out quickly. The liquefied component does not enhance at all. Abscess walls and septa enhance in arterial phase and wash out quickly or slowly. Pyelonephritis lesions typically enhance initially less than the adjacent parenchyma, quickly enhance similarly the parenchyma and enhance less to it in late parenchymal phase, in which lesions are best depicted. Considering gallbladder, appendix, bowel in diverticulitis or intestinal inflammatory disease, thickening of the wall with arterial phase enhancement happens, except in gangrenous areas. If there is perforation, gas and/or peritoneal fluid and/ or complication with an adjacent phlegmon or abscess occur. CEUS aids in distinguishing phlegmon from an abscess, in measuring the size of the abscess and in defining its internal structure, which influence directly in the therapeutic choice: drainage and antibiotics versus medical treatment alone. CEUS also provides a valuable tool in the follow-up of the lesions: size diminishment, reduction in wall enhancement, and even use of endocavitary ultrasound contrast to check the patency or location of drainage tubes. CEUS findings and usefulness, as well as technical tips to optimise imaging, will be explained with different cases.

Learning Objectives:

1. To learn the CEUS image findings of acute inflammatory conditions and their complications (gallbladder, kidney, inflammatory bowel disease and complicated diverticulitis).
2. To become familiar with the indications, advantages and limitations of CEUS.
3. To review technical issues from a practical standpoint.

Principles of imaging and radiation protection

A-0895 14:00

Chairperson's introduction

C.J. Caruana; Msida/MT (carmel.j.caruana@um.edu.mt)

Medical imaging devices are instruments which measure a physical property of tissue voxels (e.g., linear attenuation coefficient in CT). This is crucial to keep in mind as the quantitative view of medical images gains traction among the radiology community. The 3D matrix of voxel values are then visualised as a grey scale (or colour) image by means of a Look-UP-Table (LUT). By good image quality, one means that the device can demarcate the voxels properly (for high spatial resolution) and that the physical property values of the voxels have been measured accurately (inaccuracy renders the image unusable) and with a low uncertainty (for high contrast resolution). On the other hand the higher the precision with which we want to measure the values the higher is the patient dose in CT or the SAR level in the case of MRI. The optimization which is the creation of the right level of image quality whilst avoiding unnecessary patient risk is therefore crucial. Staff safety also needs careful attention. In these presentations we will present the principles of image

formation, image quality, basic optimisation and protection of patient and staff from ionising radiation and other physical agents (e.g., magnetic field and gradient fields in MRI) for ETC Levels I and II.

Session Objectives:

1. To understand the technical and methodological principles of computed tomography.
2. To understand the technical and methodological principles of magnetic resonance tomography.
3. To learn the principles of radiation biology and radiation protection.

A-0896 14:06

A. Principles of computed tomography

M. Kortesiemi; Helsinki/FI (mika.kortesiemi@hus.fi)

Computed tomography (CT) is an imaging method producing 3D image data of the patient. Like any other x-ray modality, the contrast in the CT image is based on the x-ray attenuation. The physical interactions behind the attenuation also produce radiation exposure to the patient. The majority of the cumulative radiation exposure in radiology is produced by CT. Therefore, proper justification and optimisation of CT studies are essential factors in diagnostic radiology. The CT image data is acquired from the patient with a rotating x-ray tube and detector; both mounted on the opposite sides of the rotating gantry structure. In a multi-slice CT scanner (MSCT), a large number (up to thousands) of raw-data projections are measured from different angles, representing the net attenuation of x-rays across the patient. These raw-data projections are then used to calculate the image slices - or rather the volume - representing the 3D attenuation map of the patient. Thus, the CT image reconstruction is an inverse problem, deducing the 3D image from the raw-data "shadow" signal. Mathematical image reconstruction methods have traditionally been based on filtered back-projection, enhanced in the past decade with iterative reconstruction techniques, and recently starting to utilise even deep-learning (a type of artificial intelligence). Modern CT imaging enables very fast, high resolution and wide coverage scanning, acquiring up to 640 axial slices per rotation in axial scan mode, and even 73 cm length per second with high pitch helical scan with a dual-source CT scanner. Development of CT is continuing strong.

Learning Objectives:

1. To understand the physical basis of image formation of computed tomography and of the physics of helical, multidetector and dual-source CT.
2. To learn the scale of Hounsfield units and the principle of window centre and width.
3. To become familiar with modern CT technology.
4. To understand the principles of optimising CT protocols with a focus on patient dose reduction.

A-0897 14:34

B. Principles of magnetic resonance imaging

D. Sappey-Mariniere; Lyon/FR (Dominique.Sappey-Mariniere@univ-lyon1.fr)

After a rapid survey of Nuclear Magnetic Resonance (NMR) discoveries through the numerous Nobel prizes, the fundamental principles will be presented through the quantum aspects of the spin states of hydrogen nucleus, the most targeted candidate in MRI, and the use of three magnetic fields, the static B₀ field, the resonant B₁ field, and the gradient G, for spin polarization and excitation, and space encoding for image reconstruction, respectively. Relaxation processes, called T₁ and T₂, will be described to understand the signal measurement and to explain their role in image contrast using a standard spin-echo sequence. Conventional MRI sequences, including T₁, T₂, T₂* tissue contrasts, will be presented to provide an initial comprehension of MRI interpretation, to learn about typical artefacts, and to understand safety issues in MRI.

Learning Objectives:

1. To become familiar with the physical basis of image formation in MRI including the principles of pulse sequences and relaxation times.
2. To become familiar with the typical appearance of tissues, organs and main pathological processes of the most commonly used sequences in MRI, including T₂-weighted sequences, T₁-weighted sequences, STIR sequences, FLAIR sequences, other inversion recovery sequences, T₂*- / susceptibility-weighted sequences and MR angiography sequences.
3. To learn typical artefacts on MR imaging and to discuss their respective causes.
4. To understand absolute or relative contraindications against MR imaging and safety issues in the MR environment with regard to patients and staff.

A-0898 15:02

C. Radiation protection

J. Damilakis; Iraklion/GR (damilakis@med.uoc.gr)

The use of ionising radiation for medical imaging requires careful thought so that expected benefits outweigh potential radiation-induced risks. This presentation will provide an overview of medical radiation protection. Specifically, it will cover the main interactions of x-rays and gamma rays with

matter and will explain why the photoelectric effect and Compton scatter are the most common effects in diagnostic imaging. The basic principles of medical radiation protection as outlined by ICRP will be described, and the importance of patient and staff dosimetry in diagnostic and interventional radiology will be explained. Methods and tools will be presented that can be used to limit patient dose. Paediatric patients are more sensitive to radiation than adults. The exposure of pregnant patients to medical X-rays is often a complex case and involves emotionally sensitive issues for both prospective parents, radiologists and referring physicians. A program for dose management of pregnant and paediatric patients requiring diagnostic and interventional procedures will be described. Fluoroscopically-guided interventional procedures are associated with relatively high occupational doses. This presentation will give key points to remember for staff dose management in fluoroscopy and interventional radiology procedures.

Learning Objectives:

1. To understand the phenomena of x-ray interaction with matter and their effect on image quality and dose.
2. To provide an overview of patient and staff dosimetry in diagnostic and interventional radiology.
3. To understand the basic principles of radiation protection, as outlined by the ICRP (International Commission on Radiological Protection).
4. To become familiar with the concepts and tools for dose management in radiology with regard to adult and paediatric patients.

14:00 - 15:30

Navigating tumour phenotype with advanced imaging analysis

A-0899 14:00

Chairperson's introduction

E. Sala; Cambridge/UK (es220@cam.ac.uk)

Session Objectives:

1. To become familiar with the concept of tumour microenvironment and habitat imaging.
2. To learn what information habitat imaging and radiomics can provide on tumour heterogeneity.
3. To understand how machine learning and artificial intelligence can be used in radiomics.

A-0900 14:05

Understanding tumour micro environment: the role of habitat imaging

J. O'Connor; Manchester/UK (james.o'connor@manchester.ac.uk)

Tumours are complex 3D structures at the anatomical, physiological and metabolic levels. Imaging methods, such as CT, MRI, PET, SPECT and ultrasound can map the spatial variation in these scales. In particular, imaging can detect sub-regions with differing anatomical or microenvironment signatures, which have been referred to as 'tumour habitats'. It is hypothesised that these habitats identify a tumour with good/poor prognosis or good/poor response to targeted therapy. In this talk, we will consider strategies and tools for identifying these habitats. We will evaluate the evidence that such approaches provide useful information to guide decision-making that merit inclusion in healthcare systems.

Learning Objectives:

1. To understand the concept of tumour microenvironment.
2. To become familiar with habitat imaging analysis tools.
3. To learn what information habitat imaging can provide on tumour heterogeneity.

A-0901 14:30

Unravelling tumour heterogeneity using radiomics

L.S. Fournier; Paris/FR (laure.fournier@aphp.fr)

Radiomics is a new 'data-driven' approach for extracting large sets of complex descriptors from routine (or not) clinical images. Advanced methods of image processing are applied to images to extract a large number of descriptors, such as texture analysis from histograms, co-occurrence matrices, fractal analysis, etc. This large set of data can be analysed using bio-informatics and bio-statistics methods then correlated to outcomes, such as treatment response or survival. The purpose of radiomics is to mine images for information on underlying biology, such as gene expression profiles (called radiogenomics), molecular profiles, expression of receptors, microenvironments such as immune cell infiltration or angiogenesis. Texture parameters more specifically

are considered to reflect tumour heterogeneity. Radiomics allows discovery of new potential biomarkers, but it is then important to demonstrate their link to tumour biology.

Learning Objectives:

1. To learn the definition of radiomics and radiomics tools available.
2. To understand what information radiomics can provide on tumour heterogeneity.
3. To understand how the radiomics features may relate to tumour biology and microenvironment.

Author Disclosure:

A-0902 14:55

Role of machine learning (ML) and artificial intelligence (AI) for quantitative radiomics

W.J. Niessen; Rotterdam/NL (w.niessen@erasmusmc.nl)

Radiomics techniques aim to establish a relation between a combination of imaging features and clinically relevant outcomes. Radiomics has primarily been applied in the oncology domain and owing to its popularity for different types of tumours radiomic signatures have been developed. Still, there are large challenges in order to bring radiomics to daily clinical practice. Challenges include the robustness and generalisability of radiomic signatures, especially in view of the large heterogeneity in imaging hardware and software, and image acquisition parameters. In this presentation, I will present the basics of a radiomics pipeline. Also, methods for the automatic optimisation of all the parameters in a radiomics pipeline are addressed. Finally, examples of this approach are shown on a variety of applications, including grading of prostate cancer, and characterisation of low-grade gliomas and liver tumours.

Learning Objectives:

1. To understand how machine learning can be used to extract radiomic features.
2. To learn how artificial intelligence can be used in radiomics.
3. To become familiar with available artificial intelligence algorithms that can be used to integrate radiomics with other patient data.

No time to lose: aortic disease, revisited

Moderator:

M. Krokidis; Cambridge/UK

A-0907 14:00

A. Diagnosis and treatment of abdominal aortic aneurysms

F. Wolf; Vienna/AT (florian.wolf@meduniwien.ac.at)

Abdominal aortic aneurysms (AAA) are relatively rare. The annual incidence of new AAA diagnoses is approximately 0.4 to 0.67 % in Western populations. Nevertheless, when radiologists report CT examinations, they will not so uncommonly find pathological changes in the abdominal aorta with a range from simple wall irregularities to large abdominal aortic aneurysms. For radiologists, it is crucial to detect, classify and report aortic aneurysms. It seems to be very complicated to measure an aortic aneurysm in the right way and decide if a stentgraft treatment is possible or not and what kind of stentgraft would be the best. But with a few tips and tricks provided in this lecture, it is relatively easy to decide if an aneurysm has to be treated and if a standard stentgraft would be possible or not. The lecture will end up with different other AAA treatment possibilities beyond the standard AAA stentgrafts - anchors, snorkels, branches and chimneys. For diagnostic radiologists, it makes no sense to plan such complicated procedures - but it is really important to know what is technically possible in order to describe these stentgrafts with its possible complications in the right way in follow-up CT examinations.

Learning Objectives:

1. To learn about the definition and classification of abdominal aortic aneurysms.

2. To understand the relevant information and measurement to plan an endovascular aortic repair.
3. To get familiar with the different possibilities of endovascular treatment including anchors, snorkels, branches and chimneys.

A-0908 14:30

B. Acute diagnosis and imaging in aortic dissection

R. [lezzi](mailto:lezzi@it.romeo.it); Rome/IT (roberto.iezzi.md@gmail.com)

Aortic dissection is the most common acute emergency condition of the aorta, often resulting in the death of the patient. The overall outcome is determined by the type and extent of dissection and the presence of associated complications; therefore, evaluation of the entire aorta, branch vessels, and iliac and proximal femoral arteries is recommended to aid in treatment planning. Early diagnosis and treatment are essential for improving the prognosis. Patients may present with the classic history of acute onset of tearing central chest pain that radiates to the back. Stanford type A dissection involves the ascending thoracic aorta, and the dissection flap may extend into the descending aorta. Type A dissections account for 60%-70% of cases, requiring urgent surgical intervention to prevent extension into the aortic root, pericardium, or coronary arteries. If untreated, type A dissections are associated with a mortality rate of over 50% within 48 hours. Stanford type B dissection involves the descending thoracic aorta distal to the left subclavian artery and accounts for 30%-40% of cases. Management takes the form of medical treatment of hypertension unless there are complications due to an extension of the dissection. CT imaging of the aorta is fast and widely available, which are the important features in making an accurate diagnosis quickly in unstable patients. Multidetector CT allows imaging of the entire aorta with rapid acquisition and data reconstruction to provide prompt and accurate diagnosis and to help identify relevant complications that may have an impact on treatment and management.

Learning Objectives:

1. To learn about definition and classification of aortic dissections and subtypes.
2. To understand the importance of accurate diagnosis for appropriate treatment planning.
3. To appreciate the need for acute diagnosis and treatment indication.

A-0909 15:00

C. Endovascular treatment in aortic dissection

J.P. [Schaefer](mailto:schaefer@rad.uni-kiel.de); Kiel/DE (jp.schaefer@rad.uni-kiel.de)

Acute aortic dissection represents a life-threatening condition, which must be diagnosed immediately. CTA is considered the imaging modality of choice, offering all relevant information on the pathoanatomy with highest spatial resolution. Stanford classification is used to distinguish between type A- and B-dissections, whereas the left subclavian artery represents the border between the two types. Actually, surgical repair is the method of choice and indicated in type A-dissection, and endovascular repair is the method of choice in type B-dissection if indicated. Type B-dissection may be uncomplicated or complicated. For uncomplicated type B, best medical treatment is the method of choice, and it is defined by no further symptoms, relief of symptoms and absence of additional dissection associated findings. For complicated type B, endovascular repair including a variety of interventions is the method of choice, and it is defined by mesenteric, renal, peripheral and spinal malperfusion, progressive dissection, aneurysm forming, uncontrollable hypertension, rupture, progressive periaortic and pleural haemorrhage, severe hypotension and shock. Regarding symptom onset and imaging-based diagnosis, type B-dissection is classified as acute (<2 weeks), subacute (2-8 weeks), and chronic (>8 weeks). Endovascular repair usually includes prosthesis placement in the descending aorta, to seal the proximal entry tear. This excludes the perfusion of the false lumen along the covered aortic segment and restores the blood flow into the true lumen, maintaining and improving the visceral and peripheral perfusion. Additionally, target visceral artery stenting, membrane fenestrating or embolizing may be indicated. Protocolled CTA follow-up is mandatory.

Learning Objectives:

1. To learn about endovascular treatment possibilities for aortic dissections.
2. To understand the role of radiology in modern treatment of aortic dissections.
3. To appreciate the need to combine the radiological information with the clinical situation.

Demystifying MRI: things you always wanted to know

Moderator:

I. Seimenis; Alexandropolis/GR

Session Objectives:

1. To learn about the basic concepts of NMR and relaxation.
2. To understand how MR images are produced.
3. To learn about standard MRI pulse sequences.

A-0910 14:00

A. Basic MR: the building blocks of pulse sequences

A. [Webb](mailto:webb@lumc.nl); Leiden/NL (a.webb@lumc.nl)

This lecture will start by covering the basic principles of magnetic resonance: the net magnetisation produced within a patient, why a radiofrequency pulse has to be applied, and how the MR signal is detected. Pulse transmission and MR signal detection are then linked to the body coil and receive array coils used in a conventional MRI setup. Next, the dependence of the signal on the T1, T2 and T2* relaxation times will be explained. The sequences necessary to introduce T1 (inversion-recovery), T2 (spin-echo) and T2* contrast into the signal will be covered. Finally, the reasons why different tissues have different relaxation times will be discussed, as well as how pathology can alter these relaxation times.

Learning Objectives:

1. To learn about how NMR signals are produced.
2. To understand the basic concepts of relaxation.
3. To learn about the operation of inversion-recovery and spin-echo pulse sequences.

A-0911 14:30

B. MR imaging basic concepts: how to turn signals into images

D.J. [Lurie](mailto:lurie@abdn.ac.uk); Aberdeen/UK (d.lurie@abdn.ac.uk)

To generate images in MRI, NMR signals must be "labelled" with their location. Three techniques of spatial encoding are employed, all of which use the magnetic field gradient. By sending electrical current (hundreds of amperes) through a gradient coil, a magnetic field is produced whose strength which varies linearly with the position inside the scanner bore. In frequency-encoding, the NMR signal is recorded while a field gradient is applied. Since the magnetic field varies with position along the gradient direction (e.g. X), the NMR resonant frequency (Larmor frequency) is a function of position, so the detected signal contains a range of frequencies; analysing the frequency content generates a one-dimensional projection of the water-distribution within the patient. A method called phase-encoding is employed in the second in-plane dimension (e.g. Y); here, the gradient is pulsed on and off prior to measurement of the signal, affecting the phase of the NMR signal as a function of position. Finally, the slice itself is defined using selective-excitation, in which the radiofrequency pulse used for NMR excitation is specially-shaped and is applied in the presence of a field gradient perpendicular to the slice plane (e.g. along Z). To generate data for an image of NxN pixels, the pulse sequence is usually applied N times, varying the phase-encode gradient amplitude with each repetition. A two-dimensional Fourier transform of the raw data matrix yields the MR image, which can be encoded with NMR parameters (T1, T2, diffusion etc.) information to assist diagnosis.

Learning Objectives:

1. To learn how magnetic field gradients encode spatial information.
2. To understand the main ways in which field gradients are used.
3. To appreciate the basic concepts of data collection and image reconstruction in MRI.

A-0912 15:00

C. Practical MRI: a toolkit of standard MR pulse sequences

G. [Hagberg](mailto:hagberg@tuebingen.mpg.de); Tübingen/DE (gisela.hagberg@tuebingen.mpg.de)

The MR-sequence is an essential tool to measure MR-properties in tissues, increased contrast between these and quantify relevant data. Besides furnishing the desired tissue-derived MR signal, the sequence must allow spatial encoding to take place as efficient as possible to enable patient compliance, and high-quality MRI at the same time. Starting with a brief introduction regarding MR-tissue properties and spatial encoding in k-space, I will describe the fundamental MR toolkit, based on single echo spin-echo (SE)

and gradient-echo (GE) and show how these are extended to different multiple-echo regimes. Basic image contrast and how imaging parameters: repetition time, TR; echo time, TE; flip angle, FA; inversion delay, diffusion gradients, etc.; influence contrast will be described. The possibility to further enhance imaging by adequate spin-preparation: inversion or magnetisation transfer pulses etc.; will also be discussed. Imaging speed can be achieved while remaining in the single echo regime by faster RF pulsing (shorter TR) giving valuable information linked with magnetic susceptibility like in the GE-based FLASH method, based on spoiling of unwanted echoes. Another possibility is to use multiple (spin) echoes to read out different k-space lines, and hereby speed up spatial sampling, like in the SE-based method RARE. An alternative possibility that further extends available image contrast is to retain the full magnetisation in GE-based sequences and acquire images in the different steady-state-free-precession regimes. The latter techniques have gained momentum through the advent of magnetic fingerprinting and are evolving into another fundamental part of the standard MRI-toolkit.

Learning Objectives:

1. To learn about common types of MR pulse sequence.
2. To understand the difference between gradient-echo and spin-echo.
3. To appreciate the factors influencing choice of pulse sequence.

Back to basics: how to interpret a chest radiograph?

A-0913 14:00

Chairperson's introduction

S.P.G. [Padley](#); London/UK

Session Objectives:

1. To increase the radiologists' confidence in chest radiography reading.
2. To recognise and interpret the typical abnormalities.
3. To understand the limitations of chest radiography.

A-0914 14:05

A. A chest radiography reading guide

N. [Howarth](#); Chêne-Bougeries/CH (nigel.howarth@grangettes.ch)

The presentation will provide a reading guide for the frontal and lateral chest radiograph. The most useful signs in chest radiology will be introduced, using side-by-side plain film and CT imaging to help understand the imaging features. Although the clinical value of the chest X-ray remains undiminished, errors of interpretation of the chest X-ray remain one of the most frequent causes of malpractice issues. The skills required for accurate interpretation of the chest radiograph will be explored. The objective is to help you improve your performance in plain film interpretation of the chest.

Learning Objectives:

1. To learn about chest radiograph quality criteria.
2. To learn about the normal features.
2. To learn which difficult areas to concentrate on.

A-0915 14:18

B. Alveolar, interstitial and nodular syndromes

F. [Molinari](#); Lille/FR (francescomolinari.dr@gmail.com)

Many acute or chronic diseases of the lung may manifest at imaging with the appearance of an alveolar, interstitial or nodular syndrome. All of these imaging syndromes are well known to thoracic radiologists and can be detected at chest radiography. Especially when interpreted in the correct clinical setting, alveolar, interstitial or nodular opacities can provide hints to the diagnosis. In this presentation, the typical imaging signs that allow to make a diagnosis of an alveolar or interstitial disease or suspect the presence of pulmonary nodules will be reviewed by using anatomic and imaging correlation between chest radiograph and CT.

Learning Objectives:

1. To learn about alveolar opacities characteristics.
2. To learn how to recognise the presence of interstitial changes.
3. To understand the chest radiograph limitations for lung nodule detection.

A-0916 14:31

C. Lobar atelectasis

D. [Tack](#); Baudour/BE (denis.tack@skynet.be)

Lobar collapse or closure of a pulmonary lobe is associated with a loss of volume and results in reduced or absent gas exchange, a condition where the alveoli are deflated down to little or no volume. This presentation aims to

review the radiographic and CT signs of lobar collapse, or loss of volume, and associated abnormalities when for example the cause of the collapse is a bronchial obstruction of a mass. Differentiation of lobar collapse and consolidation will be discussed. Distinct entities will be imaged such as aerated lobar collapse and chronic lobar collapse without mass-like consolidation.

Learning Objectives:

1. To review the signs of lobar atelectasis on frontal chest radiograph.
2. To learn about the complementary role of lateral view.
3. To explain the differences with other causes of lung opacity.

A-0917 14:44

D. Pleural syndrome

A.P. [Parker](#); Bergen/NO (apparkar@gmail.com)

Chest radiographs are particularly useful to diagnose pneumothorax, albeit smaller ones may be missed on radiographs. Pneumothorax is commonly seen as an area of hyperlucency with lack of vessels in the apical and the lateral regions on the photograph performed standing or sitting. Pneumothorax in the supine position is best seen as the deep sulcus sign as the air moves anteromedially and subpulmonic. Pneumothorax can be spontaneous (either primary or secondary) or iatrogenic. It is important to recognise the "do-not-miss" state of tension pneumothorax, which can be fatal if left untreated. A partial pneumothorax is seen when part of the lung is still adherent to the chest wall. It is, however, important to differentiate it from bullous lung disease, which sometimes may be difficult on radiographs, and may require a CT for a definite diagnosis.

Learning Objectives:

1. To learn how to identify partial pneumothorax.
2. To be able to identify signs of compressive pleural effusion.
3. To be aware of the limitations of bedside chest x-ray for pneumothorax detection.

A-0918 14:57

E. Mediastinal syndrome

M. [Occhipinti](#); Florence/IT (mariaelena.occhipinti@gmail.com)

Chest radiography has been traditionally used to evaluate the chest, including lung parenchyma, airways, and mediastinum. Despite the wide use of computed tomography imaging, chest radiography still plays a fundamental role in the detection and characterisation of mediastinal lesions through the use of mediastinal lines, stripes, and interfaces. Lines and stripes are formed by air outlining thin or thick intervening tissue on both sides, respectively. Interfaces are formed when structures of different densities contact with one another, such as in the azygosoesophageal recess. The recognition and understanding of the anatomic basis of these mediastinal lines, stripes, and interfaces along with their normal and abnormal appearances allow radiologists to develop an appropriate differential diagnosis of mediastinal lesions before obtaining additional information by using chest computed tomography or magnetic resonance imaging.

Learning Objectives:

1. To review the normal mediastinal lines.
2. To learn about the normal and abnormal mediastinal contour.
3. To know how to use the silhouette sign to localise mediastinal opacities.

Knee sports injuries and postoperative MRI

Moderators:

L.W. Bancroft; Orlando, FL/US

A.J. Grainger; Leeds/UK

A-0919 14:00

A. Sports-related injuries of the knee: what does the orthopaedic surgeon need to know?

T.T. [Miller](#); New York, NY/US (millertt@hss.edu)

The anatomy of the normal ACL and menisci will be reviewed, followed by a discussion of the appearances of various abnormalities of the ACL and menisci, as well as mechanisms of injury and injury patterns. Associated injuries will be discussed. Recommendations will be made for imaging the postoperative meniscus.

Learning Objectives:

1. To learn about what to include in knee MRI dictation templates.
2. To understand the most common sports-related injury patterns in the knee.
3. To appreciate which specific orthopaedic indications should prompt additional information in the dictation.

A-0920 14:30

B. ACL reconstruction and cartilage repair

C. [Weidekamm](#); Vienna/AT (weidekamm@icloud.com)

ACL reconstruction aims to stabilise the knee and prevent chondral and meniscal injuries, which are sequelae of anteroposterior translation and are associated with early osteoarthritis. The idea of the double-bundle ACL graft was to restore normal joint kinematics by anatomic reconstruction of the anteromedial and the posterolateral bundle of the original ACL. This was expected to improve clinical outcomes and restore anterior and rotational knee stability. The single-bundle technique, however, causes less osseous defects and is still a popular technique. Complications, such as ACL graft failure, impingement, cyclops lesion, arthrofibrosis, and patellar inferior syndrome, are discussed. The second part of this presentation will illustrate cartilage repair techniques and imaging findings. The radiologist must be familiar with the different cartilage repair procedures and characteristics in cartilage imaging to evaluate long-term progression or failure. Abnormal postoperative findings include hypertrophic filling, incomplete integration of the transplant into the surrounding cartilage, or subchondral defects, osteophytes, cysts, and persistent bone marrow oedema and joint effusion.

Learning Objectives:

1. To review the common and uncommon ACL reconstruction techniques.
2. To appreciate the expected and abnormal MR imaging findings after ACL reconstruction.
3. To understand common cartilage repair techniques, and corresponding normal and abnormal postoperative MRIs.

A-0921/A-0922 15:00

C. Interactive case discussion

T.T. [Miller](#); New York, NY/US (millertt@hss.edu)

C. [Weidekamm](#); Vienna/AT (weidekamm@icloud.com)

Postoperative imaging after ACL or cartilage repair is indicated in patients with ongoing pain/instability or repetitive injury. Radiography remains the initial imaging modality; however, a further assessment with CT or MRI is recommended. With a clear emphasis on MRI, we will review normal postoperative findings and complications after ACL reconstructions and cartilage repair. The case discussion will cover the most significant pathologies and pitfalls, and normal postoperative findings will be illustrated.

Learning Objectives:

1. To appreciate common patterns of athletic injury in the knee.
2. To become familiar with the diagnostic features of failed ACL reconstructions, intact and failed cartilage repair.
3. To consolidate the knowledge gained from the session with interactive cases of pre- and postoperative MRI.

Paediatric radiology for the general radiologist

A-0923 16:00

A. Pitfalls in paediatric chest and abdomen

M. [Raissaki](#); Iraklion/GR (mraissaki@yahoo.gr)

A pitfall is defined as a likely mistake or problem in a given situation, an unexpected danger or difficulty. In pediatric radiology, two of the most demanding modalities include chest and abdominal radiography as well as ultrasonography. Chest and abdominal radiography carry numerous pitfalls due to superimposition of different structures into a two-dimensional image. Pitfalls can be related to the technique itself, especially in uncooperative patients. Knowledge of anatomy, physiology of respiration and basic radiographic principles aid in the identification of abnormalities and increase the sensitivity of the tests. Pediatric ultrasonography can be fun, nevertheless thoroughness, appropriate technique, attention to details and avoidance of satisfaction of search syndrome is always important. Knowledge of developmental changes and the entities unique to children is essential for the pediatric and general radiologist to avoid significant interpretive errors. Consideration of history and appreciation of age and the clinical condition of the patient are vital components of clinical pediatric radiology.

Learning Objectives:

1. To review the basic principles of the paediatric chest radiographs through common mistakes.
2. To emphasise pitfalls when imaging the paediatric abdomen.
3. To learn to avoid the most common pitfalls.

A-0924 16:45

B. Paediatric MSK imaging: normal variants or real injuries?

F. [Saez](#); Barakaldo/ES (fersaez@yahoo.com)

The skeleton of a child is a developing system with a variety of changing normal appearances. Imaging studies, especially plain films, are requested for many clinical reasons, and the radiologist is in the position to determine if an image is a normal finding or we are dealing with a lesion. The way physis and epiphysis grow, ossify, and fuse constitutes a great source of physiologically bizarre appearances, which the radiologist must be familiar with. This talk will concentrate on the plain film diagnosis of some of the most common musculoskeletal variants. Other imaging modalities will also be shown when appropriate for the case. Irregularities, asymmetries, partial fusions, hypo- or hyper-dense bone areas, accessory bones, prominent normal structures, external artefacts, and potential fracture lines are the most often encountered pseudolesions. A defective radiological technique may also be potentially misleading. Patient age, the location of the supposed "abnormality" and lack of significant local symptoms are key factors. Usually, plain films, correlated with regional clinical findings, are the only imaging method that is required. However, in certain doubtful situations, ultrasound, CT, MRI, Bone Scan, or even biopsy, may be needed to reach the right diagnosis. Unnecessary overuse of these imaging modalities and the subsequent family anxiety that ensues from this overuse should be avoided with careful analysis of the X-ray and clinical findings.

Learning Objectives:

1. To become familiar with the normal variants.
2. To identify the key imaging findings to differentiate between normal variants and disease.
3. To learn how to integrate age, location and clinical history with the radiological features before establishing a diagnosis.

Diagnosis and management of acute pancreatitis

Moderator:

C. Triantopoulou; Athens/GR

A-0925 16:00

A. The 2012 revised Atlanta Classification: what has really changed?

T.L. [Bollen](mailto:tbollen@hotmail.com); Nieuwegein/NL (tbollen@hotmail.com)

The lexicon of acute pancreatitis (AP) has changed since the publication of the 2012 Revised Atlanta Classification (RAC) which replaces the 1992 Atlanta Classification. The RAC makes a distinction between necrotising pancreatitis and interstitial pancreatitis, depending on the presence or absence of tissue necrosis, respectively. Necrotising pancreatitis is subdivided into three forms: pancreatic parenchyma alone (very rare), peripancreatic tissues alone (extrapancreatic necrosis or EXPN), or combined necrosis (most common). Associated collections are either termed acute necrotic collections (ANC) (incomplete wall) or walled-off necrosis (WON) (completely encapsulated). Fluid collections in interstitial pancreatitis are termed acute peripancreatic fluid collection (APFC) (incomplete wall) or pseudocyst (completely encapsulated). The distinction between the various subtypes of AP has implications for prognosis. Interstitial pancreatitis has a mortality of less than 3% and can virtually always be treated conservatively. Pancreatic necrosis, particularly in the presence of infection, is associated with mortality rates as high as 25%, and surgical management may be required. Patients with EXPN have a significantly better prognosis than those with combined necrosis if necrosis remains sterile, but have a similar outcome in case of infected EXPN. For complete reporting in AP, it is essential to describe the presence of pancreatic necrosis (site and extent) and presence of pancreatic collections with all its features (location, shape, size, homogeneity, degree of encapsulation, and presence of haemorrhage or gas bubbles). Associated findings, such as the presence of pleural effusion, ascites, vascular abnormalities, extrapancreatic parenchymal, biliary, and gastrointestinal complications should be evaluated as well.

Learning Objectives:

1. To be aware of the new terminology for the evaluation of acute pancreatitis.
2. To learn about how to report imaging findings.
3. To understand the relationship between imaging findings and prognosis.

A-0926 16:30

B. Role of imaging in diagnosis of acute pancreatitis: new trends

G. [Zamboni](mailto:gzamboni@hotmail.com); Verona/IT (gzamboni@hotmail.com)

Imaging has an important role in the management of acute pancreatitis, first of all in the differentiation between edematous and necrotising pancreatitis. In order to be accurate in this differential diagnosis, imaging - usually contrast-enhanced CT- must be performed with the appropriate timing: the optimal interval between symptoms onset and imaging is 72 hours. Before this, there is a risk of not recognising necrosis, thus misclassifying the disease. CT can recognise the presence of necrosis and define if it is parenchymal only, extra-parenchymal only or both parenchymal and extra-parenchymal. This has important implications, because parenchymal necrosis may lead to ductal disruption, resulting in the disconnected duct syndrome or in collections that are replenished with pancreatic juice with amylase. Imaging has an important role in defining the presence of collections and in classifying them according to the Revised Atlanta classification: a differentiation between fluid and necrotic collections should be made, in order to plan the best treatment for the patient, including collection drainage or surgery when indicated.

Learning Objectives:

1. To learn about the proper timing of imaging studies in acute pancreatitis.
2. To learn about the imaging manifestations of necrotising pancreatitis.
3. To understand the different nature of fluid collections with regard to further therapy.

A-0927 17:00

C. Interventional radiology in acute pancreatitis: why, when and how

M.M. [Maher](mailto:m.maher@ucc.ie); Cork/IE (m.maher@ucc.ie)

Acute pancreatitis may have a benign course with minimal abdominal pain and hyperamylasemia or may be life-threatening, usually due to the development of infected pancreatic necrosis, haemorrhage and/or multisystem organ failure. Fortunately, 70-80% of patients with acute pancreatitis have a benign self-limiting course. In the initial management of acute pancreatitis, assessment of metabolic disturbances and systemic organ dysfunction is critical. In more

severe cases, cross-sectional imaging (Ultrasound, Computed Tomography and MRI) plays a prominent role in the assessment of the degree of severity and/or development of complications. It is important that imaging is performed strategically in patients with severe acute pancreatitis as findings on imaging studies frequently impact management and play a central role in determining the appropriate timing of surgery and image-guided interventions. In this presentation, we will review imaging findings in severe acute pancreatitis and specific imaging findings associated with common complications. The question of when, where and why interventional radiology plays a role in the management of severe acute pancreatitis will be discussed. In addition, we will briefly discuss how common and novel interventional techniques may be used optimally to improve patient outcome.

Learning Objectives:

1. To learn indications for interventions and type of complications that requires treatment.
2. To understand how likelihood of success of these interventions vary with severity.
3. To review management of local complications of pancreatitis by interventional radiology.

EuroSafe Imaging and the European Basic Safety Standards Directive: progressing patient safety

G. [Frija](mailto:guy.frija@aphp.fr); Paris/FR (guy.frija@aphp.fr)

EuroSafe Imaging is the European Society of Radiology's flagship initiative for promoting quality and safety in medical imaging. Launched in 2014, EuroSafe Imaging leads numerous activities to support and strengthen medical radiation protection across Europe through the implementation of the 13 actions of its Call for Action 2018. Among other activities, EuroSafe Imaging has provided guidance and practical tools to support compliance with the European Commission Directive 2013/59/Euratom ("Basic Safety Standards Directive"), which lays down basic safety standards for protection against the dangers arising from exposure to ionising radiation. It entails substantial new requirements in various areas, e.g. improving the protection of patients in medical imaging procedures, improving the protection of workers, and improving the protection of the public in particular from natural radiation sources. The Directive entered into force in February 2018. This talk will present the EuroSafe Imaging initiative, its achievements to date and future activities. Moreover, it will provide an overview of the BSS Directive and its contribution to promoting patient safety in medical imaging.

Learning Objectives:

1. To explore the aims and objectives of EuroSafe Imaging and its achievements to date.
2. To appreciate aspects of the Basic Safety Standards Directive, which will further progress patient safety.
3. To consider what the future holds for EuroSafe Imaging.

A-0929 16:16

Patient safety: beyond radiation protection

K. [Azevedo](mailto:kbazevedo@ualg.pt); Faro/PT (kbazevedo@ualg.pt)

Patient safety is a broad field of knowledge and intervention and can be divided into three domains namely: structural factors; processes; and outcomes. Medical imaging services receive a considerable number of patients every day that undergo several number of different procedures. It is important to highlight that each procedure has a potential to cause harm to the patient and this potential is present even before the first contact with the patient and ends after the last contact with the patient. It is clear that the leading objective of an imaging service is to diagnose and treat the patient, but at the same time do no needless damage. To increase patient safety the first step is to make it an institutional cultural theme. Beyond radiation-related issues, patient safety can be affected by the importance given by the management to this subject, communication, feedback and non-punitive response to error, adequate staffing, infection control, adequate continuous professional development, handoffs and transitions, and teamwork in the imaging service and with other units, such as inpatient wards, and the imaging services. The radiographer and the radiologist are key elements in the medical imaging services. To receive and prepare the patient, to perform the exams, from their programming, their execution, their quality evaluation and to diagnose and treat the patient, there

Postgraduate Educational Programme

are several factors that may influence patient safety, not only at the imaging service level but also at the whole healthcare institution level.

Learning Objectives:

1. To appreciate the scope of patient safety related to medical imaging services.
2. To consider a selection of examples of patient safety beyond radiation protection, optimisation and justification.
3. To explore the important roles of radiographers and radiologists in working collaboratively to best ensure patient safety.

A-0930 16:32

Value-based imaging and patient safety

A. [Brady](mailto:adrianbrady@me.com); Cork/IE (adrianbrady@me.com)

The value-based healthcare concept is growing in importance, as part of a trend away from concentration on the delivery of volume-based services, and towards concentration on the specifics of delivering value-based care to individuals and the population as a whole. The components of what constitutes value differ among physician, provider and patient groups, and thus the parameters of value in healthcare are not fixed. The original model of value-based healthcare began consideration of value at the point when a patient received a diagnosis; the impact of radiology was effectively excluded, given that much of the work of radiology departments are geared towards arriving at a diagnosis in the first instance. This talk will focus on this "classical" model, and explore how and why it should be varied to include the impact of radiology on delivering value-based healthcare to patients. The impact of considering the value of radiology in patient care regarding ensuring patient safety will be explored.

Learning Objectives:

1. To learn about the developing model of value-based healthcare.
2. To appreciate how and why radiology should be included in this model.
3. To understand how this may impact upon patient safety.

A-0931 16:48

Patient safety related education and training

J. [McNulty](mailto:jonathan.mcnulty@ucd.ie); Dublin/IE (jonathan.mcnulty@ucd.ie)

Patient safety is a major priority for all healthcare professions and one of the biggest areas of public focus. There is no question that embedding the theme of patient safety in undergraduate medical and radiography curricula, together with making it a core part of all postgraduate or specialist education and training, has the potential to improve patient safety. While there has been a lot of focus on this in terms of other professional groups, there is a lack of information regarding the inclusion of patient safety topics within undergraduate radiography curricula or indeed within radiology training programmes. Radiographers and radiologists encounter numerous patient safety issues which stretch far beyond the area of radiation protection. The responsibilities of radiographers and radiologists overlap substantially across most areas; thus team-working within the medical imaging environment is key to ensuring a safe environment for our patients. Recent evidence from the European Federation of Radiographer Societies (EFRS) demonstrated that patient safety is a deeply embedded concept within undergraduate radiography curricula across Europe, however, variations, some of which are significant, do exist in terms of the topics covered, the teaching and assessment methods, and the depth or level in which subjects are taught. This presentation will explore aspects of patient safety-related education and training for radiographers and will highlight the current opinions of the ESR and EFRS in this regard.

Learning Objectives:

1. To emphasise the importance of education and training in progressing patient safety in medical imaging.
2. To consider the current status of patient safety in radiography and radiology curricula.
3. To appreciate the activities of the EFRS and ESR in the area of patient safety education and training.

A-0932 17:04

Patient perspectives on patient safety in medical imaging

E. [Briers](mailto:erikbriers@telenet.be); Hasselt/BE (erikbriers@telenet.be)

Safety for patients in medical imaging is linked to the department of "Medical Imaging - Radiology". It depends on several elements, there is the "why" they are there, the "what" will happen, the "how" does this work and the other personal but important aspects to be in a new environment. Safety has by itself different "imaging" aspects, and there is the radiation, the eventual contrast, the small space, the length of time of being unable to move and others, all of these are important but shall be offset versus the "why" the patient is there. The patient will balance some of the known facts (to him) and associated safety risks versus the risks of having a disease that may or may not cause him a big quality of life loss. The risk taken should be in relation to the expected benefit. A repeated CT-scan for lung cancer looks quite different from a CT-scan for a common cold which no-one would do. The information that the

patient needs to be able to weigh the risks versus the benefit should come from multiple sources, the medical team is multi-professional, and all can contribute. They should explain each for his part how the (not yet confirmed) disease could evolve and what the benefit of the final diagnosis would be. On the risk side, careful listening to the patient and taking note of previous experiences in imaging and beyond, allergies, psychological issues with confined spaces, being very young or old, all matter and can influence the procedure taken.

Learning Objectives:

1. To understand what patients feel about patient safety in medical imaging.
2. To appreciate the value of active engagement with patients to enhance and promote patient safety.
3. To consider initiatives to implement patient-engagement at the institutional or national level.

CT radiation risk in children: an overview

A-0933 16:00

Chairperson's introduction

E. Cardis; Barcelona/ES

Session Objectives:

1. To learn about the radiological protection issues related to CT scanning in paediatric populations.
2. To understand the state-of-the-art in radiation induced detriment from scanning.
3. To appreciate the need for optimisation in paediatric CT scanning.

A-0934 16:05

A literature update

H. [Ducou Le Pointe](mailto:hubert.ducou-le-pointe@aphp.fr); Paris/FR (hubert.ducou-le-pointe@aphp.fr)

Ultrasound and MRI are the preferred techniques in paediatrics; nevertheless, the use of computed tomography remains essential. In normal use, deterministic effects of ionising radiation are not to be feared (organ doses reach up no more than to tens milligrays). Cancer is the main stochastic effect of ionising radiation. Pediatric population is a subject of concern due to high tissue radiosensitivity and their long life expectancy. Model-based risk estimations predicted cancer risk associated with pediatric CT scan. Epidemiological studies seem to show a positive association between radiation dose from CT scans and the incidence of leukaemia and cancers. These results are questioned due to small sample size and methodological biases (lack of information about the indication of CT scans, reverse causation, risk factor confounding). Results of a large (950 000 children) European epidemiologic study called EPI-CT (EPIdemiological study to quantify risks for paediatric Computerized Tomography and to optimise doses) are expected soon.

Learning Objectives:

1. To learn about the nature of the risk of CT for children.
2. To understand how the risk is evaluated.
3. To appreciate the difficulty to draw conclusions based on the literature analysis.

A-0935 16:25

Ongoing studies and first results of the European EPI-CT study

E. Cardis; Barcelona/ES

"no abstract submitted"

Learning Objectives:

1. To learn about the largest epidemiological study (1 million patients) of the health impact of CT radiation in young people and ongoing complementary studies.
2. To understand strengths and limitations of the study and to discuss the results.
3. To appreciate the study's implications for optimisation in paediatric imaging.

A-0936 16:45

Communicating benefits and risks to parents and carers

C. [Granata](#); *Genoa/IT*

In the last two decades, the role of CT in paediatric imaging has strengthened, thanks to better image quality and shorter duration of the exam. However, concerns about the exposure of children to the relatively high CT radiation dose have been increasingly raised. Consequently, health care providers and imaging professionals sometimes must face parents' negative perception of radiation risk-benefit ratio. Experts and the public perceive the risk differently. A one-in-a-million risk is perceived as a low risk by an expert, whereas parents may perceive that the "one" could be their loved ones. Therefore, it should be ensured that patients, parents, and carers receive the information they need about CT radiation risks in a way they can understand. When establishing a dialogue in a clinical setting, it is important to talk slowly, use plain language, analogies, and metaphors, repeat key messages, and encourage questions. The expected outcome of the dialogue is that parents/patients trust health care professionals, as they have understood that the benefits of a necessary CT scan always outweigh any associated risk.

Learning Objectives:

1. To learn how to establish a dialogue in a clinical setting with parents and carers.
2. To understand goals and challenges of communicating risks and benefits of CT studies in children.
3. To appreciate the importance of parent and caregiver-centred communication.

A-0937 17:05

Daily practical challenges in CT for children

C. [Owens](#); *London/UK* (owensc@gosh.nhs.uk)

Children pose a particular challenge as patients in CT, as they are small, mobile and particularly radiation sensitive. Therefore it is important to tailor the examination, customising for each child. Optimising image quality is vital with attention to detail paramount. There are various tips and tricks in terms of immobilisation and distraction devices and important procedure such as ensuring that the child is in the epicentre of the scanner which has a very important role in good image acquisition.

Learning Objectives:

1. To learn about the potential challenges and obstacles faced when performing CT in children.
2. To understand how to tackle these challenges.
3. To appreciate the tips and tricks which can assist in acquisition of diagnostic CT images in children.

17:25

Questions and answers

16:00 - 17:30

Room O

Cardiac

RC 1603

Acute chest pain and cardiac imaging

Moderator:

P. Croisille; *Saint-Etienne/FR*

A-0938 16:00

A. Acute chest pain: who should see the patient first, the doctor or the CT department?

M. [Gutberlet](#); *Leipzig/DE*

"no abstract submitted"

Learning Objectives:

1. To become familiar with existing clinical triage scores in acute chest pain and their strengths and weaknesses.
2. To learn about the potential of cardiac CT in the management of acute chest pain patients.
3. To outline recent updates and future developments for triaging patients with acute chest pain.

A-0939 16:30

B. Myocardial perfusion in acute coronary syndrome (ACS): necessity or luxury?

R. [Vliegenthart](#); *Groningen/NL* (r.vliegenthart@umcg.nl)

Myocardial perfusion imaging (MPI) has a role in the triage setting of acute chest pain patients without ST-elevation myocardial infarction. MPI is used to confirm or exclude myocardial ischemia/infarction and estimate prognosis, in case of low or intermediate risk of an acute coronary syndrome (ACS). In

patients with prolonged chest pain, normal/non-diagnostic ECG, and initial negative blood biomarkers, rest MPI has been demonstrated to improve patient outcomes. A normal rest MPI result has a high negative predictive value for ACS and events. After symptoms have resolved, use of stress MPI is to be preferred. There is increasing evidence that MPI can also have value in the diagnostic management of patients suspected of unstable angina or non-ST-elevation myocardial infarction. When used appropriately, non-invasive imaging can reduce the number of missed diagnoses, and guide the management of patients with suspicion of ACS. This lecture covers the imaging techniques used to assess myocardial perfusion, including nuclear imaging, magnetic resonance imaging, and computed tomography perfusion. Contemporary guidelines and current use of MPI techniques in acute chest pain will be discussed.

Learning Objectives:

1. To introduce the acquisition techniques of myocardial imaging: nuclear imaging, MRI, CT.
2. To become familiar with the challenges in using myocardial perfusion in the acute setting.
3. To discuss the possible role of perfusion imaging in acute coronary syndromes.

A-0940 17:00

C. Late gadolinium enhancement (LGE) and more: the role of MRI in and after ACS

J. [Bremerich](#); *Basle/CH* (jens.bremerich@usb.ch)

Imaging plays a critical role in acute coronary syndrome (ACS). After initial treatment, noninvasive imaging is used to guide therapy further. This paper shall review current diagnostic algorithms with respect to strengths and limitations as well as future directions. In ACS, coronary catheter angiography is considered the first line imaging modality to confirm acute coronary artery disease with the advantage to perform angioplasty within a single procedure. Magnetic resonance imaging (MRI) plays a limited role in acute diagnostic workup but is of utmost importance for further therapy guidance. Cardiac MRI provides an assessment of viability in coronary artery disease for planning revascularisation. Moreover, alternative diagnoses such as myocarditis may be confirmed when coronary angiography did not confirm the initially suspected acute coronary syndrome. Myocarditis and infarction may present in a similar fashion including chest pain, ECG abnormalities and elevated markers of myocardial damage such as troponin. Cardiac MRI is a powerful tool to evaluate prognostic indicators such as the presence and size of infarction, myocardial haemorrhage or microvascular obstruction, myocardium at risk and it is the gold standard for myocardial function. Moreover, MRI shows macrostructural damage such as aneurysm formation, perforation, or papillary muscle rupture. Cardiac MRI is useful to exclude other causes of acute chest pain such as aortic dissection or intramural hematoma. Although catheter angiography remains the first-line modality in ACS, MRI provides added value to establish an alternative diagnosis and to guide further therapy.

Learning Objectives:

1. To become familiar with the technique of late gadolinium enhancement.
2. To learn about quantitative assessment of LGE.
3. To learn about the predictive power of LGE in ACS.

Breast cancer screening and treatment: how much is too much?

A-0941 16:00

Chairperson's introduction

G. [Forrai](#); *Budapest/HU* (forrai.gabor@t-online.hu)

Breast screening is a well designed and scientifically proven, evidence-based procedure. However, some scientists question the current method, raising some arguments regarding overdiagnosis and overtreatment. In this State-of-the-Art Symposium, we will analyse these problems, based on epidemiological and statistical data. New approaches, e.g. active monitoring as a treatment option would be discussed - in order to attempt to decrease unnecessary surgeries.

Session Objectives:

1. To understand the epidemiological issues of screening.
2. To understand that there are lesions not to be recalled from screening.
3. Learn about 'active monitoring' as a new treatment option.

A-0942 16:05

Overdiagnosis in breast cancer screening: the epidemiologist's view
S.W. Duffly; London/UK (s.w.duffly@qmul.ac.uk)

Overdiagnosis in cancer screening is essentially an epidemiological concept. It is defined as cancer which would not have been diagnosed in the patient's lifetime if screening had not taken place. This definition has no reference to pathology or treatment. Estimation of overdiagnosis is complicated by underlying trends in incidence taking place independently of screening and by lead time. In this presentation, we discuss the information required for reliable estimation of benefits of screening in terms of a breast cancer mortality reduction and the opportunity for less aggressive therapy. We propose a method of estimation of overdiagnosis, based on relative risk of cancer by time since the last screen, which addresses the lead time issue and provides the opportunity for sensitivity analyses to explore a range of potential underlying incidence estimates. We demonstrate the method's use on NHS Breast Screening Programme data to estimate the total excess of breast cancers due to overdiagnosis, and the excess or deficit, due to screening, of cancers receiving radical treatment (mastectomy and/or chemotherapy). We consider these estimates in the context of the mortality benefit associated with mammographic screening.

Learning Objectives:

1. To learn about estimation of overdiagnosis with minimal assumptions.
2. To understand the potential biases in estimating favourable and unfavourable effects of screening.
3. To appreciate the connection between the epidemiological definition of overdiagnosis and its clinical implications.
4. To understand the arguments for and against organised screening programmes.

A-0943 16:28

What can the radiologist do to limit overdiagnosis?
R.M. Pijnappel; Utrecht/NL (r.m.pijnappel@umcutrecht.nl)

Screening has been proven to be beneficial to women who do attend all rounds in a screening program. Nevertheless, screening has some limitations. The balance between harm and benefits is delicate. To detect all cancers, the test used for screening should be as sensitive as possible. Despite this, there will always be a gap between test sensitivity and program sensitivity. The difference between test and program sensitivity will be explained during the session. The optimal test for breast cancer screening is under debate. FFDM and Tomosynthesis (DBT) compete to be the best test. The advantages and disadvantages of both FFDM and DBT will be discussed. Recall rate plays an important role in relation to program sensitivity. This relationship will be explained. This explanation will give insight to the policy not to recall every lesion and therefore accept false-negative results. Apart from limiting overdiagnosis in a screening environment, radiologist play an important role in overdiagnosis in the assessment of recalled cases. Ultrasound of the breast and especially ultrasound of the axilla constitute an important part of this overdiagnosis. The optimal timing for performing an ultrasound of the axilla in the workflow is defined by recall rate, a positive predictive value of the recalled lesion, tumour board availability and other logistics items. It is more complex than the BI-RADS score alone. By using the optimal screening test, controlling the recall rate and optimising the assessment of recalled cases, radiologists can play an important role in minimising overdiagnosis.

Learning Objectives:

1. To estimate test sensitivity in relation to programme sensitivity in screening.
2. To learn what the optimal test for population based screening is: FFDM or tomosynthesis in relation to overdiagnosis.
3. To understand that there are lesions not to be recalled from screening.
4. To learn the place of the ultrasound of the axilla: in BI-RADS 4, 5 or never?

A-0944 16:51

Are there breast cancers we do not have to treat?
M.G. Wallis; Cambridge/UK (matthew.wallis@addenbrookes.nhs.uk)

Not all breast cancers are the same. IHC subtypes replaced grade and now 12 genetic subtypes of breast cancer all of which have different prognosis and respond differently to treatment. Treatment de-escalation is not new, simple mastectomy has replaced Halstead mastectomy, and now conservation with radiotherapy is routine. Side effects of current treatment are physical, cosmetic and psychosocial, ranging from death from catastrophic sepsis to lymphoedema, chronic pain and musculoskeletal symptoms. Number Needed to Treat quantifies the potential for, but trials are needed to identify which individual woman can safely avoid some or all treatment. It is difficult to recruit to these trials because public risk perception does not match reality as shown by the increasing numbers of bilateral mastectomies in the United States. The concept of low-risk cancer or the need for less treatment is a difficult explain in

the face of advertising and fundraising campaigns frequently centred around fighting cancer or the new wonder drug. This is led for calls to relabel lower risk cancers with terms like IDLE. Radiology is changing surgical paradigms. Atypia is managed by vacuum excision, there are trials of no surgery for low-risk DCIS and investigating the role of needle biopsy to identify women with a complete pathological response to NAC who might not need surgery. For those women with low-risk disease, we need to offer and make clear that careful radiological monitoring within a trial is an active treatment option not just 'being abandoned to follow up'.

Learning Objectives:

1. To review side effects of current treatments.
2. To be able to discuss what lesions we could consider reducing treatment burden.
3. To learn about radiological options to the current surgical treatment paradigm.
4. To learn about 'active monitoring' as a new treatment option.

State-of-the-art imaging of postoperative joints

Moderator:

M.F. Reiser; Munich/DE

A-0945 16:00

A. Postoperative shoulder
C.W.A. Pfirrmann; Zurich/CH

Imaging of the postoperative shoulder is challenging because of various surgical techniques, distorted anatomy and the presence of artefacts because of metallic implants. The most commonly performed surgical procedures include rotator cuff reconstruction, instability surgery, and joint replacements. The radiologists should have knowledge of these techniques. In this presentation, these surgical techniques, the normal imaging findings after these procedures and the abnormal findings as well as imaging strategies will be discussed.

Learning Objectives:

1. To explain the most frequently used surgical techniques for glenohumeral instability, subacromial decompression, rotator cuff repair and arthroplasty, and their imaging appearance.
2. To describe potential postoperative complications.

A-0946 16:30

B. Postoperative knee
E.H.G. Oei; Rotterdam/NL (e.oei@erasmusmc.nl)

In this masterclass, we will review the indications for the most commonly performed surgical techniques in the field of meniscal repair, knee ligament reconstruction, and knee cartilage repair, followed by a brief explanation of the surgical procedure. We will also highlight recent advances in joint preserving procedures around the knee. Of each discussed technique, the normal postoperative appearance on imaging will be presented, with an emphasis on MR imaging. This is followed by a discussion on the assessment of potential complications. Among the discussed topics will be complications after ACL reconstruction (tunnel positions, graft re-rupture, impingement, arthrofibrosis, cyclops lesions), assessment of meniscus re-tear after surgical repair, and assessment of the success after cartilage repair procedures.

Learning Objectives:

1. To explain the most frequently used surgical techniques for meniscal repair, ligament reconstruction and cartilage repair.
2. To describe potential postoperative complications.

A-0947 17:00

C. Postoperative ankle and foot
M.J. Ereno Ealo; Galdacano/ES (mjeren@gmail.com)

Foot and ankle traumatic pathologies are frequent conditions. Diagnosis, treatment and subsequent management of foot and ankle traumatic pathologies are important to avoid big deformities. The most current and innovative techniques of internal fixation and their applications will be shown.

Very different injuries and cases will be detailed: surgical management and complications of high-energy fractures, tibia pilon fractures; calcaneus, talus and Lisfranc lesions, diabetic (Charcot) foot, Morton's Neuroma, hammer toe, tarsal coalition, adult acquired flatfoot. Also, patients with arthroplasty, arthrodesis and triple fusion and ankle replacement should be recognised.

Learning Objectives:

1. To explain the most frequently used surgical techniques for osteosynthesis, instability, tendon repair and arthroplasty, and their imaging appearance.
2. To describe potential postoperative complications.

16:00 - 17:30

Neuro

RC 1611

The degenerative cervical spine

Moderator:

N. Chidambaranathan; Chennai/IN

A-0948 16:00

A. Degenerative uncovertebral and facet disease

J. Van Goethem; Antwerp/BE (johan.vangoethem@uantwerpen.be)

Neck pain is a common problem with many possible causes. The facet joint and the uncovertebral joint are frequently involved in degenerative cervical spine disease. It is important to learn how to differentiate normal and asymptomatic changes that occur with age from abnormal findings that are causing neck and/or arm pain. I will demonstrate the use of plain film, CT, SPECT and MRI in diagnosing an offending uncovertebral or facet joint. Many of these offending joints can be targeted specifically, leading to easy and fast pain reduction in many patients with specific neck pain.

Learning Objectives:

1. To learn about the physiological and pathophysiological degeneration of the cervical spine.
2. To understand the role of imaging in the diagnosis and clinical decision making in the degenerative cervical spine.
3. To appreciate the clinical relevance of imaging findings in the degenerative cervical spine.

A-0949 16:30

B. Cervical spinal stenosis and cervical spondylotic myelopathy

A.S. Gersing; Munich/DE

Degenerative changes of the cervical spine may be caused by mechanical overload or may occur during the ageing process. Patients with spinal stenosis may present with clinical symptoms ranging from neck pain to spastic paraparesis. Imaging is crucial in these cases in order to identify the cause of these clinical symptoms and to select the appropriate treatment option. Spinal stenosis is caused by certain pathological features that occur during the degenerative process, e.g. marginal osteophytes of the vertebrae, hypertrophy of the ligaments and intervertebral disc degeneration with herniation. Radiographs, CT as well as CT-myelography and MR imaging are the common imaging modalities used for the assessment of the severity of the spinal canal stenosis. Next to the assessment of soft tissue structures and osseous structures of the vertebrae, especially T2-weighted MR imaging is crucial for the assessment of signal changes within the myelon. One of the most important aspects assessed with MR imaging is the differentiation between signs of acute myelopathy and myelomalacia, caused by irreversible damage of the spinal cord. These aspects are of importance for the selection of the adequate treatment option, especially in order to decide between conservative or surgical treatment.

Learning Objectives:

1. To learn about the pathophysiology and imaging findings in spinal stenosis and cervical spondylotic myelopathy.
2. To understand the relation between imaging findings and clinical presentation.
3. To appreciate the importance of imaging findings and the clinical presentation with respect to possible treatment options.

A-0950 17:00

C. The postoperative cervical spine

S. Looby; Dublin/IE

Imaging is a routine part of follow up for the postoperative cervical spine. A knowledge of the surgical techniques and/or the hardware used for cervical surgical and instrumentation procedures is very helpful in understanding the postoperative imaging appearances. A knowledge of the imaging modalities and when to use them is required. Ways to reduce metal artefact in imaging should be implemented. Radiography provides information on cervical spine fixation or metallic hardware placement. CT provides information on cervical

spine alignment, hardware placement and integrity, and bone graft incorporation or complications. MRI is helpful for complications of surgery not directly related to hardware. These include signs of CSF leakage, pseudomeningocele, epidural or other haemorrhage and infection. In the context of the degenerative cervical spine, MRI shows residual or recurrent disk osteophyte complex. Long-term sequelae of cervical spine fusion such as hardware failure, advanced degeneration, post laminectomy spondylolisthesis and epidural and other scar tissue are detected by follow up imaging. The entity of the failed back surgery syndrome needs to be considered with the postoperative cervical spine and what to look for in imaging it. The combination of understanding the surgical techniques used, using the correct imaging modality for the patient symptoms and having a systematic approach to the imaging evaluation, renders imaging of the postoperative cervical spine safe, practical and useful.

Learning Objectives:

1. To learn about the imaging findings and pitfalls of postoperative cervical spine imaging.
2. To understand the heterogeneity of imaging findings and their clinical relevance.
3. To appreciate the importance of standardised imaging, interpretation and reporting of postoperative imaging findings in the cervical spine.

E³ - European Diploma Prep Session

E³ 1623

Chest

A-0951 16:00

Chairperson's introduction

J. Vilar; Valencia/ES (vilsamper@gmail.com)

In this session, the speaker, all of them experts in thoracic imaging will approach the main aspects of chest radiology related to the European Training Curriculum, levels I and II. These topics are the objective of preparation for the European Diploma examination. In the examination, there will be questions related to knowledge, skills and decision making that the authors of the three lectures will offer to the audience. Please pay attention to basic facts, differential diagnosis, the value of imaging techniques, diagnostic clues, and management issues related to the topics of the session.

Session Objectives:

1. To understand the most important signs in chest imaging.
2. To learn the imaging features of benign and malignant lesions of the lung.
3. To become familiar with the imaging appearance of common lesions of the mediastinum, pleura and chest wall.
4. To understand the role of different imaging modalities including hybrid imaging in diagnosing and staging neoplasms of the chest.

A-0952 16:06

A. Fundamentals of chest imaging

M. Occhipinti; Florence/IT (mariaelena.occhipinti@gmail.com)

Chest imaging remains one of the most complicated subspecialties of diagnostic radiology. The fundamentals in the interpretation of chest imaging are the knowledge of the normal anatomy as well as the radiographic signs. Anatomy of the respiratory system and its variants in the different imaging techniques will be reviewed, including chest radiography, CT and MRI. Monitoring and support devices such as different types of tubes and lines will be shown along with their correct position in the chest. Chest radiography signs are helpful in establishing a particular diagnosis of chest diseases. Therefore, their recognition and understanding is of particular interest for general and subspecialised thoracic radiologists. During the presentation, many radiographic signs will be discussed, including silhouette sign, air bronchogram, air crescent sign, cervicothoracic sign, gloved finger sign, golden S sign, deep sulcus sign, *coeur en sabot* sign, doughnut sign, double density sign, hilum convergence sign, hilum overlay sign.

Learning Objectives:

1. To learn the anatomy and normal variants of the respiratory system, heart and vessels, mediastinum and chest wall and to confidently identify these on radiographs, CT and MRI.
2. To gather an in-depth understanding of the most common chest radiography signs (including silhouette sign, air bronchogram, air crescent sign, cervicothoracic sign, tapered margins, gloved finger sign, golden sign, deep sulcus sign).
3. To learn the appearance and correct position of monitoring and support devices (tubes and lines).

A-0953 16:34

B. Inflammation and tumours of the lung

A. Nair; London/UK

"no abstract submitted"

Learning Objectives:

1. To understand the imaging features and differential diagnoses of diffuse infiltrative and alveolar lung disease and atelectasis.
2. To become familiar with thoracic diseases in immunocompetent, immunocompromised and post-transplant patients.
3. To become familiar with the differentiation of solitary and multiple pulmonary nodules, benign and malignant neoplasms, hyperlucencies and their potential aetiology and evaluation.
4. To understand the role of different imaging modalities including hybrid imaging in diagnosing and staging neoplasms of the chest.

A-0954 17:02

C. Mediastinum, pleura and chest wall

A.P. Parkar; Bergen/NO (apparkar@gmail.com)

The normal appearance of the diaphragm is usually similar on both sides. The diaphragm may be elevated on either side due to abdominal tumours, paresis of the phrenic nerve, traumatic rupture, or subpulmonic pleura effusion. The pleura may be thickened due to effusion, fibrosis with or without calcifications or due to malignancy. The chest wall has a varying normal appearance according to the shape of the rib cage and sternum. The mediastinum is a complex anatomic area which is affected by changes in vascular system and lymphadenopathy. In addition, various diseases like infections and tumours can be seen in the mediastinum. The postoperative chest radiograph is sometimes challenging to read because it usually is done in a supine position and only a front image is performed. It is important to recognise "do-not-miss" pathology such as pericardial fluid, tensions pneumothorax, or malpositioned tube and central lines.

Learning Objectives:

1. To become familiar with the imaging features of common pathologies of the diaphragm, pleura and chest wall on radiography, CT and MRI of the chest.
2. To learn the imaging features and causes of mediastinal and hilar diseases.
3. To understand the imaging features of disorders of the pulmonary vascular system and great vessels.
4. To learn the typical imaging features of the postoperative chest.

Other; Thirona, Departmental spinoff, Mevis Medical Solutions, Departmental Licence agreement.

A-0956 16:06

How to set up and run a multidisciplinary meeting

C. Dromain; Lausanne/CH (Clarisse.Dromain@chuv.ch)

Since few years, evidence has shown that multidisciplinary tumour boards (MTB) improve diagnostic accuracy, adherence of clinical practice guideline and clinical outcomes. However, new factors impact the efficiency of MTB including oncologic disease becoming more and more complex, the increased number of oncologic patients, multiplicity of new therapeutic options and new diagnostic approaches, the development of network operation and the need for multidisciplinary apart from oncology. The efficiency of MTB will depend upon the limited available resources especially for transverse specialities (diagnostic radiology, interventional radiology, nuclear medicine, pathology) and the need for high quality required in highly specialised medicine. In addition to its

primary goal, optimal treatment management in complex cases, MTB also have an education and a social value role. Key elements for running an effective MTB are the selection of patients, preparation of cases, which questions to ask the MTB, the presence of the referring clinician, availability of all findings (clinical, images, pathology etc.), appropriate equipment for images display and direct reporting of the MTB decision. Other parameters of importance are the date and location of the MTB, the role of the chairman, the delay between the announcement of the cases and the MTB, the order of cases presentation and the link with other TBMs. Good running of MTB also need the availability of images with PACS for review, availabilities of histopathological information and availability of clinical and other information. Projection equipment is also needed to display imaging +/- pathology slide.

Learning Objectives:

1. To learn how to best structure a multidisciplinary meeting to avoid wasting time.
2. To appreciate the various roles in a multidisciplinary meeting and how they influence meeting organisation.
3. To learn how to integrate modern tools for improved data collection, communication and evaluation in tumour boards.

A-0957 16:24

Preparation for tumour boards: how to increase efficiency of the radiologist?

D. Regge; Turin/IT (daniele.regge@ircc.it)

Radiologists are pivotal for the success of MTBs. The probability of reaching a treatment decision for a patient is largely increased when radiologists participate in the meeting, and patient survival improves among several types of cancer. However, MTBs add on to radiologist's workload significantly due in particular to the time required to review cases prior to meeting. Increasing efficiency in the preparation of tumour boards will impact favourably on radiologist's workload, increase efficiency and reduce costs for healthcare providers. The lecture aims to provide practical tips and knowledge on technical advancements that may support the radiologists in preparing for MTBs.

Learning Objectives:

1. To learn how effectively prepare for a multidisciplinary tumour board meeting.
2. To appreciate the clinician's perspective and understand the expectations towards the radiologist.
- 3 To learn how to concisely and efficiently communicate relevant findings.

Author Disclosure:

D. Regge: Author; Springer. Consultant; im3D. Research/Grant Support; Sanitas. Speaker; GE Healthcare, GE Medical Systems.

A-0958 16:42

Physical or virtual multidisciplinary meetings?

E. Neri; Pisa/IT (emanuele.neri@med.unipi.it)

"no abstract submitted"

Learning Objectives:

1. To understand the trade-offs of physical and virtual meetings.
2. To learn how to best set up remote access to a multidisciplinary meeting.
3. To understand how to organise and structure regional multidisciplinary tumour board meetings.

A-0959 17:00

Maximising the added value of tumour boards

C.D. Becker; Geneva/CH

Organ- or disease- specific multidisciplinary tumour boards play a key role for the selection of appropriate modern treatment for patients with neoplastic disease. Radiologic subspecialty expertise is essential and required for both diagnosis and treatment. In the age of personalised medicine, a precise diagnosis must include many different aspects, including morphologic and functional, metabolic, molecular and genetic elements, quantification and individual longitudinal follow- up. Closer integration of all these findings will be required in the future in order to offer the best possible treatment to all patients. Minimally invasive vascular or percutaneous image- guided interventional techniques are gaining increasing importance in tumor treatment. These techniques may be used for curative, adjuvant or palliative indications, and either in an alternative or adjunctive - sequential fashion for a variety of neoplastic diseases. Therefore it is also important that interventional radiology has its place in the multidisciplinary organisation, including decision making at tumor boards.

Learning Objectives:

1. To understand the role and challenges of institutional multidisciplinary guidelines including imaging.
2. To learn about integrating diagnostic information before tumour board meetings.
3. To learn how to include the role of interventional radiology in tumour board meetings.

Radiation protection: all you need to know

A-0960 16:00

Chairperson's introduction: Evolving radiographers' role in radiation protection

B.R. [Mussmann](mailto:bo.mussmann@rsyd.dk); Odense/DK (bo.mussmann@rsyd.dk)

The system of radiological protection is built on science, experience and ethics reflected in the basic principles in ICRP103, i.e. optimisation of protection, dose limitation and justification. Radiographers are important stakeholders in the maintenance of the system, both legally, ethically and practically. The session reviews different aspects of radiation protection that may form the basis of further development of radiographers' roles and responsibility.

Session Objectives:

1. To understand radiographers' current legal responsibilities regarding radiation protection.
2. To consider the role radiographers play in application of the justification principle.
3. To review recent optimisation techniques for projection radiography.
4. To appreciate how radiographers can best communicate risk-benefit information to patients.

A-0961 16:05

The Basic Safety Standards Directive: early experiences of implementing BSS

S.J. [Foley](mailto:shane.foley@ucd.ie); Dublin/IE (shane.foley@ucd.ie)

The European Commission issued its most recent radiation protection Directive (2013/59/Euratom) in December 2013 which repealed five other Directives (including 97/43/Euratom) and had a deadline for transposition by all Member States of the EU by February 2018. Therefore this presentation will review the European-wide adoption of the new Directive, which takes into account new recommendations from the ICRP in light of new scientific evidence and is hoped will strengthen the culture of radiation safety throughout Europe. While the Directive remains faithful to and maintains the already well-accepted pillars of radiation protection - justification, optimisation and dose limitation, these are further strengthened in this Directive. Further new requirements under the Directive will also be discussed, including obligations related to recording dose information and communicating benefit/risk to patients. Additional responsibilities have also been designated to a number of professionals which will impact the work of both radiographers and radiologists alike, so all imaging staff need to be aware of its implications. This will ensure the true ethos of the Directive can be effectively implemented into routine clinical practice. Finally, some potential challenges for practical adoption of the Directive will be addressed.

Learning Objectives:

1. To familiarise attendees with the European BSS Directive (2013/59).
2. To discuss the additional responsibilities of radiographers and radiologists under the Directive.
3. To understand how the implementation of the BSS Directive may affect practice.

A-0962 16:23

Enhancing the culture of justification

K.B. [Lysdahl](mailto:Kristin.Bakke.Lysdahl@usn.no); Kongsberg/NO (Kristin.Bakke.Lysdahl@usn.no)

Justification of referrals is a primary principle in radiology, with impact within and beyond radiation protection. The practice of justification influences the quality of patient care, the professionals' working conditions and the allocation of healthcare resources. Still, reported frequencies of unjustified examinations to indicate implementation challenges, explainable by the complexity of the principle. Justification of an examination demands an overview and balancing of a number of relevant benefits and risks, based on outcome predictions. Moreover, the people involved may appraise the benefits and risks differently, and the distribution of responsibility and power in the decision-making process may not be clear. The presentation will address the potential for radiographers to contribute to justified examinations. They can contribute by vetting the amount and quality of information in the referrals, by providing supplementary information, and by authorising referrals according to guidelines. The

possibilities, preconditions and scope of the radiographers' contribution will vary according to cultural and organisation aspects, training and regulations, locally and nationally. Some lessons can be learned by the radiographers' perceived role in justification, reported in the literature. Initiatives from the radiation protection environment to improve adherence to the principle of justification are summarised in the key concepts of Awareness, Appropriateness and Audit. The presentation will consider elements of the AAA approach, and offer reasons why increased involvement by radiologist and radiographers are called for. Finally, initiatives particularly relevant for the imaging departments will be highlighted, including guideline implementation, education, clarification of roles and collaboration in the referral process.

Learning Objectives:

1. To appreciate the key role of justification within radiation protection.
2. To be familiar with the role radiographers can play in justification.
3. To consider initiatives for improving adherence to the principle of justification.

A-0963 16:41

Opportunities for optimising dose in digital radiography

P.H. [Hogg](mailto:P.Hogg@salford.ac.uk); Salford/UK (P.Hogg@salford.ac.uk)

From a dose optimisation perspective, general descriptions of image quality that are divorced from the abnormality to be considered are likely to give less accurate and possibly unreliable results. With a range of perspectives in mind, this presentation offers a reflective critical commentary on contemporary image quality definitions in relation to the abnormality to be considered. Building on this, a definition of clinical image quality is then proposed which considers the purpose of the imaging examination; image quality definitions such as this would likely result in 'personalised' optimisation which should result in more valid and reliable dose optimisation outcomes. With a personalised definition in mind contemporary visual and physical approaches to image quality assessment, in pure and modified forms, will be considered in relation to optimisation and the abnormality to be considered. The presentation will then examine potential pre-emptive personalised image quality assessment optimisation approaches that might be implemented before exposure; post-acquisition personalised image quality assessment will also be examined similarly. The presentation will conclude by offering practical steps which might be taken to optimise images, with dose and personalised image quality in mind. Some consideration will be given to the role of Artificial Intelligence (AI) could play in the assessment of personalised image quality in optimisation, with or without human observers as part of the interpretation process.

Learning Objectives:

1. To discuss the limitations of image quality as a parameter for use in optimising dose in medical imaging examinations.
2. To discuss a range of visual and physical techniques that can be used to assess medical image quality.
3. To discuss a range of practical measures which might be implemented to minimise radiation dose whilst maintaining a level of image quality that is fit for purpose.

A-0964 16:59

The radiographers' role in benefit-risk communication

J. [Portelli](mailto:jonathan.portelli@um.edu.mt); Msida/MT (jonathan.portelli@um.edu.mt)

By now all EU Member States should have implemented the requirements specified in the BSS Council Directive 2013/59/EURATOM into their respective national legislation, thereby ensuring that relevant practices abide by the revised basic safety standards for the protection against dangers arising from exposure to ionising radiation. In effect, apart from the specific responsibilities relating to the justification and optimisation of each medical radiation exposure, referrers and/or practitioners are now legally obliged to provide each patient or their representative with adequate information relating to the benefits and risks associated with the radiation dose to be received from a proposed medical imaging procedure that involves radiation. While referrers and practitioners may have already been satisfying this 'new' responsibility in their daily practice, the fact that this is now specifically defined within regulations should oblige more health professionals to be attentive to fulfil this responsibility as effectively as possible. This lecture will, therefore, seek to outline and emphasise the key role radiographers play in benefit-risk communication. It will highlight the importance of radiographers being knowledgeable of radiation-related concepts, as well as the associated benefits and risks of medical imaging procedures they perform. Additionally, the need for radiographers to develop and have effective communication skills will also be emphasised, since these are necessary to allow them to convey adequate information in accordance to the needs and preferences of different patient groups and their families, as well as to other health professionals that may be involved in the patient's care.

Learning Objectives:

1. To understand new legislative requirements under the BSS Directive.
2. To be aware of the key role radiographers play in benefit-risk communication.
3. To understand key principles for appropriate benefit-risk communication.

The old spine: challenges of imaging and treatment

Moderator:

R. Pedersen; Toensberg/NO

A-0969 16:00

A. Degeneration of the old spine: relevance of findings and differential diagnosis

V.N. Cassar-Pullicino; Oswestry/UK (Victor.Pullicino@nhs.net)

With increasing age degeneration of the spine is inevitable with a tendency to affect all segments from cervical to lumbosacral junction. The underlying pathophysiology is related to the failure of the supporting osteo-ligamentous structures which can manifest itself in an isolated fashion, involving contiguous levels or affecting non-contiguous segments. Failure of the three articulations at each discovertebral motion segment (disc and facet joints) predisposes to micro-movement and a cascade of disc degeneration and facet degeneration promoting disc herniation, facet joint hypertrophy and spondylolisthesis or retrolisthesis. It is, however, important to note that despite visualisation of these structural changes on imaging, one cannot correlate irrespective of severity, associated clinical findings. However, these pathophysiological processes are not uncommonly symptomatic with patients presenting with spinal pain, radiculopathy or myelopathy. The emphasis of this talk is to demonstrate these degenerative processes and their complications ranging from spinal stenosis which can be at multiple sites, to deformity which can be incapacitating and difficult to treat. The combination of advanced degeneration with deformity can alter the balance of the spine and promote unusual biomechanical forces which can overwhelm the bone strength of the vertebral bodies which in the presence of metabolic disease results in bone failure producing destructive discovertebral changes within the spine.

Learning Objectives:

1. To explain the pathophysiology of degenerative changes in the spine.
2. To describe the imaging findings of degenerative diseases of the spine.

A-0970 16:30

B. Fractures: bone fragility in the elderly, assessing osteoporosis and bone quality and differential diagnosis

G. Guglielmi; Andria/IT (giuseppe.guglielmi@unifg.it)

Osteoporosis is still considered one major public health problem, dealing with vertebral fractures and hip fractures; also, it is largely known that mortality is also increased after vertebral fractures. Currently, the diagnosis of osteoporosis, measured by dual-energy x-ray absorptiometry (DXA), is based on areal bone mineral density (aBMD), but osteoporotic fractures can also occur when aBMD is still above the pathologic range. Several imaging modalities, such as computed tomography (CT) scans and magnetic resonance imaging (MRI), have been used to improve bone assessments and its relation to fracture risk prediction. Among these the most applied is quantitative CT (QCT) scans, that can measure volumetric BMD (vBMD) and trabecular bone score (TBS), attempting not only to measure the "bone quantity" but also the "bone quality", by means of the study of microarchitecture, structure, bone turnover and bone strength. MRI is also being studied as a tool to assess vertebral bone density based on bone marrow fat content; in fact, vertebral osteoporosis is characterised by thinning trabecular and cortical bone and an increase in fat. A comprehensive assessment of fracture risk requires data on bone density, fracture history, and bone quality, which can be provided by several imaging modalities, each with its advantages and disadvantages. Clinically, DXA remains to most widely available and used technique to assess BMD as it is the only validated method to diagnosis osteoporosis by WHO T-score criteria. The role of densitometers has expanded to include VFA and TBS, though accessibility to these add-on tools is still limited.

Learning Objectives:

1. To explain the pathophysiology of osteoporosis in the spine.
2. To describe the imaging findings of spinal osteoporosis and its consequences.

A-0971 17:00

C. Interventional radiology: is there still a place for vertebroplasty and kypho-/stentoplasty

C. Binkert; Winterthur/CH (christoph.binkert@ksw.ch)

The first reports of vertebroplasty were published in the late 1980s. Over the years the technique of polymethylmethacrylate injection under fluoroscopic guidance hasn't changed much. In clinical practice, vertebroplasty became an established therapy for painful mostly osteoporotic fractures. Randomised trials against conservative therapy have consistently shown a benefit for vertebroplasty- the latest study was the VAPOUR trial. On the other hand, vertebroplasty wasn't superior to a sham procedure in three large trials the latest being VERTOS IV. In all sham trials patients benefitted from the intervention (vertebroplasty and sham procedure), so the question is why the sham procedure worked. Despite these trials, vertebroplasty is still offered to many patients suffering from painful vertebral body fractures because of general good pain relief, high patient satisfaction and very few complications. As with many IR procedures, appropriate patient selection is important. Besides the clinical exam (tenderness on percussion) and history (sudden onset of different pain), an MRI should be performed beforehand. Best outcomes were observed with fractures dark on T1 and bright on T2 fatsat/STIR. For pain relief, vertebroplasty seems sufficient. If height restoration is intended kyphoplasty (balloons) or stentoplasty (balloon expandable stents) can be used. The concept of the stent is to avoid recollapsing after deflating of the balloon. For a successful height restoration, the fracture needs to be mobile, which is typically the case within the first 10-14 days.

Learning Objectives:

1. To explain the procedures of vertebroplasty and kyphoplasty.
2. To discuss the current role of vertebroplasty and kyphoplasty in spinal fractures.

Joint Session of the ESR and ESHI^{MT}

ESR/ESHI(MT)

Hybrid and translational imaging: the bigger picture

A-0972 16:00

Chairpersons' introduction (part 1)

O. Ratib; Geneva 14/CH

Hybrid imaging combining molecular imaging (PET or SPECT) with anatomical and functional imaging (CT and MRI) offers a scope of new clinical applications. The development of new radiotracers for PET imaging opens a new perspective for more objective evaluation of the efficacy of new treatments. The emergence of hybrid PETMR imaging offers new perspectives for functional hybrid imaging and tissue characterisation. The combination of both modalities improves the accuracy and reproducibility of diagnostic procedures.

Session Objectives:

1. To illustrate examples of clinical relevance for hybrid imaging.
2. To highlight the translational aspects of hybrid imaging.
3. To introduce the session faculty and objectives of the presentations.

A-0973 16:03

Chairpersons' introduction (part 2)

C.C. Cyran; Munich/DE (clemens.cyran@med.uni-muenchen.de)

The concomitant acquisition of morphological, functional and molecular information using hybrid imaging techniques allows for a high diagnostic accuracy in the detection of tumour manifestations and the timely differentiation of responders from non-responders using different tracers and in various tumour entities. Clinically available tracers such as [18F]-FDG, [68Ga]-DOTA-TATE/-TOC, [18F]-PSMA und [18F]-DOPA allow for the visualisation of glucose metabolism, tumour receptor and protein expression, or enzymatic activity, depending on the indication and tumour entity. Modified criteria for monitoring response to molecular anti-cancer agents are increasingly integrating functional imaging information (Cheson criteria, PERCIST) to improve the standardised and reproducible assessment of therapy response by imaging studies and their application as qualified imaging biomarkers. An array of novel radiotracers for PET and SPECT imaging is under translational development for a broad range of applications in imaging of neurodegenerative, cardiovascular and oncological diseases. The theranostics concept of tracers such as DOTA-TATE and PSMA for radionuclide therapy in metastasised cancer patients has shown success in selected patient groups

Postgraduate Educational Programme

and may serve as a blueprint for future application of novel compounds in oncological therapy.

Session Objectives:

1. To illustrate examples of clinical relevance for hybrid imaging.
2. To highlight the translational aspects of hybrid imaging.
3. To introduce the session faculty and objectives of the presentations.

A-0974 16:05

Prostate-specific membrane antigen (PSMA) PET/MR: guiding clinical management of prostate cancer

P.A.T. Baltzer; Vienna/AT

Prostate-specific membrane antigen-based PET has rapidly changed the way prostate cancer is diagnosed. It provides a highly accurate tool to detect, stage and grade prostate cancer and can further be used to guide and monitor treatment. It further allows a theranostic approach to treat prostate cancer. On the other hand, MRI provides the to date most accurate tool to image-based prostate cancer detection in the prostate. In addition, its superior soft tissue contrast is considered to be superior to CT in many respects. Whether PET-MRI is indeed superior to PET-CT regarding the staging of prostate cancer is a matter of debate, and empirical data regarding this topic is sparse. The talk will address the learning objectives given below.

Learning Objectives:

1. To learn about the requirements in clinical management of prostate cancer.
2. To understand the potential role of PSMA PET/MR in the management of prostate cancer.
3. To learn about the advantages of the hybrid PET/MR technique in this setting.
4. To become familiar with typical findings and pitfalls of hybrid PSMA PET/MR in the evaluation of prostate disease.

A-0975 16:30

On the horizon: novel PET tracers with translational potential

G. Cook; London/UK (Gary.Cook@kcl.ac.uk)

There are few hallmarks of cancer that we cannot exploit with imaging. In particular, there are several PET and SPECT probes that can measure abnormal metabolic processes (e.g. 18F-FDG, 99mTc-sestamibi), proliferation (e.g. 18F-FLT, 18F/11C-choline), receptor overexpression (e.g. 68Ga-dotatate, 68Ga-PSMA), apoptosis (e.g. 18F-ML10), hypoxia (e.g. 18F-MISO, 64/62Cu-ATSM) and angiogenesis (e.g. 89Zr-bevacizumab, 18F-RGD), amongst others. While some of these tracers are useful for diagnosis and phenotyping, many are of interest for predicting early treatment response, especially in the setting of targeted biologic therapies where an early reduction in tumour volume is not expected and where morphologic CT and MRI are therefore limited. Of current interest is the evaluation of response to immunotherapies that may cause pseudoprogression caused by immunocellular infiltration before subsequent tumour shrinkage. In this situation, early pseudoprogression may also be seen with an 18F-FDG PET and hence the interest in more specific tracers such as 89Zr or 99mTc-PDL1 antibody. While PET and SPECT probes are invaluable in reporting on underlying biological tumour characteristics, both CT and MRI provide valuable supportive information in hybrid imaging scanners allowing anatomical reference as well as some functional measurements, e.g. cellularity with DWI and perfusion with DCE MRI / pCT. The ultimate goal of predicting which patients will respond to which treatment, or at least to determine non-response as soon as possible, is not fully achieved in the clinic with imaging as yet but some areas are now contributing to clinical practice, e.g. 18F-FDG PET/CT to guide treatment escalation/de-escalation in lymphoma.

Learning Objectives:

1. To become familiar with future targets in oncologic hybrid imaging.
2. To learn how hybrid imaging can support the oncologist in diagnosis and therapy response assessment.

A-0976 16:50

Advances in theragnostics: monitoring radionuclide therapy

H. Ilhan; Munich/DE (Harun.Ilhan@med.uni-muenchen.de)

The use of radiolabeled compounds for molecular imaging and therapy represents two pillars of nuclear medicine and serves as a perfect example of the theragnostic concept for decades. In recent years hybrid PET/CT imaging using Somatostatin-Receptor- (SSR-) and Prostate Specific Membrane Antigen- (PSMA-) targeting Peptides established as an indispensable tool in the management of Neuroendocrine Tumor (NET) and Prostate Cancer (PC) patients. The selective uptake and accumulation pattern paved the way for the therapeutic application of beta- and alpha-emitting compounds. FDG-PET and the implementation of the PERCIST criteria have demonstrated value in the evaluation of therapy response in tumours with high metabolic activity. However, up to date little is known about the value of specific PET-compounds that are used in the theragnostic concept of radionuclide imaging and therapy.

In clinical practice, response assessment and therapy monitoring are still based on morphological criteria, whereas the value of PET-derived information remains unclear. Currently, SSR- and PSMA PET imaging has not yet been validated for therapy monitoring in NET and PC patients. Nonetheless, response evaluation to radionuclide therapy based on PET-information has been proposed, however, mainly in retrospective single-center studies with low patient numbers. Current imaging guidelines state that the value of PET imaging in the assessment of response to radionuclide therapy remains unclear as decreased PET-tracer uptake after radionuclide therapy does not necessarily indicate response and might be attributed to other factors such as dedifferentiation. However, recent data indicate that there might be a high value of PET-imaging for response assessment.

Learning Objectives:

1. To learn the principles of radionuclide imaging and therapy in the concept of theragnostics.
2. To understand the differences and common ground between morphological and molecular imaging.
3. To discuss new approaches for response assessment in radionuclide therapy.

Professional Challenges Session

PC 16

How to organise nationwide ischaemic stroke care (and make multidisciplinary teams work)

A-0977 16:00

Chairperson's introduction: Stroke care in Austria: small country, small challenge?

C. Loewe; Vienna/AT (christian.loewe@meduniwien.ac.at)

The recent developments in the mechanical treatment of ischemic stroke provide fantastic chances to patients but also cause great challenges to the healthcare providers. These interventions are highly specialised but not very frequent, whereas the training and the continuous "maintenance" of skills for Interventionalist's represent a critical issue in the establishment of this service. Different approaches to this problem have been developed and propagated, and some of them should be discussed during this session. Furthermore, some relevant questions will be raised including how many Neurointerventionalist's are needed? How many centres are needed? Is a multidisciplinary group combining all available forces preferable compared to highly experienced specialists from only one medical subspecialty? Should the patient be moved to the Center where the specialist is on duty, or should the specialist travel around? Beside these potentially obvious questions, it should also be discussed what kind of organisation model could be attractive in the future for the young generation for doctors, and how we can ensure that our Strokes will be treated accordingly in the future. Even if this session possibly cannot answer all these questions, the awareness about these issues should be increased, and possible ways for possible solutions should be presented. As an introduction to the topic and the idea of this session, the Austrian situation will be presented exemplifying that different approaches to the same challenge are tried out even in a rather small Country like Austria.

Session Objectives:

1. To discuss the challenges in establishing and running a nationwide ischaemic stroke care.
2. To realise the importance of multidisciplinary team work for successful stroke care service.
3. To learn about possible training, education and certification in ischaemic stroke care.

Author Disclosure:

C. Loewe: Speaker; Siemens, Bracco, GE Healthcare.

A-0978 16:05

What you should know being involved in a nationwide ischaemic stroke service

P. Papanagiotou; Bremen/DE (papanagiotou@me.com)

The recent EVT RCTs made convincingly clear that a paradigm shift in the organisation of acute stroke care pathways is urgently needed. In the prehospital phase, the definition of patient triage and transfer protocols are

Postgraduate Educational Programme

important. There are two options for the patient transfer protocol in the acute stroke setting: in the first, a patient who is triaged as potentially EVT eligible is transferred directly to a Comprehensive Stroke Center where EVT could be offered. In the second option, a patient is transferred initially to a Primary Stroke Center where IVT is offered if the patient is eligible and then transferred further to a Comprehensive Stroke Center where EVT may be offered if indicated. In the in-hospital phase, an optimised stroke management protocol is required. Improvements in in-hospital stroke management can translate into faster treatment. Every stroke centre should have an optimised stroke management protocol to reduce the "door-to-treatment" time. An on-demand, 24-7-365, stroke reperfusion service, is also required. Emergency services are instructed to bring patients with a suspected stroke directly to the stroke treatment room, which should be located in proximity to the CT scanner. After the neurological examination, an unenhanced CT scan, CTA and CT perfusion are performed. Within the 4.5-h time window, patients are treated with IV t-PA immediately. If an occlusion of large intracranial vessel is found, the decision to perform endovascular therapy is based on the clinical condition of the patient, the time window, and the imaging criteria of the CTA and CT perfusion.

Learning Objectives:

1. To provide an overview about recent data/guidelines about endovascular stroke treatment.
2. To get familiar with the currently accepted/recommended treatment options.
3. To give an outlook about ongoing trials.

A-0979 16:23

Do you like to travel? Move the patient or the doctor?

J.-P. Pruvo; Lille/FR (jean-pierre.pruvo@chru-lille.fr)

Neuro-interventional mechanical thrombectomy is now standard of care for acute ischemic stroke from large vessel occlusion (LVO) and may be extended beyond the traditional 6-hour time window in patients that are properly selected by neuroimaging. Although ideally patients should be transferred to a higher standard, comprehensive stroke centres for intervention, whether on IV t-PA ("Drip and Ship") or not, such transfers delay treatment by an average 100 mins, significantly reducing the chance of a good outcome. In an effort to reduce delays to intervention, a recently reported alternative whereby neuro-interventionalists are transported by taxi to perform treatment in primary stroke centres ("Drip and Drive") has shown feasibility and effectiveness. Worldwide, health care systems are currently evaluating various ways to improve access to emergent stroke care for eligible patients, including training more specialists, telemedicine models, extending the workforce, etc... Guiding principles for patient safety include the accuracy and reproducibility of neuroimaging process leading to indication to treat, reduction of unexpected sources of delay or failure to treat, i.e. adequate training of staff, successful parallel processing, availability of materials, adequate quality and performance of interventional equipment, safety of femoral puncture and closure technique, availability of neurosurgical backup in case of major complication, and adequacy of post-thrombectomy neurological care. Ultimately, whether the patient or the doctor is "shipped" to the site of intervention, attention to quality remains the best guarantee of good outcomes.

Learning Objectives:

1. To provide an overview about institutional requirements for a successful endovascular stroke care.
2. To discuss possible solutions including moving the patient to an interventional centre or move the doctor to the patient.
3. To outline the "ideal world" scenario.

A-0980 16:41

Are you experienced, trained or certified? Certification, subspecialisation, specialisation: friend or foe of the patient?

A. Berdis; Augsburg/DE

"no abstract submitted"

Learning Objectives:

1. To get an overview about different certification programmes in interventional stroke treatment.
2. To discuss the risks and benefits for the patients of dedicated certifications, ensuring continuous service for the future.
3. To get familiar with possible future concepts of training and education.

A-0981 16:59

Do you need help? Train the cardiologist, neurosurgeon, interventional radiologist

T.J. Papiela; Krakow/PL (msjpopie@cyf-kr.edu.pl)

In Poland, despite the lack of refunds from the National Insurance Company (NIC) between January 2012 and December 2016, a total of 586 mechanical thrombectomies (MT) in acute ischemic stroke with the use of new generation devices were performed in 24 centres. In 78% of cases, the MT teams were composed of a neurologist and an interventional neuroradiologist. In the remaining, the neurointerventionist was a neurosurgeon (3%), a vascular surgeon (1%), or intervention cardiologist (1%). Only 15 of these centres

worked 24h/7 days a week, and only 2 performed over 40 procedures each. According to the regulation of the Ministry of Health (MH) of October 16, 2018, apart from (neuro) interventional radiologists, also neurosurgeons, neurologists, cardiologists, angiologists and vascular surgeons were admitted to performing the MT procedure. The minimum requirement was to perform "at least five intracranial vessel treatment procedures performed alone or in the presence of a Proctor who performed at least 50 intracranial procedures". A Pilot Program was launched in 7 centres currently performing most MT procedures. In each of these centres, there are min. three teams that can work on a continuous basis on call, 24h / 7 days a week. In most of these centres, procedures are performed by experienced (neuro) interventional radiologists. Each of the participating centres is obligated to conduct training for doctors of other specialities. After finishing the Pilot Program, a network of 17-20 centres capable of performing MT procedures will be created covering the entire territory of Poland.

Learning Objectives:

1. To provide an overview about the situation in Poland: who is doing the endovascular stroke service and who will do it in future?
2. To outline possible problems to ensure continuous service 24/7.
3. To discuss the role of interventional (neuro) radiologists as trainer for other disciplines.

A-0982 16:00

A. Drug-induced lung disease

C.M. Schaefer-Prokop; Amersfoort/NL

"no abstract submitted"

Learning Objectives:

1. To learn about the various CT patterns of lung injury.
2. To understand the role of imaging in their recognition.
3. To discuss differential diagnoses.

A-0983 16:30

B. Smoking-related lung disease

S.R. Desai; London/UK

"no abstract submitted"

Learning Objectives:

1. To learn about the classification of smoking-related lung diseases.
2. To understand the most common CT patterns.
3. To highlight newly-recognised entities.

A-0984 17:00

C. Inhalation: lung injury beyond smoking

J.A. Verschakelen; Leuven/BE (johny.verschakelen@uz.kuleuven.ac.be)

Non-smoking related inhalation lung injury is usually secondary to chronic or repetitive occupational or environmental exposures but may also result from inhalation of smoke or of chemical products of combustion, a condition that is mostly associated with significant morbidity and mortality. Every year new agents causing pulmonary injury are described, and although many are isolated cases, others prove to be clustered or repetitive events with more or less specific imaging features. The clinical and radiological presentation of inhalational lung injury depends on one hand on the chronicity of inhalation, the amount and phase of the inhaled agent and its toxicity to the lung, and on the other hand on the reaction of the lung to this injury. This presentation will focus on the CT features seen after non-smoking related lung injury caused by direct chemical toxicity to the bronchial tree and lungs and by chronic or repetitive inhalation of particulates and organic dusts. Attention will also be given to the inflammatory syndrome seen in hypersensitivity pneumonitis.

Learning Objectives:

1. To learn about the various causes of environmental lung diseases.
2. To understand the changes related to acute lung injury.
3. To describe the long-term sequelae of inhalation lung injury.

How to deal with the epidemics of thyroid nodules?

A-0985 16:00

Chairperson's introduction

A.S. [Germano](mailto:asgermano@gmail.com); *Amadora/PT (asgermano@gmail.com)*

Recently, concerns regarding possible overdiagnosis and overtreatment of thyroid carcinomas have been raised. They are based on an exponential rise in the incidence of thyroid carcinomas in developed countries (the "epidemics" of thyroid nodules), concerning mainly small well-differentiated carcinomas, along with a low and stable mortality rate. Potential reasons for these epidemics include the unveiling of a pool of subclinical tumours due to increased availability and access to health care units, increase in the number and improved sensitivity of imaging procedures, with consequent detection of incidentalomas in CT, MR, Doppler, and PET examinations, exhaustive histological examination of thyroid specimens, and screening for thyroid nodules. The coexistence of factors responsible for a true increase in thyroid carcinomas is also possible, namely radiation exposure, smoking, obesity, and iodine intake status. High-resolution ultrasound and ultrasound-guided fine needle aspiration are the best tools to identify and characterise thyroid nodules. However, it is unfeasible to biopsy every single detected nodule. To address this problem, different guidelines on how to deal with thyroid nodules have been published worldwide, and are continuously being updated. Likewise, a uniform system for reporting thyroid cytology, the Bethesda system, which includes an attributed risk of malignancy and a management recommendation for each diagnostic category, was created. Different approaches have been attempted to decrease the epidemics: a proposal of active surveillance rather than surgery for microcarcinomas in selected cases; a nomenclature revision of the encapsulated thyroid carcinoma; an update of the Bethesda system, multidisciplinary tumour boards, with clinicopathologic case discussion.

Session Objectives:

1. To understand the concept of the world epidemics of thyroid nodules.
2. To learn about the reasons for this epidemic.
3. To be updated on current guidelines as to how to deal with thyroid nodules.
4. To explain the indeterminate diagnosis on cytology and histology.
5. To discuss approaches to reduce/stabilise the incidence of thyroid nodules detection.

A-0986 16:05

The endocrinologist perspective

I. [Sapinho](mailto:inessapinho@sapo.pt); *Amadora/PT (inessapinho@sapo.pt)*

We will begin this multidisciplinary session by discussing the true impact of the widespread use of imaging techniques, combined with increased medical surveillance and access to health care services in the generation of the epidemic of thyroid nodules. Ultrasound studies of asymptomatic individuals have reported an incidental detection of 35 to 67%. The important issue is the concerns with malignancy and hyperactivity. So, we will discuss the diagnostic pathway of a patient with a thyroid nodule. Nowadays, thyroid cancer is one of the most frequent endocrine malignancies, with a higher prevalence in females. It's, already, every third cancer in females in most countries, like in Portugal. However, overdiagnosis is also an issue because its occurrence rate has extraordinarily risen in the two past decades, whereas mortality rates have not changed. Finally, we will discuss the rare emergencies related to thyroid nodules, paying special attention to the preoperative and postoperative causes.

Learning Objectives:

1. To understand the causes of high prevalence of thyroid nodules worldwide.
2. To outline the diagnostic pathway of a patient with a thyroid nodule.
3. To be aware of the problem of overdiagnosis.
4. To recognise the rare emergencies related with thyroid nodules.

A-0987 16:20

The radiologist role

A.S. [Germano](mailto:asgermano@gmail.com); *Amadora/PT (asgermano@gmail.com)*

High-resolution ultrasonography is, without a doubt, the best imaging technique to detect and characterise thyroid nodules. It is also the best way to guide fine-needle aspiration biopsy of thyroid nodules and lymph nodes. However, it is neither possible nor desirable to biopsy every detected nodule, because the procedure is not exempt from complications, the percentage of indeterminate cytology results is not negligible, and most thyroid carcinomas are well-

differentiated and have an indolent course. The challenge is to identify the very rare/aggressive malignant nodules among the very common benign ones. Radiologists are partially responsible for the epidemics of thyroid nodules. To achieve Excellency in the evaluation of thyroid nodules, a radiologist needs, beyond a top ultrasound equipment and acquisition of diagnostic and interventional skills, to be updated on the nuances of the current guidelines regarding ultrasound malignancy risk stratification of thyroid nodules. The 2017 EU-TIRADS will be emphasised. It is also fundamental, in order to appreciate uncertainties in cytology and pathology results, to recognise the recent changes in the World Health Organisation classification of tumours of endocrine organs, the modifications of the staging system for differentiated thyroid cancer, presented in the 8th Edition of the American Joint Committee on cancer, and also the recent updates on the Bethesda System for reporting thyroid pathology. Regarding microcarcinomas (<1cm), active surveillance is being considered as an alternative to surgery. To be implemented, patient preferences need to be taken into account, together with an adequate clinical setting, available resources, and medical expertise.

Learning Objectives:

1. To become familiar with the current guidelines for ultrasound malignancy risk stratification of thyroid nodules-emphasis on the EU-TIRADS.
2. To learn how to deal with the incidentally detected thyroid nodules in other imaging modalities.
3. To understand the concept of "active surveillance" of thyroid nodules.

A-0988 16:35

The surgeon intervention

M. [Allen](mailto:mallen@hospitaldaluz.pt); *Amadora/PT (mallen@hospitaldaluz.pt)*

The Surgeon's intervention (or not) in the patient with nodular thyroid disease is to be taken as a part of a treatment plan. Three topics will be addressed. To know when to send a patient to surgery. Sending patients to an Endocrine Surgeon doesn't necessarily mean "send a patient to surgery". Depending on the clinical presentation, echographic features and cytology result in a decision as to be achieved. From the clinical evaluation, compressive symptoms like neck or swallowing discomfort, hoarseness, history of thyroid cancer and mediastinal goitres are to be considered. The importance is to have a team that works together and decides the best treatment to a given patient. To understand what the surgeon needs to know before performing a thyroidectomy. The surgeon needs precious information from the Endocrinologist, the Radiologist, the Cytopathologist, the ENT preoperative evaluation, but above all, he/ she needs to understand the Patient expectations from treatment and Balance risk/benefit of a given surgical strategy. Total thyroidectomy and Unilateral lobectomy, have a low incidence of complications, but regardless of the surgical skills and annual case-load, they are not ZERO. To be aware of potential surgical risks and complications. Intra and Post-operative complications and ways to anticipate, prevent and deal with them will be addressed. From bleeding, lesion of recurrent and superior laryngeal nerve, hypoparathyroidism, surgical site infection, to Surgical scar issues. When a surgical procedure goes according to plan and has no complication, the only thing that is left is a scar. Hopefully scarcely identifiable.

Learning Objectives:

1. To know when to send a patient to surgery.
2. To understand what the surgeon needs to know before performing a thyroidectomy.
3. To be aware of potential surgical risks and complications.

A-0989 16:50

The pathologist assessment

P. [Borrhalo](mailto:pnunes1@campus.ul.pt); *Amadora/PT (pnunes1@campus.ul.pt)*

Fine needle aspiration (FNA) plays a central role in distinguishing benign thyroid nodules that can be managed conservatively from those with suspicious or malignant features requiring further management. However, its performance needs to be selective, since systematic FNA of all nodules, regardless of the size or appearance, is superfluous and may lead to unnecessary diagnostic surgery. A standardised report of thyroid ultrasound (US) findings facilitates correlation with cytology, enhancing the ability to reach a precise diagnosis. The Bethesda System for reporting thyroid cytology (TBSRTC) was a very important development, creating a uniform system for reporting thyroid cytopathology and recognising its limits. Each six-diagnostic category is associated with a specific risk of malignancy (ROM) and a respective clinical management recommendation. An updated TBSRTC recently published includes advances in the molecular diagnosis of thyroid nodules and the noninvasive encapsulated follicular variant of papillary thyroid carcinoma (FV-PTC), renamed as noninvasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP) which, together with well-differentiated thyroid tumours of uncertain malignant potential (WD-TUMP) represents a true "gray zone" of "follicular patterned" thyroid lesions, that needs to be characterized in order to outright the diagnosis of carcinoma and avoid unnecessary aggressive treatment. Papillary microcarcinoma of the thyroid (PMCT) contributes to the epidemics of thyroid nodules. PMCT is incidentally

Postgraduate Educational Programme

found in otherwise healthy humans by ultrasonography and FNA, but surgical therapy is only required for patients who have high-risk factors, such as clinically apparent lymph node metastasis and massive extra-thyroid extension.

Learning Objectives:

1. To appreciate the utility of conjoint ultrasound/cytology evaluation of thyroid nodules.
2. To understand the cytology diagnosis limits: The Bethesda System.
3. To learn about the indeterminate histology diagnosis: WDT-UJP and NIFTP.
4. To recognise the pathologist contribution to the epidemics: the incidentally detected microcarcinomas.

A-0990 17:05

Multidisciplinary case presentation and discussion: "The thyroid-team decision: when to follow and when to go beyond the guidelines"

A.S. [Germano](mailto:asgermano@gmail.com); [Amadora/PT](mailto:asgermano@gmail.com) (asgermano@gmail.com)

In the same manner, as a multidisciplinary board meeting, selected cases of both straightforward and challenging "real-life" cases, regarding patients with thyroid nodules, will be presented and discussed. The "thyroid-team", comprising an endocrinologist, a radiologist, a surgeon, and a pathologist, will present thyroid nodules that are unmistakably benign or malignant, but also pseudo-nodules, incidentally detected thyroid nodules, those with indeterminate cytology and/or histology results, microcarcinomas, metastatic lymph nodes with no evident thyroid nodule detected, and radiology-cytology discordant cases. Distinctive patient features, including age, symptoms, and co-morbidities, will be fitted into the decision-making process.

Learning Objectives:

1. To learn the rationale for multidisciplinary decision-making in standard situations.
2. To discuss challenging diagnosis cases.

Musculoskeletal interventional procedures

Moderators:

L.W. Bancroft; Orlando, FL/US
A.J. Grainger; Leeds/UK

A-0991 16:00

A. Diagnostic and therapeutic injections in the athlete: pearls and pitfalls

P. [Peetrons](mailto:ppeetrons@his-izz.be); [Brussels/BE](mailto:ppeetrons@his-izz.be) (ppeetrons@his-izz.be)

The major pitfall in musculoskeletal ultrasound-guided procedures is the incorrect diagnosis. Many patients are now referred to the interventional radiologist from other institutions or private practice. Among them, the radiologist in charge of the interventional procedure discovers incomplete or entirely wrong diagnoses. It is then mandatory to get all imaging and clinical information before doing the procedure. The preparation of the procedure includes in these cases a full study of the images performed elsewhere and a full new ultrasound investigation. A typical example for this is the asking to perform PRP in a rotator cuff for a so-called "partial rupture" which is in fact a "full thickness tear" and not a "intra-tendinous interstitial tear". The second pitfall is a misunderstanding of the ultrasound possibilities of covering the lesion with the probe AND a safe route for the needle. An example of this is to inject a tear in the distal biceps brachii tendon for PRP or needling treatment. The so-called Cobra position could not demonstrate the tear if too proximal, and from the anterior approach, the tendon is covered by the artery and the nerve, making the procedure unrealistic. The second part of the lecture describes the different techniques of injection: direct or indirect, with different positions and angles of the needle, emphasising the search for the best approach, not only the safest but the one showing best the needle and the target. Some examples will be given involving upper and lower limbs tendon, ligament and joint injections.

Learning Objectives:

1. To become familiar with the most common requests and indications for sports-related injections.
2. To learn about technical considerations for performing MSK injections.
3. To understand reasons to delay injections or avoid certain injectables.

A-0992 16:30

B. Injectables, percutaneous tendon fenestration and tenotomy: clinical outcomes and current evidence

J.A. [Jacobson](mailto:jjacobsn@umich.edu); [Ann Arbor, MI/US](mailto:jjacobsn@umich.edu) (jjacobsn@umich.edu)

For joint abnormalities and tendinopathy, there exist many percutaneous treatment options. Anaesthetic agents are often combined with corticosteroids to inject joints and bursae for diagnostic and therapeutic purposes. All anaesthetic agents are cytotoxic to chondrocytes and synovial cells to some degree. Corticosteroids may be used to decrease inflammation within a synovial space. The use of corticosteroids to treat tendinopathy is counterintuitive, as inflammation is not present, injection into tendon causes tenocyte death, the analgesic effect of corticosteroids is short-lived, and the tendon pathology is not treated. Several ultrasound-guided tendon treatments can be used for tendinopathy. One treatment is tendon fenestration or tenotomy, where a needle is passed through the abnormal tendon segment repeatedly to break up the degenerative process, induce bleeding and inflammation, and initiate tendon healing. Anti-inflammatory medication should be avoided so as not to interfere with the healing response. Another procedure is the injection of autologous whole blood while fenestration, which increases growth factors and other substances to promote tissue healing. Since the majority of growth factors are stored within platelets, the injection of platelet-rich plasma during fenestration has also been used. With this technique, the autologous whole blood is centrifuged to concentrate the platelets for injection. All three of these percutaneous tendon treatments have been shown to be effective, although it is controversial which technique is best. There are more controversial percutaneous tendon treatments, such as injection of mesenchymal stem cells, human amniotic membrane, and deer antler velvet.

Learning Objectives:

1. To be aware of the indications and benefits of available injectables used to treat sports-related injuries.
2. To learn about technical considerations for performing tendon fenestration and tenotomy.
3. To become familiar with the current evidence on results of MSK procedures in the literature.

A-0993 17:00

C. Interactive case discussion (Part 1)

P. [Peetrons](mailto:ppeetrons@his-izz.be); [Brussels/BE](mailto:ppeetrons@his-izz.be) (ppeetrons@his-izz.be)

Interactive voting will be the main goal of this section lecture. Some cases will be presented to the audience, summarising the previous lecture on pitfalls and techniques of interventional procedures in musculoskeletal ultrasound. Ten questions will follow, performing a good summary about what is important to remember in this field.

Learning Objectives:

1. To learn the targeted approach to injecting joints, ligaments, tendons and tendon sheaths.
2. To appreciate pitfalls to avoid in MSK procedures for treatment of sports-related injuries.
3. To understand evidence-based data on various MSK procedures in order to give patients realistic expectations after treatment.

Author Disclosure:

P. Peetrons: Consultant; Canon Medical.

A-0994 17:15

C. Interactive case discussion (Part 2)

J.A. [Jacobson](mailto:jjacobsn@umich.edu); [Ann Arbor, MI/US](mailto:jjacobsn@umich.edu) (jjacobsn@umich.edu)

The purpose of the interactive case discussions is to emphasise the teaching points made in the prior lecture reviewing injectables, percutaneous fenestration, and tenotomy. One topic to be addressed will be the imaging findings and potential treatment algorithm for greater trochanteric pain syndrome. In this clinical scenario, a true distended and inflamed bursa is not common, and the primary pathology relates to gluteal tendinopathy. Before pursuing an interventional procedure, conservative management such as proper eccentric physical therapy should be exhausted. The next consideration could be an injection of corticosteroid in the subgluteus maximus (or trochanteric bursa) for the primary purpose to provide temporary pain relief so that the patient can tolerate eccentric physical therapy. The corticosteroid injection is not used as an anti-inflammatory agent as true inflammation is not present, and the pain relief is typically short-lived. If the patient again fails eccentric physical therapy, then the patient may be offered percutaneous fenestration, autologous whole blood injection, or platelet-rich plasma injection. While all three have been shown to be effective, it is still unclear which treatment is best. The dramatic differences in cost should be a consideration when selecting the tendon treatment.

Postgraduate Educational Programme

Learning Objectives:

1. To learn the targeted approach to injecting joints, ligaments, tendons and tendon sheaths.
2. To appreciate pitfalls to avoid in MSK procedures for treatment of sports-related injuries.
3. To understand evidence-based data on various MSK procedures in order to give patients realistic expectations after treatment.

Renal transplantation

A-0995 16:00

Chairperson's introduction

T. El-Diasty; Mansoura/EG (teldiasty@hotmail.com)

A kidney was the first and is the most frequently transplanted organ. Imaging evaluation of potential renal donors is crucial to detect renal and extrarenal abnormalities that might preclude donation or lead to alteration of the surgical approach. Despite improved surgical techniques and transplantation management, complications do occur and, if left untreated, may lead to catastrophic consequences. Vascular complications include renal artery stenosis and renal artery and renal vein thrombosis. Urologic complications include urinary obstruction and leak, and peri-transplant fluid collections. Nephrogenic complications include acute tubular necrosis, graft rejection, chronic allograft nephropathy, and neoplasm. Early diagnosis and treatment of these complications are essential to prevent graft failure and other significant morbidities to the patients. Ultrasound can accurately depict and characterise many of the potential complications of renal transplantation and increasingly magnetic resonance imaging and computed tomography also facilitate this role. In addition, interventional radiologic techniques allow nonsurgical treatment. This refresher course highlights the role of imaging in the selection of kidney donors, the imaging features of renal transplantation complications and their interventional management.

Session Objectives:

1. To become familiar with the role of imaging in the selection of renal donors.
2. To understand the role of imaging in transplant dysfunction and other abnormalities.
3. To illustrate the capabilities of Interventional Radiology in renal transplantation.

A-0996 16:05

A. Preoperative evaluation of donors (cadaveric or living)

C. Nicolau; Barcelona/ES (cnicolau@clinic.ub.es)

Living renal donor transplantation is the best option for recipient and graft survival. Imaging evaluation is crucial for selecting proper donors, adequate kidneys and the best surgical approach. In this lecture, we will review the current role of CT / MR techniques in the selection process of renal donors and the CT / MR acquisition protocols of renal donors including the use of multiplanar reconstructions such as maximum intensity projections and three-dimensional volume-rendering. Moreover, we will describe the main reportable findings of the CT/MR studies. Accurate anatomic information about the donor's renal parenchyma, renal vasculature and collecting system should be provided to ensure a successful outcome for renal transplantation.

Learning Objectives:

1. To learn about CT/MR techniques in evaluation of cadaveric and living renal donors.
2. To learn about the role of imaging in the selection process of renal donors.
3. To understand the role of image post-processing in planning transplantation.

A-0997 16:28

B. Multiparametric US for diagnosis and intervention

D.Y. Huang; London/UK

"no abstract submitted"

Learning Objectives:

1. To be familiar with the appearance of renal transplant dysfunction at multiparametric US.
2. To understand the role of US modes in other renal transplant abnormalities, such as stone disease, tumours and inflammatory or ischaemic changes.
3. To understand the limitations of US modes in renal imaging and intervention.

A-0998 16:51

C. CT/MRI/angiography for diagnosis and intervention

A. Coutinho Santos; Lisbon/PT (a.icoutinho.santos@gmail.com)

Renal transplantation is the treatment of choice of patients with end-stage renal disease. The detection, accurate diagnosis, and timely management of complications of renal transplantation are crucial to avoid graft loss and mortality, and this assessment may involve a multiplicity of imaging modalities. Although ultrasound is the first-line technique used, CT and MR provide excellent anatomic detail and are often helpful, especially when ultrasound findings are inconclusive. CT accurately characterises the size and location of peritransplant fluid collections (e.g., seromas, hematomas, lymphoceles, urinomas) and has a high sensitivity in the detection of calculi. Moreover, it allows percutaneous drainage or aspiration of fluid collections and abscesses and biopsy of neoplastic lesions. CT angiography and increasingly MR angiography have replaced conventional angiography in vascular complications. The last remains the diagnostic reference standard and is used to guide endovascular treatments (e.g., percutaneous angioplasty in renal artery stenosis). However, CT angiography implies radiation exposure and iodinated contrast material is potentially nephrotoxic, which may be contraindicated when renal function is decreased. MR angiography overcomes these limitations, especially with non-contrast-enhanced techniques, and also assures a global evaluation of the renal transplant and peritransplant region with excellent tissue differentiation. With regard to neoplastic complications, both CT and MRI are superior to ultrasound for staging of renal transplant tumour and evaluation of lymphadenopathy or metastases. In addition, some image-guided interventional procedures allow nonsurgical treatment, for example, thermal ablation is a safe and effective therapy in de novo renal allograft renal cell carcinomas.

Learning Objectives:

1. To learn about the CT/MRI appearance of renal transplant dysfunctions.
2. To understand the role of CT/MRI/angiography for interventional procedures.
3. To understand the role of CT/MRI/angiography modes in other renal transplant abnormalities.

Head and neck imaging

A-0999 08:30

A. Cystic neck lesions

A. [Borges](mailto:borgalexandra@gmail.com); Lisbon/PT (borgalexandra@gmail.com)

Cystic and cyst-like lesions are commonly found in the head and neck and have a unique differential diagnosis based on the patient's age and precise anatomic location. Whereas in children, most are of embryonic/developmental origin, in adults infectious/inflammatory and cyst-like lesions predominate. Imaging plays an important role in the differential diagnosis and treatment planning, by showing the exact anatomic location, relationship with adjacent structures and architectural features and by guiding tissue/fluid sampling for cytological and biochemical analysis. Ultrasound is the preferred modality to assess superficially located lesions. It is free of ionising radiation and provides real-time guidance for tissue sampling. CT or MRI may be required for deep-seated lesions, to assess the deep extent of transspacial cysts or to refine the differential by showing other associated findings. Radiologists should be aware of potential cyst mimics: Very homogeneous lesions which can have a pseudocystic appearance (such as nodal involvement by lymphoma) and solid lesions with extensive cystic/necrotic degeneration (such as lymph node metastasis from HPVp16+ squamous cell cancer or papillary thyroid carcinoma and cystic degeneration of a schwannoma). As these cyst-like lesions are more often found in older patients, a fine needle aspiration cytology is mandatory in adult patients presenting with cystic lesions in the neck. Cytological analysis after cytopspin, flow-cytometry and biochemistry analysis of aspirated fluid can further, refine the diagnosis. In this interactive session, we will review cystic neck lesions using a site-specific approach and will highlight the added value of biochemical analysis in the differential diagnosis.

Learning Objectives:

1. To become familiar with the differential diagnosis.
2. To know the usefulness of biochemistry of FNA in the differential diagnosis.

A-1000 09:15

B. Non-traumatic head and neck emergencies

A. [Rovira-Cañellas](mailto:alex.rovira@idi.gencat.cat); Barcelona/ES (alex.rovira@idi.gencat.cat)

A wide variety of non-traumatic head and neck conditions often present at the emergency departments. CT is in most cases the first-line imaging modality, although, MRI plays an important secondary role in some cases. Radiologists must be able to know and recognise the imaging findings of most common head and neck acute conditions, which usually require a rapid intervention to avoid severe permanent damage or death. These conditions mainly include infectious process and various types of neoplasms involving the oral cavity, pharynx, deep spaces of the neck, the orbital cavity and cervical vessels and nodes. Familiarity with these conditions will facilitate early and accurate diagnosis, a proper assessment of the extent of disease, and the identification of potential complications. In this interactive session different non-traumatic head and neck conditions, which present emergently, will be presented, with a focus on radiological evaluation and interpretation.

Learning Objectives:

1. To become familiar with the most common cause of emergencies.
2. To learn the imaging criteria for differentiation.

Hepatocellular carcinoma: from diagnosis to treatment

A-1001 08:30

Chairperson's introduction

G. [Branatelli](mailto:gbranca@yahoo.com); Palermo/IT (gbranca@yahoo.com)

Hepatocellular carcinoma (HCC) is the second leading cause of cancer death worldwide. In this session, the imaging criteria to diagnose HCC noninvasively will be presented, along with the benefits of using LI-RADS terminology,

interpretation, and reporting for both clinical care and research. The newest LI-RADS and concurrent AASLD updates will be discussed. The typical and atypical appearance of HCC will be shown, along with common mimickers and useful tips of differentiation of focal hepatic nodules in the cirrhotic liver. The role of the available interventional techniques in treating patients with HCC at different stages will be reviewed. Finally, through the presentation of practical cases, the panel will discuss how to improve a patient's experience and prognosis.

Session Objectives:

1. To become familiar with the international guidelines for HCC diagnosis.
2. To understand the typical and atypical appearance of HCC.
3. To learn why, when and how to treat HCC with interventional techniques.

Author Disclosure:

G. [Branatelli](mailto:gbranca@yahoo.com): Advisory Board; Guerbet. Speaker; Bayer, Guerbet.

A-1002 08:35

A. How to diagnose HCC: new guidelines

K. [Fowler](mailto:k1fowler@ucsd.edu); San Diego, CA/US (k1fowler@ucsd.edu)

This session will focus on the imaging diagnosis of hepatocellular carcinoma in patients at risk. The attendees will learn about Liver Imaging Reporting and Data System (LI-RADS) approach to HCC diagnosis. New updates in 2018 and changes to the existing categories and approach will be discussed. The performance of LI-RADS in practice and potential regional differences in applicability will be highlighted.

Learning Objectives:

1. To learn the imaging features and criteria for HCC worldwide.
2. To understand the algorithmic approach to imaging diagnosis (LI-RADS).
3. To review emerging evidence, recent changes to diagnostic criteria and future directions.

A-1003 08:58

B. Unusual appearances of HCC and lesions that simulate HCC: can we increase diagnostic confidence?

J.M. [Lee](mailto:jmsh@snu.ac.kr); Seoul/US (jmsh@snu.ac.kr)

Hepatocellular carcinoma (HCC) poses a burden on global health. It has become the fifth most common malignant neoplasm worldwide. As HCC typically has a poor prognosis with a 5-year survival rate of only 28.6%, it is of paramount importance to achieve the earliest possible diagnosis of HCC and to recommend the most up-to-date optimal treatment strategy to increase the survival rate of patients who develop this disease. HCC is commonly diagnosed using dynamic CT and/or dynamic MRI without histological confirmation, on the basis of characteristic arterial enhancement and portal venous or delayed phase washout. HCC usually presents with typical imaging characteristics but at times can present with a broad spectrum of atypical appearances. Familiarity with unusual presentations and their imaging findings is critical to ensuring prompt, accurate diagnosis and treatment. Moreover, while imaging techniques have markedly improved in detecting small liver lesions, they often identify incidental benign liver lesions and non-hepatocellular malignancy that can be misdiagnosed as HCC. The common mimickers of HCC in the cirrhotic liver include nontumorous arterioportal shunts, rapidly enhancing hemangiomas, intrahepatic mass-forming type cholangiocarcinoma (CC), combined HCC-CC, metastases, angiomyolipomas, focal inflammatory liver lesions, and focal nodular hyperplasia-like nodules. Among them, it is essential to recognise the suggestive imaging findings for intrahepatic CC or nonhepatocellular malignancies as the management of those tumours is largely different from that of HCC. Recognition of the typical imaging findings of common HCC mimickers can reduce false-positive HCC diagnosis.

Learning Objectives:

1. To demonstrate atypical appearance of hepatocellular carcinoma at cross sectional imaging.
2. To illustrate common mimickers of hepatocellular carcinoma in cirrhotic liver.
3. To provide useful tips of differentiation of focal hepatic nodules in cirrhotic liver.

C. Interventional techniques (ablation, TACE, radioembolisation): when and how to treat

R. [Duran](mailto:rafael.duran@chuv.ch); Lausanne/CH (rafael.duran@chuv.ch)

The incidence of hepatocellular carcinoma (HCC) has been rising worldwide over the last decades and is expected to increase in the coming years. The treatment of HCC is complex and requires a multidisciplinary approach. Treatment allocation and prognostic prediction are mainly based on the Barcelona Clinic Liver Cancer (BCLC) staging system; patients are classified into five stages (0, A, B, C and D). Patient selection is crucial and involves, in

Postgraduate Educational Programme

particular, the assessment of the liver function, tumour extension and performance status although surgical treatments (resection and liver transplantation) are considered the mainstay of HCC treatment, in fact, 80% of patients present with disease that is not amenable to surgery. Interventional radiology is playing a major role in the management of these patients and provides patient-tailored therapies. Image-guided percutaneous ablation (radiofrequency ablation / microwave ablation) is the most frequently used therapeutic strategy in patients with limited disease (BCLC 0 (single tumor <2cm) and (1-3 tumors <3 cm) A). Transarterial chemoembolization is the gold standard for patients with multifocal disease (BCLC B). Yttrium-90 radioembolization is a recognised treatment option for locally advanced disease (BCLC B-C) and is challenging the hegemony of chemotherapy (sorafenib, lenvatinib, regorafenib, cabozantinib) which is the standard treatment in advanced-stage disease (BCLC C).

Learning Objectives:

1. To understand the role of each interventional technique depending on the patients' characteristics and HCC stage.
2. To review the different interventional techniques available for HCC management.
3. To review the patients' outcomes associated with interventional treatment of HCC.

A. Technology advances: from 3D to elastography

M.R.V. Pedersen; Vejle/DK (malene.roland.vils.pedersen@rsyd.dk)

New ultrasound technologies are becoming more and more used in clinical practice. 3D ultrasound scan, ultrasound contrast enhancement, elastography, and 2D Shear Wave elastography are some of the new techniques. 3D ultrasound is being used in different organs and can help diagnose. And this technology is becoming more and more used. An overview of the two main elastography technologies will be reviewed. Elastography - both Strain and Shear Wave elastography are being more and more used in the daily clinical practice. But is this elastography technology reproducible? Is elastography hype or real? What affect the elastography measurements? Are the measured values valid? How many measurements are sufficient? Which organs can be examined with elastography? Measurements reported in meter per second versus kPa - what to choose. Elastography is very often used to distinguish benign from malignant lesions. But can elastography differ between malignant and benign lesions? Studies comparing elastography in tumours have shown good reproducibility. Some of the future advances in ultrasound are 2D Shear Wave elastography, but also ultrasound in combination with other modalities such as MRI have been published recently.

Learning Objectives:

1. To review the technological advances underpinning 3D ultrasound scanning.
2. To understand the technical basis and clinical applications of elastography.
3. To become familiar with the future advances in ultrasound scanning.

A-1006 09:00

B. Early pregnancy guidelines

S. Riaz; Manchester/UK (s.riaz@salford.ac.uk)

Early pregnancy patients typically present with clinical symptoms including, previous ectopic, pain, bleeding, hyperemesis and trauma. The scan aims to exclude ectopic pregnancy, missed, threatened, or incomplete miscarriage and to determine the presence/absence of fetal heart pulsations and the presence of a fetal pole and yolk sac. The gestational sac is the first sign of early pregnancy on ultrasound and can be seen with a transvaginal ultrasound scan at approximately 3-5 weeks gestation. Transvaginal scanning is the gold standard in early pregnancy, however as it is an internal procedure it can be

declined, this along with early gestational age and a high BMI can lead to misdiagnosis. Machine quality and user competence can also limit the quality of the scan, and this should be taken into account when scanning early pregnancy. Taking all these factors into consideration optimal scanning and current guidelines are needed to make an accurate diagnosis.

Learning Objectives:

1. To review current guidelines and indications for early pregnancy scanning.
2. To understand essential requirements for optimal imaging.
3. To become familiar with pitfalls in imaging in early pregnancy.

A-1007 09:30

C. Role of ultrasound in biomechanics and sports science

R. Santos; Coimbra/PT (rutemartinssantos@gmail.com)

In the last years, the use of ultrasound (US) for the study of muscle-skeletal function has grown considerably. The reasons for such growth include the ability to study muscle morphology and its mechanical properties at relatively low cost and accessibility. The continuous improvement of US equipment, including the use of multifrequency probes and the development of new US techniques, such as elastography have contributed to make US an important method in muscle function research. Numerous studies have proven the feasibility of US for studying muscle function in non-pathological conditions. The assessment of parameters such as muscle thickness and echo-intensity allows studying muscle function and muscle morphological responses and adaptations to a variety of stimulus, in particular to muscle disuse and resistance training. Recent developments in US have enhanced our ability for studying muscle tissue mechanical properties in vivo, including changes in muscle stiffness associated with stretching and contraction. Measuring muscle stiffness allows a better understanding of muscle function as a monitor of muscle status, and it can be an indicator of the length of the muscle, as well as of its contraction status. The potential of this technique is enormous and has enabled researchers in many fields, including biomechanics and muscle physiology to probe the function of complex multiarticular muscle groups in passive and active conditions. Nevertheless, it's important to have a great knowledge of anatomy, physiology and be familiar with US technique in order to produce images of high quality and with a higher viability.

Learning Objectives:

1. To review the current role of ultrasound in elite sport.
2. To understand the challenges when using ultrasound for evaluating human performance.
3. To become familiar with best practice guidelines imaging in sport / biomechanics.

Radiomics and multiparametric MRI approaches for a better contrast in cardiac and prostate applications

B. Baeßler; Mannheim/DE (bettina.baessler@uk-koeln.de)

Over the past decades, the technical developments in MRI have enabled the clinical application of multiparametric imaging approaches, which allow for a combined assessment of different morphological and functional tissue characteristics. For multiparametric prostate MRI as well as for cardiac MRI, debates are ongoing whether this allows us to fully replace gadolinium-based examinations by native multiparametric approaches. In addition, the emerging field of radiomics, which means the extraction of a large number of mathematically or statistically derived quantitative features from medical images, thus delivering mineable datasets, delivers additional potential novel imaging biomarkers for non-contrast assessment of prostate cancer and myocardial diseases. The talk will focus on basic concepts, current debates as well as potential hurdles hindering the translation of multiparametric imaging approaches and radiomics into routine clinical practice.

Learning Objectives:

1. To learn which gadolinium-free quantitative techniques exist for cardiac and prostate MR imaging.
2. To understand the potential and limitations of quantitative, gadolinium-free parametric imaging and radiomics.
3. To appreciate the link between parametric MR imaging and radiomics and to show potential clinical applications of gadolinium-free techniques in cardiac and prostate MRI.

A-1009 08:55

From native T1 to arterial spin labelling MRI in the heart

F. Kober; Marseille/FR (frank.kober@univ-amu.fr)

This talk will give an overview of quantitative T1 mapping techniques used in cardiovascular MR. It discusses challenges with absolute T1 quantification related to the methods and to the heart itself. Because the blood signal is for some methods among the contributors to the measured absolute T1 value, there is a link between observed T1 and myocardial perfusion. Arterial spin labelling (ASL) as a non-contrast perfusion MRI method for the heart will be introduced, and several past and present approaches will be presented showing their advantages and drawbacks. The challenges of cardiac ASL compared with ASL in other organs will be outlined. It should also become clear in this talk why cardiac ASL has been frequently used in small animals, whereas human cardiac applications are still scarce.

Learning Objectives:

1. To learn how T1 is quantified and mapped in the heart and how T1 quantification is linked to perfusion.
2. To understand how arterial spin labelling acquisition is performed in the heart and why it is more challenging than in the brain.
3. To appreciate what these techniques may do better than those based on contrast agents and what they probably won't do.

A-1010 09:20

Brain perfusion and angiography using ASL in comparison with gadolinium based techniques

H.R. Jäger; London/UK

"no abstract submitted"

Learning Objectives:

1. To learn about the different non-enhanced MR angiography techniques used for imaging the extra- and intra-cranial vessels and about the principles of brain perfusion imaging with arterial spin labelling (ASL).
2. To appreciate the differences between static and time-resolved MR angiography of the intra-cranial vessels and the importance of post-labelling delay in ASL perfusion imaging.
3. To understand the clinical applications of TOF MR angiography, ASL angiography and ASL perfusion imaging techniques and their advantages and limitations.

Artificial intelligence and radiation protection

A-1011 08:30

Chairpersons' introduction (part 1)

G. Frija; Paris/FR (guy.frija@aphp.fr)

Artificial intelligence (AI) is a vehicle for improving patient outcomes, and thus it will change the practice of radiology in the next few years. AI will be a method of demonstrating the clinical value of radiology and will allow for faster and more accurate image assessment and hence diagnosis. AI will also support the training of radiologists, improve clinical knowledge, and contribute to research in medical imaging. Furthermore, AI could have knock-on impacts on radiation protection by reducing the incidence of unnecessary procedures, reducing the doses administered, increasing the image quality, and improving patient safety in general. The transformative potential of AI for the radiology profession cannot be ignored: rather practitioners must be prepared to embrace it. This session will provide an overview of how AI can enhance radiation protection in medical imaging.

Session Objectives:

1. To understand the mechanisms of how artificial intelligence (AI) can help to reduce necessary doses for imaging procedures relying on ionising radiation.
2. To appreciate which AI methods in medical imaging might be helpful for reducing dose for especially sensitive body regions or highly susceptible patients in general.
3. To learn how results from AI evaluation of radiographic images might help to influence decisions on the most appropriate methods or radiation protection measures on an individual patient basis in an early phase of patient diagnosis and therapy.

A-1012 08:33

Chairpersons' introduction (part 2)

C. Hoeschen; Magdeburg/DE (christoph.hoeschen@ovgu.de)

Using artificial intelligence in medical imaging for radiation protection purposes has three main pillars. The first pillar is that artificial intelligence can be used for investigating parameters of medical imaging procedures based on ionising radiation like image quality evaluation, exposure description and prediction of optimal imaging parameters in such sense depending on patient characteristics and diagnostic task. The second pillar is that artificial intelligence can be used to optimise image quality per dose based on advanced methods for image reconstruction, scatter reduction and thus noise and artefact reduction. The third pillar is the characterisation of patient radiation sensitivity and susceptibility for choosing the right radiation therapy or the optimal imaging procedure on individual patient base. Such radiation protection related aspects will be described in the session, and the difference will be explained in the introduction by the chairs.

Session Objectives:

1. To understand the mechanisms of how artificial intelligence (AI) can help to reduce necessary doses for imaging procedures relying on ionising radiation.
2. To appreciate which AI methods in medical imaging might be helpful for reducing dose for especially sensitive body regions or highly susceptible patients in general.
3. To learn how results from AI evaluation of radiographic images might help to influence decisions on the most appropriate methods or radiation protection measures on an individual patient basis in an early phase of patient diagnosis and therapy.

A-1013 08:35

Artificial intelligence: a tool for quality and safety improvement in radiation protection

G. Frija; Paris/FR (guy.frija@aphp.fr)

The use of artificial intelligence (AI) in medicine has attracted enormous attention, and there is a lot of research going on to implement AI in imaging. Current applications include, for example, the detection of breast cancer on mammography images, the detection of lung nodules in CT scans, and detecting pneumonia in chest x-rays. In addition, applications beyond image interpretation are on the rise. The development of AI tools in medical imaging will certainly also have an input on medical radiation protection. However, currently, there is hardly any research work on the use of AI as a tool for quality and safety improvement in imaging, although there are a number of potential applications that could help reduce doses for imaging procedures relying on ionising radiation, especially for sensitive body regions or highly susceptible patients in general. Algorithms can be used to improve image quality and dose optimisation in CT. AI-based organ recognition combined with dose estimation algorithms can provide patient-specific organ doses. This talk will present current trends of AI in radiology and provide examples how these AI systems could contribute to strengthening medical radiation protection for the benefit of patients.

Learning Objectives:

1. To learn about current trends of AI in imaging.
2. To understand how these trends could improve quality and safety.
3. To appreciate how AI could affect radiation protection.

A-1014 08:55

Artificial intelligence for scatter reduction and optimising imaging procedures

C. Hoeschen; Magdeburg/DE (christoph.hoeschen@ovgu.de)

Medical imaging based on ionising radiation is strongly suffering from two major drawbacks which result in the need for exposure levels mainly to patients but also to staff in interventional procedures higher than it might be necessary from the physical imaging process. This is the case since noise and artefacts are two of the most relevant factors deteriorating sufficient image quality for diagnostic or interventional purposes. Noise and artefacts both are strongly related to scatter that is generated in the patient body during the interaction of the X-rays with the material. Therefore ways will be discussed how the scatter contribution of the X-rays caused by patients can be estimated and thus be reduced by methods based on artificial intelligence as they have been shown by various groups and its advantages and disadvantages will be highlighted. By such scatter reduction better image quality can be gained and thus exposure levels can be reduced. In addition, this talk will briefly introduce another concept to use x-rays as efficient as possible based on optimising the imaging geometry based on artificial intelligence approaches.

Learning Objectives:

1. To learn about actual scatter reduction techniques in imaging based on ionising radiation, their advantages and drawbacks as well as the potential of optimising imaging trajectories.
2. To understand how AI-based procedures can provide a fast solution for

scatter estimation and reduction as well as for image trajectory determination.
3. To appreciate how AI can help to reduce patient dose in medical imaging with easy to implement applications.

A-1015 09:15

Artificial intelligence for intelligent reconstruction methods for radiation protection measures

C.T. [Whitlow](#); *Winston-Salem, NC/US*

"no abstract submitted"

Learning Objectives:

1. To discuss radiation exposure due to computed tomography associated with common diagnostic tests and in the setting of screening exams.
2. To describe efforts aimed at reducing radiation dose and improving image quality via conventional approaches (e.g. iterative reconstruction).
3. To introduce methods for improving image quality via novel artificial intelligence (AI)-based approaches, with quantitative results characterising noise reduction and example cases from clinical application.

A-1016 09:40

Using artificial intelligence for optimising procedures reflecting radiosusceptibility of patients

C. [Hoeschen](#); *Magdeburg/DE* (christoph.hoeschen@ovgu.de)

Radiation protection of patients is an important task in general. It has been found out that it might be even more relevant to certain patients than to others since, obviously, not all patients are prone to negative effects of ionizing radiation in the same way. Such differences are described as individual radiation sensitivity if one refers to short-term effects, especially so-called tissue reactions and as individual radiation susceptibility if one refers to long-term effects like especially cancer induction. Obviously, it is even more important to protect especially the healthy tissue of those patients who are more radiation sensitive or susceptible than those who are not. Some of the potential reasons for individual radiation sensitivity or susceptibility will be described as well as indications that and how specific analysis of imaging data could provide insights into such individual patient configuration and why this might be helpful for radiation protection. Methods based on artificial intelligence would be most promising for this task. There are also medical imaging applications with pretty high doses and especially pretty localized high doses like in interventional procedures. Thus, it would be feasible to optimize not only radiation therapy for individuals that are very sensitive but also for example interventional procedures. For planned CT examinations, it might be better to think about low-dose procedures or even of a replacement of the procedure by means of MRI if feasible in patients with extremely high risk. However, there are some ethical aspects of such approaches.

Learning Objectives:

1. To learn about radiosusceptibility and why it is important to look for it in images.
2. To understand what role AI could play in the future for optimising procedures, especially interventional procedures, from the point of view of radiation protection.
3. To appreciate the potential for new research topics bridging the gap between AI and radiation protection with respect to the individual patient.

Dead or alive: imaging of myocardial viability

A-1017 08:30

Chairperson's introduction

C. [Peebles](#); *Southampton/UK* (Charles.Peebles@suht.swest.nhs.uk)

Myocardial viability is central to the investigation and management of ischaemic heart disease (IHD). The viable myocardium is defined as 'dysfunctional myocardium that maintains the potential to return to normal function' e.g. it is alive and not dead. Dysfunctional, but viable myocardium is the end result of an ischemic myocardial injury that can either be acute (stunning) or chronic (hibernating). In the former, a single acute ischaemic injury causes temporary dysfunction that will recover after the restoration of myocardial blood flow, but there may be a delay of weeks or months for this to occur. Hibernation is the end result of chronic or repetitive ischaemia causing downregulation of myocyte metabolism and function, which will again recover the following revascularisation. Accurate identification of viable myocardium is

critical, as revascularisation of non-viable myocardium confers the risks of revascularisation without benefits of functional recovery. Conversely, failing to revascularise viable myocardium that is ischaemic may place the patient at increased risk. Two general approaches to identifying viable myocardium are the functional improvement of a regional wall motion abnormality during low dose stress or identification of myocardial scar that involves less than the full thickness of a myocardial segment. The first approach is adopted by stress echo and dobutamine stress CMR. The second approach requires the use of extracellular contrast agent and is usually performed by CMR with late gadolinium enhancement or CT with iodinated contrast and delayed imaging. This session will compare the standard techniques, and discuss their pros and cons.

Session Objectives:

1. To understand the concept of myocardial viability.
2. To understand the current state-of-the-art to image myocardial viability.
3. To outline the role of echocardiography, SPECT, CT and MRI.

A-1018 08:35

A. MRI

T. [Leiner](#); *Utrecht/NL* (t.leiner@umcutrecht.nl)

Ischemic cardiomyopathy (iCMP) is defined by the presence of flow-limiting stenoses in at least two coronary arteries and a left ventricular ejection fraction of 40% or less. In patients with iCMP, the amount of viable myocardium directly affects the short- and long-term outcome. Myocardial viability refers to those cardiomyocytes that reside in a suboptimal functional state but are alive as defined by cellular and metabolic function. These myocytes can potentially regain full functionality, resulting in improved cardiac systolic function with a combination of revascularisation and pharmacotherapy. Cardiac magnetic resonance imaging (CMR) is well-suited for the identification of both viable myocardium as well as 'dead' scar tissue and can be used to assign patients to the appropriate therapeutic strategy with high confidence. Because of its high spatial and temporal resolution, CMR can identify the presence, extent and transmural of left ventricular scar tissue as well the resulting functional impairment. In current clinical practice, two strategies are used, late-gadolinium enhancement (LGE) to detect the presence and extent of scar tissue; and low-dose dobutamine stress imaging (DS) to detect the extent of functional impairment. Both methods are complementary, but LGE is often used alone because transmural of scar expressed as a percentage of LV wall thickness has been shown to strongly correlate with the possibility of functional recovery. Promising alternative methods for detection of presence and extent of myocardial scar are T1-mapping and algorithmic analysis of myocardial signal intensity on standard cine images.

Learning Objectives:

1. To learn about how MR should be performed to assess viability.
2. To understand the strengths and weaknesses of MR compared to other techniques.
3. To learn how to report MRI for viability assessment.

Author Disclosure:

A-1019 08:58

B. Hybrid imaging

F. [Caobelli](#); *Basle/CH* (federico.caobelli@usb.ch)

The concept of myocardial viability in coronary artery disease (CAD) is derived from diverse studies, wherein an irreversible left ventricular contractile dysfunction was demonstrated even if revascularisation occurred. Many controversies still exist on the most appropriate method to assess the presence and extent of viable myocardium. Stand-alone modalities provide important data about myocardial viability, but all these techniques suffer from several limitations. As such, new methods combining different information from different modalities for the investigation of myocardial viability are highly warranted. This constitutes the fundamental basis for the development of hybrid imaging, consisting in the association of different imaging techniques, where both modalities equally contribute to image information, allowing for a comprehensive evaluation. An example of such an approach is the combination of computed tomography coronary angiography (CTCA) and myocardial perfusion imaging either with single-photon emission computed tomography (SPECT) or with Positron emission tomography (PET). Other possible applications include a combination of CTCA and cardiac magnetic resonance imaging (cMR). These approaches are expected to have several potential applications in the next future. Concurrently, new molecular imaging probes may provide invaluable tools for the guidance and monitoring of therapies. This lecture will discuss the actual state of the art of cardiac hybrid imaging as well as potential future applications.

Learning Objectives:

1. To learn about how hybrid imaging should be performed to assess viability.
2. To understand the strengths and weaknesses of hybrid imaging compared to other techniques.
3. To understand how hybrid imaging could be developed in clinical practice.

A-1020 09:21

C. CT

F. Bamberg; Tübingen/DE (fabian.bamberg@uni-tuebingen.de)

In the field of cardiac CT, substantial research efforts have recently been focused on the development of different approaches to obtain information on myocardial viability. Despite a relatively low level of scientific evidence, these approaches are currently entering the clinical arena given its high relevance for therapeutic decision-making. Analogous to the presence of late gadolinium enhancement on MRI, cardiac CT allows for the detection of delayed iodinated contrast enhancement on delayed CT acquisitions. However, from a clinical perspective, CT imaging protocols are generally combined with myocardial perfusion imaging at rest and stress. In general, such a protocol includes as a first step perfusion imaging followed by a second step that includes a low-radiation scan for the detection of delayed imaging. Further, perfusion imaging by CT can be conducted as a "single-shot" acquisition with or without dual energy or as a dynamic acquisition during rest or stress conditions. The talk will provide an overview of currently available approaches and protocols, highlighting limitations, and review the level of evidence pertaining to the role of CT for assessment of myocardial viability.

Learning Objectives:

1. To learn about the potential of CT to assess viability.
2. To understand the strengths and weaknesses of CT imaging compared to other techniques.
3. To understand how to report CT for viability assessment.

Special Focus Session

SF 17

Late effects in survivors of childhood cancer

A-1021 08:30

Chairperson's introduction

C. Owens; London/UK (owensc@gosh.nhs.uk)

This session will focus on the optimistic advances in cancer treatment which has resulted in much better survival rates. However, there is considerable morbidity with the more aggressive treatments used which result in late effects within many organ systems. This session will focus on the important role we have as radiologists in identifying, diagnosing and following up the complications of previous cancer treatments in childhood. We will focus on an organ-based approach to diagnosing the sequelae of childhood cancer treatments.

Session Objectives:

1. To learn about the cost of survival in long term survivors of childhood cancer.
2. To understand therapy related pathologies which are sequelae of cancer treatment in childhood.
3. To appreciate these disorders and to help to make early diagnoses in order to minimise long term sequelae.
4. To become familiar with the human cost of cancer survival and the effects on the daily lives from survivors of childhood cancer.

A-1022 08:37

Cardiothoracic complications

A. Secinaro; Rome/IT (aurelio.secinaro@opbg.net)

New advances in cancer diagnosis and treatment have increased survival rates in patients with cancer. The growing number of cancer survivors' results in a higher prevalence of cardiothoracic complications from cancer treatment. There is evidence of a significant incidence of cardiovascular complications among adult survivors of a variety of childhood and adolescent cancers years after treatment. Survivors are significantly more likely than siblings to report congestive heart failure, myocardial infarction, pericardial disease or valvular abnormalities. Chemotherapy-induced cardiac dysfunction is a major contributor to adverse morbidity and mortality rates in cancer patients. Both clinical symptoms and the traditional left ventricular ejection fraction may lack

sensitivity as measures of cardiotoxicity. Radiation-induced coronary artery disease has to be considered a possible cause of myocardial infarction. Novel cardio-thoracic imaging techniques such as Cardiac Magnetic Resonance and Cardiac CT can identify a high prevalence of cardiac disease among adult survivors previously undiagnosed with cardiac disease, as 2D echocardiography demonstrated limited screening performance; in particular, detailed and accurate assessment of vascular anatomy (including coronaries), myocardial tissue characterisation and biventricular volumes and global systolic function is now non-invasively achievable. In addition, chest CT is more sensitive than chest radiographs in detecting post-irradiation changes in the lungs as it is able to early detect linear or reticular "structured" opacities related to lung fibrosis.

Learning Objectives:

1. To outline chemotherapy related pathology which are sequelae of cancer treatment in childhood.
2. To illustrate with state-of-the-art imaging.
3. To summarise what the radiologist needs to know and how to find it.

A-1023 08:55

MSK

I.-M. Noebauer-Huhmann; Vienna/AT (iris.noebauer@meduniwien.ac.at)

Adult patients who had suffered from cancer during childhood may develop various late sequelae during their lifetime. Cancer- or treatment-related developmental abnormalities may occur in the growing skeleton and can cause deformities and preterm degeneration. A thorough assessment of the present clinical condition, the past medical history, and the altered post-surgical anatomy are essential for the evaluation of follow-up imaging. Also, radiation and chemotherapy lead to the typical time-dependent bone marrow and soft-tissue alterations. Those changes must be differentiated from the recurrent or metastatic disease. Hormone-related skeletal alterations and complications indicative of altered bone stability or decreased osseous blood supply must be detected early. To date, amputation can often be avoided when limb salvage is feasible, through wide tumour resection and reconstruction with modular endoprostheses. While adequate local and systemic tumour control rates can be achieved with those megaprotheses, various complications may still occur. Detailed knowledge of the imaging appearance of such complications, which have been categorised according to the ISOLS classification system, is indispensable. Clear imaging strategies and systematic evaluation algorithms can help radiologists to reliably assess the late post-therapeutic sequelae and to detect potential complications in survivors of childhood cancer.

Learning Objectives:

1. To discuss clinical manifestation of late effects to the MSK system following chemotherapy.
2. To illustrate and suggest best methods of radiological follow-up with case studies.
3. To suggest an algorithm to help radiologists to recognise these findings.

A-1024 09:13

Neuro

R. Gunny; London/UK

"no abstract submitted"

Learning Objectives:

2. To categorise the types of abnormalities.
3. To illustrate these complications.

A-1025 09:22

Fertility issues: male and female (Part 1)

L. Rocher; Le Kremlin-Bicêtre/FR (laurence.rocher@bct.aphp.fr)

The survival rate for children with cancer is about 80 %. Infertility remains one of the most common complications. However, infertile patients with previous cancer treatment require the same complete biological and imaging screening compared to other patients: the infertility status may have other and curative explanations. In women, decreased fecundity is a late effect that arises after chemo- or radiotherapy, as it has been shown that pregnancy is less likely to occur in survivors who have received hypothalamic/pituitary radiation, ovarian/uterine radiation, or treatment with high doses of alkylating agents. Furthermore, the number of eggs in their ovaries may be reduced to such an extent that they will reach menopause much earlier than the average age of 51 years. Follicle counts represent ovarian reserves and can be evaluated with echography. Oocytes make an anti-Mullerian hormone (AMH), which can be measured in blood. In males, these treatments may damage spermatogenesis leading to impaired fertility. Semen analysis and hormonal status are non-invasive methods for estimation of male fecundity. Low levels of Inhibin B and high levels of FSH reflect the impaired spermatogenesis. Testicular hypotrophy with coarse/striated echogenicity reflects those damages. Leydig cell hyperplasia with a multinodular pattern may rarely occur. Methods for fertility preservation need to be suggested before treatment. Concerning pre-pubertal

Postgraduate Educational Programme

children, testicular tissue or ovarian cryopreservation may be performed with efficient results much advanced in girls compared to boys. Concerning post-pubertal children, oocyte cryopreservation is privileged in girls and sperm conservation is the simplest method in boys.

Learning Objectives:

1. To describe the potential effects that chemotherapy has on fertility in males and females.
2. To illustrate with case studies.
3. To discuss how we can help to overcome these issues using radiology.

A-1026 09:31

Fertility issues: male and female (Part 2)

C. Berger; Saint-Etienne/FR (claire.berger@chu-st-etienne.fr)

In Europe, 300 000 individuals had cancer during childhood and survived. Infertility remains one of the most common complications. However, infertile patients with previous cancer treatment require the same complete biological and imaging screening compared to other patients: the infertility status may have other and curative explanations. In women, decreased fecundity is a late effect that arises after chemo- or radiotherapy, as it has been shown that pregnancy is less likely to occur in survivors who have received hypothalamic/pituitary radiation, ovarian/uterine radiation, or treatment with high doses of alkylating agents. Furthermore, the number of eggs in their ovaries may be reduced to such an extent that they will reach menopause much earlier than the average age of 51 years. Follicle counts represent ovarian reserves and can be evaluated with echography. Oocytes in follicles make an anti-Müllerian hormone (AMH), which can be measured in blood. In males, these treatments may damage spermatogenesis leading to impaired fertility. Semen analysis and hormonal status are non-invasive methods for estimation of male fecundity. Low levels of Inhibin B and high levels of FSH reflect the impaired spermatogenesis. Testicular hypotrophy with coarse/striated echogenicity reflects those damages. Leydig cell hyperplasia with a multinodular pattern may rarely occur. Methods for fertility preservation need to be suggested before treatment. Concerning pre-pubertal children, testicular tissue or ovarian cryopreservation may be performed with efficient results much advanced in girls compared to boys. Concerning post-pubertal children, oocyte cryopreservation is privileged in girls and sperm conservation is the simplest method in boys.

Diagnosing ductal carcinoma in situ (DCIS)

Moderator:

C. Van Ongeval; Leuven/BE

A-1027 08:30

A. New radiologic-pathologic knowledge on DCIS

A. Frigerio; Turin/IT (alfonso.frigerio@gmail.com)

A modern rethinking of ductal carcinoma in situ must take off from the awareness of the utter inadequacy of the terminology currently in use. Already in 1976, Jensen, Rice and Wellings remarked that "ductal carcinoma in situ of the human breast is of lobular (acinar) origin". While the latest (2012) WHO Classification decided to omit the name 'ductal' from the definition of the most common type of invasive breast carcinoma, it still fails to recognise the inconsistency of this descriptor for its intra-epithelial counterpart. It is time to move to a new inter-disciplinary approach where a mutually respectful interaction between radiologists and pathologists should take full advantage of new imaging techniques and new pathologic methods to achieve better characterisation of the different types of breast lesions and their clinical-biological potential. A new classification and terminology based on the site of tumour origin (acinar vs ductal), as best displayed by diagnostic imaging paired with modern pathologic techniques as large-format histologic sections, should open the way to a better understanding of the lesion biology, eventually improving treatment planning decisions. This lecture will include a discussion of different subtypes of in situ lesions; neoductogenesis as an important feature

that should be recognised and reported; the potential of mammographic tumour features as synergistic prognostic factors alongside classical pathological and modern molecular patterns. Overcoming long-lasting barriers to effective communication would be the pre-requisite to a new professional setting where all specialists involved mutually enhance the benefits of their clinical knowledge.

Learning Objectives:

1. To learn about different types of DCIS.
2. To become familiar with the risk of developing cancer.
3. To appreciate radiologic-pathologic correlations.

A-1028 09:00

B. Imaging DCIS

J. Camps Herrero; Valencia/ES (juliacamps@gmail.com)

In this presentation, common radiologic manifestations of DCIS in mammography and ultrasound will be reviewed, taking into account that microcalcifications are the most common mammographic manifestation of DCIS. Types of microcalcifications with the highest PPV will be reviewed, as well as uncommon radiological findings (distortion, asymmetry or spiculated lesions without associated microcalcifications). The importance of the anatomical lobule and macroscopic anatomy (large-format histology) cannot be overstressed as it is, together with the sick lobe theory, the best way to understand the distribution of DCIS lesions in all radiological modalities, especially in MRI. Breast MRI is the most sensitive technique for DCIS, MRI can detect up to 48% of cases not detected by mammography, especially in non-calcifying lesions (around 25% of DCIS). The most common MRI appearance of DCIS will be discussed (non-mass lesion in 60-80% of the cases, nodular mass in 14-41%) emphasising that morphological signs are more important than kinetics in DCIS, as well as the non-specific value of DWI. Overlap of imaging features with benign disease or high-risk or B3 lesions is an important issue because it is the cause of false positive findings, potential signs to differentiate between all entities will be reviewed.

Learning Objectives:

1. To become familiar with the imaging appearances of DCIS on mammography, ultrasound and MRI.
2. To understand the evidence on MRI for evaluating DCIS.
3. To appreciate the overlap of imaging features of DCIS and benign disease.

A-1029 09:30

C. Diagnosing DCIS with biopsy

M.G. Wallis; Cambridge/UK (matthew.wallis@addenbrookes.nhs.uk)

Although a proportion of DCIS (particularly low grade) is found in association with other a benign lesions, the majority present with either micro-calcification on mammography or non-mass like enhancement on MRI. Currently, we have no imaging tests that can reliably determine benign from atypia from cancer, so tissue diagnosis is mandated. Surgical biopsy has been replaced by image guided needle biopsy. The challenge for the operator is accurate targeting and obtaining adequate volume to give the pathologist the best chance of making a correct diagnosis. Given accurate targeting then the of the volume of tissue taken becomes a balance of cost vs benefit. Relatively small volumes of tissue are needed to confirm the benign disease, but the accurate exclusion of an invasive component is better with a larger size. It is clear from long-term follow-up of DCIS that conventional treatment fails the 15 to 20 % who develop invasive disease, a few of whom then die from breast cancer. There is a larger group that never progress is within their lifetime which means that we have either cured them or just overtreated them. Traditional pathology and genetics suggest that there is a low-risk group that either never progresses or if they do they develop low-risk invasive disease. To date, the majority of studies trying to determine which high-grade DCIS will progress have been underpowered and lack validation in independent cohorts, so none are in clinical practice. Three international trials are investigating operative management vs active monitoring for low-risk DCIS.

Learning Objectives:

1. To learn about the indications for biopsy when DCIS is suspected based on imaging.
2. To become familiar with the advantages and disadvantages of different biopsy techniques.
3. To appreciate the risk of overdiagnosis and overtreatment with DCIS.

Diffuse low-grade gliomas: new things you should know

Moderator:

I.N. Pronin; Moscow/RU

A-1030 08:30

A. Molecular basis for classification, treatment and predicting outcome in low-grade gliomas

V.C. Keil; Bonn/DE (Vera.Keil@ukbonn.de)

Diffuse low-grade gliomas (LGG) are glial tumours with a high degree of diversity on a histological and genetic level. Their histopathology and genetics determine indeed the course of the disease. Will the lesion remain stable for decades or will it progress dynamically both regarding volume and malignancy? The individual answer to this question determines therapeutic decisions, follow-up planning and therapy monitoring. Neuropathologists define the exact diagnosis of a tumour. But neuroradiologists can make use of multiple MRI and PET imaging tools to non-invasively approximate the histology of a lesion and in consequence its potential for dedifferentiation. While "conventional" MR imaging techniques are still the basis of glioma assessment, more recent quantitative methods expand our insights about a lesion and can provide greater certainty about a presumed diagnosis. DSC-MRI, DCE MRI, ASL, MR spectroscopy and many more imaging techniques of the quantitative and molecular imaging spectrum have become essential diagnostic pillars in glioma assessment. Molecular imaging is however not yet at a point that unequivocal scientific results rendered watertight imaging biomarkers to rely on in LGG assessment. There are conflicts about the additive value of multiple imaging techniques, the reproducibility of results, histopathological correlation and also feasibility in clinical practice. This opening presentation provides an overview of the most widely used techniques in molecular imaging and their current benefits and limitations for a noninvasive LGG assessment in contrast to standard, non-quantitative MRI.

Learning Objectives:

1. To learn about the role of imaging in the context of histopathology regarding the prediction of outcome.
2. To understand the role of conventional and quantitative beyond diagnosis.
3. To appreciate the translational approach of diagnosis and monitoring of glial tumour based on the histopathological background.

A-1031 09:00

B. Imaging patterns suggestive of different (molecular) subtypes of low-grade gliomas

M. Smits; Rotterdam/NL (marion.smits@erasmusmc.nl)

Primary brain tumours are histopathologically subtyped into World Health Organisation (WHO) grades I to IV, according to - increasing - degrees of malignancy. These grades provide prognostic information and guidance on management, such as radiotherapy and chemotherapy after surgery. Despite the confirmed value of the WHO grading system, a multitude of studies and prospective interventional trials indicate that tumours with identical morphological criteria, i.e. of the same WHO grade, can have highly different outcomes. To personalise brain tumour management, we need additional diagnostic markers that can differentiate tumours beyond the current morphological WHO grading system. Molecular markers can distinguish subtypes of tumours within the same morphological type and WHO grade, and are therefore of great interest for personalised medicine. Recent genomic-wide studies have resulted in a far more comprehensive understanding of the genomic alterations in gliomas, and the suggestions of a new molecularly based classification. MR imaging phenotypes can serve as non-invasive surrogates for tumour genotypes and as such provide important information on diagnosis, prognosis, and, eventually, personalised treatment. The newly emerged field of radiogenomics links specific MR imaging phenotypes with gene expression profiles. In this presentation I will discuss the three best known tumoural genotypes with prognostic and - potential - therapeutic consequences: 1. isocitrate dehydrogenase (IDH) mutation, 2. 1p19q deletion, and 3. methylguanine methyltransferase (MGMT) promoter methylation. I will give an overview of the known and potential MR imaging features of these genotypes, and their value and validity in a clinical context.

Learning Objectives:

1. To learn about whether there is a change of pattern recognition based on conventional and quantitative imaging approaches.
2. To understand the heterogeneity of low-grade gliomas based on histopathology and imaging.

3. To appreciate the perspectives and challenges of diagnostic imaging in phenotyping low-grade gliomas.

M. Smits: Other; Independent reviewer (EORTC-1410) with Parexel Intl. Corp. (financial compensation paid to institution).

A-1032 09:30

C. Advanced imaging in low-grade gliomas

N. Bulakbasi; Mersin/TR (nail.bulakbasi@kyrenia.edu.tr)

Low-grade gliomas (LGGs) are typically IDH mutant, diffusely infiltrating, slow-growing gliomas having moderately increased cellularity generally without mitosis, necrosis and microvascular proliferation. "Supra-total" resection of LGG significantly increases overall survival by delaying malignant transformation compared with a simple debulking. The exact diagnosis is crucial for treatment planning. Data from meta-analysis support the addition of diffusion and perfusion-weighted MR imaging and MR spectroscopy (MRS) in the diagnosis of suspected LGGs. Typically, LGGs have lower cellularity (ADC), angiogenesis (rCBV), capillary permeability (Ktrans), and mitotic activity (Cho/Cr ratio) than those of high-grade gliomas (HGGs). The identification of 2-hydroxyglutarate in MRS with spectral editing gives a clue about its IDH status. A gradual decrease in minimum ADC values and increase in Cho/Cr ratio and maximum rCBV values and the emergence of lactate and free lipid at MRS in time, are consistent with the tumour progression and the poor prognosis. Small tumour diameters, artefacts due to bone or air interfaces, vascular structures, hemorrhagic, cystic/necrotic and calcific changes in the tumoral area can cause critical distortions in quantifying parameters. So, the selection of a proper ROI avoiding these kinds of areas is critical to obtain proper quantified results. The quantitative multiparametric MR imaging of LGGs either can improve the diagnostic accuracy of their differential diagnosis or can assess their prognosis.

Learning Objectives:

1. To learn about the spectrum and diagnostic value of the available advanced imaging techniques in neuro-oncology.
2. To understand the added value and possible pitfalls using quantitative MRI techniques in addition to conventional MRI.
3. To appreciate the importance of standardisation of advanced MR image acquisition in the clinical practice of neuro-oncology.

E³ - European Diploma Prep Session

E³ 1723

Musculoskeletal

A-1033 08:30

Chairperson's introduction

F. Saez; Barakaldo/ES (fersaez@yahoo.com)

The musculoskeletal system is one of the important areas which form part of the European diploma in radiology. All radiologists should understand and become familiar with the imaging appearances of the different pathologies that may involve the MSK system. This session will be very valuable in this regard, as the speakers will deal with most of the MSK topics which are part of the European training curriculum, levels I and II.

Session Objectives:

1. To understand typical and atypical imaging features of traumatic disorders of the musculoskeletal system.
2. To learn typical imaging features of benign and malignant bone tumours.
3. To become familiar with the imaging appearance of degenerative and inflammatory disorders of the musculoskeletal system.

A-1034 08:36

A. Traumatic disorders of the musculoskeletal system

L. Meacock; London/UK (lisameacock@nhs.net)

Musculoskeletal trauma is regularly encountered in the Emergency Department. Certain injuries have challenging imaging appearances or may have associated soft tissue injuries the Radiologist should be alert to. Failure to recognise or misinterpretation of these conveys significant risks. This case-based lecture will focus on imaging characteristics of common and the more challenging appendicular musculoskeletal injuries, with an emphasis on appropriate imaging and understanding of the underlying mechanism of injury.

Learning Objectives:

1. To gain appreciation of typical fracture patterns and their accompanying soft tissue injuries.
2. To develop an understanding of the underlying mechanisms of injury in appendicular trauma and correlate with imaging findings.

3. To understand the benefits and disadvantages of different imaging modalities in assessing trauma involving the skeleton and soft tissue in differing age groups.

A-1035 09:04

B. Bone tumours

M.-A. [Weber](mailto:marc-andre.weber@med.uni-rostock.de); Rostock/DE (marc-andre.weber@med.uni-rostock.de)

Primary bone tumours are categorised according to their tissue of origin into cartilage, osteogenic, fibrogenic, fibrohistiocytic, haematopoietic, vascular, lipogenic tumours and several other tumours like Ewing sarcoma and giant cell tumour. Also, they are classified into benign, malignant and semi-malignant, as well as tumour-like lesions. They are rare, but found on radiographs during an investigation of a painful skeletal region or incidentally. The radiograph is the first method to distinguish benign from malignant lesions: at first by analysing the aggressiveness of a lesion according to the classification of Lodwick and second by analysing the mineralisation of the tumour matrix. The matrix may be osteolytic, osteoblastic, or mixed: osteolytic with matrix mineralisation. Based on the Lodwick classification an overview of the three main types of bone destruction patterns visible on radiographs will be given with many examples: type 1: geographic (with a: well-defined border with sclerotic rim, b: well-defined border without sclerotic rim, c: ill-defined border); type 2: geographic with moth-eaten or permeated pattern; type 3: small, patchy, ill-defined areas of lytic bone destruction with moth-eaten or permeated pattern. Periosteal reactions are also indicators of lesion aggressiveness and will be demonstrated. MRI is the best additional imaging modality for local staging, as it allows for accurate assessment of the extent of the disease and the effect of the tumour on the surrounding structures including the joint, neurovascular structures, muscle compartments and skin. MRI also gives details of the extent of the compartmental involvement to help complete excision of the tumour.

Learning Objectives:

1. To learn the typical imaging features of common bone tumours.
2. To understand the typical imaging features of "don't touch" ("leave-me-alone") lesions.
3. To become familiar with the imaging manifestations of haematological disorders.

A-1036 09:32

C. Degenerative and inflammatory disorders of the musculoskeletal system

J.-B. [Pialat](mailto:jean-baptiste.pialat@chu-lyon.fr); Lyon/FR (jean-baptiste.pialat@chu-lyon.fr)

Imaging findings of degenerative disorders of the joints are often found, but the correlation to clinical symptoms is not straightforward. After a descriptive approach of radiographic, computed tomography (CT) and magnetic resonance imaging (MRI) semiology, the clinical relevance of these findings will be discussed in the light of actual evidence. Considering the spine, degenerative disorders of lumbosacral and cervical levels are the most clinically relevant. All structures are affected with a variable association of ageing disk degeneration and bulging, bony spurs of vertebral bodies, and osteoarthritis of the face joints (zygarthrosis). These lead to an extensive range of local and radicular pain, or less frequently, to a progressive compression of the spinal cord or of the cauda equina roots resulting in specific neurologic deficits. The thoracic spine is usually considered less often in the spectrum of symptomatic degenerative disorders, but imaging findings are common. These degenerative disorders have to be considered as potential factors in the genesis of pain in patients with ageing static impairments focussing on destabilisation due to vertebral compressive fractures. A comprehensive approach to imaging manifestations of infection, inflammation and metabolic diseases of the musculoskeletal system will end the lecture. Particular focus will be made on the role of radiography, CT, MRI and nuclear medicine techniques to explore these pathologies. An emphasis will also be given to specific findings, which will guide the radiologist in his diagnosis, and will help him rule out some erroneous aetiologies.

Learning Objectives:

1. To understand the imaging presentation of degenerative disorders of the joints and to appreciate their clinical relevance.
2. To learn the imaging features and clinical features of degenerative disease of the spine, disc and facet joints.
3. To become familiar with the typical imaging manifestations of infection, inflammation and metabolic diseases of the musculoskeletal system.

Emergency Imaging

RC 1717

Small bowel obstruction: improve your reading and reporting competences

A-1037 08:30

Chairperson's introduction

S. [Romano](mailto:stefromano@libero.it); Naples/IT (stefromano@libero.it)

The small bowel obstruction represents one of the most common causes of the acute abdomen in patients arriving in the Emergency Departments. The introduction to the session presentations will be focused on a brief excursion on definitions and signs and on the main role of the radiologist involved in reporting the exams in giving essential and important information to the clinicians and surgeons requested for a correct therapeutic planning on the patient. The role of the MDCT and of the DECT will be also shortly noted and considered.

Session Objectives:

1. To learn how to confidently diagnose small bowel obstruction.
2. To understand how to identify the transition point rapidly.
3. To become familiar with the signs of ischaemia.

A-1038 08:35

A. Step 1: confirm the mechanical small bowel obstruction (SBO)

I. [Millet](mailto:milletingrid@wanadoo.fr); Montpellier/FR (milletingrid@wanadoo.fr)

A small bowel obstruction is defined by an intestine transverse diameter greater than 25mm. It can be due either to a focal obstacle on the bowel that prevents the normal alimentary bolus flow or to a global stop of the bowel peristalsis. It is then very important to differentiate those two types of SBO, respectively a mechanical SBO from a functional ileus because they don't have the same management nor prognosis. We used the term "mechanical" SBO when there is a transition zone between dilated upstream loops and collapsed downstream ones. To localise precisely the transition zone, multiplanar reconstructions and particularly the coronal view can be very helpful. The faeces-sign, defined as gas bubbles mixed with particulate matter in dilated segments of small bowel, when present (about 40% of cases) can help to identify the transition zone. However, the faeces-sign should not be used to guide treatment decisions.

Learning Objectives:

1. To differentiate a functional ileus from a mechanical SBO.
2. To know the diagnostic value of the feces-sign for depicting the transition zone.
3. To become familiar with multiplanar reconstructions for finding the transition zone.

A-1039 09:02

B. Step 2: identify the SBO cause

J.R. [Olalla Muñoz](mailto:olalla.jos@gmail.com); Murcia/ES (olalla.jos@gmail.com)

Small bowel obstruction (SBO) is a common clinical syndrome accounting for 12-20% of hospital admissions of acute abdominal pain and supposes a leading cause of surgical emergencies. Adhesions, together with hernias and malignancies, entail more than 80% of SBO aetiologies and remain the major cause of post-operative SBO. Current evidence-based guidelines establish CT the preferred imaging technique for the diagnosis of adhesive SBO (ASBO), especially in doubtful cases to exclude other cause of obstruction. The diagnosis of ASBO is primarily one of exclusion because adhesive bands are not generally seen at conventional CT; only an abrupt change or beak at the site of obstruction combined with kinking and tethering of adjacent bowel suggests the diagnosis. Recently, CT has been proved to be accurate as a patient-selection tool into operative versus nonoperative treatment groups. Several CT findings like the location of the transition zone, the presence of faeces sign, beak sign, whirl sign, a closed-loop configuration, and a high-grade SBO must be assessed because they are related to the success or failure of nonsurgical treatment. Other causes of localised mural thickening in the transition zone are Crohn disease, neoplasia, intussusception, radiation, hematomas, endometriosis. Finally, gallstone ileus, foreign bodies, or bezoar constitute rare causes of SBO but with an easier radiological diagnosis.

Learning Objectives:

1. To know the CT findings allowing adhesive bands to be diagnosed.
2. To know the list of SBO causes with bowel wall thickening at the transition zone.
3. To become familiar with some rare causes of SBO.

A-1040 09:29

C. Step 3: look for bowel ischaemia

R. [Smithuis](#); *Leiderdorp/NL (rsmithuis@cistron.nl)*

The most common cause of small bowel obstruction is an adhesion. An adhesion can obstruct the bowel in two ways. The most common is when the adhesion crosses the bowel leading to a simple obstruction. Ischemia will be an uncommon finding since the bowel proximal to the obstruction has a normal vascularisation. Things are quite different when a loop of small bowel crawls under an adhesion. Due to peristalsis more bowel may pass under the adhesion until it gets stuck resulting in a closed-loop obstruction. This always leads to venous obstruction and strangulation with ischemia. In any small bowel obstruction, it is the job of the radiologist to determine on CT whether it is a simple obstruction for which conservative treatment is the best option or a closed loop obstruction which needs immediate surgery. Closed loop obstruction can be diagnosed by looking for a cluster of bowel loops with mesenteric oedema and two points of obstruction. CT-scanning is done in the late arterial phase after delivery of intravenous contrast at a rate of 5 ml/sec for optimal bowel wall enhancement. Do not give oral contrast.

Learning Objectives:

1. To optimise the CT protocol for assessing bowel wall enhancement.
2. To learn how to diagnose a closed-loop mechanism.
3. To know the CT findings for diagnosing ischaemic complication.

09:56

Panel discussion: How important is the role of CT in deciding on operative or non-operative patient management?

E³ - Rising Stars Programme: EFRS Radiographers' Basic Session

BR 17

The future of radiology: what it could mean for new radiography graduates

A-1041 08:30

Chairperson's introduction: What will radiology departments look like in the future?

G. [Paulo](#); *Coimbra/PT (graciano@estescoimbra.pt)*

It's well known that the technological evolution and new scientific progress have increased the organisational complexity of healthcare. One of the major contributors to this complexity increase is the influence of medical imaging technology development. There is no doubt that modern healthcare is every day more and more dependent of medical imaging diagnostic and therapeutic procedures, which dramatically contributes to the increase of hospital efficiency, providing more effective and less invasive patient care. The development of medical technology, together with the several pressures on health systems are the potential drivers for the exponential increase of the number of imaging procedures (but not always followed with the necessary increase of radiographers and radiologists). Although this might be seen, in general, as a very positive aspect, reality shows that medical imaging is being seen more as a commodity and therefore there is an urgent need to develop a new paradigm for medical imaging departments, to maintain our identity. The development of a European Radiology Model, based on strategic management tools and professional role development are the key points to maintain the medical imaging procedures under the supervision of the radiological family and increase the visibility and the importance of radiology in health systems, based on a value-based healthcare model. Appropriateness criteria combined with audit and accreditation are the key to the development of a modern European radiology model.

Session Objectives:

1. To consider the drivers for change within radiology departments.
2. To appreciate the brief history of evolution within radiology departments.
3. To consider how radiology departments may look in future years.

A-1042 08:35

Future role extension for radiographers

H.H. [Hjemly](#); *Oslo/NO (Hakon@radiograf.no)*

Development of the professional role of radiographers in the Nordic region has been substantial since the profession was established in the early 70s. In parallel with the development and academising of radiography education, there has been a gradual change in the tasks previously performed by other groups, as well as the continuous supply of new tasks as a result of the significant advances in computing and technology in diagnostic imaging and radiation therapy. My presentation will focus on the current status of the scope of

practice for radiographers in the Nordic region, educational possibilities and projects. Based on research done by The Nordic Institute for studies in Innovation Research and Education (NIFU) I will present recommendations on role Development, drivers and barriers for radiographers to take greater responsibilities in diagnostic imaging.

Learning Objectives:

1. To understand the current status of role extension for radiographers.
2. To be aware of the international drivers for role extension within radiographic practice.
3. To appreciate the possible development options for radiographer role extension.

A-1043 08:53

Evolving imaging technologies

J.G. [Stowe](#); *Dublin/IE (john.stowe@ucd.ie)*

With the explosion of Artificial Intelligence (AI) a review of what AI is and is not is highly appropriate at this time. We sometimes ascribe too much value and trust to that 'intelligence' and a reminder that computers are essentially counting machines should be first and foremost. Computer-aided detection (CAD) is not new but with advances in the use of neural networks and machine learning we can produce creative and successful advances in this area. In the newest generation AI offerings, what we are talking about is advanced pattern recognition, and we must be careful that bias in the training of the 'machine learning' does not result in flaws in what could otherwise be pattern recognition that is equivalent to if not superior to humans. A review of the number and frequency of press releases and publications is a testament to the growth and importance of this technology. Disseminating of diagnostic imaging information is also a challenge and an area of continuing research and development. There is a tendency to use software that is traditionally intended for social media use however this brings into question ethics, regulatory compliance and governance. Software platforms are evolving to provide credible and secure repositories for the storage, control and tracking of the way we disseminate information rather and we must be cognizant of the issues, and acceptable practice of the management of this data in this new age of evolved data protection regulation as accountability has never been higher.

Learning Objectives:

1. To be aware of impending developments with regards to imaging equipment.
2. To consider the potential role for artificial intelligence (AI) within imaging.
3. To appreciate the future role of social media and computing within radiology departments.

A-1044 09:11

Changing the delivery of radiology, responding to the needs of our patients

K.G. [Vikestad](#); *Oslo/NO (karivi@oslomet.no)*

The continuous emerge of new technologies; together with increasing age of patients and number of examinations being performed represents a big challenge within radiology. This has led to delays in the interpreting and reporting of x-rays, meaning that it takes a long time from examinations is being performed until reports with the results of the patients' x-rays are ready for the referring doctor. Congestion of unreported x-rays represents one of the biggest challenges within the delivery of radiology services today. This could result in delays in patients receiving important treatment, thus putting patients at risk. Shortage of radiologists is also contributing to delays in the delivery of radiology services. Further, with the advanced technology within radiology may lead to radiologists prioritise the more advanced examinations, meaning that the skeletal x-rays are given less priority. Educating and training radiographers to perform reporting, particularly skeletal reporting, is one way to reduce the congestion of unreported x-rays. Radiographers are experts in viewing x-rays, and with proper education and training, they could perform reporting at a comparable level to the radiologists. Reporting radiographers could thus solve the bottleneck of radiology service delivery, resulting in effective and correct reporting of x-rays and shorter response time for patients.

Learning Objectives:

1. To be aware of the current challenges facing radiology service delivery.
2. To consider the opportunities available for developing and improving the delivery of radiology services.
3. To appreciate the needs of patients when developing a radiology service.

A-1045 09:29

What will radiology look like in 30 years?

C. [Beardmore](#); *London/UK (CharlotteB@sor.org)*

The provision of high quality efficient personalised services for patients is the priority for imaging and diagnostics services, with services focused around the patient; this will continue to be our goal. A team working utilising all the available proven technologies will be essential, much of the technical aspects of the role will be automated; radiographer practitioners will need to offer flexibility, creativity and continually adapt their role as robotics capability continues to advance rapidly. Research must continue to be a core part of the

radiographer's professional role in order to ensure that the rapidly changing innovations/robotics can be researched and translated into practice efficiently, where there is evidence to demonstrate a benefit for patients. The development of the radiography profession must, therefore, adapt to the changing context of this environment but ensure that research skills remain embedded within the professional education and training in order to ensure that the patients receive personalised care including the changing technological capabilities of equipment including Artificial intelligence and precision medicine. Robotics and increasing availability of vast amounts of data will enable ongoing change. The radiographers' role will change, but the radiographer must remain the patient facing carer across the service supporting patients during their diagnosis and onto their next steps along their personalised pathway of care. Their role needs to be considered within the context of the entire imaging team to ensure that the development of their skills and competencies effectively enable delivery of excellent patient care.

Learning Objectives:

1. To understand the key drivers for change within radiology.
2. To understand the possible areas for development over the next 30 years.
3. To appreciate how radiology may look in 2049.

Elbow imaging: from detailed anatomy to pathology

Moderator:

I. Sudol-Szopińska; Warsaw/PL

A-1046 08:30

A. The medial and lateral epicondyle

M.O. [De Maeseneer](mailto:michel.demaeseneer@uzbrussel.be); Brussels/BE (michel.demaeseneer@uzbrussel.be)

Bony landmarks at the lateral epicondyle include the tubercles, intertubercular sulcus, supracondylar ridge, and epicondylar ridge. Tendons include the brachioradialis, ECRL, ECRB, EDC, EDM, ECU and anconeus. Ligaments include the radial collateral ligament, annular ligament and LUCL. Pathological conditions include ligament tears, tendinosis, tendon tears and posterolateral instability. Bony landmarks at the medial epicondyle include the tubercles, intertubercular sulcus, epicondylar face and supracondylar ridge. Tendons include the pronator teres, FCR, Palmaris longus, FCU, FDS. Ligaments include the different components of the UCL. Pathological conditions include ligament tears, tendinosis, tendon tears, and VEO. Understanding bony landmarks at the epicondyles help understand tendon and ligament changes. Pathological conditions are then more easily assessed including tendinosis, tendon tears, ligament tears, VEO and posterolateral instability.

Learning Objectives:

1. To explain the anatomic considerations and pathophysiology of abnormalities that involve the medial and lateral epicondyles of the humerus.
2. To describe the imaging findings of abnormalities that involve the medial and lateral epicondyles of the humerus.

A-1047 09:00

B. Biceps and triceps

A. [Tagliafico](mailto:ataglifaco@sirm.org); Genoa/IT (ataglifaco@sirm.org)

The biceps brachii muscle consists of two heads, the short head and the long head. The two muscle bellies can have some degree of interdigitation proximal to the distal tendon, but they have two separate tendons, one for each muscle at the radial tuberosity insertion. The tendon of the short head attaches distally and slightly anteriorly at the radial tuberosity, whereas the tendon of the long head attaches more proximally. Distal biceps insertion is reinforced by a thin fibrous structure called lacertus fibrosus. Common lesions of the biceps tendons at the elbow include complete ruptures with retraction of the muscle belly or partial tears with different imaging appearance. Partial tears can involve the short or the long head of the biceps brachii tendon. Imaging can shift the therapeutic management from surgical to conservative especially in patients with partial tears. Other disorders related to the distal biceps brachii muscle include impingement and bicipito-radial bursitis. Brachialis muscles injuries are extremely rare. Triceps tendon ruptures can be acute traumatic or more commonly chronic overuse causing degenerative changes to the insertion. Rupture of the distal triceps tendon is uncommon and it may be unrecognised on clinical examination. The most common disruption is an avulsion from the osseous tendon insertion. MRI and US are useful in preoperative planning because it shows whether the rupture is complete or

partial. Sometimes, triceps muscle may be a factor contributing to ulnar nerve luxation at the elbow.

Learning Objectives:

1. To explain the anatomic considerations and pathophysiology of abnormalities that involve the biceps and triceps brachii.
2. To describe the imaging findings of abnormalities that involves the biceps and triceps brachii.

A-1048 09:30

C. Plica and cartilage

L. [Cerezal](mailto:Cerezal@gmail.com); Santander/ES (lcerezal@gmail.com)

Synovial plicae are folds of synovial tissue, remnants of embryonic septae of the normal articular development. Plicae have not well-known function and are usually asymptomatic. Chronic inflammation secondary to direct trauma, repetitive sports activities or surgical procedures of the elbow affects the elasticity of the synovial folds and can become symptomatic, sometimes termed elbow synovial fold syndrome, or posterolateral impingement. With elbow motion, the thickened fibrotic plicae can irritate the synovium, leading to inflammatory synovitis and radial head or capitulum articular cartilage wear. The painful snapping of the elbow joint is the most common clinical manifestation. This condition is not uncommon and commonly misdiagnosed as lateral epicondylitis. MRI and CT or MR arthrography are useful tools in the diagnosis of elbow synovial fold syndrome and for exclusion other causes of lateral elbow pain and snapping. Cartilage injuries usually affect the weight-bearing joints, such as the hip and knee and the elbow is one of the least affected joints. Chondral injuries of the elbow usually occur secondary to a previous injury such as elbow dislocation, fractures or chronic mechanical overload in manual workers, throwing sports or people using crutches and wheelchairs. Morphological MRI allows a precise assessment of macroscopic lesions of the articular cartilage. Furthermore, advanced MRI techniques also enable evaluation of the biochemical or ultrastructural composition of articular cartilage and detect early chondral damage.

Learning Objectives:

1. To explain the anatomic considerations and pathophysiology of abnormalities that involve the elbow plicae and articular cartilage.
2. To describe the imaging findings of abnormalities that involve the elbow plicae and articular cartilage.

Dose reduction and image quality implications of iterative image reconstruction in CT

A-1049 08:30

Chairperson's introduction

K.N. [Bolstad](mailto:kirsten.bolstad@helse-bergen.no); Bergen/NO (kirsten.bolstad@helse-bergen.no)

Ever since the development of the first CT, the quest has been to get as much information as possible, in the shortest amount of time as possible. In the early days of CT, the reconstruction time per image was limited by computer power and effective reconstruction algorithms. The filtered back projection algorithms (FBP) were a compromise between reconstruction speed and image noise. Iterative reconstruction algorithms (IR) takes into account a mathematical assumption of the system which results in less image noise but with a longer reconstruction time compared to FBP. Today, with more powerful and faster computers IR is a part of the daily routine. The noise reduction can either be used to improve image quality at the same dose or maintain similar image quality at a lower dose, typically 25-40% dose reduction compared to FBP. Recently, more advanced model-based iterative reconstruction algorithms have become commercially available with a reconstruction time suitable for the clinical routine. These algorithms take into account a mathematical model of the entire system, from the focal spot size and x-ray spectrum to the detector system, resulting in a nearly "noise-free" image. The dose saving potential for these newer algorithms is up to 80-90% compared to FBP. However, the application of IR does not come without a cost. Even though the image noise is reduced, the appearance of the image may change. Each vendors IR has a different appearance and different dose saving potential. Radiologists need time to get used to the new appearance.

Session Objectives:

1. To learn about the origins of dose reduction using iterative image reconstruction in CT.
2. To understand dose reduction using iterative image reconstruction in CT.
3. To learn about solutions and workarounds.

A-1050 08:35

A. Basics of iterative image reconstruction in CT
M. Kortensniemi; Helsinki/FI (mika.kortensniemi@hus.fi)

Computed tomography image reconstruction is a mathematical process where the raw data projections (sinogram data) acquired during rotational CT scan exposure are transformed into volumetric (3D) image data. As such, reconstruction is an inverse problem, with no direct analytical solution. Traditional algorithms (filtered back-projection) approximate the true acquisition method and are prone to artefacts and noise. Iterative reconstruction methods approach the final solution gradually in steps and may take quantum statistics, physical properties and limitations of image acquisition more faithfully into account. Thus, a more accurate and correct outcome may be achieved. However, more detailed modelling of the actual CT acquisition system, physics, optics and object also increase the calculation time and related CPU requirements. Especially, the forward projection phase (calculation of simulated raw-data) on each iteration step is computationally intensive. More optimised reconstruction techniques with clinically acceptable reconstruction times are under active research. As the main diagnostic benefit, higher image quality in terms of lower noise and artefacts can be achieved by using iterative methods, and/or a lower radiation dose. However, users should be aware that current iterative reconstructions potentially alter the image texture in different clinically relevant contrast and detail levels. Therefore, sufficient clinical image quality should be verified when applying iterative techniques on new exam indications and protocol optimisation.

Learning Objectives:

1. To learn about the basic aspects of iterative reconstruction.
2. To learn about potential dose reduction via iterative reconstruction.
3. To compare iterative reconstruction with other techniques.

A-1051 08:58

B. Iterative image reconstruction in clinical practice: dos and don'ts
H. Alkadhi; Zurich/CH (hatem.alkadhi@usz.ch)

The application of Computed Tomography (CT) imaging is paralleled by concerns regarding its potential risks. These concerns have led to the development of a set of strategies for optimising and lowering the radiation dose of CT. Of these techniques, iterative reconstruction algorithms represent a powerful tool, because they allow lowering the dose at a constant noise level and image quality. However, caution must be taken when iterative reconstruction algorithms are being used, and radiation dose can be lowered only to a level where information in the CT images are not lost. This presentation reviews the clinical challenges of using iterative reconstruction techniques in CT imaging, with a focus on low radiation dose examinations. The benefits and potential pitfalls of iterative reconstruction techniques are discussed in this presentation.

Learning Objectives:

1. To understand the radiologist's requirements for image reconstruction.
2. To learn about current best practice in image reconstruction for clinical CT.
3. To learn about the potential benefits and pitfalls of using iterative reconstruction in clinical CT.

A-1052 09:21

C. Image quality assessment of iterative reconstruction: pitfalls and future directions
C. Walsh; Dublin/IE (clwalsh@stjames.ie)

Iterative reconstruction (IR) algorithms offer the potential to provide diagnostic quality scans at a lower dose. IR is significantly different to the previously used Filter Back Projection technique, both in the way images are reconstructed, and in how the software is implemented on CT systems. Manufacturers have different versions of IR software, new IR products appear on the market at a relatively fast rate, and some versions have a high degree of user configurability. To exploit the potential dose savings, centres need confidence that diagnostic image quality is maintained as dose decreases. While dose measurements are comparatively straightforward, the standard physical image quality tests have limitations when assessing clinical image quality, particularly for IR images. For example, non-anthropomorphic test objects have limited clinical relevance or may interact sub-optimally with software designed to produce anatomical images. Some image quality metrics have a technical requirement that systems are linear shift invariant, which is not met by nonlinear IR algorithms. This presentation reviews the pitfalls of using existing image quality tests and overviews some of the developments which provide improved utility for assessing and optimising iteratively reconstructed images. These include developments to standard image quality measurements, and task-based approaches using model observers. The practical aspects of implementing image quality controls in an increasingly sophisticated technological environment are considered. The role of clinical assessment of image quality, and whether the analysis of 'big data' can contribute to IQ assessment in the future, is also discussed.

Learning Objectives:

1. To learn about basic image quality metrics employed in CT.
2. To understand why image quality assessment is difficult with iterative reconstruction.
3. To learn about up-and-coming methods for image quality assessment.

Thoracic emergencies

Moderator:

B. Ghaye; Brussels/BE

A-1053 08:30

A. Chest trauma

M. Brink; Nijmegen/NL (M.Brink@rad.umcn.nl)

Chest injuries are important contributors to mortality in major trauma patients. Although chest X-ray can be used as a screening tool in patients with life-threatening airway-breathing or circulatory problems, MDCT is the modality of choice to detect and characterise thoracic injury. MDCT with intravenous contrast has a very high diagnostic accuracy for predominantly pulmonary and vascular injuries. In this session, we will discuss three entities with high impact on patient morbidity and mortality. Pulmonary contusion is a commonly reported entity in high-energy trauma patients but is frequently confused with other causes of pulmonary opacification in trauma patients. Diaphragmatic ruptures need immediate operative intervention, but these injuries are rare and can be missed at MDCT. Finally, major aortic injury has very high mortality if left untreated, and should immediately be recognised. However, accurate diagnosis and adequate treatment depend on appropriate patient selection for MDCT, type and aspect of aortic injuries, scanning technique, and knowledge of mimickers of aortic injury.

Learning Objectives:

1. To describe CT features of pulmonary contusion.
2. To learn about signs of diaphragmatic rupture.
3. To know when to suspect and how to confirm aortic injury.

Author Disclosure:

M. Brink: Grant Recipient; Canon Medical Systems. Speaker; Canon Medical Systems Europe.

A-1054 08:53

B. Haemoptysis

M.-P. Revel; Paris/FR (marie-pierre.revel@aphp.fr)

Haemoptysis represents a potentially life-threatening condition which requires urgent management and care. It is defined by the expectoration of blood during coughing, originating from the lower respiratory tract. The immediate risk is airway compromise in case of severe haemoptysis, whereas small haemoptysis can be less urgently managed. There are various definitions of severity, from 100 mL to 1 L of blood expectorated in 24 hours. The severity also depends on the underlying cause and cardiopulmonary status of the patient. For severe haemoptysis, it is essential first to localise the bleeding side, which can be shown by chest x-ray, demonstrating alveolar opacities of the right or left lung. If not, CT scan will help to localise the bleeding side by showing ground-glass opacities in non-dependent lung areas. Most bleedings are of systemic origin, involving the bronchial arteries or other enlarged systemic arteries, which can be treated by embolisation. Contrast-enhanced CT is recommended in stable patients, to help to depict the normal or ectopic origin of the bronchial arteries. More rarely, bleeding is due to damaged pulmonary arteries, showing false aneurysms of mycotic or traumatic origin or tumoral invasion. In exceptional cases, bleeding can be due to the bronchial fistulization of an aortic aneurysm, with a very poor prognosis.

Learning Objectives:

1. To learn about the main causes and mechanisms of massive haemoptysis.
2. To review the role of CT in the assessment of site and cause of bleeding.
3. To learn about the bronchial artery anatomy assessment on CT.

A-1055 09:16

C. Diagnosing PE

G. Aviram; Tel Aviv/IL (aviramgalit@hotmail.com)

Pulmonary embolism (PE) is a life-threatening diagnosis, which has an increased incidence with ageing. Since it has a non-specific clinical presentation, the initial approach when acute PE is suspected should be clinical pre-test probability assessment, using validated clinical decision rules.

If PE is "unlikely", negative D-dimer excludes PE. Recently the D-dimer cutoff level was adjusted to age. When PE is "likely" or if D-dimer levels are elevated above the new threshold, the patient should be referred for CT pulmonary angiography (CTPA). Technological advancements to improve CTPA quality with reduced radiation doses and contrast volume include lowering the kVp, noise reduction strategies, and spectral CT. Though CTPA is highly accurate, diagnosing isolated subsegmental embolism often poses diagnostic and therapeutic dilemmas. Acute PE patient's management can vary between admission to intensive care unit to immediate discharge for home treatment. It should be based on clinical, laboratory and imaging evaluation. The diagnostic CTPA data can contribute to immediate risk stratification. There are various CT parameters for PE severity assessment, among them, increased right to left ventricular diameter ratio, reflux of contrast to the IVC, and reduced left atrial volume, which will be discussed.

Learning Objectives:

1. To learn about optimising CT angiography indications.
2. To be aware of the causes of imaging inconclusiveness.
3. To learn how to identify signs of acute right ventricular dysfunction.

G. Aviram: Research/Grant Support; My institution received a research grant from Philips Health Care.

A-1056 09:39

D. Vascular intervention in thoracic emergencies

I. Bargellini; Pisa/IT (irenebargellini@hotmail.com)

Over the past years, interventional radiological procedures have become essential for the prompt management of life-threatening thoracic vascular emergencies, thanks to their low invasiveness and increased availability. According to the European guidelines for the treatment of aortic diseases, Thoracic Endovascular Aortic Repair (TEVAR) represents the first-line treatment modality for the management of several thoracic aortic emergencies, including traumatic and spontaneous ruptures, complicated type B dissections, intramural hematomas and penetrating ulcers. In fact, the high technical success rate and the low morbidity and mortality rates enable prompt management in the emergency setting and do not preclude future surgical procedures, if needed. Likewise, bronchial and non-bronchial arteries embolization has become the treatment of choice for severe hemoptysis, after failure of medical and endoscopic treatment, with an immediate success rate > 70%. Safety of embolisation is guaranteed by superselective catheterisation of the bleeding vessels and by correct choice of the most adequate embolic agent. Finally, over the past years, catheter-directed thrombolysis and/or thrombus debulking have been proposed as safe and effective treatment options in high- and intermediate-high risk patients with pulmonary embolism. Specifically, the 2014 European guidelines consider catheter-direct revascularization as an alternative to surgical embolectomy for high-risk patients in whom full-dose systemic thrombolysis is contraindicated or has failed. For the success of all these procedures, however, it is essential for interventional radiologists to be adequately trained and skilled and to work within dedicated multidisciplinary teams, to share decisions and manage possible complications.

Learning Objectives:

1. To learn about bronchial embolisation for life-threatening haemoptysis.
2. To review endovascular procedures for management of severe PE.
3. To understand the role of the interventional radiologist in aortic trauma management.

Quantitative imaging in oncology

A-1057 08:30

Chairperson's introduction

J. O'Connor; Manchester/UK (james.oconnor@manchester.ac.uk)

Images are inherently heterogeneous. In oncology, there is much current interest in quantifying this spatial variation and using this information to derive 'heterogeneity biomarkers'. At the within tumour level, these biomarkers tend to either identify sub-regions of a tumour that are markedly abnormal or characterise how heterogeneous each individual tumour is. Current research studies are establishing whether or not such biomarkers have value in monitoring tumour response to therapy, or in determining prognosis and prediction of outcome. In addition, alternate approaches compare the variation between multiple lesions in one individual and how this may inform personalised medicine. In this session, various quantitative imaging

approaches are discussed that give rise to heterogeneity biomarkers, with emphasis on their current uses, pitfalls and future directions.

Session Objectives:

1. To understand the impact of tumour heterogeneity on diagnosis and treatment.
2. To learn the basics of quantifying heterogeneity in tumours.
3. To review the future impact of imaging heterogeneity in tumours.

A-1058 08:35

A. Intra- and intertumoural heterogeneity and the impact for cancer diagnostics

M. Eisenblätter; Münster/DE (eisenblaetter@uni-muenster.de)

Malignant tumours are biologically complex systems with spatially variable gene expression patterns, consecutively variable biochemistry, histopathology and macroscopically variable structure. In the tumour microenvironment, genetic variability of tumour cells meets external stressors and the host immune system. The result is a regional heterogeneity of stromal architecture, biological activity and expression of, e.g. chemokines and growth factors. Consecutively, the development of tumour vasculature, nutrient supply, cell growth and death etc. exhibit significant, regional variation. This variation occurs within a single tumour lesion, between a primary tumour and metastasis and of course and pronounced between tumour lesions - even of the same tumour type - in different individuals. Generally, a high degree of heterogeneity is associated with poor prognosis and is at the same time increasingly relevant for therapy selection and monitoring, due to ever more specific therapy approaches. Various imaging approaches allow for visualisation of spatial heterogeneity in tumours. However, recorded and documented information is often limited to lesion size and macroscopic heterogeneity. In this context, relevant information, silently acquired even during clinical standard examinations, is ignored and dismissed unused. A rigorous analysis of all radiologic imaging data can help to discover this hidden information and provide additive information on tumour biology, relevant for tumour therapy. This talk is intended as an overview of the different levels of tumour heterogeneity, experimental and established imaging approaches to assess tumour heterogeneity and the possibility to provide adequate biomarkers for state of the art tumour therapy by integrated image data analysis.

Learning Objectives:

1. To learn about tumour heterogeneity.
2. To review current strategies to explore biological heterogeneity.
3. To understand how this heterogeneity impacts diagnosis and treatment.

A-1059 08:53

B. Quantitative image biomarkers for targeted tumour therapies

R. García Figueiras; Santiago de Compostela/ES (roberto.garcia.figueiras@sergas.es)

Clinical imaging systems are a significant source of non-invasive imaging biomarkers (IBMs) that may reflect important biological properties of cancers. IBMs can provide quantitative information on tumour hallmarks and can be used to evaluate tumour heterogeneity. They may also help us to understand the mechanism of action of therapies and their effects on tumour microenvironment, offering objective measures of change in response to therapy. This presentation will explain the biologic basis for a number of commonly available IBMs obtainable clinically. Beside this, we'll illustrate how quantification of IBMs is undertaken and provide the validation of such measurements. Finally, the role of IBMs for the assessment of therapy response will be reviewed.

Learning Objectives:

1. To learn how heterogeneity can be quantified from images.
2. To understand the main classes of heterogeneity on imaging.
3. To review limits and pitfalls of features extraction.

A-1060 09:11

C. From quantitative imaging to radiomics and deep learning

H.K. Hahn; Bremen/DE

"no abstract submitted"

Learning Objectives:

1. To learn how to optimise the acquisition of images for quantitative imaging.
2. To understand image processing which may impact quantification.
3. To become familiar with the concepts behind quantification including machine learning approaches.

A-1061 09:29

D. Imaging heterogeneity and genomic variability in ovarian cancer

E. Sala; Cambridge/UK (es220@cam.ac.uk)

Cancer is caused by genetic (DNA) and epigenetic alterations and frequently arises as a clonal growth from a founder cell. The subclonal heterogeneity provides the basis for inter-metastatic heterogeneity which is of utmost clinical importance. New tumour sampling techniques and circulating tumour DNA methods may allow for more comprehensive evaluation of clonal composition.

As both primary tumours and metastatic lesions are spatially and temporally heterogeneous, they would require multiple biopsies to extract and analyse small portions of tumour tissue, which still doesn't allow for a complete characterisation of the tumour genomic landscape. Therefore, imaging has great potential for a comprehensive evaluation of the entire tumour burden in ovarian cancer as it is noninvasive and is already often repeated during treatment in routine practice, on the contrary of genomics or proteomics, which are still challenging to implement into clinical routine. While initial retrospective studies linking phenotype with genotype in ovarian cancer have shown a high prognostic power, they do not provide any spatial information as quantitative imaging features are generated and averaged over the entire tumour assuming that tumours are heterogeneous but well mixed. This approach ignores spatial heterogeneity readily apparent on imaging. Indeed recent genomics work has highlighted the presence of intratumor variation in gene mutation and expression. However little effort is any has been put into integrating imaging, histopathology and genomics and thus there is a clear need for well designed prospective studies focused on the meaningful integration of phenotype and genotype rather than genomics in isolation.

Learning Objectives:

1. To learn about the application of imaging tumour heterogeneity in ovarian cancer.
2. To understand how heterogeneity on imaging may relate to biological heterogeneity.
3. To become familiar with concepts such as imaging phenotypes and signatures.

Multidisciplinary Session

MS 17

Multidisciplinary approach to the diabetic foot

A-1062 08:30

Chairperson's introduction

E.N. [Brountzos](mailto:ebrountz@med.uoa.gr); Athens/GR

Diabetes mellitus (DM) has become a global epidemic. According to the World Health Organization, the number of people with diabetes increased from 108 million in 1980 to 422 million in 2014, while the worldwide prevalence of diabetes in 2013 was 8.3%. Moreover, 1.6 million deaths were directly caused by diabetes in 2016, as DM is a major cause of cardiovascular events and advanced peripheral arterial disease leading to limb amputations due to diabetic foot ulceration (DFU). The management of DFU requires a comprehensive multidisciplinary approach which should include radiologists, diabetologists, vascular surgeons, interventional radiologists. Prompt differential diagnosis between pure neuropathic or mixed neuro-ischemic DFU is essential for limb salvage, as major amputation rates are particularly high without rapid revascularisation. Following the clinical assessment, imaging is vital in order to verify the presence and assess the magnitude of arterial disease but also to evaluate soft tissue and bone infections. Once the diagnosis of vascular involvement is set, and the appropriate drug therapy has been administered, revascularisation by open surgical bypass or peripheral endovascular procedures should be offered immediately, to enable fast wound healing and avoid infection that would compromise the limb. Both surgical and endovascular treatment options result in high limb salvage rates at long-term follow-up, and the decision between the two methods should be case-sensitive. Recent advancements in endovascular procedures have significantly broadened the indications and increased their efficacy. Following successful reperfusion, proper wound care, drug therapy and strict clinical and imaging follow up are fundamental for limb salvage.

Session Objectives:

1. To appreciate the magnitude of the diabetic foot as a societal problem.
2. To understand the role of radiological imaging and interventional radiology in the diagnosis and treatment of the diabetic foot.
3. To learn the role of surgical treatment of the diabetic foot.

A-1063 08:35

Diabetic foot: a societal problem

V. [Lambadiari](mailto:Lambadiari@med.uoa.gr); Athens/GR

"no abstract submitted"

Learning Objectives:

1. To appreciate the scope of the problem.
2. To learn the prevalence of the arterial ulcers and the amputation risk.
3. To learn the prevention and care of foot ulcerations.

A-1064 08:50

Imaging evaluation of the diabetic foot

O. [Papakonstantinou](mailto:Papakonstantinou@med.uoa.gr); Athens/GR (sogofianol@gmail.com)

Soft tissue and bone infections are common complications in diabetic foot that can be underdiagnosed leading to delay of treatment and, finally, amputation. Imaging findings and techniques, potential and limitations of plain radiographies, CT, US, scintigraphy, and, with a special focus, MRI will be discussed, aiming at the differential diagnosis between soft tissue and bone infection, between neuropathic osteoarthropathy and osteomyelitis as well as identification of complications such as abscesses, fractures and infarcts. Subsequently, we will touch upon the capabilities of high-resolution MR imaging techniques to provide an accurate mapping of the run-off vessels, which will eventually determine which patients further need DSA and therapeutic interventions.

Learning Objectives:

1. To learn how to image soft tissue and bone infections.
2. To learn how to image arterial perfusion: CTA and MRA.
3. To learn when to use DSA.

A-1065 09:05

Interventional radiological treatment (IR)

S.C. [Spiliopoulos](mailto:Spiliopoulos@med.uoa.gr); Athens/GR (stavspiliop@med.uoa.gr)

Endovascular treatment is today an established option for both critical limb ischemia (CLI) and lifestyle limiting intermittent claudication in subjects with diabetes mellitus (DM). Particularly in patients with tissue loss, prompt revascularisation is highly important to improve limb perfusion, facilitate wound healing and attain limb salvage avoiding major amputation-associated morbidity and mortality. The technological advancements in the field of endovascular devices, as well as the continually increasing experience in endovascular techniques, have broadened the indications of endovascular therapies and have made possible the successful treatment of even small-vessel infrapopliteal and inframalleolar arterial disease (PAD), typical in subjects with diabetic foot disease. Angioplasty and stenting are the main tools for the management of the peripheral arterial disease. Limb salvage rates reported in the literature reach up to 90% at ten years follow up highlight the long-term efficacy of endovascular treatment. However, mid-term loss of patency resulting in clinical relapse and frequent re-interventions is the most significant drawback of endovascular treatment. Drug-eluting technologies-mainly drug-eluting stents and drug-coated balloons- significantly improve patency rates and clinical outcomes according to data from multiple multicenter randomised trials, while new technologies such as percutaneous atherectomy and shock-wave lithoplasty are currently under investigation. Tissue perfusion modalities in order to evaluate and monitor the outcomes of endovascular procedures are currently under development, while the impact of angiosome-guided revascularisation and pedal arch reconstruction on wound healing requires further investigation. Well-designed, multicenter, prospective trials are necessary to investigate the impact of novel endovascular technologies in PAD patients with DM.

Learning Objectives:

1. To learn when interventional treatment is indicated.
2. To learn the tool kit.
3. To learn the results of IR treatment.

A-1066 09:20

Surgical management of the diabetic foot

G. [Geroulakos](mailto:Geroulakos@med.uoa.gr); Athens/GR (ggeroulakos@med.uoa.gr)

Limb loss is a significant risk in patients with diabetic foot ulcers. It is estimated that 15% to 20% of patients with diabetes will develop foot tissue lesions ranging from simple cellulitis through ulcer and abscess to osteomyelitis and gangrene. About 15% to 20% of patients with foot ulcers will need an amputation. The surgical strategy has several aims. The first step is to control the infection by a combination of appropriate antibiotic therapy with drainage of pus, removal of necrotic tissue and minor amputation if needed. The second step involves assessment of the limb ischemia. Lack of arterial blood flow reduces the supply of oxygen and nutrients, the delivery of antibiotic agents and impedes wound healing. Although arterial disease in diabetic patients typically affects the distal vessels, preoperative imaging often reveals multi-level occlusions and diffuse disease, which necessitates challenging distal revascularisation either endovascularly or by surgery. Endovascular

Postgraduate Educational Programme

revascularisation is more appropriate in patients with relatively focal disease in arteries above and below the knee. Bypass to the tibial or pedal vessels with autogenous vein is the gold standard for patients with diabetes and complex tibial disease and has greater durability than endovascular procedures. Primary amputation is indicated in case of overwhelming infection that threatens the patient's life, when tissue necrosis secondary to arterial disease has destroyed the foot or when a prolonged course of treatment is associated with a poor prognosis for a successful outcome.

Learning Objectives:

1. To learn what the goal of surgery is in treating the diabetic foot infections.
2. To learn how to prevent osteomyelitis.
3. To learn when to amputate and to what extent.

A-1067 09:35

Multidisciplinary case presentation and discussion

E.N. [Brountzos](mailto:ebrountz@med.uoa.gr); Athens/GR (ebrountz@med.uoa.gr)

Diabetes mellitus (DM) has become a global epidemic. According to the World Health Organization, the number of people with diabetes increased from 108 million in 1980 to 422 million in 2014, while the worldwide prevalence of diabetes in 2013 was 8.3%. Moreover, 1.6 million deaths were directly caused by diabetes in 2016, as DM is a major cause of cardiovascular events and advanced peripheral arterial disease leading to limb amputations due to diabetic foot ulceration (DFU). The management of DFU requires a comprehensive multidisciplinary approach which should include radiologists, diabetologists, vascular surgeons, interventional radiologists. Prompt differential diagnosis between pure neuropathic or mixed neuro-ischemic DFU is essential for limb salvage, as major amputation rates are particularly high without rapid revascularisation. Following the clinical assessment, imaging is vital to verify the presence and assess the magnitude of arterial disease but also to evaluate soft tissue and bone infections. Once the diagnosis of vascular involvement is set, and the appropriate drug therapy has been administered, revascularisation by open surgical bypass or peripheral endovascular procedures should be offered immediately, in order to enable fast wound healing and avoid infection that would compromise the limb. Imaging of eye and orbital pathologies

Moderator:

M.M. Lemmerling; Ghent/BE

A-1068 08:30

A. Traumatic lesions of the eye and orbit

A. [Allianou](mailto:allianou@neuchatel.ch); Neuchâtel/CH

In this lecture, the commonest types of traumatic injuries of the eye and the orbit will be reviewed. The role of CT and MRI in the emergency setting will be emphasised when dealing with fractures and soft tissue injuries. The most common types of facial fractures involving the orbit (blow-out fractures, tripod fractures, Le Fort type II and III, latero-facial fractures, as well as pan-facial fractures) and their radiologic features will be mentioned. A systematic discussion will include associated injuries of the ocular muscles, globe, lacrimal sac, vascular structures, the base of the skull and dura, as well as cranial nerves. Emphasis will be given to what the clinicians need to know and how to report the radiologic findings in a structured way.

Learning Objectives:

1. To become familiar with imaging features of orbital fractures.
2. To learn about traumatic lesions of the eye and orbital soft tissues.
3. To review acute and chronic complications after orbital trauma.

A-1069 09:00

B. Infection and inflammation in the eye and orbit

K. [Erb-Eigner](mailto:K.Erb-Eigner@charite.de); Berlin/DE (Katharina.Erb@charite.de)

Infectious and inflammatory diseases of the eye and orbit play a major role in ophthalmology. However, diseases manifesting posterior to the globe are not detectable by ophthalmoscopy, and cross-sectional imaging is often necessary for diagnostic work-up. Radiologists should be familiar both with the anatomy of the eye and orbit and with the imaging features of the most common infectious and inflammatory diseases. Magnetic resonance imaging (MRI) has excellent soft tissue contrast and is the first choice method in most cases. This Refresher Course will present typical MR examination protocols and outline the benefits of multiparametric imaging. Basic clinical features and typical imaging findings in infectious and inflammatory disorders of the orbits including optic neuritis, abscesses, sarcoidosis and idiopathic inflammatory disorders will be discussed. Other topics include emergency findings which require immediate communication and what to report to clinicians to achieve the best outcome for patients.

Learning Objectives:

1. To become familiar with infections and inflammation in different orbital structures.
2. To discuss imaging features of infection and inflammation in the eye and orbit.
3. To learn how to reach the final diagnosis.

Author Disclosure:

K. Erb-Eigner: Consultant; Author of Atlas on Orbital MRI at Pantavision.

A-1070 09:30

C. Benign and malignant masses of the eye and orbit

P. [De Graaf](mailto:p.degraaf@vumc.nl); Amsterdam/NL (p.degraaf@vumc.nl)

Ocular and orbital masses in adults and children represent a spectrum of (rare) benign and malignant lesions that can be challenging to diagnose and treat. Most patients with intra-ocular masses are diagnosed on clinical grounds by means of extensive clinical investigation by the ophthalmologist. High-resolution MRI has emerged as an important imaging modality for pretreatment assessment, i.e. confirmation of diagnosis and staging disease extent. The role of CT is limited. Orbital mass lesions, usually presenting with proptosis and/or visual decline, need to be analysed by MRI in order to characterise the type of lesion. The most important intra-ocular and orbital mass lesions will be shown, and specific signs on imaging will be reviewed.

Learning Objectives:

1. To discuss advanced imaging techniques in tumoural orbit lesions.
2. To review intraocular tumours.
3. To become familiar with intraorbital masses.

Prostate MRI: the accreditation issue

A-1071 08:30

Chairperson's introduction

J. [Richenberg](mailto:jonathan.richenberg@bsuh.nhs.uk); Brighton/UK (jonathan.richenberg@bsuh.nhs.uk)

It is widely accepted that multi-parametric MRI (mpMRI) is 'good' in prostate cancer. But what does 'good' mean? How do we measure 'good'? And how do we make 'good' universal? This session considers a strategy to rapidly roll out mpMRI across Europe without sacrificing quality. Before acceding to the clamour for mpMRI, radiologists, urologists and oncologists need to acknowledge that mpMRI is complex: to acquire and to interpret pre-biopsy mpMRI means that radiologists become the praetorian guard of prostates pre-biopsy implies a 'yes/no' approach and specialists are more prepared to make such decisions (less PIRADS 3) The first talk explores optimisation of images and proposes standards on acquisition, the second talk explores the benefits of a multidisciplinary approach to prostate cancer diagnosis, the place of specialist centres and the role of the radiologist within this setting; the third talk addresses some of the aspects that surround the accreditation of individuals and centres in the reporting of mpMRI including the concept of on-going performance assessment. In this new era of cardiac imaging, virtual colonoscopy and now radiologically driven prostate cancer diagnosis, accreditation and standard setting becomes crucially relevant, and controversial as doubtless the panel discussion at the session's end will demonstrate!

Postgraduate Educational Programme

Session Objectives:

1. To understand the emerging role of the multidisciplinary approach for prostate cancer.
2. To discuss the role of the radiologist in the multidisciplinary approach to prostate cancer.
3. To discuss the accreditation and certification issues for prostate imaging.

A-1072 08:35

A. Prostate MRI: minimum and optimal requirements
N.N.

Learning Objectives:

1. To understand the minimum requirements for multiparametric MR of prostate cancer.
2. To understand how to optimise MR imaging technique at 3T and 1.5T.
3. To review sequence parameters and scan optimisation for prostate imaging.

A-1073 08:58

B. Towards a European accreditation of prostate imaging centres
V. Logager; Copenhagen/DK (vibeke.loegager@regionh.dk)

Imaging in itself is nothing. It is in the context of diagnosing and treating the patients that imaging becomes valuable and important. To ensure the best use of expensive equipment when finding the correct diagnosis with the least delay, it is necessary to ensure high quality. The multidisciplinary team approach has the potential to ensure this. The expert panel discussions aim to give the optimal treatment to every patient at the right time. Also, an information feedback loop is arranged in this forum, when imaging, histology and patient outcome are held up against each other. Despite guidelines, quality in imaging is not guaranteed. It is necessary to ensure reproducibility and homogeneity in imaging of technical parameters, in scanning procedures, reading and reporting. Reference, specialist prostate centres could be a way to go. High-end centres that are involved in international research with a high volume of examinations, in co-operation with the clinicians, pathologists and oncologists, will gain substantial experience. This includes doing multidisciplinary team meetings. By having a reference centre, it could be possible to measure any institutions image quality and report validity against the international standards of care. To make this possible, it is necessary to agree upon suitable and measurable indicator parameters on quality. In order to know that, what you do, is in line with the standard of care level, we must decide how we most reliable can measure our contribution, from referral to examination and further to the finalised report.

Learning Objectives:

1. To learn about the role of the radiologist in the multidisciplinary approach for prostate cancer.
2. To discuss the requirements for a specialist prostate centre, with emphasis to the imaging issue.
3. To understand quality indicators for prostate MRI.

A-1074 09:21

C. Towards a certified radiologist

H.C. Thoeny; Fribourg/CH (Harriet.thoeny@h-fr.ch)

MRI of the prostate is increasingly performed in many centres before a biopsy. On one hand, this allows performing targeted biopsies in case of detection of a suspicious lesion and on the other hand to avoid biopsy in case of a normal prostate MRI. The correct diagnosis is therefore of utmost importance. False positive results lead to unnecessary biopsies including side effects, unnecessary fear and increasing costs, whereas false negative results lead to underdiagnosis of significant prostate cancers. A correct diagnosis is crucial, and besides correct image interpretation, the radiologist needs an in-depth understanding of prostate pathologies and knowledge of the potential treatment options. Strong collaboration in the multidisciplinary tumour boards together with urologists, pathologists, oncologists and radiation therapists with regular feedback is the prerequisite for quality control of the radiologist. Furthermore, level III European Training Curriculum for prostate imaging defines the expected knowledge of the radiologist performing prostate MRI. In many European countries certified prostate cancer centres exist, however, the exact role of the radiologist has to be defined and is becoming increasingly important. The European Society of Urogenital Radiology (ESUR) provides yearly specific teaching courses on prostate imaging allowing continuous education. In line with breast units, the certified radiologists performing prostate MRI need a certain number of exams every year, the exact minimum number has to be defined based on future studies as well as an evaluation based on feedback from pathology.

Learning Objectives:

1. To understand the need for a certified radiologist in a prostate unit.
2. To illustrate the level III European Training Curriculum for prostate imaging.
3. To discuss how to certify radiologists for prostate imaging.

09:44

Panel discussion: Prostate units: is the radiologist in or outside the core team?

A. Stroke mimics

M.M. Thurnher; Vienna/AT (majda.thurnher@meduniwien.ac.at)

The correct and prompt diagnosis of ischemic stroke and/or stroke mimics is crucial to assist clinicians in proper triaging and therapy decisions. A stroke mimic represents a non-stroke disorder with a presentation suggestive of acute ischemic stroke. The list of possible stroke mimics consists of seizures and postictal phenomena, headaches, metabolic disturbances, toxicities, and space-occupying lesions. A variety of non-neurological conditions such as systemic infection, cardiovascular events, and psychiatric issues may also masquerade as acute ischemic strokes. In this lecture, key-imaging features of stroke mimics will be discussed in detail.

Learning Objectives:

1. To become familiar with the different entities that can mimic a stroke.
2. To know the usefulness of perfusion studies in the differential diagnosis.

A-1076 11:15

B. Acquired toxic-metabolic encephalopathies

K. Karli Oguz; Ankara/TR (karlioguz@yahoo.com)

Acquired toxic-metabolic encephalopathies encompass a wide range of causes including metabolic causes like hypo-/hyperglycemia, hepatic and uremic encephalopathy, or osmotic demyelination, hypertension, exposure to toxic substances, or drug abuse. Clinical history is extremely important in the evaluation of the patient. Best recognised on MRI, these disorders tend to show bilateral and symmetrical involvement of the deep grey matter and cerebral white matter. Some peculiar locations, DWI features and clues from proton MR spectroscopy will guide the radiologists on the way to the diagnosis. In this session, participants will review and practice the imaging features of the most common acquired toxic-metabolic encephalopathies with representative cases.

Learning Objectives:

1. To review the most common causes.
2. To learn the MRI and CT appearances of these lesions.

ESR meets Pakistan

EM 3

The role of radiology in major healthcare challenges faced by Pakistan

Presiding:

M.H. Akram; Islamabad/PK

L.E. Derchi; Genoa/IT

A-1077 10:30

Introduction

M.H. Akram; Islamabad/PK (drhamidakram@gmail.com)

Infections and malignancies are two major health challenges being faced by Pakistan. Amongst the infections, though gastroenteritis, pneumonia, typhoid and malaria are not uncommon, the major challenges are hepatitis and tuberculosis mainly due to their chronic nature, a variety of presentations, complications and lengthy management. Regarding malignancies; though in Pakistani women the incidence of breast cancer is one of the highest in Asia, the most common cancer which involves a reasonable proportion of both sexes is cancer of the lip and oral cavity. To deal with these three major diseases, radiology is playing a crucial role, not only in diagnosis and early detection of complications but also in the management.

Postgraduate Educational Programme

Session Objectives:

1. To learn about oral cancer in Pakistan and the role that radiology plays in its management.
2. To appreciate the role of radiology in living donor liver transplant in advanced cases of chronic hepatitis.
3. To understand the variety of radiological findings in tuberculosis.

A-1078 10:35

Imaging of oral cancer

N. Ud Din; Lahore/PK (najam200@gmail.com)

The actual burden of head and neck cancer in Pakistan is 18.74% of all new cancers. The incidence of oral cancer was highest in males, averaging 11% in 2012. The social and cultural habits across different provinces of the country seem to determine the increasing variable incidence of head and neck cancer in Pakistan. The obvious high risk is associated with the use of betel, areca and chewable tobacco besides family history, smoking habits, occupation and socioeconomic status. In a cross-sectional study, up to 40% of the participants were chewing at least one of these items on a daily basis. The bulk of the oral cancers were along the alveolus. Economic losses related to head and neck cancer in Pakistan totalled US\$16.9 billion in 2010, equivalent to 0.26% of the region's economic output. Estimated direct cost of treatment of disease caused by smoking was Rs.68 billion in the year 2000. The economic consequences of head and neck cancer in South Asia are significant. Multidisciplinary management is critical in addressing this burden. The bulk of our patients present with advanced, stages three and four diseases. Staging, treatment planning, follow up and surveillance rely on imaging with CT/MR and PET/CT routinely. Nutrition, speech, hearing, swallowing therapy, rehabilitation support and palliative care are all challenges. Advanced disease at presentation, poor performance status and suboptimum compliance besides limited financial support undermine the treatment outcomes. Approximately 40% of these patients with head and neck tumours die within one year in spite of definite curative treatment.

Learning Objectives:

1. To understand the peculiar causes of high incidence of oral cancer in different regions of Pakistan.
2. To become familiar with the spectrum and scale of advanced disease in Pakistan.
3. To appreciate the variation in imaging and therapeutic practices across Pakistan.

Role of radiology in developing a living donor liver transplant programme

A.I. Rana; Islamabad/PK (atifrana1@gmail.com)

Pakistan has one of the highest prevalence rates for viral hepatitis in the world. In a country of approximately 200 million people and a 7% combined burden of hepatitis B virus (HBV) and hepatitis C virus (HCV), it was imperative to have indigenous liver transplantation (LT) program in Pakistan. Living donor liver transplant was initiated in 2012 in our centre, and so far, more than 650 transplants have been performed. Radiology has been at the forefront in this endeavour. Our contribution includes preoperative donor work up with a CT to calculate liver attenuation index, liver volumetric analysis as well as delineation of vascular anatomy for surgical planning. All patients undergo an MRCP as well for biliary anatomy. In the post-operative period, both recipient and donor may require imaging to look for complications such as post-operative collection, vascular complications, or biliary strictures. The most common recipient complication in our patients is a biliary stricture, occurring in about 22% of patients. Our interventional radiologists play an important part in treating these as well as other complications such as post-operative collections, portal vein stenosis or arterial complications.

Learning Objectives:

1. To learn about steps in setting up a successful living donor liver transplant program in Pakistan.
2. To understand requirements of preoperative imaging of potential donors.
3. To learn about various postoperative complications in transplant recipients and role of diagnostic as well interventional radiology in managing them.

Many faces of tuberculosis

U. Siddique; Peshawar/PK (ummara_81@hotmail.com)

Tuberculosis (TB) is one of the biggest health issues, and in Pakistan, around 430,000 people contract TB with about 70,000 deaths attributed to it, every year. Pakistan ranks 5th globally among the 22 high TB burden countries,

contributes an estimated 43% of the disease in the Eastern Mediterranean region and has the fourth highest prevalence of multidrug-resistant TB globally. TB can involve any organ of the body, e.g. respiratory, cardiac, central nervous, musculoskeletal, gastrointestinal and genitourinary systems. Timely diagnosis is paramount since delayed treatment leads to severe morbidity. Therefore radiological workup is necessary for diagnosis. TB can present with a variety of radiological findings. In complicated TB, owing to delayed diagnosis, clinical and radiologic features of TB may mimic malignancy. Although in many cases biopsy or culture specimens are required to make a definitive diagnosis, it is imperative that radiologists understand the typical distribution patterns and imaging manifestations of TB in various organ systems. The goal of this talk would be to delineate the classical imaging findings in many presentations of TB like a stroke with tuberculomas, sciatica in caries spine, chronic diarrhoea in ileocecal TB, constrictive pericarditis causing congestive hepatopathy, cervical adenitis mimicking metastasis and vague pelvic pain in TB related to pelvic inflammatory disease. It is important to define a novel checklist to confirm TB presenting with different faces on imaging. Improvements in TB management can be made by raising the index of suspicion, having better knowledge of specific radiological patterns of disease and extensive screening studies.

Learning Objectives:

1. To learn about the prevalence of tuberculosis in Pakistan.
2. To understand the variety of radiological findings in tuberculosis, its diagnosis and complications.

11:45

Panel discussion: Why are oral cancer, chronic hepatitis and tuberculosis more common in Pakistan, and in which scenarios is the role of radiology crucial in the management of these diseases?

E³ - European Diploma Prep Session

E³ 1823

Breast

A-1083 10:30

Chairperson's introduction

M.H. Fuchsjaeger; Graz/AT (michael.fuchsjaeger@medunigraz.at)

The European Diploma Prep Session on Breast aims to provide a preparation for future European Diploma in Radiology (EDiR) candidates. Topics are defined by the European Training Curriculum (ETC), and sessions are held in close cooperation with the European Board of Radiology (EBR). A short briefing on the EDiR examination as well as 2 sample questions (1 MRQ and 1 Short Case) and 1 sample case of the CORE examination (Clinically Oriented Reasoning Evaluation) will be presented in order to get the audience acquainted with the format. These three cases will include lesion detection and characterisation with mammography, ultrasound of the breast and breast MRI. The content of the session which will provide an overview on mammography, breast cancer diagnosis and interventions as well as multimodality imaging of the breast reflects ETC Level I - 'first three years of learning' and ETC Level II - 'Fourth and fifth years of training (general radiologist standard)' learning objectives.

Session Objectives:

1. To understand the methodological principles of mammography.
2. To learn the mammographic appearance of benign and malignant lesions of the breast.
3. To become familiar with the imaging appearance of benign and malignant breast lesions.

A-1084 10:36

A. Fundamentals of mammography

F. Kilburn-Toppin; Cambridge/UK

Mammography is the gold standard for breast cancer detection both in the symptomatic and screening population. This talk will first review the anatomy of the breast in relation to mammographic appearances, allowing accurate interpretation of imaging findings. The importance of mammographic technique will be discussed, highlighting the importance of both compression and positioning of the breast for detection of malignancy. The use of additional mammographic views will be reviewed with case examples, and important artefacts will be covered. Finally, the use of mammography in screening will be covered, with European recommendations for high-quality screening and recommendations for radiology practice. The controversy about the use of mammographic screening regarding reduction in mortality and overdiagnosis and overtreatment will also be discussed.

Postgraduate Educational Programme

Learning Objectives:

1. To understand the anatomy, normal variants and abnormalities of the female breast.
2. To become familiar with the technical aspects of diagnostic mammography, especially in regard to dose and image quality.
3. To become familiar with the principles of current practice and risk/benefit analysis in breast cancer screening.

A-1085 11:04

B. Breast cancer diagnosis and interventions

C. [Van Ongeval](#); *Leuven/BE (chantal.vanongeval@uz.kuleuven.ac.be)*

The breast composition and appearance of benign diseases and breast cancer at mammography, ultrasound and MRI will be discussed by the presentation of a correctly structured report of the imaging and interventional procedures. Personal and family history impacts the decisions made during an exam and should be reported. Description of the density according to ACR BI-RADS® lexicon (a,b,c,d) indicates the mammographic (Mx) sensitivity. Description of all Mx abnormalities (asymmetry, mass lesion, architectural distortion and microcalcifications) includes position, size, distance to the nipple, relation to other lesions in the breast. Palpable mass and/or Mx abnormality are investigated with ultrasound (US) of the whole breast and axillary (level 1,2,3) region. The US report includes breast composition, location, description of shape, margins, size of the lesion and evaluation of the lymph nodes(LN), and comparison with previous exams. Depending on the suspiciousness and type of lesion, additional core-needle or vacuum-assisted (ultrasound, stereotactic, MRI guided) biopsies need to be done (assessment categories BI-RADS® lexicon). If needed the lesion(s) should be marked with a clip. The three main indications of the additional use of breast magnetic resonance imaging (MRI) are the pre-operative extent of disease evaluation in the ipsilateral and contralateral breast (i.e. lobular carcinoma, dense breast, young women, discordant Mx/US information), neo-adjuvant therapy evaluation, screening of gene mutation carriers. An assessment report integrating the findings on MX, US, MRI and the second look US, is preferred. Communication with the referring physician and surgeon on the radio-pathological results and eventually use pre-operative localisation technique is advised.

Learning Objectives:

1. To learn the different presentation of normal breast patterns and the appearance of common benign diseases and of breast cancer at mammography, ultrasound and MRI.
2. To understand principles and basic application of standardised diagnostic categorisation systems such as the ACR breast imaging reporting and data system (BI-RADS®).
3. To become familiar with indications, contraindications and technical aspects of image-guided interventional breast procedures (fine needle aspiration, core needle biopsy, vacuum-assisted biopsy, presurgical localisation).

A-1086 11:32

C. Advanced imaging of the female breast

E.M. [Fallenberg](#); *Munich/DE*

"no abstract submitted"

Learning Objectives:

1. To understand the role of advanced imaging techniques in evaluation of the breast.
2. To use the added value of new techniques for lesion classification in mammography, ultrasound and MRI.
3. To recognise the major imaging issues for common indications of breast imaging.

A-1087 12:30

Autoimmune pancreatitis

R. [Pozzi Mucelli](#); *Verona/IT*

Autoimmune pancreatitis (AIP) represents a distinct form of chronic pancreatitis. Histologically, AIP is characterised by a dense lymphoplasmacytic infiltrate of mainly CD4+ T lymphocytes and immunoglobulin G4 plasma cells, located around the pancreatic ducts with mass-forming regions of fibrosis. AIP has been classified into focal or diffuse forms. The differential diagnosis between focal AIP and pancreatic adenocarcinoma represents a medical need

since AIP responds to steroid therapy and surgery should be avoided. CT and MRI findings of AIP are characterised by an enlargement of the gland, either focal or diffuse. At CT the affected areas are isodense before contrast enhancement, hypodense (due to hypervascularity) in the arterial phase with the progressive increase in density in the venous and late phases following contrast administration. The involved areas appear hypointense on T1-weighted MR images, mild hyperintense on T2-weighted images with reduced diffusion at DWI. The lesion appears hypovascular during the arterial phase, with progressive enhancement and delayed retention of contrast in the venous and late phases. MRCP is able to assess the involvement of the pancreatic duct system and these features are important in the differential diagnosis with the pancreatic adenocarcinoma in which the main pancreatic duct is characterised by single short stenosis, with marked dilation of the upstream ductal system. In cases in which AIP involves the head of the pancreas, dilation of the common bile duct and the intrahepatic ducts can be seen.

Learning Objectives:

1. To learn about autoimmune pancreatitis.
2. To understand imaging findings of pancreatic adenocarcinoma mimickers.
3. To appreciate differential diagnosis criteria with pancreatic adenocarcinoma.

A-1088 13:00

Paraduodenal pancreatitis

G. [Morana](#); *Treviso/IT (gmorana61@gmail.com)*

Paraduodenal pancreatitis is a form of chronic pancreatitis involving the duodenal wall in the region of the minor papilla and is considered a distinct entity with peculiar pathological findings. The frequent presence of the so-called heterotopic pancreatic tissue in the duodenal wall may reflect the incomplete involution of the dorsal pancreas in this region and contribute to an obstruction of the outflow in this area. Histologically there is thickening and scarring of the duodenal wall that extends to the adjacent pancreatic tissue and/or cystic changes in the duodenal wall. Occasionally some of the cysts may have a diameter of several centimetres. The clinical profile of PP is middle-aged men, heavy drinkers and smokers with painful pancreatitis, associated with vomiting and weight loss due to duodenal stenosis and impaired motility. The most characteristic imaging finding at CT and MRI is a sheet-like mass between the head of the pancreas and the C-loop of the duodenum (the so-called groove). The mass is hypodense/hypointense to the pancreatic parenchyma. Contrast-enhanced dynamic images show a delayed and progressive enhancement in the late phase that reflects the fibrous nature of the tissue. Cystic lesions are well depicted in the groove or the duodenal wall, especially in T2-weighted images. In early stage MPD is normal; in advanced cases, pancreatic head or entire gland are involved, showing findings of chronic obstructive pancreatitis, with ductal dilatation. There is an absence of vascular encasement, with a leftward displacement of the gastroduodenal artery without obstruction.

Learning Objectives:

1. To learn about autoimmune paraduodenal pancreatitis.
2. To understand imaging findings of paraduodenal pancreatitis.
3. To appreciate differential diagnosis criteria with pancreatic adenocarcinoma.

V.N. Cassar-Pullicino; *Oswestry/UK*

A-1089 13:30

Acute trauma: patterns in the peripheral skeleton

J. [Teh](#); *Oxford/UK (jamesteh1@googlemail.com)*

A systematic approach to analysing trauma imaging of the peripheral skeleton is presented. Typically, imaging begins with x-rays. A step-wise approach may reveal subtle abnormalities that should prompt further action. For example, the presence of a Second fracture on x-ray suggests an ACL injury and thus should lead to an MRI scan. It should be recognised that in trauma, certain injuries cannot occur in isolation; therefore a dislocated radial head on elbow x-ray should prompt imaging of the whole forearm, as Monteggia fracture-dislocation may be present. Understanding mechanisms of injury allow the radiologist to predict patterns of injury. So if bone bruising is present on MRI in the lateral femoral condyle and medial patella, a lateral patellar dislocation should be suspected, and a specific search for an injury of the medial retinaculum should be made. Conversely, recognising classic patterns of injury

can allow the mechanism of injury to be deduced. This lecture will focus on classical patterns of acute trauma in the peripheral skeleton.

Learning Objectives:

1. To become familiar with the imaging manifestations of common important injuries in the upper and lower limb.
2. To understand the underlying mechanism that result in combination of injuries.
3. To learn how to best employ imaging modalities in their diagnosis.

A. Head and neck emergencies in children

A. Rossi; *Genoa/IT (andrearossi@gaslini.org)*

Children presenting with acute disease involving the head and neck often display an aspecific clinical picture characterised by pain, fever, malaise, and local or generalised swelling. Regional involvement ranges from the orbits to the paranasal sinuses, temporal bone, skull base, craniocervical junction, upper airway, and neck. Emergent presentations in the head and neck compartment can be grossly categorised into traumatic and non-traumatic, the latter comprising infectious, inflammatory, congenital, and neoplastic conditions. Imaging studies play a fundamental role in the diagnosis of these conditions and provide a basis for subsequent management, including the identification of situations that may dictate immediate surgical treatment. The choice of the most appropriate imaging method is significantly influenced by the patient's clinical conditions and stability (or lack thereof). Although both ultrasound and X-rays often are used, this presentation will mostly focus on findings at CT and MRI.

Learning Objectives:

1. To become familiar with the different entities.
2. To identify the key imaging findings.

A-1102 14:45

B. Acute neurological child beyond trauma

A. Sánchez-Montañez; *Barcelona/ES (anchelsanchezmed@gmail.com)*

This presentation reviews the brain imaging findings of the most common acute neurological non-traumatic disorders in pediatric patients. From the clinical point of view, a wide differential diagnosis of diseases that can occur abruptly in the emergency room is discussed. The most frequent acute symptomatology and manifestations are seizures, headache, irritability, lethargy, paresis, fever, nausea and vomiting. Beyond trauma, there are other entities to consider when a pediatric patient has an acute neurological clinical presentation. Among them, vascular aetiology stands out, whether in the form of an arterial stroke, venous thrombosis or vascular malformation. Other important causes are infections, drugs and their side effects, tumours, metabolic and demyelinating diseases. Neuroimaging techniques include computed tomography (CT), magnetic resonance (MR) and, even cerebral ultrasound in neonates and infants. The combination of basic neuroimaging methods and other advanced techniques such as angiographic and perfusion studies, allow proper differential diagnosis, correct management of the acute neurological onset in children and its subsequent follow-up.

Learning Objectives:

1. To become familiar with the most common cause of acute neurological emergencies.
2. To learn the imaging criteria for differentiation.

Quantification of perfusion reduction by using 2D parametric parenchymal blood flow following partial spleen embolisation in patients with hypersplenism

T. Meine¹, S.K. Maschke¹, M. Kirstein¹, J. Renne¹, T. Werncke¹, C. Dewald¹, F. Wacker¹, B.C. Meyer², J.B. Hinrichs¹; ¹Hannover/DE, ²Berlin/DE (Meine.Timo@mh-hannover.de)

Purpose: To analyze the feasibility of 2D Parametric Parenchymal Blood Flow (2D-PPBF) for the quantification of perfusion reduction following partial spleen embolization (PSE).

Methods and Materials: 15 PSE procedures in 14 patients with hypersplenism were included (2015-2018). Outcome was measured via platelet count before and after PSE. To quantify changes in spleen perfusion following PSE using 2D-PPBF, the acquired digital subtraction angiography (DSA) series were post-processed. A reference region-of-interest (ROI) in the splenic artery and a target ROI outlining the embolization territory of the splenic tissue were placed in corresponding areas on DSA pre- and post-PSE. The Wash-In-Rate (WIR), the 50%-to-Peak (Peak_{0.5}), the Arrival-to-Peak (Peak_{Arrival}), the Mean-Transit-Time (MTT) and the Area-Under-the-Curve-per-ROI-Area (AUC) were assessed and the ratios to the reference ROI were calculated. Mean and standard deviation of the ratios were determined. Comparisons between pre- and post-embolisation data were made using a Wilcoxon signed-rank test.

Results: Platelet count increased significantly following PSE from 41.200 ± 19.468 to 103.066 ± 70.350 platelets/microliter (p=0.02). In the embolized splenic territory, the pre-/post-embolisation 2D-PPBF parameter changed significantly: WIR 1.05 ± 2.18 / 0.09 ± 0.07 (p=0.03), Peak_{0.5} 3.30 ± 0.88 / 4.28 ± 1.18 (p=0.011), Peak_{Arrival} 1.95 ± 0.77 / 3.20 ± 1.45 (p=0.027), MTT 4.82 ± 1.23 / 6.39 ± 1.79 (p=0.005) and AUC 0.81 ± 0.79 / 0.13 ± 0.08 (p=0.01).

Conclusion: 2D-PPBF is an objective approach to quantify the perfusion reduction of embolized splenic tissue following PSE. It may be used to assess angiographic outcome and set angiographic endpoints for PSE.

B-0002 08:38

Role of multidetector CE-CT before transcatheter endovascular embolisation in active arterial bleedings

A. Borzelli¹, A. Paladini², F. Amodio¹, E. Cavaglia¹, R. Niola¹; ¹Naples/IT, ²Novara/IT (antonio.borzelli@libero.it)

Purpose: Identify the role of CE-CT in active bleedings' detection according to clinical evidence and biomoral parameters of patients.

Methods and Materials: 1480 CE-CTs were performed between June 2014 and June 2017 for suspected active bleeding (median patient age 45; 902 M, 578 F) in emergency setting, due to clinical and laboratory evidence of serum haemoglobin value lowering.

Results: In 793 CE-CT cases revealed active bleeding followed by angiography. In the remaining 687 cases, CT was negative, but due to clinical and laboratory values worsening, in 89 of them angiography was performed, revealing active bleeding in 65 patients; the latter owing to pseudoaneurysms, intracavitary bleedings or through percutaneous drainages. Among the 793 CT-positive patients, in 64, angiography did not reveal active bleedings and 28 of these were patients affected by DIC or wide small and diffuse bleedings, while in 36, CT revealed small active bleedings not detectable by the following angiography. In the last year (June 2017-February 2018) we considered CT-false-positive patients and in 31 of them angiography was not performed for wide small and diffuse bleedings or for small bleedings detected by CT, preferring clinical and laboratoristic follow-up. In 2 cases, owing to worsening of symptoms and laboratory parameters, angiography was performed, showing active bleeding followed by successful endovascular embolisation.

Conclusion: Multidetector CE-CT showed elevated accuracy in revealing active bleedings, but a correct assessment of clinical and laboratory conditions of patients is essential in the presence of mismatch between imaging findings and clinical conditions. In particular, in cases of wide small and diffuse bleedings and very small focal bleedings, only strict clinical and laboratory follow-up is appropriate, to evaluate later the necessity of diriment angiography.

B-0003 08:46

Selective intraarterial embolisation as a treatment for haemorrhoid pathology: preliminary study

M. Ferrer Puchol¹, A. Gregorio², E. Esteban¹, F.J. Blanco¹, V. Primo², L. Andreo², M. Villalta Santamaria¹, R. Ramiro¹, J. Solaz Solaz¹; ¹Alzira/ES, ²Denia/ES (lolesferrer@ono.com)

Purpose: To present patients with bleeding haemorrhoids treated by selective intraarterial embolisation of superior rectal artery (SESRA).

Methods and Materials: We present twenty-one patients with disabling chronic rectal bleeding, evaluated by a proctologist, who indicated SESRA as the best therapeutic alternative. The mean age was 60.5 years (45-81). The stage of the haemorrhoidal disease was II/III. They were not suitable for other treatments. They were admitted the same day as embolisation. The inferior mesenteric artery was catheterized using a visceral catheter and superior rectal arteries were catheterized with microcatheter (2.7F). The occlusion of rectal arteries was made by PVA particles (300-500 microns in size) and coils 2-3 mm and particles, verifying the absence of distal flow. All patients were discharged at 24 h. After one month, the surgeon evaluated the patients clinically and with anoscopy.

Results: In 19/21 cases, the embolisation was successful, one patient presented inferior mesenteric artery spasm and the procedure was suspended and other suffered infrarenal aortic aneurysm avoiding the catheterization. Clinical success was 19/21, follow-up: 2-29 months. One patient presented pain (VAS 3) that disappeared after 5 days. The rest did not experience any discomfort after the procedure. One patient presented rectal bleeding and prolapse, and he is pending surgical revision. Anoscopy performed at 1 month showed significant improvement in haemorrhoids. No complications were detected.

Conclusion: The initial results suggest that SESRA is safe and well tolerated and with advantage of absence of anorectal trauma. Additional studies were needed to evaluate treatment's efficacy.

B-0004 08:54

Post-TIPS encephalopathy: are there any predictive factors?

C. Perazzini¹, P. Fonio², A. Doriguzzi Breatta³, D. Righi², D. Rossato², G. Gandini²; ¹Clermont Ferrand/FR, ²Turin/IT, ³Castelnuovo Don Bosco/IT (chiara.perazzini@alice.it)

Purpose: To evaluate hepatic encephalopathy (HE) after trans-jugular intrahepatic porto-systemic shunt (TIPS) related to: age, international normalized ratio (INR), creatinine, bilirubin, platelets, portal thrombosis and model for End-of-stage Liver Disease score.

Methods and Materials: Retrospective study of 118 patients (53 males and 65 females, mean age 54 y/o) that from January 2008 to June 2013 underwent TIPS and a 6 and 12 months follow-up. HE staged according to West Haven criteria and simplified in moderate and severe has considered. Continuous variables tested for normality with the Shapiro-Wilks test. Comparisons employed non-parametric tests for k distributions and Anova test for $n > 2$ correlated distributions. Categorical variables arranged in $r \times c$ tables studied with the Chi-square or with Fisher's exact test. Statistical significance set at two-tails $p < 0.05$. Analysis carried out with source software.

Results: The overall HE incidence after 6 moths is 36%: 29/118 patients present a moderate HE, 13/118 a severe one, 74/118 are not affected. Any statistical significance exists between biographical data, INR, creatinine, bilirubin, platelets, portal thrombosis and HE. Portal thrombosis has protective effect. At 12 months, 9/118 patients underwent liver transplantation, 2/118 died. 107/118 remaining have been re-evaluated: any statistical significance exists between biographical data, INR, creatinine, bilirubin, platelets and the incidence of HE. INR, lower bilirubin and a higher platelet are associated with a lower probability of HE.

Conclusion: INR, lower bilirubin, higher platelet count, without statistical significance and portal thrombosis, are associated with a lower HE incidence 12 months after TIPS.

B-0005 09:02

Retrograde stent implantation of the celiac artery via the pancreaticoduodenal anastomosis

F. Pedersoli¹, P. Isfort¹, M. Zimmermann¹, M.F. Schulze-Hagen¹, S. Keil¹, C.K. Kuhl¹, P. Bruners¹; Aachen/DE (fpedersoli@ukaachen.de)

Purpose: The antegrade recanalization of a high-grade stenosis of the celiac artery directly from the aorta may present sometimes a challenge. In fact, in the absence of vascular stump ("flash-occlusions") or pronounced calcification of the aortic wall, the trial may remain frustrated. Therefore was investigated the possibility of a retrograde alternative in the case of difficult antegrade access from the superior mesenteric artery, via the inferior and superior pancreaticoduodenal artery, the gastroduodenal artery, and the common hepatic artery.

Methods and Materials: We performed a retrospective analysis of all patients, who underwent a stent implantation in the celiac trunk from 01/2010 to 12/2017. The data on the indication to the intervention, the access, the material used, the stent model and the follow-up were collected.

Results: In 34 patients was performed a stent implantation into the celiac trunk. The antegrade approach was successful in 30 patients (88%). An antegrade passage of the occlusion or stenosis was not possible in 4 (12%) patients. In these cases, a 5F catheter was placed in the proximal superior mesenteric artery. Then the stenosis could be overcome with 2.4 F microcatheter and micro-wire. Subsequently, the tip of the micro-wire was captured in the aorta with a snare and pulled out in the femoral introducer sheath with a rendezvous technique and then used as a guide for the antegrade implantation of a balloon-expandable stent into the celiac trunk.

Conclusion: Retrograde access to the celiac trunk by pancreaticoduodenal arcade represents a valid alternative if antegrade access is not possible

B-0006 09:10

High-flow priapism: colour Doppler findings and embolisation

G. De Magistris, F. Pane, F. Corvino, F. Giurazza, M. Coppola, F. Amodio, M. Silvestre, E. Cavaglià, R. Niola; *Naples/IT* (giuseppedemagistris74@gmail.com)

Purpose: To retrospectively evaluate the efficacy of colorDoppler detectability and the safety of transcatheter arterial Embolization for High-flow Priapism

Methods and Materials: Over a 8-year period, 10 patients (mean age 32 years; range 13-65 years) admitted to our department with traumatic high-flow priapism, were reviewed. The patients were evaluated with clinical and imaging findings (colorDoppler ultrasonography and Angiography). Diagnostic Angiography demonstrated fistulas between the cavernosal artery and the corpora cavernosa, these communications were embolized with coils and gelatin sponge. A colorDoppler follow-up was performed at 2 weeks and 3-6 months after procedure

Results: At the admittance, colorDoppler detected pseudoaneurysms/fistulas in 9 patients. In 8 of 10 patients a single embolization was sufficient for complete resolution, 2 patients had recurrence of Priapism (confirmed by colorDoppler Imaging) in the subsequent 1- 3 weeks and required a second procedure. 9 patients were embolized with coils and one with sponge. At 3-6 months follow-up, colorDoppler US confirmed the absence of fistula and recanalization of the embolized cavernosal artery. All patients had normal erectile function at 6 months

Conclusion: ColorDoppler is useful to detect fistulas and to monitor the effectiveness of embolization. Superselective transcatheter embolization of the internal pudenda artery is efficacy, compared to other techniques, and has a high rate of preserving erectile function

B-0007 09:18

Role of c-arm computed tomography-assisted adrenal vein sampling in the assessment of adrenal hypersecretion syndromes

A. Pisano, M. Tiplaldi, G. Orgera, F. Laurino, A. Laghi, M. Rossi; *Rome/IT* (andrea.pisano21@gmail.com)

Purpose: Adrenal Vein Sampling (AVS) is a gold standard procedure in the diagnostic work up of adrenal hypersecretion syndromes. However, it is burdened by high failure rates due to technical issues and in particular for the right vein catheterization. Therefore, we investigated the impact of C-arm Computed Tomography-Assisted AVS (C-AVS) in comparison to standard AVS.

Methods and Materials: From September 2010 to January 2018, a total of 40 procedures were retrospectively reviewed: 23 AVS (group A) and 17 C-AVS (group B). Overall, 36 patients (90%) had primary hyperaldosteronism clinical features, and 4(10%) suffered from ACTH-independent Cushing's Syndrome with bilateral macronodular hyperplasia.

All patients were infused with 50 microL/h cosyntropin 30 minutes prior the procedure. After catheterization of the right and left adrenal vein, C-arm-CT was performed in group B during CE selective injection, to confirm correct catheter position. Technical success was defined by adequate bilateral sampling, intended as a selectivity index (SI) >3.

Results: Technical success was obtained in 52,2% of group A (12pt), while in 47,8% of the cases sampling did not prove diagnostic. On the other hand, technical success was achieved in 82,4% of group B (14pt), whereas 11,7% of them did not meet SI criteria and 1 procedure was aborted due to contrast-media reaction. Technical success was significantly higher in group B than in group A (82,4% vs. 52,2%; p-value <0.05). There was no procedure-related complication.

Conclusion: Despite limited data, C-AVS improved the overall success rate of AVS, as it proves crucial for an optimal catheterization of adrenal veins.

B-0008 09:26

Long-term follow-up of giant visceral artery aneurysms endovascular treatment: a single centre experience

M. Tiplaldi¹, M. Pignatelli¹, G. Orgera¹, F. Laurino², A. Laghi¹, M. Rossi¹; ¹Rome/IT, ²Eboli/IT (tipaldi.andrea@gmail.com)

Purpose: Purpose of this study is to assess the immediate and long-term safety and effectiveness of Giant visceral artery aneurysms (visceral aneurysm > 5cm) endovascular treatment in a single center case series.

Methods and Materials: Eight cases of GVAAs (7M, 1F) have been treated in our institution, between August 2006 and June 2017, and were retrospectively reviewed. Embolization was performed with coiling and/or fragment of guidewires and/or embolic agents and/or stents. Technical success was defined as the correct exclusion of the sac at the last angiogram, while clinical success was defined as the complete relieve of clinical symptoms, if previously present. Follow-up was performed with CT angiography at 1,3, 12 and 24 months or phone survey if patients were referred to other centers.

Results: Technical and clinical success were obtained in 100% of the cases. One minor complication, consisting in an asymptomatic ischaemia of the spleen, and one major complication, consisting in a 4cm splenic abscess concurrently with a small infarctual area, occurred. The median time follow-up was 48 months (range 6 to 84 months) and demonstrated the correct exclusion of the sac in 100% of the cases. One patient died five years after the treatment for causes not related to the procedure.

Conclusion: The first line treatment of visceral artery aneurysms is, nowadays, the endovascular one rather than open surgery. Our series have shown that this indication, thanks to the low morbidity and mortality rates associated with, should be expanded even for GVAAs.

B-0009 09:34

Transjugular portal vein stenting: an original approach for palliative treatment of portal vein stenosis/occlusion in neoplastic patients

A. Mazzaro¹, F.L. Gatti¹, R. Bettini¹, N. Mandruzzato², A. Contro¹, G. Mansueto¹; ¹Verona/IT, ²Trieste/IT (andrea.mazzaro1558@gmail.com)

Purpose: To evaluate risks and benefits of portal vein stenting as a palliative procedure in a pool of oncologic patients.

Methods and Materials: Between April 2014 and August 2018 we treated 12 patients with neoplastic portal vein stenosis/occlusion performing portal vein stenting. In 5 of them was used a transhepatic access and in 7 a transjugular access. Portal stenting has less than 200 cases reported in the literature, most of them with transhepatic access. Transjugular access is an original/unique variant. To evaluate the procedure we considered technical and anatomical success, procedural complications and mortality, 30 days mortality, modifications in clinical and laboratory parameters (haemoglobin, haematocrit, albumin, ALT, bilirubin and INR). Technical success was assessed with intra-procedural portography while complications and anatomical success with follow-up MDCT.

Results: In all the procedures technical and anatomical success was achieved with no intraprocedural or early mortality. Two patients treated with transhepatic access developed complications (hepatic abscess and hepatic haematoma). No patient with transjugular access developed complications. All patients showed improvement of clinical conditions and of laboratory parameters (four or more of the six parameters considered) in 30 days, even those who developed complications.

Conclusion: Portal vein stenting in oncologic patients was performed safely, it resolved portal vein's stenosis/occlusion leading to a relief of portal hypertension-related symptoms and an improvement in the quality of life. In our experience transjugular access is less invasive and reduces the risk of hepatic bleeding, however it has to be performed by TIPS procedure expert operators.

B-0010 09:42

Use of Onyx (ethylene vinyl alcohol copolymer) in haemorrhage embolisation procedures

R. Marcello, G. Assegnati, A. Di Blasi, F. Cortese, D. Konda, E. Pofi; *Rome/IT* (robermarcello@gmail.com)

Purpose: The purpose of our study was the evaluation of the effectiveness and reliability of the "Onyx" device (ethylene vinyl alcohol copolymer) in the treatment of bleeding by trans-catheter embolization technique.

Methods and Materials: 14 Patients in our retrospective analysis underwent transcatheter embolization for bleeding control. All patients underwent diagnostic angiography with trans-femoral access to confirm the findings obtained with US and ce-TCMS investigation work-up. The coaxial technique was always applied in performing all procedures with a 5 Fr diagnostic catheter (Sim 1 Imager, Boston Scientific, USA) combined with a microcatheter 2.7 Fr. (Progreat Terumo, JAP). In all cases "Onyx" (ethylene vinyl alcohol copolymer) was used as embolization material. The source of the bleeding was duodenal ulcer in 5 cases, 2 gluteal haematomas, 1 haemorrhoidal pseudoaneurysm, 2 intraparenchymal renal aneurysms in one case, 1 vascular malformation of the gastric fund, 1 haemorrhage after hip prosthetic replacement, 1 renal

angiomyolipoma, 1 abdominal wall haematoma and 1 retroperitoneal haematoma.

Results: Prompt cessation of bleeding was achieved in all patients. No immediate or late complications were observed with regards to all procedures carried out. No unwanted embolization of other vascular areas was observed.

Conclusion: According to our retrospective analysis, the reliability and effectiveness of "Onyx" (ethylene vinyl alcohol copolymer) as embolization material emerged during many bleeding trans-catheter embolization procedures in different anatomical sites.

B-0011 09:50

Tips and tricks of emergency TIPS in patients affected by severe portal hypertension

A. Borzelli¹, A. Paladini², F. Amodio¹, E. Cavaglia¹, R. Niola¹; ¹Naples/IT, ²Novara/IT (antonio.borzelli@libero.it)

Purpose: To evaluate the main causes of failure in TIPS performed in emergency setting in critical patients affected by severe portal hypertension.

Methods and Materials: Between Jan 2014 and Jan 2018, we retrospectively considered 72 TIPS performed in emergency setting in critical patients (medium patient age 52; 45 M, 27 F) with severe portal hypertension and affected by variceal bleeding (42), refractory ascites with hepatorenal syndrome (15) and hepatic coma (15). In all cases, we used an e-PTFE-covered stent and in all cases we employed a US-assisted technique to reach the portal vein system once catheterised one of the hepatic veins.

Results: In 12 cases, TIPS was not possible. In 7 patients, we observed a marked distortion in liver anatomy due to chronic liver disease with loss of normal anatomical relationship between portal vein system and hepatic veins, which were too thin. In 3 cases, due to anatomic distortion, it was possible to reach only a small peripheral portal vessel, with subsequent impossibility to make the shunt; in 1 case, we noticed a iatrogenic lesion of portal vein during the procedure with subsequent thrombosis of the stent; in 1 case, malpositioning of the stent with early thrombosis not solved by proximal and distal extension of the shunt.

Conclusion: The main cause of technical success of emergency TIPS performed in critical patients with severe portal vein hypertension is the marked anatomical distortion of the liver, in particular, its vascular anatomy. It is necessary to reduce the failure rate, to employ a US-assisted approach and, if required, a percutaneous sentinel catheter into the main branch of portal vein, to guide the radiologist during the procedure.

Application of artificial intelligence-based image optimisation algorithm in aorta CTA with low tube voltage and reduced contrast medium volume

M. Wang, Y. Wang, Y. Wang, M. Yu, M. Wang, Z. Jin; Beijing/CN (hwjwm@163.com)

Purpose: To evaluate the impact of artificial intelligence (AI)-based image optimization algorithm on improving aorta computed tomography angiography (CTA) image quality (IQ) at 80 kVp tube voltage and 40 mL contrast medium (CM) compared with a conventional iterative reconstruction (IR) algorithm at 120 kVp.

Methods and Materials: Sixty patients referred for aorta CTA examination were assigned to one of two groups at random on NeuViz 128 CT. Group A underwent an 80 kVp protocol with 40 mL CM (320 mg I/mL) and divided into two subgroups according to reconstruction algorithm (IR for group A1 and further AI-based image optimization for group A2). Group B was scanned with the standard 120 kVp, 80 mL CM and IR algorithm. The quantitative assessment of IQ included aorta attenuation, noise, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). A five-point scale (5-excellent, 1-low) was used by two radiologists independently for qualitative image analysis.

Results: The image noise was significantly reduced while SNR and CNR were significantly increased in the order of group A1, B and A2 (all $P < 0.001$). Compared with group B, the subjective IQ score of group A1 was significantly lower ($P = 0.03$) while that of group A2 has no significant difference ($P = 0.926$). The effective dose and CM volume of group A were reduced by 79.18% and 50%, respectively than that of group B.

Conclusion: The AI-based image optimization for aorta CTA with low kV and reduced CM produced IQ comparable to conventional aortic CTA protocol.

B-0013 10:38

Real-time patient-specific CT dose estimation for single- and dual-source CT using a deep convolutional neural network

J. Maier, S. Dorn, E. Eulig, S. Sawall, M. Kachelrieß; Heidelberg/DE (joscha.maier@dkfz.de)

Purpose: Common dosimetric quantities in CT such as the CTDIvol or the DLP do not appropriately represent the actual patient dose. More sophisticated methods are not real-time capable. Therefore, we propose the deep dose estimation (DDE), a deep learning-based approach to estimate patient dose distributions in real time.

Methods and Materials: The gold standard to calculate patient-specific dose distributions is to perform a Monte Carlo (MC) simulation that models the physics of CT dose deposition. Being computationally expensive, MC cannot be applied in real time. To overcome this drawback without losing accuracy we developed DDE: a deep convolutional network for CT dose estimation. DDE uses a U-net architecture that takes a two-channel input consisting of a CT volume and a first-order dose estimate volume, which can be calculated analytically at the cost of a forward projection. Using this input, DDE is trained to reproduce MC dose distributions. Here, we generalized DDE to dual-source CT and demonstrate its potential to derive accurate dose distributions.

Results: Applied to test data, DDE yields dose estimates that differ by less than 3% on average from the ground truth MC simulation. Our experiments demonstrate that DDE applies similarly to single- and dual-source scans, different anatomical regions, different shaped filters, different tube voltages and tube currents.

Conclusion: This study demonstrates the potential of deep convolutional neural networks to derive accurate CT dose estimates. Once trained, a 256x256x48 voxel volume can be processed with DDE in 250 ms while achieving the same accuracy as MC simulations.

B-0014 10:46

Dose team: an estimate of radiation dose reference levels for CT exams

M. Montesano, M. Rengo, S. Badia, N. Panvini, S. Picchia, D. Bellini, I. Carbone, A. Laghi; Latina/IT (marta.mon@hotmail.it)

Purpose: The aim of the study was to identify radiation dose reference levels for CT exams in our institution.

Methods and Materials: A Dose team was established (two radiologists, a TSRM, a radiology resident, the risk manager, the medical director and the medical physicist) whose first objective was to evaluate the quality of the images on 1000 oncological follow-up and to assess the amount of dose delivered through dedicated dose monitoring software (DoseWatch, GE Healthcare). The Dose length product (DLP) has been evaluated for the different anatomical regions for head, neck, thorax, abdomen-pelvis and thorax-abdomen-pelvis. The quality of the images in the different anatomical districts was subsequently assessed.

Results: The quantitative analysis allowed to identify the average DLP for the different anatomical districts. The mean dose for the different anatomical districts was for the brain (570.35 mGy-cm ± 121.32), for the neck (211.58 mGy-cm ± 93.12), for the thorax (160.91 mGy-cm ± 41.81), for the abdomen-pelvis (425.93 mGy-cm ± 122.90) and for the thorax-abdomen-pelvis (685.89 mGy-cm ± 240.04). In all anatomical districts a good image quality was obtained.

Conclusion: The dose monitoring system and the establishment of a Dose team made it possible to identify radiation dose reference levels for CT for individual anatomical districts.

B-0015 10:54

Clinical indications for computer tomography (CT) diagnostic reference levels (DRLs)

S. Yu, P. Chu, R. Smith-Bindman; San Francisco, CA/US (bill.chu@ucsf.edu)

Purpose: To contribute to the creation of CT radiation dose benchmarks for specific clinical indications for adults (≥ 15 years). We report the distribution of radiation dose metrics based on CT scans submitted in 2016-2017 to a large international dose registry comprised of 160 institutions from 7 countries. The registry was supported through the US National Institutes of Health (NIH) and Patient Centered Outcomes Research Institute (PCORI).

Methods and Materials: We describe median (target) and 75th percentile (benchmark) doses for CT dose index volume (CTDIvol) and dose length product (DLP) by three clinical indications from the European Study on Clinical DRLs (EUCLID).

Results: Sample sizes: sinusitis $N=28,946$, cervical spine/trauma $N=83,919$, pulmonary embolism $N=83,882$. CTDIvol target (50%) and benchmark (75%) values (in mGy), respectively: sinusitis (14 and 20), cervical spine/trauma (18 and 26), pulmonary embolism (10 and 15). Corresponding DLP values (in mGy-cm) were: sinusitis (235 and 339), cervical spine/trauma (878 and 1390),

pulmonary embolism (388 and 596). Sinusitis scans were 68% lower in both CTDIvol and DLP compared to routine head scans. Pulmonary embolism scans were 23% higher in CTDIvol and 8% higher in DLP compared to routine chest scans.

Conclusion: Dose metrics from large multi-center studies can help create representative DRLs that can be used for dose optimization and institutional evaluation of CT radiation doses specifically for clinical indications to know if their doses routinely exceed these benchmarks. Having clinical indication DRLs at institutions can lead to indication-specific dose-optimized protocols.

B-0016 11:02

Automatic noise and vessel density measurement for CT angiography quality assurance

S. Zargaran, F. Wozniak, M. Dewey; Berlin/DE

Purpose: This work aims to automate the vessel density and noise measurements in coronary CT angiography as part of quality assessment. So far this is done manually by measuring the mean (density) intensity and standard deviation (noise) within a uniform and consistent region of about 1 square cm containing contrast agent (i.e. aorta).

Methods and Materials: We used 567 coronary CT scans from the randomized DISCHARGE trial across 26 sites. We initially applied the Canny edge detection and then used Hough transform to find circles with pre-specified radii which should correspond to the aorta. Additional heuristics regarding the expected position along or aorta were also applied to eliminated obvious errors. Thereafter density and noise were measured within the circles.

Results: For evaluation, automated measurements that differ from the manual measurements up to a certain threshold, were marked as correct. As such, noise difference tolerances of 5, 10 and 15 HUs led to a noise accuracy of 47%, 67% and 78%, respectively. Similarly, density difference tolerances of 25, 50 and 75 HUs led to a density accuracy of 71%, 90% and 96%. Finally, the combined (noise,density) difference tolerances of (5,25), (10,50) and (15,75) led to accuracies of 37%, 61% and 75%.

Conclusion: An automatic method for quality assurance of noise and vessel density in coronary CT angiography was feasible and has the potential to reduce time and manual effort.

Impact of ESR iGuide in the diagnostic workflow of paediatric patients with abdominal pain

M. Gabelloni, C.A. D'Amore, R. Morganti, L. Faggioni, C. Spinelli, E. Neri; Pisa/IT (mgabelloni@sirm.org)

Purpose: To determine the impact of the ESR iGuide clinical decision support system in reducing the rate of inappropriate emergency paediatric diagnostic examinations.

Methods and Materials: 352 paediatric patients referred to Emergency Department of BLINDED Hospital between 2011 and 2016 were retrospectively evaluated. All patients had presented with abdominal pain. Clinical data were entered into the ESR iGuide system to compare appropriateness scores of suggested versus actually performed examinations, and the agreement between them was assessed using Cohen's k coefficient.

Results: Out of all ultrasound examinations performed, only 70% (255/352) were considered appropriate by ESR iGuide. Computed tomography (CT) was suggested as appropriate in 70% (249/352) of patients, but only 2 of them went ahead with it. Two other patients underwent CT, although it would have been designated as inappropriate according to ESR iGuide. Abdominal X-ray was suggested as appropriate in 253 patients and performed in 18 of them. Four other patients underwent abdominal X-ray when suggested as inappropriate by ESR iGuide. Finally, 9 patients underwent chest X-ray, which was suggested as appropriate by ESR iGuide in 5 patients. Magnetic resonance imaging and scintigraphy were not assessed because unavailable in our emergency department. The agreement between imaging examinations suggested by ESR iGuide and those actually performed was poor (Cohen k less than 0.2).

Conclusion: Strict adherence to the ESR iGuide system would lead to a significant increase in the number of emergency paediatric CT examinations performed instead of ultrasound studies, potentially resulting in higher patient radiation exposure and overall costs.

B-0018 11:18

Semi-supervised multi-to-one style transfer to improve the quality of CT images

B. Ren¹, L. Li², S. Wang², C. Xia²; ¹Amherst, MA/US, ²Beijing/CN (xchen@infervision.com)

Purpose: The quality of CT images depends on various factors, such as radiation dose, convolution kernel and resolution. CNN-based methods are sensitive to small variations of image quality, i.e., small perturbations in noise level, texture, contrast, brightness, etc.

Methods and Materials: To address this problem, we proposed an image standardisation method which is capable of transforming images from different domains to one target domain, without its domain information and without changing its content. The model first decomposes an input image into content and style latent codes, which are independent of one another. The codes are able to reconstruct the original image or standardise the image to the target domain by replacing the style code. For the target domain, we reduced its style code variance and took the mean of style codes for standardisation. A domain discriminator was also applied to determine whether two images belong to the same domain.

Results: To verify effectiveness of the proposed method, our model was trained in a semi-supervised manner. For training, each supervised step updates the model with paired images from collaborating hospital followed by one unsupervised step which learns from unpaired data provided by Infervision. With the same experimental setting, the false positive (fp/np) was reduced to 2.17 from 2.62 after standardisation on 310 test cases, while recall only decreases slightly from 82.4% to 80.9%.

Conclusion: In our attempt to address the issue by a cycleGAN-inspired unsupervised model, results have shown a significant improvement of image quality and detection performance on the transformed images.

Protocol repetition in whole-body MR imaging within a large population-based cohort study: behavior of radiologic technologists and potential of automated image quality assessment

C. Schuppert¹, R. von Krüchten¹, J.G. Hirsch², D.C. Hoinkiss², S. Selder³, O. von Stackelberg¹, H.-U. Kauczor¹, F. Bamberg⁴, C.L. Schlett¹; ¹Heidelberg/DE, ²Bremen/DE, ³Munich/DE, ⁴Freiburg/DE

Purpose: We aim to assess the frequency of protocol repetition in whole-body MR imaging within the multi-center German National Cohort (NAKO) in consideration of local, staff-dependent and technical influences. We further intend to determine its effect on scan time, and whether or not automated image quality assessment is able to predict protocol repetition.

Methods and Materials: All subjects enrolled in the MR substudy of the NAKO until December 31, 2016, were included in the analysis (n=11,347). Whole-body imaging was performed at five different sites, employing a uniform set of twelve protocols. All acquisitions were carried out by trained radiologic technologists (RT), whose decisions for protocol repetition were made without supervision or technological advice. Image quality parameters were derived automatically from the acquired images.

Results: RT acquired at least one repeat protocol in 12% (n=1,365) of subjects. The frequency of repetition differed across protocols (p<0.0001) as well as across sites (range: 5.28%-24.34%, p<0.0001), and varied over time (p<0.0001). The mean total scan time of 62.6min increased by 4.8min (95%CI: 4.5-5.2min) in subjects with protocol repetition(s). Several automatically derived image quality parameters were retrospectively predictive for protocol repetition, particularly image sharpness and signal-to-noise ratio, although their predictive value was not uniform for all protocols.

Conclusion: MR protocol repetitions are remarkably prevalent even in the highly standardized and static setting of a large cohort study. Automated image quality assessment shows predictive value for the RT's decision to perform protocol repetitions and has potential to improve time- and cost-efficiency of MR imaging studies.

Preliminary results of a neural network for the automatic detection of chest X-ray incorrect exposure

R. Casale; Portogruaro/IT (robby_82@hotmail.it)

Purpose: To assess the accuracy of a convolutional neural network (CNN) for the automatic detection of incorrect underexposure in chest X-ray.

Methods and Materials: A dataset of n=260 chest X-rays was evaluated, n=128 X-rays with correct exposure and n=132 with incorrect x-ray exposure (underexposure). For the neural network training were used 203 X-rays (100 correctly exposed X-rays + 103 underexposed X-rays) using Inception_v3 architecture. Subsequently, testing was performed with the remaining images (28 correctly exposed X-rays + 29 underexposed X-rays). Then sensibility,

specificity, receiver operating characteristic curve (ROC) and area under ROC (AUC) were computed.

Results: The neural network correctly classified 27 of 29 underexposed X-rays and 23 of 28 of correctly exposed X-rays. Sensibility and specificity were 0.93 and 0.82, respectively; AUC value was 97.17% (95% CI: 93.11%-100%).

Conclusion: Preliminary results demonstrated that neural network has the potential to distinguish between underexposed X-rays and those correctly exposed with an accuracy of 88%. The goal is to supply auxiliary and reproducible information to assist radiologists and technologists when chest X-ray quality is less obvious.

B-0021 11:42

Patient-centric initiative to reduce radiation dose to paediatric patients in computer tomography for improved patient safety in a tertiary care facility in Pakistan

M. Yusuf; Karachi/PK (mohammad.yusuf@aku.edu)

Purpose: An initiative to reduce radiation dose to pediatric patients during Computed Tomography's chest and abdomen related procedures based on international best practices for improved safety.

Methods and Materials: An assessment was carried out to determine the level of radiation dose being employed for pediatric patients for CT chest and abdomen examinations and was also compared to the international recommendations. The Informatics team covered all domains from technical to educational to address the higher radiation dose. Internationally defined best practices and radiation dose reference levels were identified. CT modalities were configured for appropriate reduced dose protocols, technologists were educated, radiologists were consulted on the image quality and reduced radiation dosage, an in-house system was developed to extract, process and archive the radiation dose results of each procedure and finally produce meaningful reports.

Results: The initiative managed to reduce the pediatric Chest and Abdomen procedure's average CT radiation doses by 43% and 62% respectively compared to the average radiation dose that was delivered in procedures prior to the initiative. This also resulted in bringing the dose levels within the reference levels defined by international bodies. For comparison, ICRP publication 87 reference levels were utilized.

Conclusion: Adopting a patient centric approach in a proactive manner, the team was able to assess and identify an area that had a direct bearing on patient care and was able to plan and implement an environment that provided significant reduction in the radiation dose being administered to pediatric patients during CT chest and abdomen examinations.

B-0022 11:50

Quality assessment of structured multi-parametric MRI reports of the prostate based on RADLEX mapping of urosurgical key information content

M.E. Maros¹, F. Siegel¹, B. Kämpgen², P. Sodmann², W. Sommer³, S.O. Schönberg¹, T. Henzler¹, C. Groden¹, H. Wenz¹; ¹Mannheim/DE, ²Rimpar/DE, ³Munich/DE (matt.maros@gmail.com)

Purpose: The Prostate Imaging Reporting and Data System (PI-RADS v2) was developed to provide imaging and reporting standards of multi-parametric prostate MRI (mpMRI). Urologist rely heavily on radiological reports when planning prostate biopsies. We investigated whether 1) mapping urosurgically relevant key content to RADLEX terms might be feasible to assess radiological report quality with regard to clinical usability 2) and compared it to a fully-automated guideline-based quality assessment.

Methods and Materials: A single center retrospective cohort study of 1028 consecutive patients (01/2017-09/2018; mean age 67.2, range 22-89 yrs) with suspected prostate pathology and mpMRI were retrieved from local RIS archives. All reports were generated using a structured reporting tool (www.smart-radiology.com). Independent blinded urologist reviewed 299 mpMRI reports and defined biopsy relevant key information content (KIC). An automatic, cross-lingual mapping of German reports, clinical KIC, and PI-RADSV2 guideline to RADLEX terms was performed using a proprietary information extraction software (www.empolis.com). Then these RADLEX converted texts were compared using free web-tool (radreport-query.com) generated cosine similarity index and Wilcoxon rank-sum test statistics.

Results: RADLEX mapping of urologist-defined key content identified 267 while PI-RADSV2 guideline revealed 248 terms. The identified terms showed a highly significant correlation ($p < 0.001$). RADLEX similarity scores of the reports were significantly higher ($p < 0.001$) when compared to urosurgical KIC (mean = 0.24, 0.11-0.33) than with PI-RADS guideline content (mean = 0.18, 0.06-0.28).

Conclusion: Biopsy-relevant key RADLEX content could serve as an important quality measure of mpMRI reports of the prostate to improve communication with urologists and to support their planning of invasive interventions.

Moving beyond the bookshelf: an investigation into the use of social media journal clubs in radiography practice

S.N. Mullen¹, M. O'Connor²; ¹Galway/IE, ²Dublin/IE (sineadnemullen@gmail.com)

Purpose: The introduction of mandatory continuous professional development (CPD) by CORU in October 2015, has increased demand on Radiographers to participate in CPD activities. Social media and digital communications have become prominent features of society and popular methods of communication and information sharing. Therefore, it is important to assess whether such technologies can contribute to CPD in Radiography.

Methods and Materials: A Facebook journal club was established to investigate the opinions of Radiographers regarding the use of social media facilitated journal clubs in contributing to CPD. Four teaching hospitals were chosen at random to participate. Six Radiographers from each centre were invited to participate. Two peer reviewed articles were discussed throughout the study. An online survey was used to establish the opinions of Radiographers.

Results: A response rate of 79% was obtained. Radiographers felt positive towards the use of social media as a tool in contributing to CPD. There was a slight disparity in opinion between newly qualified Radiographers and more senior members of the team, with newly qualified radiographers afraid of appearing "unprofessional" if found using social media in the department, and senior members being more open towards the use of social media for CPD purposes.

Conclusion: Respondents felt positive towards the use of social media facilitated journal clubs. Advantages of social media facilitated journal clubs are convenience and increased interaction with others. Limitations of social media facilitated journal club use in Radiography are a perceived poor professional reflection and the encroachment into an already compromised personal life.

B-0024 10:38

Written patient information in radiology: an Irish perspective

S.S. Azman, E. McDermott, M.-L. Ryan; Dublin/IE (marie-louise.ryan@ucd.ie)

Purpose: Provision of information before patients attend their radiology examination plays an important role in enhancing patient experience and ensuring consent. Patient information leaflets (PIL) are used to support the verbal consultation between the patient and radiology team. This project aimed to ascertain whether public and private radiology services across Ireland use PILs for general, CT and ultrasound examinations, at what point PILs are given to patients and also to analyse the information included.

Methods and Materials: All radiology departments in Ireland were contacted (n=52). The manager of each participating department (n=23) was interviewed to understand at what point PILs are given to patients, and PILs were then collected from the participating departments. Analysis on 34 PILs across the three modalities was conducted under the following sub-headings- general content; radiology-related content; PIL design.

Results: 65% of the 23 participating facilities distribute PILs, with 35% being in the form of a written letter in advance of the examination. 74% send PILs by post while the remaining 26% use mixed methods depending on the modality and patient type. Each PIL varied in terms of the amount, depth and categorization of information. The most common information included is the nature of the procedure, the experience during the procedure and result availability after the examination.

Conclusion: There is a need to standardise PILs used in Irish radiology departments as both the method and timing of distribution and the information is not consistent, thus potentially impacting the knowledge imparted on the patient.

B-0025 10:46

Influences on radiographers' choice of immobilisation methods in paediatric radiological examinations

S. Christie, C. Ng, C. Sá dos Reis; Perth/AU (*claudia.sadosreis@curtin.edu.au*)

Purpose: To identify the main influences on radiographers' decisions about immobilisation methods in paediatric radiological examinations.

Methods and Materials: Australian and New Zealand radiographers were recruited to complete an online questionnaire identifying their use of different immobilisation methods and the influences on their choices. Follow-up interviews were conducted to further explore the findings. Institutional approval was obtained. Closed-end questions were analysed using frequencies and non-parametric tests (Fisher's exact and Mann-Whitney U), while content analysis was applied to open-end questions and interview data.

Results: 65 completed questionnaires were received; 7 respondents also participated in interviews. Parental holding was the most likely method to be used (96.9%), but psychological methods (87.7%) were considered preferable as using less force and causing less distress to children and parents. Mechanical and chemical methods were not often used. Participants sought to adapt their immobilisation practice to each situation, often using the child's age as a guide. Existing informal workplace training was perceived as adequate but not optimal. Opinions were divided over whether introducing written guidance would limit radiographers' ability to adapt to different situations.

Conclusion: Immobilisation is a case-by-case activity which requires radiographers to seek a balance between different factors, consistently constrained by examination type and resource availability. Patient age was the most commonly considered factor, although this was acknowledged to be an imperfect guide. Short placements at paediatric institutions are recommended as a useful way of improving immobilisation education. Increased support from governing bodies is also required.

B-0026 10:54

Informed consent in diagnostic imaging: an evaluation of current practice

A. Ramlau; Hatfield/UK (*a.ramlau@herts.ac.uk*)

Purpose: It is normally assumed that all attending patients have given their informed consent for imaging investigations, although variations may exist in the form in which this is provided. The purpose of this study was to conduct an audit of current practice regarding gaining informed consent within NHS diagnostic imaging departments throughout the United Kingdom.

Methods and Materials: A cross-sectional survey was conducted involving lead superintendent radiographers within NHS sites in Scotland, Wales, England and Northern Ireland. The survey explored methods in which information on radiological examinations and procedures was disseminated to patients; radiographer practices with regard to gaining informed consent; and staff knowledge of consent policies. Responses were analysed using descriptive statistics and outcomes were matched according to guidelines provided by the Health and Care Professions Council (HCPC) and College of Radiographers (CoR).

Results: The survey yielded a response rate of 46% (220/478). The findings demonstrated mixed awareness of policy documents, together with variations in the methods used for disseminating information to patients and gaining informed consent.

Conclusion: Some radiographers appear to have a cursory knowledge of consent policies. There is a lack of standardisation regarding practices for disseminating information to patients as well as for gaining informed consent from patients. The study highlights a possible need for more explicit guidance for gaining informed consent, to enhance patients' clinical outcomes and reduce the likelihood of litigation.

B-0027 11:02

Perceptions about the practice of seeking informed consent in paediatric imaging

J. Portelli¹, J. McNulty², P. Bezzina¹, L.A. Rainford²; ¹Msidra/MT, ²Dublin/IE (*jonathan.portelli@um.edu.mt*)

Purpose: To investigate health professionals' and parents' perceptions about the practice of seeking informed consent for paediatric imaging examinations.

Methods and Materials: This research is part of a larger multi-phase study performed at a large general hospital in Malta, which also serves as a primary paediatric referral centre. Following institutional board approval, a purposive sample of radiographers, radiologists, paediatricians, emergency physicians and parents were invited to attend for an audio-recorded semi-structured interview with the primary author. Participants were asked questions about different aspects related to the imaging of paediatric patients, including their thoughts and opinion about the practice of seeking informed consent for such examinations.

Results: Nineteen health professionals and seven parents willingly took part in the study. Following thematic analysis of the transcribed interview data, one of the dominant themes that emerged highlighted a general misconception that informed consent was primarily sought in paediatric imaging so as to provide a

legal safeguard to the respective health professionals against any possible future medical liability issues that could arise. Furthermore, parents generally expressed feelings of heightened anxiety and concern when referring physicians and/or radiographers asked them to provide their written consent, with many interpreting this to mean that the imaging examination would involve higher risks for their child.

Conclusion: The findings highlight a need for relevant authorities to address the noted misconceptions and raise awareness about the true purpose of informed consent, which is to ensure that patients and/or their representatives are provided with relevant information that empowers their health decisions.

B-0028 11:10

Radiographers and scientific research: the Italian experience

M. Zanardo¹, A. Capaldo¹, M. Codari¹, D. Catania¹, P. Cornacchione², S. Durante³; ¹Milan/IT, ²Rome/IT, ³Bologna/IT (*moreno.zanardo@unimi.it*)

Purpose: Research plays a fundamental role in the development and growth of radiographers' skills. The aim of this study was to investigate how radiographers are currently involved in scientific research and how to increase their involvement in this field.

Methods and Materials: The Italian Federation of Scientific Radiographers Societies (FASTeR) proposed a national online survey. The questionnaire was composed of multiple-choice questions, using a 5-point Likert scale to identify radiographers' involvement (1 no involvement, 5 active participation) and skill level (1 no formation, 5 adequate formation).

Results: We obtained 315 participants (159 male), mean age of 40±12, 51 (16%) with a master's degree and 293 (93%) workers. Only 13 (4%) radiographers feel themselves adequately trained on research methodology during their qualification, with a mean evaluation of 2.6±1.0. Only 26 (8%) were actively involved in research activities 2.4±1.3. Only 10 (3%) radiographers did not consider research important for their work and professional growth 4.1±1.0, and 23 (7%) affirmed they did not have time for research, while 194 (62%) radiographers were fascinated by participating in research projects. Most of radiographers lack basic knowledge about Evidence-Based Medicine and scientific database (Pubmed/Medline or EMBASE). Continuing Medical Education (CME) courses were the most desirable instrument to improve research methodology, with both theoretical and practical sections 4.2±1.0. Limitations in conducting research projects were a poor knowledge of English and limited involvement by other professional figures.

Conclusion: To improve radiographers' involvement and skills in research, research methodology CME courses with theoretical and practical section should be activated.

B-0029 11:18

The construction of care in CT

R.K. Forton¹, M. Hardy², A. Sargeant²; ¹Norwich/UK, ²Bradford/UK (*rachael.forton@nnuh.nhs.uk*)

Purpose: Patient-centred care and the 'patient voice' are core components of UK healthcare policy and practice guidance. This study explored how care is perceived and experienced within the high-technology environment of CT.

Methods and Materials: A grounded theory (GT) methodology using semi-structured interviews obtained primary data from CT radiographers and patients. Recruitment was performed at a 1200-bed teaching hospital over a 6-month period.

Results: The patient-radiographer relationship and the radiographer's role in providing care within CT are complex and multifaceted. Both patients and radiographers perceive CT imaging as an integral part of the overall patient care and treatment pathway. As such, the act of being imaged is perceived as a care process. While image acquisition is recognised as a task-orientated and technical process, the human element of providing care is cognitive, dynamic and responsive to individual need. Importantly, patient confidence in the care received was influenced by the radiographer's ability to build a trusting relationship and display technical competence. This in turn facilitated active compliance resulting in a technically accurate examination. Despite previous literature suggesting that technical environments create a barrier to care, patients within this study confirmed that radiographers provide care commensurate to the nursing ideals represented by the 6Cs (care; compassion; competence; communication; courage; commitment).

Conclusion: A new model of care encompassing both technical components and patient centeredness has been constructed and will be presented. This model promotes a new vision of patient-centred care based on care perceptions within high-technology environments.

B-0030 11:26

Mobile radiography services can improve the utilisation of diagnostic imaging among nursing home residents

E. Kjelle, K.B. Lysdahl, H.M. Olerud; Kongsberg/NO (*elin.kjelle@usn.no*)

Purpose: To determine utilisation of diagnostic imaging among nursing home residents and the impact of mobile radiography services on utilisation rates.

Methods and Materials: The number of examinations made on nursing home residents in 11 hospitals in Norway was collected for the year 2015, which involved five hospitals with mobile service facilities and six without. The data included anatomical region/organ/organ system, modality, and place of examination (hospital or nursing home). Using the 24,805 nursing home beds in the included areas as a proxy for residents, the utilization rates were compared in areas with and without mobile radiography services, using the chi-squared test.

Results: A total of 11,066 examinations, 0.45 per nursing home bed, was carried out. Of these, 87% were plain radiographs, 8% were CT scans and 4% were ultrasound examinations. In areas with mobile radiography services, the proportion was 50% per bed, compared to 36% in areas without, χ^2 (df=1, n=11,066)=470.39, p<0.001.

Conclusion: Mobile radiography services increase the overall utilization of examinations among nursing home residents significantly. Nonetheless, the rates of diagnostic imaging are still low compared to the rates for the Norwegian population in general, which is 0.9 examinations per person per year. This study clearly indicates an under-utilisation of diagnostic imaging among nursing home residents and suggests extended use of mobile services to be one possible remedy. This study has been submitted to BMC Geriatrics in 2018.

B-0031 11:34

Burnout level of personnel working in radiology departments in Hungary

D. Sipos¹, A. Pandur², A. Kedves¹, V. Varga², M. Csima¹, I. Repa¹, Á. Kovács¹; ¹Kaposvár/HU, ²Pécs/HU (cpt.david.sipos@gmail.com)

Purpose: Burnout phenomenon among healthcare professionals is the current problem. Burnout may have wide negative impact that can undermine personal and professional life of the individual, also the quality and the effectiveness of the healthcare system.

Methods and Materials: Radiology department workers who were members of the Hungarian Society of Radiographers were invited to participate in our online survey during June to September 2018. Maslach Burnout Inventory (MBI) and SF 36 survey was used to measure burnout levels and participants health status. Self-made questionnaire was made to determine demographic attributes. All data were analysed using SPSS V 24.0. Descriptive statistics, independent samples t test, ANOVA, Kruskal Wallis analysis were performed to examine the relationship between given demographic characteristics and the three dimensions of burnout at the significance level of p<0.05.

Results: Total of 404 radiology department workers participated in the survey with the average age of 40.08 years (SD12.18; 22-70). The sample had high mean burnout score for emotional exhaustion (34.28; SD 12.98) and depersonalisation (12.81; SD 6.62) compared to MBI norms. Personal achievement mean (41.03; SD 8.70) showed higher mean compared to MBI norms. Educational level, years spent in health care system, current financial situation had significant influence for all three dimensions of burnout (p<0.05). Type of workplace had significant impact on emotional exhaustion (p=0.001).

Conclusion: Our study indicates that high number of radiology department workers are experiencing occupational burnout at emotional exhaustion and depersonalisation dimension. These results vary according to demographic and work-related factors.

B-0032 11:42

VERTIM: pilot study evaluating influence of adding nature images in imaging departments' waiting rooms, according to different aesthetic approaches, on patients' perceived anxiety

M.P. Loiseau Audirac, C. Bader, C. Castermans, I. Quintana; *Bordeaux/FR* (loiseau.marie19@yahoo.fr)

Purpose: Study about influence of physical environment of imaging departments' waiting rooms on pre-examination patients' perceived anxiety. The main objective is to estimate the difference in state anxiety, perceived by patients in 3 types of waiting room environment "Nature GREEN", "Nature SEA", "Nature ZEN" compared to a reference environment "Standard waiting room" and to evaluate emotional perception and satisfaction of patients for each environment.

Methods and Materials: 400 patients' anxiety score was measured by STAI-Y trait and state scales after 12 minutes' immersion time. Emotional perception for environment was evaluated by "Scale of the perceived attractiveness" of Sophie Rieunier and satisfaction of patient with digital analog scale.

Results: The "Nature GREEN" environment is the only one where it is observed a significant 10% decrease in state anxiety score compared to the reference group "Standard waiting room". This is also where patients' satisfaction score is the highest. Affective perception scores for environment are better in "Nature GREEN" and "Nature SEA".

Conclusion: "Nature GREEN" environment has proven its effectiveness in reducing patients' pre-examination anxiety in imaging department. A multi-centre study would be needed to establish evidence-based recommendations for care space design.

B-0033 11:50

Value-based practice (VBP) training for radiographers

R.M. Strudwick¹, A. Newton-Hughes², S. Gibson³, J. Harris⁴, M. Gradwell³, E. Hyde⁵, J. Harvey-Lloyd¹, T.J. O'Regan⁶, J. Hendry⁷; ¹Ipswich/UK, ²Salford/UK, ³Canterbury/UK, ⁴Guildford/UK, ⁵Derby/UK, ⁶Lancashire/UK, ⁷Kingston/UK (r.strudwick@uos.ac.uk)

Purpose: Value-based practice (VBP) is the consideration of a patient's values in decision-making. VBP takes into account and highlights what matters to the patient. By patient values we mean the unique preferences, concerns and expectations each patient brings to a practice encounter which must be integrated into clinical decisions for the patient¹.

Methods and Materials: A small team made up of radiography educators have adapted materials from a VBP handbook, originally developed for medicine. The handbook, conceived by Professor Bill Fulford and Dr. Ashok Handa², has been adapted for use by diagnostic and therapeutic radiographers. The scenarios included in the text have been piloted with radiographers and undergraduates at study days and in teaching sessions. We are grateful to the participants for their input. Raising the awareness of values is essential to enable contemporary person-centred care. Sustainable implementation, however, depends on a whole-systems approach where patients are put at the centre of service delivery. The handbook introduces the concept and provides examples of individual values.

Results: We have facilitated two successful study days focused on VBP in radiography and teaching sessions with student radiographers.

Conclusion: Our aim has always been to share this material; we advocate that all radiographers must gain an understanding of VBP and adopt the approach in practice. The handbook acts as a method of raising awareness. The result is the beginning of VBP conversations in radiography; when embedded, VBP will provide assurance that we put the patient as the centre of everything we do.

Comparison of ultra-high frequency US with contrast enhanced MR Angiography and conventional US in the evaluation of carotid atheromatous plaques

R. Picascia¹, D. Berritto², C. Liguori³, M. La Porta⁴, A. Reginelli⁵, R. Grassi³; ¹Villaricca/IT, ²Acerra/IT, ³Naples/IT, ⁴San Severo/IT, ⁵Torre Annunziata/IT (robertopicascia@gmail.com)

Purpose: to compare diagnostic capabilities of an innovative ultra high frequency ultrasound (HFUS) system with conventional-US and Contrast Enhanced MR Angiography (CEMRA) in the evaluation of atherosclerotic carotid plaque in order to categorize stable vs unstable atheromas.

Methods and Materials: 16 carotid plaques (11 patients), causing at least a 30% luminal stenosis, were analyzed. Patients underwent to: Color-Doppler US, HF US and CEMRA. Parameters evaluated were: • Qualitative: Presence/absence hyperechoic spots and of hypoechoic core; fibrous cap (FC) delineation • Quantitative: main plaque and lipid core diameters; fibrous cap thickness

Results: HFUS was able to discriminate qualitative characteristics in all plaques. Quantitative values showed significant differences: using HFUS bigger dimensions were measured (mm 4.7-7.8, 6.7-8.7, 3.7-5.8 on three axes), as the lipid core (mm 0.8-2.1, 0.8-1.5, 1.2-2.4). FC thickness showed specific values on High Frequency US (0.10-1.5 upward; 0.45-1.7 downward) while it was clearly assessable only in 3 patients at conventional US. MRI showed always the FC but a precise dimension was never assessable.

Conclusion: HFUS is a reliable technique in defining qualitative and quantitative carotid plaque features, highlighting dimensions of the plaque, size of the lipid component, and thickness of the fibrous cap, known as most important predictors of atheroma vulnerability. Moreover this new technique has good reproducibility, fast speed of execution and good spatial resolution, in the absence of ionizing radiation.

B-0035 10:38

Contrast-enhanced perfusion patterns in predicting stroke in vulnerable plaque: a cohort study of carotid stenosis in Chinese patients

H. Yungian, J. Jiang, M. Chen; *Shanghai/CN (18721619656@163.com)*

Purpose: To investigate the correlation between contrast-enhanced ultrasound perfusion patterns of carotid artery vulnerable plaque and the degree of carotid stenosis, which provides the basis for early diagnosis of cerebral ischaemic stroke.

Methods and Materials: From March 2018 to June 2018, 202 patients with carotid plaque who underwent CEUS were enrolled in this study. The patients who did not undergo CTA or DSA examination within 1 weeks after CEUS examination were excluded. The stenosis of carotid artery was determined by CTA or DSA as gold standard. Finally, 80 patients were analysed (35 patients in the stenosis group and 45 patients in the non-stenosis group). The appearance of enhancement in plaques were observed and the enhancement level of the plaques was divided into I-IV grades according to enhanced ultrasound findings of carotid plaques. The patients were divided into plaque base entering mode and plaque surface entering mode by the CEUS perfusion pattern when the contrast agent enters the plaque. The correlation between the CEUS perfusion pattern and the degree of carotid stenosis was analysed.

Results: The enhanced level of carotid plaque between the stenosis group and the non-stenosis group showed statistically significant difference. The plaque of the stenosis group and the non-stenosis group entered the plaque with different patterns, and the difference was statistically significant.

Conclusion: There remains a significant correlation between the enhancement level of carotid plaque and the degree of carotid stenosis, and the different CEUS perfusion patterns are closely correlated with the degree of carotid stenosis.

B-0036 10:46

Is automatic plaque quantification reliable: an analysis of spectral multienergy CT

G. Corrias¹, G. Micheletti², J. Suri³, G.M. Argiolas², P. Lucatelli⁴, L. Saba¹; ¹Caigliari/IT, ²Monserrato/IT, ³Denver, CO/US, ⁴Rome/IT (corriasgmd@gmail.com)

Purpose: To compare semi-automatic plaque quantification on different energy levels of DECT to inform standardization efforts for single-energy protocols where difference is to be avoided, as well as to explore opportunities in multi-energy protocols where differences are intended.

Methods and Materials: Retrospective study enrolling 36 patients who underwent DECT of the carotids. Seven energy levels were reconstructed (keV: 40, 66, 70, 76, 86, 100, 120). Plaque subcomponent analysis was performed for each energy separately, without modifying lumen and wall segmentations using commercially available software (vascuCAP, Elucid Bioimaging).

Results: Normality of each energy was tested using the Kolmogorov-Smirnov Z test. Since most were not distributed normally, a Wilcoxon test was performed to check differences with a p value <0.05. Differences of component volumes were in the order of the reproducibility coefficient (RDC) at the closest energy levels (calcium 66keV vs 70keV : Z value:-2.1; p<0.05; LRNC 66keV vs 70keV; Z value:-2.5, p<0.05; Matrix 66keV vs 70keV:-2.3, p<0.05), and documented that differences increased with difference in energy.

Conclusion: Plaque component analysis has been known to provide important prognostic information on plaque progression and adverse acute cardiovascular events. We established that standards efforts should specify differences of no greater than ±2 keV for single-energy protocols, and have established base data on which exploiting intended differences might be of value were they to be processed by algorithms designed to exploit these differences beyond what single energy may reasonably be expected to do, such as speculated vs. dense calcium, or differing stages of IPH, for example.

B-0037 10:54

Carotid plaque instability and neovascularisation assessment using contrast-enhanced ultrasound and superb micro-vascular imaging

M. Radzina, A. Lioznovs, A. Jukna; *Riga/LV (lioznov1@gmail.com)*

Purpose: There are several causes for cerebral ischaemia and if risk factors are diagnosed timely, the risk of stroke can be significantly reduced. One of the main risk factors for cerebral ischaemia is the unstable atherosclerotic plaque in the arteries. The purpose of the study was to analyse multi-parametric US techniques ability to confirm the plaque's instability more precisely than the baseline investigation of Duplex US.

Methods and Materials: In prospective research conducted in the period from 2017 to 2018, were included 22 patients with unstable plaque which were detected with duplex, every patient was analyzed with CEUS, SMI and CTA methods. The results were histologically proven in 8 cases.

Results: Unstable plaque was diagnosed in 22 patients using duplex and in 21 patients using CT. Comparing both methods statistically significant correlation was found (rs = 0,781; p = 0,0001). The neovascularization was diagnosed in 13 (59.1%) patients by CEUS - in 6 (46.2%) plaques showed neovascularization grade 1 and in 7 (53.8%) plaques were detected grade 2. Using SMI method neovascularization were found in 12 (54.5%) patients, with statistically significant correlation between CEUS and SMI (r s = 0,801; p = 0,0001). Histology showed vasa vasorum presence in all CEUS positive cases from 2-23 microvessels with positive tendency (p>0.05) within endarterectomy material and significant difference with positive correlation to stenosis grade (70-90%) (p=0.03)

Conclusion: New ultrasound methods such as CEUS and SMI provide additional information on detecting atherosclerotic plaque instability and vasa vasorum with positive correlation to stenosis grade.

B-0038 11:02

Early embolisation after carotid artery stenting: role of MR-DWI as pre-procedural predictor and discriminant between intra- and post-procedural events

F. Guarasci, R. Faletti, M.A. Ruffino, M. Fronza, M. Gatti, G. Varetto, D. Righi, P. Rispoli, P. Fonio; *Turin/IT (guarasci.fab@gmail.com)*

Purpose: To evaluate the incidence of intra- and early post-procedural micro-embolism during Carotid Artery Stenting and the role of DW-MRI in the characterization of carotid plaque activity.

Methods and Materials: This prospective study included 50 patients who underwent CAS with two different mesh-covered stents. All patients had carotid plaque DW-MRI pre-procedure (except for patients with re-stenosis after endarterectomy, 13/50, 26%), brain DW-MRI pre-proc., at 1h, 24h and 30 days post-proc., clinical evaluation and Doppler US pre-proc., at 24h and 30 days post-proc. Imaging analysis (quantitative and qualitative) was performed in a double-blinded fashion by two radiologists.

Results: No statistically significant differences between the two type of stents both in the incidence at 1h (p=0.23), 24h (p=0.36) and in the volume of new brain lesions at 24h (p=0.27). A total of 34 new lesions in 19 patients (38%) were found: 4 (11.8%) at 1h, 30 (88.2%) at 24h post-proc. The 30-day DWI-MR showed complete resolution of all lesions and no evidence of new lesion. The incidence of new lesions at 24h resulted higher in patients with positive carotid plaque DW-MRI (12/16, 75%, vs. 0/21, 0%, with a LR+ of 6.25), results paralleled by the ADC value (0.83+/-0.21 vs 1.42+/-0.52).

Conclusion: The majority of early asymptomatic brain lesion did not occur during the procedure but in the ensuing 24h. A positive pre-proc. carotid DW-MRI was associated with an increased incidence of micro-embolizations after CAS.

B-0039 11:10

Ultrasonographic evaluation of changes in carotid arteries in patients with hypertension after a stroke

P. Gac, E. Trzmielewska, M. Poreba, G. Mazur, M. Sobieszczanska, R. Poreba; *Wroclaw/PL (pawelgac@interia.pl)*

Purpose: The aim of study was to estimate the frequency of ultrasound-assessed changes in carotid arteries in patients with hypertension after a stroke.

Methods and Materials: 111 patients were qualified for the study. They represented two study groups: patients with arterial hypertension after a stroke in their medical history (group A, n=59) and patients with arterial hypertension without stroke in the medical history (group B, n=52). In the studied group an ischemic stroke was observed in 88.1%, and a hemorrhagic stroke- in 11.9%. Ultrasound examination of carotid arteries was carried out in all patients.

Results: Significantly higher IMT (intima-media thickness) was observed in group A in comparison to group B (1.09±0.23 mm vs.0.87±0.31 mm; p<0.05). The remaining parameters of ultrasound examination of carotid arteries didn't differentiate group A from group B. The type of stroke, the time elapsed since the stroke and the number of ischemic events didn't determine statistically significant differences in ultrasonography of carotid arteries in contrast to the effectiveness of blood pressure control. In group A, patients with well-controlled hypertension were characterized by lower IMT than patients with non-controlled hypertension (0.95±0.24 mm vs. 1.24±0.21 mm; p<0.05). The regression analysis showed that higher BMI and higher blood glucose concentrations are independent risk factors for higher IMT, while the use of β-blockers is an independent protection factor against higher IMT.

Conclusion: In the studied group of patients with hypertension after a stroke, the IMT value in ultrasound examination of carotid arteries may constitute an indicator of high prognostic significance.

B-0040 11:18

Comparison between high-frame rate vector flow and computational flow dynamics in the carotid bifurcation: evaluation of a protocol study
A. Goddi¹, T. Frattini¹, M. Bozzetto², C. Bortolotto³, L. Milan¹, D. Zatelli², R. Novario¹, F. Calliada³, A. Remuzzi²; ¹Varese/IT, ²Bergamo/IT, ³Pavia/IT (chandra.bortolotto@gmail.com)

Purpose: Combining 2D ultrasound High-frame rate Vector Flow (HiFR-VF) and 3D Computational Fluid Dynamics (CFD) on the carotid bifurcation (CB) may allow the clinical validation of a new approach to obtain a comprehensive assessment of the blood flow field. This initial study aimed at ensuring the effectiveness of a protocol designed for a future multicentric prospective study.

Methods and Materials: A CB with severe stenosis at B-mode and Doppler US was enrolled. HiFR-VF provided the 2D velocity vectors from multidirectional plane waves and allowed the quantification of the complex flows and wall shear stress (WSS) measurements at different locations. The 3D model of the diseased vessel was reconstructed starting from a 3D FFE MRI multi-chunk sequence that makes use of the inflow effects of blood to visualize vessels. Subsequently, CFD simulation of the CB was performed and the flow field was characterized using velocity streamlines, while reciprocating disturbed flow was described using the oscillatory shear index. HiFR-VF and CFD findings were compared to analyze the ability of HiFR-VF in identifying areas of vascular wall exposed to oscillatory WSS.

Results: WSS findings with HiFR-VF showed good agreement with the CFD simulation results. In particular, the areas of abnormal WSS obtained with the two modalities, matched.

Conclusion: Although WSS can only be estimated in a 2D plane with HiFR-VF, nonetheless oscillating WSS can be detected and correlate with the CFD results. Preliminary findings show that the study protocol was correctly designed and can be used for prospective clinical investigation.

Carotid intima-media thickness (CIMT) as a diagnostic marker of transient ischaemic attacks (TIA)
D.J. Petrovic; Belgrade/RS (dusanpetrovic736@gmail.com)

Purpose: To establish the correlation between CIMT and TIA and the correlation between the quantitative and qualitative characteristics of the plaque in the wall of the carotid arteries and the occurrence and type of TIA.

Methods and Materials: 120 patients with TIA were tested by duplex ultrasonography and compared to the control group (n=25) compatible in age and gender. Among the ultrasonic parameters, the following ones were examined: CIMT, the presence and size of the plaque, and the presence of ulceration on the free surface of the plaque. Group of patients with TIA was divided into subgroups based on aetiopathological mechanism (embologenic, haemodynamic and coagulopathy). The Student's t test and Pearson χ^2 test were used for statistical analysis.

Results: Statistically, CIMT was significantly higher ($p<0.05$) among the patients with haemodynamic and embologenic TIA in comparison with the control group. The frequency of the plaque larger than 70% was statistically significantly higher ($p<0.01$) among the patients with embologenic and haemodynamic TIA in comparison with the control group. Regarding the frequency of ulceration, the difference between the group of patients with embologenic TIA and the control group was highly statistically significant ($p<0.01$).

Conclusion: CIMT and the size of the plaque (larger than 70%) correlate with the occurrence of haemodynamic and embologenic TIA. The presence of ulceration on the free surface of the plaque correlates with the occurrence of embologenic TIA. Early diagnosis of carotid artery disease is of paramount importance from the aspect of stroke prevention, and ultrasound plays a pivotal role therein.

B-0042 11:34

Ultrasound estimation of carotid intima media thickness: semiautomatic versus manual measurement
G. Lastella, F. Wiedenmann, C.B. Monti, F. Secchi, M. Ali, F. Sardaneli; Milan/IT (giulia.lastella@unimi.it)

Purpose: To evaluate and compare manual and semiautomatic carotid intima-media thickness (CIMT) assessment.

Methods and Materials: Ultrasound B-mode images of 200 consecutive patients who underwent color-Doppler of supra-aortic trunks with RS80A Prestige, Samsung Healthcare from 5/2017 to 12/2017 were retrospectively

evaluated. For each patient, CIMT was measured on the same image of the right common carotid artery, selected by an experienced (≥ 5 years) radiologist. Two different readers performed all measurements using both the manual and the semiautomatic method, randomly ordered sessions, separated by at least one week, the least experienced reader (2 years) repeating all measurements 4 weeks apart. Images were graded for quality by considering the quality index (QI), ranging from 0.00 to 1.00 automatically provided by the software.

Results: When all 200 cases were included, inter-reader reproducibility was significantly higher ($p=0.010$) for manual CIMT (bias=81%,-0.017 mm, coefficient of reproducibility(CoR)=0.143 mm) than semiautomatic CIMT (bias=75%,-0.001 mm,CoR 0.170=mm), while intra-reader reproducibility did not differ significantly($p=0.847$). When only cases with IQ ≥ 0.75 were considered (n=158), inter-reader reproducibility was significantly higher ($p=0.006$ for semiautomatic CIMT (bias=86%.0.001 mm,CoR=0.092 mm) than manual CIMT, while intra-reader reproducibility was not significantly different ($p=0.772$). Concordance between semiautomatic and manual CIMT was fair ($\kappa=0.341$) with an agreement of 80% on the whole sample, and fair ($\kappa=0.341$) with an agreement of 80% in cases with IQ ≥ 0.75 .

Conclusion: To achieve the best accuracy of semiautomatic CIMT, high quality index should be sought. Nevertheless, semiautomatic CIMT assessment with AutoIMT cannot yet substitute manual calculations in the attribution of cardiovascular risk.

B-0043 11:42

Comparative study of common carotid intima-media thickness in type 2 diabetics and non-diabetics in Port Harcourt, Nigeria
O. Moemenam¹, R. Njeze², E. Okwudire², U. Ezenwugo¹; ¹Port Harcourt/NG, ²Enugu/NG (meetle1@gmail.com)

Purpose: Intima media thickness (IMT) is a measure of atherosclerotic burden in diabetes mellitus (DM), and measurement of carotid IMT has been used as a surrogate for atherosclerosis in less accessible coronary and cerebral arterial systems. We aimed to compare carotid intima-media thickness (CIMT) in type 2 diabetics with controls and correlate CIMT with age, sex, BMI and duration of disease.

Methods and Materials: This was a cross-sectional study of 350 Type 2 diabetics and 350 controls recruited by systematic sampling between February 2015 to June 2016 in Port-Harcourt, Nigeria. CIMT was measured by ultrasound 1cm proximal to the carotid bulb and data was analyzed using statistical package for social sciences (SPSS) version 20, at significance level of $p<0.05$.

Results: Type 2 diabetics had significantly higher CIMT than non-diabetics ($1.09\pm 0.25\text{mm}$ vs $0.94\pm 0.24\text{mm}$, $p=0.001$). There was significant correlation between CIMT and age in type 2 diabetics ($r=0.53$, $p=0.001$), controls ($r=0.76$, $p=0.001$), and with duration of DM ($r=0.194$, $p=0.001$). Negative correlation between CIMT and BMI in the type 2 diabetic participants ($r=-0.913$, $p=0.001$) was observed. CIMT was significantly higher in male compared to female diabetics ($p=0.001$). There was no significant difference in the prevalence of carotid plaques between type 2 diabetics and non-diabetics (22.8% vs 19.4%; $p=0.32$) or between left and right carotid arteries.

Conclusion: CIMT was greater in diabetics compared with controls, and correlated with age in both groups. CIMT may be used as a measure of atherosclerotic disease in our environment.

Weight loss in obesity, impact on carotid intima media thickness and cardiovascular risk factors: a longitudinal study
B. Domènech-Ximenos, V. Cuba Camasca, J. Daunis-i-Estadella, S. Pedraza Gutierrez, J.M. Fernández-Real, J. Puig Alcàntara; Girona/ES (bl.domenech@gmail.com)

Purpose: Obesity increases the burden of atherosclerosis and, therefore, represents a risk factor for clinical cardiovascular disease. Intima media thickness (IMT) is a noninvasive marker of subclinical atherosclerosis. It remains unclear whether weight loss in obese subjects is accompanied by a reduction in consistent with a lowering of risk of cardiovascular events. We evaluated the effects of bariatric surgery and of a conservative approach (diet and exercise) on carotid IMT and cardiovascular risk factors in obese subjects.

Methods and Materials: We studied 163 individuals [a control group of 75 healthy participants (40 women, age 42 years (31-51), body mass index (BMI) 24.33 (22.23-27.2)) and 88 obese subjects (52 women, age 46 (38-52), BMI 43.37 (40.18-47))]; 22 (25%) obese subjects underwent bariatric surgery. We recorded weight, BMI, blood pressure, cholesterol, triglycerides, fasting glucose, insulin, and insulin resistance index and calculated Framingham Risk Scores (FRS). Carotid IMT was evaluated by ultrasound. The impact of weight loss on carotid IMT at 2-year follow-up was evaluated with regression models.

Results: At 2-year follow-up after bariatric surgery, BMI had decreased from 45.45 to 27.75 kg/m² ($p<0.001$) and FRS decreased from 15 (10-16) to 13 (8-15) ($p=0.035$). Mean carotid IMT decreased from 0.85 ± 0.13 mm to $0.65 \pm$

0.05 mm ($p < 0.001$), a reduction of 0.005 mm per kg of weight lost. Conservative approach did not impact cardiovascular risk markers.
Conclusion: Weight loss after bariatric surgery substantially reduces carotid IMT values consistent with a lowering in risk of cardiovascular events.

Incidence of vertebral fractures in patients with β -thalassaemia major in treatment with oral bisphosphonate

F. Pellegrino, M. Pontrelli, R. Mungari, M. Fortini, M.R. Gamberini, M.C. Zatelli, M.R. Ambrosio, M. Giganti; Ferrara/IT (fabiopellegrino07@gmail.com)

Purpose: To analyze the efficacy of oral bisphosphonate therapy (alendronate and risedronate) in patients with β -Thalassaemia evaluating incidence of vertebral fractures (VFs) and bone mineral density (BMD) values.

Methods and Materials: 60 patients (31 M, 29 F) with β -thalassaemia major of average age 35.02 ± 6.32 afferent at the center of Ferrara were selected retrospectively with age > 25 years, at least 1 between reduced BMD (Z-score < -2 premenopausal women and men aged < 50), osteoporosis (T-score < -2.5), ≥ 1 fragility fracture. We analyzed BMD values, thoracolumbar radiographs for VFs evaluation (according Genant classification) and biochemical data at 2, 3 and 5 years.

Results: The mean duration of therapy was 6.23 ± 1.93 years. We observed an improvement from baseline of lumbar spine BMD of 4% to 2 yr of treatment, 2% to 3 yr and 3% to 5 yr. BMD is increased by 1% in the femur (F) and 2% at the neck of the femur (FN) at 2 yr of treatment, at 3 yr + 1% (F) and 0% (FN), at 5 aa -3% (F) and -2% (FN). Incidence of new vertebral fractures was of 27%.

Conclusion: Therapy was useful in rising BMD at the lumbar level with an improvement of Z and T-score and in stabilizing BMD at the femoral level (F and FN) in the first 3 yr of therapy with a slight reduction at 5 yr, but VFs in these well-treated patients were still common and morphometry measurement remains a useful test in surveillance of these patients.

B-0046 10:38

Lumbar spine bone mineral density Z-score discrepancy by DXA and QCT in thalassaemic major patients

F. Pellegrino, L. Perrucci, M. Pontrelli, M.R. Gamberini, M. Fortini, I. Gagliardi, M.C. Zatelli, M.R. Ambrosio, M. Giganti; Ferrara/IT (fabiopellegrino07@gmail.com)

Purpose: Dual X-ray absorptiometry (DXA) is the most common mode of bone mineral density (BMD) evaluation in young adults with β -thalassaemia major (TM). In addition to DXA that determines an areal BMD, Quantitative Computerised Tomography (QCT) also detects volumetric BMD which is independent of bone size. Our aim is to evaluate concordance of BMD values in thalassaemic patients obtained by QCT and DXA.

Methods and Materials: We enrolled 15 patients with TM from the Hospital of Ferrara who underwent both a DXA scan of lumbar spine in regular follow-up and an unenhanced CT, performed for other causes, within 4 months. CT images of lumbar spine were evaluated with a quantitative dedicated post-processing software calculating volumetric BMD for L1-L4 vertebrae. BMD values of both methods were expressed as Z-scores and T-scores and the results were correlated.

Results: Of 10 patients (6 males < 50 aged, 4 premenopausal woman), the overall prevalence of severely low bone density (Z-score ≤ -2) was 9/10 (90%) by DXA and 3/10 (30%) by QCT with concordance in 4/10 patients (40%). In all 10 patients of this group QCT Z-score was higher than DXA Z-score with significant difference (p -value = 0.002). 5 patients (>50 years old) showed T-score ≤ -2.5 correspondent to osteoporosis both on DXA and QCT with 100% of concordance.

Conclusion: Our data show a discrepancy in lumbar BMD Z-scores by DXA and QCT in thalassaemic patients suggesting that DXA BMD could be falsely low in young subjects with short bones and QCT could be more accurate to assess it.

B-0047 10:46

Opportunistic osteoporosis screening using hydroxyapatite-specific vertebral bone mineral density measurements derived from dual-layer CT
 J.H.W. Bodden, F. Roski, J. Hammel, K. Mei, T. Baum, A. Laugere, E.J. Rummeny, A.S. Gersing, B.J. Schwaiger; Munich/DE (jannis.bodden@tum.de)

Purpose: To evaluate the applicability of in vivo hydroxyapatite (HA)-specific bone mineral density (BMD) measurements based on non-contrast-enhanced phantomless dual-layer spectral CT (DLCT).

Methods and Materials: BMD were obtained using spectral information from DLCT as well as with quantitative CT (QCT) examining a spine phantom with three artificial vertebral bodies with known HA densities, while simulating different patient positions and grades of obesity. Furthermore, HA-specific BMD values were determined using non-contrast routine DLCT in 174 vertebrae (33 patients; 66 ± 18 years; 33% women; 45% with prevalent fractures) and the results were compared with QCT-based BMD. The discriminative power of HA-specific BMD for differentiating subjects with versus without osteoporotic fractures was analysed using ROC analyses, also for an extended cohort of 79 patients (66 ± 18 years; 52% women; 38% with prevalent fractures).

Results: HA-specific BMD measurements in the phantom were more accurate than QCT, particularly when simulating obese patients. In vivo, strong correlations were shown between DLCT and QCT ($r = 0.987$, $p < 0.001$) and a high agreement in a Bland-Altman plot was observed. ROC areas under the curve (AUC) were 0.889 for QCT- and 0.878 for DLCT-based BMD in 33 patients. The AUC for the extended cohort was 0.858 for HA-specific BMD measurements, with an optimal cut-off at 81 mg/ml.

Conclusion: In vivo, DLCT-based HA-specific BMD measurements showed comparable results to QCT measurements as well as for distinguishing patients with vertebral fractures and those without. This suggests that HA-specific BMD measurements obtained from phantomless DLCT may be used for opportunistic osteoporosis screening.

B-0048 10:54

Consistency of bone mineral density assessments between dual-energy CT and quantitative CT

M. Chen, H. Yuan; Beijing/CN (chenmin@bjmu.edu.cn)

Purpose: To evaluate the consistency of bone mineral density (BMD) measurements between a phantomless dual-energy CT scanner and conventional quantitative CT (QCT) in vitro.

Methods and Materials: QCT and dual-energy CT scans of 23 fresh sheep vertebrae were performed on the same CT scanner which generated dual-energy images from rapid kilovoltage switches (80kv-140kv). A fixed tube voltage of 120kv was applied for QCT scans with the bone equivalent phantom placed below the samples. Trabecular BMD analyses of QCT images were performed using QCTpro software. The dual-energy CT images were processed to generate calcium hydroxyapatite (HAP) density images based on HAP-water material pairs. HAP densities of the same regions were measured. Pearson correlation, paired t test, and intraclass correlation coefficient (ICC) were applied for consistency assessment.

Results: BMD measurements of QCT ranged from 136 mg/cm^3 to 486 mg/cm^3 , and the BMD measurements of DECT ranged from 128 mg/cm^3 to 419 mg/cm^3 . BMD derived from DECT images were significantly lower than that of QCT ($p < 0.001$), while they displayed a strongly linear correlation ($r = 0.989$, $p < 0.001$). The ICC between the two measurements was 0.974 ($p < 0.001$).

Conclusion: In vitro, the HAP densities acquired by dual-energy CT displays a highly linear correlation with BMD measured by QCT of the same specimens. Although the results from dual-energy CT were not completely same as QCT, the phantomless dual-energy CT has the potential to be applied for BMD assessment clinically.

B-0049 11:02

Metacarpal bone diameter increases constantly, but escalated resorption of the inner surface at menopause explains decreased bone mineral density - a study in 1492 adult women

C. Samuelsson, J. Kälvesten, M. Wilczek, T.B. Brismar; Stockholm/SE (carlsamuelsson@gmail.com)

Purpose: To assess how bone morphology and mineralization changes with age in women.

Methods and Materials: The non-dominant hand was analyzed with digital X-ray radiogrammetry (DXR) in 1,429 women aged 40-74 years undergoing mammography screening twice with 18 to 24 months interval, depending on age. Yearly change in bone parameters was calculated by averaging the individual changes.

Results: Both the inner and outer diameter of the metacarpals increased with age while DXR bone mineral density (DXR-BMD) decreased. There was a continuous increase in outer diameter in adult age while there was a five-fold increase in yearly inner diameter growth and DXR-BMD loss during 48 to 53

years of age. In the age-interval 40-47 the change in W and ID was on average 4.65um and 8.8 um /year respectively, compared to 1.9 um and 49 um /year after 53 years of age.

Conclusion: The faster decrease in DXR-BMD observed during and after menopause is caused by resorption of the inner cortical surface, increasing the inner diameter that no longer is matched by the increase in outer diameter. To our knowledge it has not previously been shown how individual bone diameter changes with age in adults. The automatized analysis and high reproducibility of DXR-BMD made that analysis possible in a great number of subjects despite a short time-interval. We speculate that most bones in the human body grow in the same pattern as observed in the metacarpals, partly explaining the decreasing BMD at older age.

Author Disclosures:

J. Kälvesten: Employee; Previous employee at Sectra, that produces the DXR software.

Sarcopenia and osteoporosis in patients with cancer diagnosis: evaluation with CT

S. [Ivanoski](mailto:slavoivanoski@gmail.com)¹, V. Vasilevska Nikodinovska², ¹Ohrid/MK, ²Skopje/MK

Purpose: To evaluate the prevalence of sarcopenia in patients with and without diagnosis of malignant tumour. To assess the relationship between sarcopenia and osteoporosis in patients with malignancy.

Methods and Materials: 70 patients age ≥ 65 (mean age 71.5), 33 male and 37 female, that underwent abdominal CT were included in the study. Half of patients (N=35) had diagnosis of malignant tumour, majority colorectal cancer (37%). Trabecular bone mineral density at level of L1 vertebral body, in upper vertebral body part, using single slice technique, was measured for detecting osteoporosis. Density and cross-section area of psoas muscles at L3 vertebral body mid level were measured for diagnosing sarcopenia. Cut-off values for CT detection of sarcopenia and osteoporosis established by previous researches were used. Chi square test, Pearson correlation, and linear regression analysis were performed.

Results: 40% of patients with diagnosis of malignant tumour had muscle density diagnostic for sarcopenia, compared to 11.4% in patients without cancer. Differences for sarcopenia, assessed by psoas muscle density values, between patients with malignancy and non-malignant group were statistically significant ($\chi^2=6.06$, $p=0.016$). Osteoporosis values weren't significantly different between groups ($\chi^2=0.06$, $p=0.811$). There was moderate correlation between bone density and psoas muscle density in patients with malignancy ($r=0.441$, $p<0.05$). Regression analysis showed sarcopenia was positively correlated with age (odds ratio=1.169, $p=0.036$) and malignancy (odds ratio=0.117, $p=0.08$).

Conclusion: Sarcopenia is significantly higher in patients with diagnosis of cancer, compared to patients without malignancy diagnosis. Sarcopenia is associated with osteoporosis in malignancy and should be mentioned in abdominal CT report.

B-0051 11:18

Changes in bone marrow fat upon dietary induced weight loss

M. [Spurny](mailto:manuela.spurny@med.uni-heidelberg.de), Y. Jiang, R. Schübel, T. Nonnenmacher, C.L. Schlett, O. von Stackelberg, H.-U. Kauczor, T. Kuhn, J. Nattenmüller; Heidelberg/DE

Purpose: Bone marrow fat (BMF) is an ectopic fat storage depot connecting metabolism and bone health. Evidence on changes in BMF with weight loss is limited. Therefore we aimed to analyze changes in BMF content following dietary induced weight loss.

Methods and Materials: Magnetic resonance imaging data of the HELENA-trial, an RCT among 143 non-smoking, obese participants (BMI at baseline between 25 and 40 kg/m², 50% female), were used to quantify BMF content before and after a 12 week dietary intervention phase. Regions of interest (2cm²) were evaluated manually on a post-processing software (OsiriX, Pixmeo SARL, Bernex, Switzerland) using the proton density fat fraction map, based on mean counts from L1 and L2. The study cohort was divided into weight loss quartiles based on changes in body weight between baseline and week 12.

Results: Average BMI at baseline was highly similar across the weight loss quartiles (Q1: 32.1 \pm 4.1kg/m²; Q2: 31.1 \pm 3.7kg/m²; Q3: 30.9 \pm 3.4kg/m²; Q4: 31.5 \pm 3.7kg/m²). Diet induced weight loss varied between 0.0 \pm 0.2% for Q1 to -11.3 \pm 0.6% for Q4. Relative changes in BMF were 0.7 \pm 2.4%, -3.5 \pm 2.0%, -1.4 \pm 2.4%, and -12.7 \pm 3.3% for Q1 to Q4. Across all four weight loss quartiles and for the two group comparison Q1 vs. Q4 there was a significant difference ($p<0.01$) for changes in BMF. For the two group comparisons Q1 vs. Q2 and Q1 vs. Q3 there were no significant differences ($p>0.05$) observed.

Conclusion: Our data suggest that BMF levels decrease with weight loss. Further research will unravel the association between the amount of weight loss and BMF.

B-0052 11:26

Fat mass does not increase the precision error of trabecular bone score measurements

C. [Buonomenna](mailto:buonomenna.ciriaco@gmail.com)¹, C. Messina¹, S. Gitto¹, A. Biacca², D. Albano³, L.M. Sconfienza¹; ¹Milan/IT, ²Novara/IT, ³Palermo/IT

Purpose: We investigated the in-vivo effect of increasing BMI and waist circumference on TBS precision error.

Methods and Materials: A population of postmenopausal Caucasian women was distributed in three different BMI (normal, overweight, class I obesity), plus two further groups based on waist circumference (WC) diameter (≤ 88 cm and >88 cm respectively). In-vivo precision error was calculated on 30 consecutive subjects that were scanned two times, with patient repositioning. Coefficient of Variation, percent least significant change (LSC%) and reproducibility were calculated according to the International Society for Clinical Densitometry guidelines.

Results: Ninety-five women aged 66 ± 10 (mean \pm standard deviation) were included. No significant differences were found for BMD and TBS precision errors, respectively, when comparing BMI groups and WC groups. BMD reproducibility ranged from 95.9% (BMI >30 kg/m²) to 97.5% (BMI <25 kg/m²). TBS reproducibility ranged between 95.8% (BMI= 25-29.9 kg/m², WC >88 cm) and 96.6% (BMI <25 kg/m²). With the exception of obese group, a significant difference was found between BMD and TBS reproducibility, being that of TBS slightly lower than BMD. A significant decrease of TBS was found between normal and obese subjects, as well as between WC groups; BMD variations between groups were not statistically significant.

Conclusion: TBS precision error is not affected by BMI and WC differences. TBS reproducibility showed to be slightly lower than that of BMD, but this difference was mitigated in obese patients. A negative association was found between the amount of fat mass and TBS mean values.

Dual-energy computed tomography in calcium pyrophosphate deposition: initial clinical experience

J. [Legrand](mailto:legrand.julie@ghicl.net)¹, T. Pascart¹, L. Norberciak¹, F. Becce², J.-F. Budzik¹; ¹Lille/FR, ²Lausanne/CH (legrand.julie@ghicl.net)

Purpose: To determine the dual-energy computed tomography (DECT) attenuation properties of meniscal calcifications in calcium pyrophosphate deposition (CPPD) in vivo, and assess whether DECT was able to discriminate meniscal CPP deposits from calcium hydroxyapatite (HA) in subchondral and trabecular bone.

Methods and Materials: Patients with clinical suspicion of crystal-related arthropathy and knee DECT scans were retrospectively assigned to CPPD (n=19) or control (n=21) groups depending on the presence/absence of chondrocalcinosis on DECT. Regions of interest were drawn in meniscal calcifications, non-calcified menisci, as well as subchondral and trabecular bone. Five DECT parameters were obtained: CT numbers (HU) at 80 and 140 kV, dual-energy index (DEI), electron density (ρ_e), and effective atomic number (Z_{eff}). The four different knee structures were compared using mixed linear models.

Results: Meniscal calcifications (n=89) in CPPD patients had mean \pm SD CT numbers at 80 and 140 kV of 257 \pm 64 and 201 \pm 48 HU, respectively; with a DEI of 0.023 \pm 0.007, and ρ_e and Z_{eff} of 140 \pm 35 and 8.8 \pm 0.3, respectively. Meniscal CPP deposits were readily distinguished from calcium HA in subchondral and trabecular bone ($p\leq 0.01$), except at 80 kV separately ($p=0.28$). Z_{eff} and ρ_e both significantly differed between CPP deposits and calcium HA in subchondral and trabecular bone ($p<0.0001$).

Conclusion: This proof-of-concept study shows that DECT can discriminate meniscal CPP deposits from calcium HA in subchondral and trabecular bone in vivo, paving the way for the biochemical signature assessment of intra- and juxta-articular calcium crystal deposits.

B-0054 11:42

Retrospective study of foot and ankle dual-energy CT in gouty arthritis patients without first metatarsophalangeal joint uric acid crystal deposition

H. [Yang](mailto:yphot@naver.com)¹, Y.-S. Hong², J. Gong Yong³, Y.K. Lee¹, S.K. Kim¹, J.H. You¹, E. Park¹; ¹Jeonju/KR, ²Gwangju/KR, ³Chonju/KR

Purpose: To evaluate the accuracy and which DECT findings are characteristic of diagnosing foot and ankle gout in patients without uric acid crystal deposition in first metatarsophalangeal joint (MTPJ).

Methods and Materials: Among 97 foot and ankle DECT obtained from January 2016 to September 2017, 27 foot and ankles without first MTPJ green pixelation were enrolled. Two blinded musculoskeletal radiologists evaluated the images and classified the examination findings as positive or negative for

the presence of uric acid crystals. Readers also assessed following results of green pixelation: volume, site, size, shape, vanishment after increase minimal HU from 130 to 150. Reference standard was the results of joint aspiration and over one year clinical follow up. Logistic regression analyses were conducted to identify which findings were significantly associated with gout.

Results: The sensitivity and specificity of DECT without first MTPJ green pixelation was 0.96 and 0.67. The mean volume of green pixelation was 1.7cm³. All false negative patients had submillimeter artifact. The DECT findings showed significant differences between artifact and gout with respect to shape, vanishment after increase minimal HU from 130 to 150, site (p<0.05). Multivariate logistic regression showed correlations between artifact and shape (non-oval, sharp, flat, odd ratio 27.4), and vanishment after increase minimal HU (odd ratio 19.2).

Conclusion: The specificity of DECT of foot and ankle without green pixelation in first MTPJ is unsatisfactory due submillimeter artifact. Green pixelation with non-oval, sharp, flat shape and which vanishes after increased minimal HU in post-processing may associated with artifact.

B-0055 11:50

7T T2*-relaxometry detects early tendon degeneration in patients with diabetes mellitus type 1 (DM1) and shows correlations with BMI and age
M. Zalaudek¹, W. Marik¹, V. Juras¹, M. Riedl¹, B. Hager¹, O. Bieri², X. Deligianni², M. Weber¹, S. Trattnig¹; ¹Vienna/AT, ²Basle/CH
(martin.zalaudek@meduniwien.ac.at)

Purpose: T2* mapping at 7T was used to investigate alterations in tendon composition and their relation to demographics of patients with DM1.

Methods and Materials: Eighteen DM1 patients (11f/7m, 28.25±7.14y, BMI 22.3±2.28) were enrolled together with eighteen sex, age and BMI matched healthy controls (11f/7m, 27.35±5.93y, BMI 21.61±2.67). MRI was performed on a 7T whole body scanner with a dedicated multichannel receive proton knee coil. FS-PDW images were acquired for morphological evaluation of patellar tendon. A variable TE sequence (10 TEs from 1.21-24.48ms) for mono-exponential T2* mapping. Differences in T2* values between diabetics and controls were compared. Sensitivity/specificity was evaluated. T2* values were correlated with BMI and age.

Results: On PDW images, tendons appeared unremarkable in all participants. Mean T2* values in patients and controls were 1.29±.41ms and 0.73±.14ms, respectively (p<0.001). AUC was 0.92 (95%CI, 0.82-1), a cut-off set to 0.89ms showed a sensitivity of 88.9% and specificity of 99.44%. BMI and T2* values correlated strong/statistically significant in diabetics (r=0.62, p<0.01) and weak in controls (r=0.26, p=0.3). Age and T2* values correlated weak in diabetics (r=0.255, p=0.31) and strong/statistically significant in controls (r=0.6, p<0.01).

Conclusion: Although inconspicuous in routine MRI, tendons of DM1 patients exhibited altered T2* values with a high diagnostic sensitivity/specificity. Furthermore, T2* values of DM1 tendons appear to be influenced by BMI. Age did not influence T2* values in DM1 patients - however, it did in controls. This may reflect a stronger impact of higher body weight to the deteriorated tendon tissue and a partial abolition of age related tendon degeneration in DM1 patients.

Predictive value of MRI radiomic features in differentiating lipoma from atypical lipomatous tumour

F. Acquafredda¹, Y. Abdelhazef², M. Zhang³, M. Guindani⁴, S. Lee⁴, D. Sarohia², R.D. Badawi², L. Nardo²; ¹Brescia/IT, ²Davis, CA/US, ³Montreal, QC/CA, ⁴Irvine, CA/US (francesco.acquafredda@gmail.com)

Purpose: To explore the predictive role of shape and texture features extracted from MR images for differentiating lipoma from atypical lipomatous tumour (ALT).

Methods and Materials: With Institutional Review Board approval, the PACS databases of multiple institutions were searched for the terms "lipoma", "liposarcoma" and "lipomatous". 3251 subjects were found and screened for pathologically proven surgically resected lipoma or ALT and pre-operative MRI study with axial T1 sequence for lesion segmentation. LifeX software was used to extract 3 shape features (volume, sphericity and compacity) and 32 texture

indices from 4 texture matrices: grey-level co-occurrence matrix (GLCM), grey-level run length matrix (GLRLM), grey-level zone length matrix (GLZLM) and neighborhood grey-level different matrix (NGLDM). Receiver-operating characteristic (ROC) analysis was used to calculate the area under the curve (AUC) and 95% confidence interval (CI) for each feature.

Results: The study included 97 patients (median age 58 years [range: 32-92], 55 women), 25 ALTs and 72 lipomas. Several shape and texture features were significantly predictive of pathological diagnosis (p<0.001). AUC values were as follows: compacity 0.83 (0.75-0.91), sphericity 0.63 (0.51 - 0.76), NGLDM busyness 0.77 (0.66-0.88), GLZLM grey-level non-uniformity (GLNU) 0.77 (0.66-0.88), run-length non-uniformity (RLNU) 0.75 (0.63-0.86), GLRLM GLNU 0.74 (0.63-0.85) and RLNU 0.74 (0.63-0.85). In multivariate analysis, compacity, busyness and GLRLM RLNU were independent predictors for pathology with odds ratio (95%CI) of 2.2 (1.5-3.2; p<0.001), 1.7 (1.1-2.7; p=0.018) and 1.0 (1.0-1.0; p=0.025), respectively.

Conclusion: Radiomic features extracted from MR images, specifically compacity and busyness, could help differentiating lipoma from ALT.

To biopsy or not to biopsy? A quantitative approach differentiating subfascial lipoma from atypical lipomatous tumour/well-differentiated liposarcoma on MRI

R. Donners, D. Harder; Basle/CH (ricardo.donners@usb.ch)

Purpose: To provide MRI-based quantitative decision support when to biopsy subfascial lipomatous tumours.

Methods and Materials: MRI of 100 histopathologically proven subfascial lipomas (n=75) and atypical lipomatous tumours/well-differentiated liposarcomas (ALT/WDL) (n=25) were reviewed retrospectively. Exclusion criteria were non-lipomatous soft tissue components, suprafascial and intraabdominal location. Ratios derived from region of interest-based signal intensity (SI) measurements of tumour and adjacent fat on T2 fat-saturated (FS) images were calculated (=mean S_{tumour}/mean S_{adjacent-fat}). Univariate regression analyses were applied and a p value <0.01 deemed significant. The discriminatory ability was assessed by ROC curve analyses. Interreader agreement was evaluated by calculation of intraclass correlation coefficients (ICC). Tumour size, location, septation and patient demographics were noted.

Results: T2 FS ratios performed well discriminating lipoma from ALT/WDL (p<0.001, area under the ROC curve (AUC)=0.89, cutoff =1.22, specificity =88%, sensitivity =80%). A T2 FS ratio >1.37 indicated ALT/WDL with 95% specificity and 64% sensitivity. Interreader agreement was excellent (ICC =0.924). ALT/WDL was significantly larger than lipoma (p <0.001, AUC=0.84, cutoff =11 cm, 92% specificity, 72% sensitivity). Combination of a T2 FS ratio <1.22 and size <11 cm as decision support would have spared 61% of lipoma patients from biopsy (combined specificity=99%, sensitivity=58%). Qualitative imaging parameters and patient demographics did not differ significantly (each p>0.022).

Conclusion: Lipomatous subfascial tumours with a T2 FS ratio <1.22 and size <11 cm are most likely benign and may not need biopsy. Tumours with a T2 FS ratio >1.37 should be biopsied even when <11 cm.

B-0058 10:46

Diffusion-weighted imaging combined with dynamic contrast-enhanced sequences in MRI as a predictor factor of malignancy in non-fatty soft tissue tumour

C. Martin¹, L. Lassale¹, N.-E. Regnard¹, F.P. Kuhn², F. Larousserie¹, V. Audard¹, D. Biau¹, J.L. Drape¹, A. Feydy¹; ¹Paris/FR, ²Zurich/CH (chachmartin@hotmail.com)

Purpose: To study the diagnostic performance of DWI criteria and DCE-MR qualitative and semi-quantitative criteria for distinction between malignant and benign soft tissue tumors.

Methods and Materials: We consecutively included 38 patients with soft tissue tumors, 15 benign and 23 malignant (biopsy proven), all had DWI and DCE-MR sequences after gadolinium injection with the same parameters. ADC values and ratio of ADC (tumor/muscle) were compared between the benign and malignant groups. Type of enhancement curve, slope of the curve, peak intensity and peak time were also compared between the two groups. Diagnostic performance of each criterion was tested.

Results: Mean ADC values and ADC tumor/muscle ratios were significantly lower in the malignant tumor group, respectively 972 versus 1472 mm²/s (p = 0.003) and 0.810 versus 2.38 (p = 0.003). ADC value analysis allowed distinction of malignant tumors with an acceptable diagnostic performance (AUC=0.772). No significant difference was found for slope (p = 0.33), peak intensity (p = 0.4) and peak time (p = 0.525) in the two groups. Type 5 curves were statistically more frequently found in the malignant tumor group (p = 0.024).

Conclusion: Analysis of ADC values and ADC tumor/muscle ratios was useful for the distinction between benign and malignant tumors. The qualitative and semi-quantitative analysis of perfusion parameters did not allow distinction between benign and malignant tumors.

B-0059 10:54

The diagnostic value of shear wave elastography for the differentiation of benign and malignant soft tissue tumours

M. [Ozturk](#), A.V. Polat, Y.S. Baris, M.B. Selcuk; *Samsun/TR*
(dr.mesutozturk@gmail.com)

Purpose: Our aim was to assess the diagnostic value of shear wave elastography (SWE) for the differentiation of benign and malignant soft tissue tumours.

Methods and Materials: Institutional ethics committee approval and informed consent from each participant were obtained for this prospective study. Fifty patients with soft tissue tumours (28 men and 22 women; mean age \pm SD: 44.02 \pm 19.13 years) were examined with SWE using virtual touch tissue imaging and quantification (VTIQ) method between May 2016 and June 2018. Five region of interest boxes were randomly placed on the lesion and tissue stiffness was measured as shear wave velocity (SWV) in meter per second (m/s). Mean SWV, maximum SWV, minimum SWV, and the difference between maximum and minimum SWV were used to compare the stiffness of the benign and malignant lesions.

Results: Thirty-one benign and 19 malignant soft tissue tumours were diagnosed. Mean SWV, maximum SWV, minimum SWV and the difference between maximum and minimum SWV values for malignant lesions were 3.00 m/s, 3.54 m/s, 2.65 m/s and 0.89 m/s, respectively. Mean SWV, maximum SWV, minimum SWV and the difference between maximum and minimum SWV values for benign lesions were 3.29 m/s, 3.91 m/s, 2.85 m/s and 0.89 m/s, respectively. No statistically significant difference was found between benign and malignant lesions for the measured SWV values ($p = 0.353$, $p = 0.418$, $p = 0.327$, and $p = 0.385$, respectively).

Conclusion: SWE did not contribute to the differentiation of benign and malignant soft tissue tumours.

B-0060 11:02

Do aggressive radiologic features of synovial sarcoma correlate with pathologic grading? A retrospective study

T.S. [Al Kuhaimi](#), A. Aljefri, M. Alshaiikh, S. Almalki, S. Bauones; *Riyadh/SA* (T.S.ALKUHAIMI@GMAIL.COM)

Purpose: To study the imaging characteristic signs of aggressive behaving synovial sarcoma (SS) in relation to the pathologic types and grading to look for statistical significance using a radiologic-pathologic correlation.

Methods and Materials: After institutional review board approval, a monocentric retrospective study was undertaken on 15 (9 Males & 6 Females; mean age of 35) histopathologically-proven SS with MRI images between January 2012 and December 2017 at King Fahad Medical City in Riyadh. Data was collected on patient's demographics and the imaging features on multiple imaging modalities, in particular MRIs which were reviewed by 2 musculoskeletal radiologists. Pathology slides were reviewed by a musculoskeletal pathologist. Data were analysed descriptively and statistically.

Results: Among multiple aggressive imaging findings of SS studied (haemorrhagic pockets, peri-lesional oedema, muscle and bone invasion, neurovascular bundle invasion, triple sign, bowl of grapes sign), the only statistically significant imaging finding that correlates with the histopathological high grade (grade 3) of SS is the neurovascular bundle invasion ($P < 0.05$). No statistically significant correlation (P value varies between 0.135 and 0.853) between other imaging characteristics and histopathologic types of SS was found. No statistically significant correlation between tumour size and its probability to metastasize ($P = 0.516$). However, large tumour size (> 5 cm), intralesional haemorrhage, bone invasion are frequently encountered imaging findings in high-grade and metastatic SS. Most common metastatic site is pleuro-pulmonary (81%).

Conclusion: Neuro-vascular bundle invasion could help predict patient histopathological grade and thus aid in disease prognostication.

B-0061 11:10

Performance of 3D texture analysis for tissue characterisation and differential diagnosis of osteosarcoma

C.S. [Lisson](#)¹, C.G.S. [Lisson](#)¹, R. Mayer-Steinacker¹, A. von Baer¹, T.F.E. [Barth](#)¹, M. [Baumhauer](#)², A.J. [Beer](#)¹, M. [Beer](#)¹, S.A. [Schmidt](#)¹; ¹Ulm/DE, ²Heidelberg/DE (catharinavonend@gmail.com)

Purpose: Differentiation between osteosarcomas and other common bone tumours such as chondrosarcoma, Ewing's sarcoma and chordoma can be a significant radiologic-histologic challenge because osteosarcomas represent a highly heterogeneous tumour group. The clinical relevance is that a distinction is important since, depending on the diagnosis, there are different therapeutic approaches with regard to (neo-)adjuvant chemo-/radiotherapy. This study

evaluates the performance of MRI-based 3D texture analysis (TA) in comparison to CT-based TA for the differentiation of osteosarcoma.

Methods and Materials: 132 patients were retrospectively evaluated: 64 with contrast-enhanced CT, 28 with non-contrast CT and 40 with contrast-enhanced MRI. All patients had a histopathological diagnosis based on the surgical specimen. TA was performed on CT/MR images obtained for routine purposes using the research software MINT, a spinoff from the DKFZ, which allows and post-process 3D measurements. Kruskal-Wallis test and Dunn-Bonferroni post hoc test were performed to identify the most discriminative texture features (kurtosis, entropy, skewness, MPP, UPP, uniformity).

Results: In MRI, the TA skewness in the T2-weighted sequences significantly differentiated osteosarcoma from chondrosarcoma ($p = 0.002$), Ewing's sarcoma ($p = 0.037$), and chordoma ($p = 0.006$). In contrast-enhanced CT, the TA entropy and MPP could significantly discriminate between osteosarcoma and chondrosarcoma ($p = 0.002$ and $p = 0.001$), Ewing's sarcoma ($p < 0.0005$ and $p < 0.0005$) and chordoma ($p = 0.038$ and $p = 0.002$). In non-contrast CT, osteosarcoma could not be differentiated.

Conclusion: Tumour heterogeneity quantified by MRI- and contrast-enhanced CT-based 3D texture analysis has the potential to differentiate osteosarcoma from chondrosarcoma, Ewing's sarcoma and chordoma.

B-0062 11:18

Diagnostic value of MR imaging with metal artefact reduction sequences in local recurrence of malignant bone tumour after joint replacement

H. [Wang](#), Y. Lu; *Shanghai/CN* (shinianxin@sjtu.edu.cn)

Purpose: To investigate the diagnostic value of MR imaging with metal artefact reduction sequences in local recurrence of malignant bone tumour after joint replacement.

Methods and Materials: 94 cases who were pathologically diagnosed with malignant bone tumour underwent clinical and imaging follow-up after joint replacement. All cases received MR scans with metal artefact reducing syngo WARP sequences and FSE sequences. The sensitivity, specificity, and consistency rate of syngo WARP sequences and FSE sequences were compared for diagnosing local recurrence of malignant bone tumours. The $Kappa$ test was used to assess the consistency of syngo WARP and FSE sequences with pathology in diagnosing recurrence respectively. ICC evaluated the consistency of MR images with pathology in measuring the volume of recurrent tumour.

Results: 35 of the 94 cases were pathologically or clinically diagnosed as local recurrence after joint replacement. Local recurrence mainly presented as soft tissue masses and bone destruction on MR images. The sensitivity, specificity, coincidence rate and $Kappa$ value of syngo WARP sequences in the diagnosis of local recurrence of malignant bone tumours were 94.3%, 94.9%, 94.7%, and 0.887, which were higher than FSE sequences. Compared with pathology, the ICC of MR images in measuring recurrent tumour volume was 0.961.

Conclusion: The syngo WARP sequences can significantly reduce metal artefacts in scanning area, and diagnose local recurrence. It also has a good consistency with pathology in evaluating the lesion volume, thus it's recommended for the standard evaluation of postoperative bone tumour.

B-0063 11:26

Denosumab response evaluation in primary osseous giant cell tumours with 18F-FDG PET/CT

A. [Kesari](#)¹, S.S. [Swamy](#)¹, S. [Sampangi](#)¹, I. [Desai](#)¹, M. [Ashok Kumar](#)², P. [Asokan](#)¹, K. [Kallur](#)¹; ¹Bangalore/IN, ²Bikaner/IN

Purpose: To assess the response of primary osseous giant cell tumor to denosumab with FDG PET-CT.

Methods and Materials: We present retrospectively evaluated 90 patients of giant cell tumor treated with denosumab in the setting of recurrence, high surgical risk, high grade lesions and monotherapy. Although most of the patients required surgery (extended curettage, en bloc resection and prosthetic reconstruction, arthrodesis, etc.), in two patients with recurrent GCT of the metacarpal and two patients with GCT of the pelvis, denosumab was used as monotherapy. Patients were followed with PET-CT with a mean of 2 years (Range: 1-5 years).

Results: PET-CT evaluation showed reduced activity in 81% of the patients and 63% of the Campanacci grade III patients on plain radiographs showed down grading to grade II following denosumab therapy. 77% of the patients showed histological evidence of interval reduction in grade of tumor.

Conclusion: Response to denosumab is noted in the form decrease in metabolic activity, ossification of the lesional soft tissue component and lytic bone. The reduction in metabolic activity was more prominent than regression in size of the primary lesion. Thus PET-CT adds to imaging response assessment in osseous GCT.

B-0064 11:34

Comparison of image quality and radiation dose between combined ATCM and FTC technique in whole-body low-dose multidetector CT in the diagnosis of multiple myeloma

M. Calvo Imirizaldu, A. Ezpona Casajús, I. Soriano, A. Paternain Nuin, M. Elorz, J.D. Aquerreta Beola; Pamplona/ES (mcalvoi@unav.es)

Purpose: This study aimed to compare image quality and radiation dose of a combined automatic tube current modulation (ATCM) technique with those of a fixed tube current technique (FTC) in whole-body low-dose multidetector CT (WBLDCT), in the diagnosis of Multiple Myeloma.

Methods and Materials: 28 consecutive patients (15 men, mean age 63.8±11.3 years) underwent unenhanced WBLDCT for evaluation of Multiple Myeloma using a third-generation dual-source CT scanner (192-slice) with dedicated tin filter, from August-2017 to September-2018. All acquisition parameters were identical in both techniques (100 kV, tin filtration) except for tube current: 18 patients were performed with ATCM and 10 patients with FTC (200 mAs). We recorded objective image noise in muscles at different anatomic levels and in the liver parenchyma, radiation dose (DLP, mSv) and body mass index (BMI, kg/m²). The Mann-Whitney *U* test was used for statistical analysis.

Results: No statistical differences were observed in the BMI estimated in both groups (p=0.94). Signal-to-noise ratio was higher in the ATCM group at scapular and pelvic girdles compared to FTC, with statistically significant differences (p=0.014; p<0.001 respectively). Objective image noise values at the upper neck and in the abdominal region found no significant differences between both techniques (p=0.191 and p=0.408). The effective radiation dose with the ATCM technique was 2.91 vs 1.49 with the FTC (p<0.001).

Conclusion: WBLDCT with ATCM technique achieves diagnostic image quality with better signal-to-noise ratio in some compromised areas as the scapular and pelvic girdles, while maintaining acceptable low radiation dose levels.

B-0065 11:42

Collagen-bound and water-bound water longitudinal relaxation time by ZTE imaging as biomarker for radiation-induced bone changes in mouse model

V. Phi Van, I. Grgic, A. Boss, M. Pruschy, M. Wurnig; Zurich/CH (valeriedoan.phivan@usz.ch)

Purpose: Collagen-bound water (CBW) and pore water (PW) components of cortical bone reflect bone porosity and organic matrix density. Our study evaluates the longitudinal relaxation time of those two compartments as biomarkers for radiation-induced bone damage.

Methods and Materials: ZTE images of mouse femur were acquired at 4.7T with 14 different inversion times (0-2,600 ms) before radiation and 3 weeks/3months after radiation at 20 Gy by the xrad system 320. Longitudinal relaxation time of the two compartments CBW, PW and CBW fraction (cbwf) for each timepoint was computed by a bi-exponential fitting. μ CT imaging were performed at the same timepoints to validate bone porosity.

Results: Baseline measurements displayed a mean T1cbw of 245 ± 110ms, a mean T1pw of 2076 ± 623ms and a cbwf of 6.9 ± 3.4%. 3 weeks after radiation, both T1 relaxation time (CBW 269 ± 89ms, p value = 0.12; PW 2204 ± 575ms, p value=0.09) and cbwf (6.4 ± 3.7%) stayed stable. After 3 months, T1 relaxation time significantly increases (T1cbw 432 ± 89ms, T1pw 3423 ± 543ms) towards the baseline. Contrarily, cbwf decreased significantly (3.7 ± 2.1%). μ CT-derived bone porosity parameter showed good correlation with both T1 relaxation time (pw: r=0.68, cbw:r=0.63) and cbwf (r=0.77).

Conclusion: Longitudinal relaxation time of CBW and PW components are sensitive towards bone porosity changes after radiation and may be useful as non-invasive tool for radiation-induced bone damage.

B-0066 11:50

Radiologic predictors of survival in soft tissue sarcoma

J. Kavanagh, J. Wunder, P. Ferguson, R. Mohankumar; Toronto, ON/CA (jokavana@tcd.ie)

Purpose: To evaluate the MRI features associated with survival after preoperative radiotherapy in soft tissue sarcoma.

Methods and Materials: A review of a prospectively collected database was performed for patients treated for extremity STS. Pre- and post-radiotherapy MRI were reviewed by two fellowship-trained musculoskeletal radiologists. Maximal tumour diameter and volumes were measured on T2-weighted sequences and the change in high T2 signal was estimated as a percentage. High T2 signal was defined as signal intensity similar to an adjacent vessel or fluid. Tumours were divided into partial response (PR), stable disease (SD) or progressive disease (PD). Local recurrence-free survival (LRFS), metastasis-free survival (MFS) and overall survival (OS) were examined using the Kaplan-Meier method and compared with log-rank test.

Results: 309 studies were available to review. There was an increase in tumour volume after RT with a mean volume increase of 132cm³ (3190cm³-

6087cm³). 117 tumours showed a partial response, 86 tumours were classified as stable disease and 106 tumours as progressive disease. Of the 166 patients assessed for T2 change 106 showed no change, 26 showed a reduction in T2 signal and 34 showed an increase in T2 signal. PD by RECIST had a worse MFS (p<0.001) and OS (p<0.001). Tumours that demonstrated an increase in T2 signal post-radiotherapy had an increased MFS (p=0.035) but no difference in LRFS or OS (p=0.079).

Conclusion: PD after radiotherapy is associated with worse MFS and OS. Increase in percentage T2 signal is associated with increase MFS but no change in OS.

Classification of malignant and benign liver tumours using a radiomics approach

M.P.A. Starmans, R.L. Miclea, S.R. van der Voort, W.J. Niessen, S. Klein, M.G. Thomeer; Rotterdam/NL (m.starmans@erasmusmc.nl)

Purpose: Primary solid liver lesions are in clinical practice manually scored by radiologists in benign or malignant based on MRIs. As the interpretation of these MRIs is challenging and observer dependent, we present a radiomics approach as an objective alternative.

Methods and Materials: T2-weighted MRIs and pathology were gathered from 119 non-cirrhotic patients with solid primary liver tumours. The malignant class consisted of HCCs, the benign class of FNHs and HCAs. The phenotype was obtained through pathology. The resulting dataset originated from 54 different hospitals, showing heterogeneity in the imaging protocols. Lesions were delineated by a radiologist. Within these regions, radiomics features quantifying shape, intensity, texture and orientation were extracted. Several patient characteristics were added as semantic features. Radiomics was performed using harmonised adaptive workflow optimisation including various feature selection, oversampling and machine learning approaches. Evaluation was implemented through a 100x random-split cross-validation, with 80% of the data for training and 20% for testing. Performance was given in 95% confidence intervals (CIs). For comparison, the tumours were manually scored by a radiologist.

Results: The AUC, sensitivity and specificity were, respectively (0.86, 0.99), (0.58, 0.89) and (0.85, 0.98) for radiomics and 0.93, 0.93 and 0.70 for the radiologist. The positive class consisted of the malignant tumours.

Conclusion: The AUC of the radiomics approach is comparable to the radiologist. However, the sensitivity is lower than the radiologist but the specificity higher. Hence, radiomics is a promising alternative or complementary approach in distinguishing malignant from benign primary liver tumours in non-cirrhotic patients.

B-0068 10:47

The histology of the right parafissural liver parenchyma: collagen is the basis for a hypoattenuating pseudolesion on CT

W.M. Klein¹, L. Sonnemans¹, S. Franckenberg², D. Gascho², M. Prokop¹, W.H. Lamers³, J.P.J.M. Hiksboers³, M. Thali², P. Flach⁴, ¹Nijmegen/NL, ²Zurich/CH, ³Maastricht/NL, ⁴St. Gallen/CH (willemijn.klein@radboudumc.nl)

Purpose: CT images of a healthy liver may show a hypoattenuating area on the right side of the falciform ligament, often noticed in the portovenous enhanced phase, and interpreted as a pseudolesion or a malignancy. The purpose of this study was to evaluate the histology of the parafissural liver parenchyma in healthy livers, and find clues for aetiology.

Methods and Materials: Biopsies of the right and left parafissural liver parenchyma were performed either during autopsy or postmortem CT. Histology was examined for the amount of collagen and fat. Left and right side parenchymas were compared using t tests and correlated to CT attenuation.

Results: 52 cadavers were included. Mean CT attenuation at the right side of the ligament was 44.9 HU (SD16.7) and left side 46.4 HU (SD16.3) (p 0.32). Excluding the fibrotic (>2% collagen) and steatotic (>5% fat) livers (n=36), significantly more collagen content was present at the right side: mean 0.71% (SD 0.49), compared to left side 0.51% (SD 0.30) (p 0.024), with equal fat

content. CT attenuation was correlated to age (Pearson -0.412, p 0.004), not to collagen or fat content.

Conclusion: The right parafissural liver parenchyma contains more collagen and an equal amount of fat compared to the left side in healthy livers. We suggest that the high collagen on the right side is a consequence of normal embryological development with disadvantaged supply to the side that is prone to becoming a pseudolesion.

B-0069 10:55

Focal peliosis hepatis: imaging features of magnetic resonance imaging with diffusion-weighted imaging

W. Mingliang, M. Zeng; Shanghai/CN (wang.mingliang@zs-hospital.sh.cn)

Purpose: To investigate the MRI and DWI (diffusion-weighted imaging) features of focal peliosis hepatis (focal PH).

Methods and Materials: The clinical and MRI data of 19 cases diagnosed as focal peliosis hepatis by pathology were retrospectively analysed. MR scan of the upper abdomen was performed preoperatively in all patients. The imaging features of the lesions were analysed, including number, location, size, shape, signal intensity, enhancement pattern, vessels within and around lesions, and perfusion disorders of hepatic parenchyma. The ADC values of the lesions and adjacent hepatic parenchyma were measured, and the differences were explored statistically.

Results: In all 24 lesions, 22 lesions were located in the right lobe and 2 lesions in the left lobe. The median size was 24.4 ± 17.2 mm (7.5-72 mm). On T1WI, 21 lesions showed slight hypointensity, 1 lesion showed slight hyperintensity and 2 lesions were isointense; all 24 lesions showed slight hyperintensity on T2WI, and isointensity or slight hyperintensity on DWI. The mean ADC value was $(1.511 \pm 0.415) \times 10^{-3}$ mm²/s in the lesions and $(1.769 \pm 0.690) \times 10^{-3}$ mm²/s in the adjacent hepatic parenchyma, which showed no difference between the two groups ($P > 0.05$). On dynamic MR images, 20 lesions showed gradually filling enhancement, 4 lesions showed markedly persistent enhancement. Punctiform or filliform vessels were found in 9 lesions. Adjacent hepatic perfusion disorders showed in 8 lesions.

Conclusion: The MRI performance of focal peliosis hepatis had a certain characteristic. MRI combined with diffusion-weighted imaging could help to make diagnoses.

B-0070 11:03

Negative biopsy of focal hepatic lesions: decision tree model for patient management

F. Vernuccio, M. Rosenberg, M. Meyer, R.C. Nelson, D. Marin; Durham, NC/US (federicavernuccio@gmail.com)

Purpose: To investigate patient- and procedure-related variables affecting the false-negative rate of US-guided liver biopsy, and to develop a standardized patient-tailored predictive model for the management of negative biopsy results.

Methods and Materials: We retrospectively included 389 patients (mean age 62 years \pm 12) undergone US-guided liver biopsy of 405 liver lesions between January 1, 2013 and June 30, 2015. We collected multiple patient- and procedure-related variables. By comparing pathology reports of biopsy and the reference standard (further histology or imaging follow-up), the biopsy results were categorized as true-positive, true-negative and false-negative. Diagnostic accuracy and diagnostic yield were measured. Univariate and multivariate analysis was performed to identify variables predicting false-negative results. A standardized patient-tailored predictive model of false-negative results based on a decision tree was fitted.

Results: Diagnostic accuracy and diagnostic yield were 93.8% (380 of 405) and 89.4% (362 of 405), respectively. The false-negative rate was 6.5% (25 of 387). Predictive variables of false-negative results at univariate analysis included body mass index, lesion size, sample acquisition techniques, and immediate specimen adequacy. The only independent predictors at multivariate analysis were patient age and Charlson Comorbidity Index. By combining lesion size and location with patient age and history of malignancy, we developed a decision tree model that predicts false-negative results with high confidence (up to 100%).

Conclusion: False-negative results are not negligible at US-guided liver biopsy. The combination of selected lesion- and patient-specific variables may help predicting patients with false-negative results where aggressive management may be warranted.

B-0071 11:11

Enhancement pattern of hepatocellular adenoma (HCA) on MR imaging performed with Gd-EOB-DTPA vs other Gd-based contrast agents (GBCAs): an intraindividual comparison

R. Cannella¹, G. Brancatelli¹, B. Rangaswamy², M.I. Minervini², A.A. Borhani², A. Furlan²; Palermo/IT, ²Pittsburgh, PA/US (rob.cannella@libero.it)

Purpose: To conduct an intraindividual comparison of the enhancement pattern of HCA on dynamic MRI study obtained following the injection of Gd-

EOB-DTPA and other GBCAs.

Methods and Materials: This is a retrospective, IRB-approved study conducted in a single institution. A search of medical records between 2008 and 2017 revealed 17 patients (all females) with at least one pathologically proven HCA who underwent liver MRI with Gd-EOB-DTPA and another GBCA (Gd-BOPTA, $n=14$; Gd-DTPA, $n=1$; Gd-DTPA-BMA, $n=1$; Gd-BT-DO3A, $n=1$) within 1 year. Enhancement of each lesion on hepatic arterial (HAP), portal venous (PVP), 2-minute and 4- to 5-minute phases was qualitatively evaluated by two abdominal radiologists. Lesions were categorised as hyper-, iso- or hypointense compared to the surrounding liver parenchyma. The presence of a peripheral pseudocapsule was also recorded. The differences in lesion enhancement were assessed using the Wilcoxon signed rank test. A p value < 0.05 was considered statistically significant.

Results: The final population included 35 HCAs (83% inflammatory subtype). There was no significant difference in lesion size ($P=0.708$) and enhancement on HAP ($P=0.317$). HCAs showed more frequently hypointensity on PVP (5/35 vs 1/35, $P=0.046$), 2-minute (13/35 vs 1/35, $P=0.001$) and 4- to 5-minute ($P < 0.001$) images obtained after injection of Gd-EOB-DTPA compared to those obtained after other GBCAs. A pseudocapsule was more frequently noted after administration of Gd-EOB-DTPA (13/35 vs 1/35, $P=0.001$).

Conclusion: Enhancement pattern of HCA differs significantly after the injection of Gd-EOB-DTPA compared to other GBCAs. Lesion hypointensity on PVP, 2-minute and 4- to 5-minute images are more frequent when using Gd-EOB-DTPA.

Multi-arterial phase EOB-MRI: different contrast enhancement pattern of focal nodular hyperplasia and hepatocellular carcinoma

S. Fiore, R. Faletti, F. Gentile, L. Pavan, F. Guarasci, M. Gerboni, M. Donalizio, M. Gatti, P. Fonio; Turin/IT (fyorello@gmail.com)

Purpose: To characterise the enhancement pattern of FNH and HCC with triple-phase arterial MRI acquisition.

Methods and Materials: Study population included 52 patients who had arterial enhancing hepatic lesions (41 HCC and 31 FNH). All patients underwent triple-phase arterial MRI acquisition using hepatocyte-specific agents (Gd-EOB-DTPA). Images were reviewed by two radiologists in consensus: contrast enhancement ratios (CER), liver-to-lesion contrast ratios (LLCR) and signal intensity (SI) were measured. Lesions were categorised based on the peak of LLCR into the following groups: 1) angiographic, 2) early arterial and 3) late arterial. Data were analysed using Wilcoxon signed-rank test.

Results: There was no difference in CER between FNH and HCC patients ($p > 0.09$). LLCR_{FNH} were significantly higher than LLCR_{HCC} in angiographic phase ($p=0.01$), whereas there was no difference in the other phases ($p=0.20$ and $p=0.82$, respectively). Moreover, in HCC group there was a significant increase of LLCR between early and middle phases ($p=0.009$) whereas in FNH group there was a decrease between the middle and the late phases ($p=0.004$). This behaviour was paralleled by the subgroup divisions: 17 (55%) FNH were classified as the 1st group, 11 (35%) as the 2nd and only 3 (10%) as the 3rd; on the other hand, the HCC were homogeneously distributed (34%, 32% and 34%).

Conclusion: This study highlights the different enhancement patterns of HCC and FNH: FNH resulted more conspicuous in the angiographic phase and the best phases for optimal visualisation of FNH were the early and middle arterial phases, whereas for HCC were the middle and the late arterial phases.

B-0073 11:27

Intra-individual comparison of contrast enhancement rates of focal liver lesions in DCE-MRI with gadoxetic acid vs gadobutrol

N.A. Bünting, A. Barabasch, C.K. Kuhl; Aachen/DE (nbunting@ukaachen.de)

Purpose: Gadoxetic acid is widely used not only for hepatobiliary phase imaging, but also as regular extracellular contrast agent for dynamic, contrast-enhanced (DCE) MR-imaging of focal liver lesions. We aimed to systematically investigate the utility of gadoxetic acid for this purpose, in comparison to gadobutrol-enhanced MRI obtained in the same patients.

Methods and Materials: 71 consecutive patients underwent DCE-MRI according to a standardized protocol on two different occasions, once with gadoxetic acid and once with gadobutrol. 26/71 patients had enhancing focal liver lesions not receiving treatment in between MRI studies. A T1-weighted 3D dynamic GRE sequence was obtained before and at defined intervals in the arterial, portal venous and equilibrium phase after i.v. application of gadoxetic acid or gadobutrol. ROIs were carefully placed in the identical enhancing position of each focal liver lesion in order to calculate and compare enhancement rates and lesion-parenchyma-contrast.

Results: Mean enhancement rates of focal liver lesions were significantly higher for gadobutrol compared to gadoxetic acid for all dynamic phases: Arterial phase 170% vs 61%, portal venous phase 250% vs 134% and equilibrium phase 216% vs 118% (each $p < 0.001$). The lesion-parenchyma-contrast in the corresponding phase of DCE-MRI was also significantly higher for gadobutrol in each dynamic phase: arterial phase 1.5 versus 1.2, portal venous phase 1.1 versus 1.0, equilibrium phase 1.2 versus 0.9 (each $p \leq 0.03$). **Conclusion:** Compared to gadobutrol, gadoxetic acid is associated with significantly lower enhancement of focal liver lesions. This will impair the detection and characterization of focal liver lesions, especially those with arterial enhancement.

B-0074 11:35

A predictive model for early recurrence of hepatocellular carcinoma after tumour resection based on whole lesion MR imaging radiomics features

Z. Zhang, H. Jiang, L. Cao, Z. Ye, J. Chen, B. Song; Chengdu/CN
(zhangzhen950708@163.com)

Purpose: To prospectively develop and validate a prediction model for early recurrence (<1 year) of hepatocellular carcinoma (HCC) using whole lesion radiomics features on preoperative gadoxetic acid-enhanced MR images.

Methods and Materials: 114 patients (79 in the training cohort and 35 in the validation cohort) with surgically confirmed HCC were enrolled in this IRB-approved study. Three-dimensional whole-lesion regions of interest were manually delineated along the tumour margins. Radiomics features were selected to build a radiomics signature using least absolute shrinkage and selection operator (LASSO) method in the training cohort. Qualitative radiological features were evaluated by two independent reviewers. Independent risk factors were identified and combined to establish a clinical-radiological model. Finally, a combined prediction model comprising the radiomics signature and all risk factors was constructed. All models were developed in the training cohort with multivariate regression analysis, and their diagnostic performances were measured by receiver operation characteristic (ROC) and decision curves and validated in an independent validation cohort.

Results: Fifty early recurrences (49.1%) were confirmed by imaging follow-up. 14 radiomics features were selected to construct the radiomic signature. The radiomics signature showed comparable performance with the clinical-radiological model in the training cohort (AUC=0.842 vs 0.885; $P > 0.05$) and the validation cohort (AUC=0.837 vs 0.880; $P > 0.05$). The combined prediction model outperformed both the radiomics signature and the clinical-radiological model in predicting early recurrence in the training and validation cohorts (AUC=0.942 and 0.890, respectively) with incremental clinical usefulness.

Conclusion: Prediction model, based on multi-sequence whole lesion MRI radiomics features, demonstrated potential in the preoperative prediction of early recurrence for HCC.

B-0075 11:43

Using MRI or CT for preoperative evaluation of HCC makes the clinical outcome different

Y.-C. Chou; Tainan/TW (yichenchou@hotmail.com)

Purpose: The recurrent rate of hepatocellular carcinoma (HCC) after treatment is high, at least partly because detecting small HCCs can be challenging before treatment. We hypothesized that different imaging modalities or using different contrast agents may affect the clinical outcome.

Methods and Materials: We retrospectively analyzed 698 patients with HCC (BCLC 0, A, B) underwent curative treatments, i.e. the operation or/and radiofrequency ablation between 2011 and 2017. There were 170 patients receiving MR with the liver-specific contrast agent (Gd-EOB-DTPA, Primovist), 111 patients having MR with nonspecific contrast agents, 188 patients having contrast-enhanced CT. Biological markers were also analyzed. After curative treatment, patients received imaging follow-up annually. Multivariate analysis and propensity score matching were used. The overall survival and tumor-free survival were calculated using the Kaplan-Meier method and compared between groups using the log-rank test.

Results: There was no significant difference in AJCC stage, Child-Pugh score, albumin-bilirubin (ALBI) score between CT and MR groups. However, the overall survival and tumor-free survival were significantly higher in MR groups than the CT group, with p -value < 0.0001 and 0.0006 , respectively. The overall median survival for CT and MR group were 3.3 and 4.0 years; and the median tumor-free survival for CT and MR groups were 1.8 and 2.4 years, respectively. The difference in clinical outcome between using liver-specific and non-specific MR contrast was not statistically significant.

Conclusion: Using contrast-enhanced MRI as the preoperative imaging modality for patients with HCC provides significantly better clinical outcomes than using dynamic CT.

B-0076 11:51

Outcomes of Yttrium-90 radioembolic treatment for large monofocal hepatocarcinoma in BCLC-A stage patients: a single-centre experience

T. Gorgatti, A. Vit, M. Sponza, V. Gavrilovic, A. Pellegrin, F. Rosella, R. Girometti; Udine/IT (tommaso.gorgatti@yahoo.it)

Purpose: There is no definite treatment for Barcelona Clinic Liver Cancer (BCLC) stage-A patients with large (>5 cm) monofocal hepatocarcinoma (HCC). We evaluated the outcomes of transarterial radioembolization (TARE) in this setting.

Methods and Materials: We retrospectively reviewed the clinical history of thirty subjects with BCLC stage-A patients with large monofocal HCC in whom TARE was offered as initial treatment between 2005-2017. TARE was performed by a pool of four interventional radiologists. Post-procedural follow-up was performed with multidetector computed tomography (MDCT) or magnetic resonance imaging (MRI) according to the Response Evaluation Criteria In Solid Tumors (RECIST) version 1.1 and/or modified-RECIST. We used Kaplan-Meier and Cox regression analyses to determine overall survival (OS) and time-to-progression (TTP), entering baseline clinical and laboratory features.

Results: Patients showed age ≥ 70 years in 16/30 cases (53%), male gender in 25/30 cases (83%), and predominant alcoholic- or HCV-related cirrhosis (22/30; 73%). Median OS was 28 months (range 10.7-45.3). Child-Pugh score B7 was the only independent predictor of shorter OS ($p < 0.05$, HR: 67.00). There was a trend toward shorter survival in larger tumors ($p = 0.098$, HR: 3.85) and increased Model for End-Stage Liver Disease (MELD) score ($P = 0.066$, HR: 4.60). Median TTP was 18 months (range 0.0-37.2). Multivariable analysis showed no independent predictors, despite a trend towards shorter TTP for higher MELD score ($P = 0.075$, HR: 5.80) and previous liver-directed therapy ($P = 0.059$, HR: 13.16).

Conclusion: TARE is a valid therapeutic option in BCLC stage-A patients with large monofocal HCC, with less satisfying results in patients with higher Child-Pugh and MELD scores.

Influence of annual reader volume on performance in a mammography screening program with independent double reading and consensus of digital mammograms

S.R. Hoff^{1,2}, T. Myklebust^{2,3}, S. Hofvind³, ¹Trondheim/NO, ²Aalesund/NO, ³Oslo/NO (solveig.roth.hoff@helse-mr.no)

Purpose: To study the influence of annual screen-reader volume on radiologists' performance in a mammography screening program using independent double reading with consensus of digital mammograms.

Methods and Materials: We collected retrospective data from 2,373,433 digital mammograms read by 121 radiologists in BreastScreen Norway from 2006-2016. Logistic regressions with robust standard errors were used to explore how sensitivity, false-positive rate (FPR), accuracy (sensitivity/FPR) and screening-cancer detection rate (SDC) were related to annual reading volume.

Results: In the range from 100 to 10,000 annual screen readings, sensitivity increased from 87 to 89%. For higher volumes, there was a decline in sensitivity to 75% at 18,000 annual readings. The FPR declined from 6.7% at 100 annual readings to 4.5% at 4000, to 4.0% at 10 000 and to 3.0% at 18 000 annual readings. Accuracy increased with 50% from 100 to 4000 annual readings, with 15% from 4000 to 10,000 and with 12% from 10,000 to 18,000 annual readings. The SDC was 4.8/1000 at 100 annual readings and 5.1/1000 at 10,000 annual readings. For higher volumes, the SDC rate declined to 3.2 per 1000 at 18,000 annual readings.

Conclusion: Our study indicated that increasing annual reader volume had only a minor effect on sensitivity or SDC rate, except for a decline in performance for readers with extremely high annual volumes. The FPR improved with increasing annual reader volume, most markedly up to an annual volume of 4000 readings.

B-0078 10:38

Conversion to digital mammography had no impact on invasive grade 3 cancer detection in the English NHS breast cancer screening programme: analysis of 11.3 million screening tests

R.G. Blanks¹, M. Wallis², R. Alison¹, J. Jenkins³, O. Kearins⁴, J. Patrick¹, R.M. Given-Wilson³; ¹Oxford/UK, ²Cambridge/UK, ³London/UK, ⁴Birmingham/UK (rosalind.given-wilson@stgeorges.nhs.uk)

Purpose: To describe and model the impact of conversion from film screen mammography (FSM) with full-field digital mammography (FFDM) in the English NHS breast cancer screening programme.

Methods and Materials: Annual screening data (KC62 returns) for each of the 80 units over the seven years from 2009/10 to 2015/16 were used to examine the impact of changing from FSM to FFDM. Regression models were used to estimate percentage and absolute change in detection rates.

Results: The recall rate to assessment (approximately 3.9%) was almost unchanged by the introduction of FFDM. After conversion to FFDM the overall cancer detection rate rose from 6.95 to 7.95 per 1000 screens, 14% (11%-17%) p<0.001. High-grade DCIS detection rate rose from 0.71 to 1.00 per 1000, 39% (28%-50%) p<0.001. Invasive grade 1 and 2 detection rate rose from 4.30 to 4.93, per 1000: 14% (10%-18%) p<0.001. Invasive grade 3 detection did not change from 1.20 to 1.22, per 1000: 2% (-5%-9%) p=0.53. The magnitude of the effect for high-grade DCIS and grade 1 and 2 invasive cancers was greater for first (prevalent) screen (age 45-52 years). Grade 3 detection rates were not affected by screen type.

Conclusion: Digital mammography has increased the overall sensitivity of screening by increasing the cancer detection rate at the same recall rate as film screen and, therefore, improved the effectiveness of the screening process. However, there has been no increase in the detection of potentially life-threatening grade 3 cancers.

B-0079 10:46

The mammographic features of 13,213 women with screen-detected non-invasive breast disease

M.G. Wallis¹, K. Clements², B. Hilton², J. Litherland³, A.J. Maxwell⁴, N. Sharma⁵, A. Thompson⁶; ¹Cambridge/UK, ²Birmingham/UK, ³Glasgow/UK, ⁴Manchester/UK, ⁵Leeds/UK, ⁶Houston, TX/US (matthewwallis492@btinternet.com)

Purpose: To describe the mammographic features of screen-detected carcinoma in situ and atypical hyperplasia in the United Kingdom (UK) Breast Screening Programme.

Methods and Materials: The Sloane project is a prospective audit of women with screen-detected non-invasive breast cancer and atypia. Screening units in the UK were encouraged to register patients and complete forms documenting imaging features, surgical management, pathology and radiotherapy (if applicable). Data were collected from 1 April 2003 to 24 October 2018.

Results: 14,057 women are registered from 82 of the 90 UK screening units to date. 13,213 have a complete pathology record: 11,335 DCIS and 1,878 'atypia'. Overall, micro-calcification was the predominant radiological feature in 11,087 (83.9%) and was present in 11,638 (88.1%). The presence of micro-calcification was directly related to 'grade': FEA 80.6%, ADH 72.1%, low-grade DCIS 79.1%, intermediate 84% and high-grade DCIS 94.5% (trend for DCIS grade Chi² 522.9 df=2, p<0.0001). Of those women with calcification, casting/linear calcification increases with 'grade': FEA 8.8%, ADH 12.5%, low-grade DCIS 19.4%, intermediate 30.6%, and high-grade DCIS 50.6%. A mass was the predominant feature in 16.8%, 17.6%, 19.3%, 14.4%, and 4.1%, respectively. After calcification, parenchymal distortion was the predominant radiological feature in 14.2% (125 of 878) cases of LISN compared to 3.3% of the other pathologies combined.

Conclusion: As the 'aggressiveness' of non-invasive screen detected cancer/atypia increases, the proportion of women presenting with calcification (and linear casting morphology) and the proportion with a mass as the predominant radiological feature decreases.

B-0080 10:54

Can we optimise the recall rate and reduce overdiagnosis? An analysis of 11.3 million screening tests from the English NHS breast cancer screening programme

R.G. Blanks¹, R.M. Given-Wilson², S. Cohen², J. Jenkins², J. Patrick¹, R. Alison¹, M.G. Wallis³; ¹Oxford/UK, ²London/UK, ³Cambridge/UK (matthewwallis492@btinternet.com)

Purpose: To model the association between cancer detection and recall rates to understand the optimal balance of harm and benefit.

Methods and Materials: Non-linear and linear regression models were used to examine and model the association between recall rate and cancer detection rate using annual screening programme information for the 80 English breast screening units (11.3 million screening tests) supplemented by previously published data from the Dutch screening programme.

Results: Low recall rates are associated with low cancer detection. As recall rates rise, the model indicates that the cancer detection rate for invasive cancers and high-/intermediate-grade DCIS reaches a near-plateau above which almost all recalls are false positive. The cancer grade predicts the point the recall rate reaches plateau. For incident screens the recall rate above which almost no additional cancers are found is 2.5% for both grade 3 and high-grade DCIS. 3.9% for grade 2 and 5.2% for grade 1. However, for low-/intermediate-grade DCIS (LIG) detection rate has no discernible plateau with detection rate increasing linearly at a rate of 0.12 (prevalent) and 0.18 (incident) per 1000 for every 1% increase in recall rate.

Conclusion: Our model predicts that there is an optimum range for recall that maximises detection of life-threatening cancers, whilst minimising harm (in England this is between 4.6% and 7% at prevalent screen and between 2.6% and 4% at incident screens).

B-0081 11:02

Additional breast cancer detection at screening mammography through quality assurance sessions between screening radiographers and coordinating screening radiologists

A.M.P. Coolen¹, B. Korte², L.E.M. Duijm³; ¹Tilburg/NL, ²Eindhoven/NL, ³Nijmegen/NL (a.coolen88@hotmail.com)

Purpose: To determine the number and characteristics of cancers additionally detected through quality assurance sessions between screening radiographers and coordinating screening radiologists.

Methods and Materials: We included a consecutive series of 431666 biennial screening mammograms, obtained at a Dutch breast cancer screening region between January 1, 2009 and July 31, 2016. Each screen was double read by 2 certified screening radiologists and the radiographers were encouraged to classify each obtained mammogram according to BI-RADS. At regular 6 week intervals the group of screening radiographers discussed with a coordinating screening radiologist the mammograms of women that were not recalled by the screening radiologists but considered suspicious by the radiographers. The coordinating radiologist then decided for each case whether secondary recall was indicated. During 2-year follow-up, we obtained data on radiological and pathological outcome of all recalled women.

Results: Altogether, 13175 women were recalled (recall rate: 3.1%), of which 2940 were diagnosed with breast cancer (6.8 cancers detected per 1000 screens). A total of 82 women (0.6% of recalls) experienced a secondary recall after the quality assurance sessions, of which 26 (31.7%) proved malignant. These 26 cancers comprised 8 ductal carcinoma in-situ (low grade: 1; intermediate grade: 7; high grade: 2) and 18 invasive cancers (≤10 mm: 1; 11-20 mm: 13; >20 mm: 4. B&R I: 9; B&R II: 7; B&R III: 2).

Conclusion: About 1% of the cancers are detected through the quality assurance sessions. A majority of these cancers is invasive and >10 mm and therefore probably not reflecting overdiagnosis.

B-0082 11:10

Two decades of biennial screening mammography: trend in the incidence of delayed breast cancer diagnosis after repeated recall for the same mammographic abnormality

B. Korte¹, J.R.C. Lameijer¹, L.E.M. Duijm²; ¹Eindhoven/NL, ²Nijmegen/NL (lemduijm@hotmail.com)

Purpose: Multidisciplinary meetings and dedicated radiological modalities (e.g., MRI, tomosynthesis) are increasingly used for the evaluation of recalled women. We determined the trend in the incidence of delayed breast cancer diagnosis after repeated recall for the same abnormality at screening mammography.

Methods and Materials: We included all women aged 50-75 years who underwent screening mammography in a Dutch breast cancer screening region between July 1, 1996 - June 30, 2006 (cohort I) and between July 1, 2006 and June 30, 2016 (cohort II). Data were collected on radiologic procedures and histopathology for all recalled women, with a follow-up period of at least 2 years. For each woman with a repeated recall and histological confirmation of breast cancer at the latest recall, two radiologists independently determined whether the woman had been recalled for this lesion at a previous screen.

Results: A total of 1411 recalled women were diagnosed with breast cancer among the 280184 screens of cohort I, resulting in a cancer detection rate (CDR) of 5.0 per 1000 screens. In 28 of these women (2.0%), a repeated recall for the same mammographic abnormality proved malignant. Among the 507828 screens of cohort II, 3504 recalled women had breast cancer, with a CDR of 6.9. In 71 (2.0%) women, a repeated recall for the same screening abnormality showed malignancy.

Conclusion: No decline in the proportion of women with a >2 year delay in breast cancer diagnosis was observed. The workup of recalled women in the Dutch breast cancer screening programme needs improvement.

B-0083 11:18

Frequency and outcome of bilateral recall at screening mammography
 J.R.C. Lameijer¹, J. Nederend¹, A.C. Voogd², V.C. Tjan-Heijnen², L. Duijm³,
¹Eindhoven/NL, ²Maastricht/NL, ³Nijmegen/NL (joostlameijer@gmail.com)

Purpose: To determine the frequency of bilateral recall at screening mammography and compare outcome with that of unilateral recall.

Methods and Materials: We included a consecutive series of 197,566 screening mammograms obtained between January 1, 2014 and January 1, 2017. During 2-year follow-up, clinical data were collected of all recalls. Screening outcome parameters were determined for women with unilateral and bilateral recall.

Results: A total of 5,629 women were recalled (recall rate 3.0%), of which 153 (2.6% of recalls) comprised a bilateral recall. Biopsy was more frequently performed in women with bilateral recall compared to unilateral recall (P<0.001). The proportion of DCIS among screen detected index cancers (lesion with highest BI-RADS) was comparable for unilateral and bilateral recall (P=0.3). Invasive index cancers after bilateral recall showed a worse tumour grading than those after unilateral recall (P=0.04). The proportion of lymph node positive invasive cancers was comparable for both groups (P=0.7), as well as hormone receptor characteristics of bilateral breast cancer after unilateral and bilateral recall. There was no difference in the proportion of true positives after unilateral versus bilateral recall (P=0.8). Unilateral recall showed a better PPV for biopsy (P=0.01).

Conclusion: Bilateral recalls comprise a small proportion of all recalls. After bilateral recall, biopsy is more frequently performed compared to unilateral recall, with a better PPV of biopsy after unilateral recall. Tumour characteristics of index cancers and bilateral breast cancers are comparable for unilateral and bilateral recall, except for a worse tumour grading of invasive index cancers after bilateral recall.

B-0084 11:26

Solitary dilated duct visualised by mammography: are we correctly classifying according to BI-RADS lexicon 5th edition?

V.J. Ayres¹, E.F. Fleury², L. Ramalho², L.d. Pompei², ¹Santo André/BR, ²São Paulo/BR (ayresve@gmail.com)

Purpose: To determinate the incidence, pathological significance and risk factors associated with the presence of solitary dilated duct visualised at mammography.

Methods and Materials: Prospectively evaluation of consecutive mammography was performed in a breast cancer control center, in accordance with local ethical approval. Patients with solitary dilated duct (SDD) at mammography were referred to additional second-look ultrasonography (US). SDD with intraductal components were submitted to percutaneous biopsy, following anatomopathological correlation. Exclusion criteria considered patients previously submitted to breast surgery.

Results: In the period from March 17, 2016 to March 10, 2017, 9,035 mammographic exams were included, 8,125 (90%) screening and 910 (10%) diagnostic exams. 135 SDD (1.49%) were identified at mammography and 94 (1.04%) second-look US were performed. Of these, 22 revealed intraductal components and had percutaneous biopsy performed. No cancer was found at biopsy results. The most prevalent histological findings were: 8 papillomas and 8 fibrocystic changes. Risk factors for mammographic SDD with statistical significance (p<0.05), using *T* test were: breast density pattern "A" or "B", breastfeeding, pregnancy, hormone replacement therapy and papillary discharge. Main mammographic and US findings associated with second-look US papilloma diagnostic with statistical significance (p<0.05), using *Chi Quadrado* test: suspicious calcification, duct diameter > 3.0mm at US, intraductal mass and hard lesion at elastography.

Conclusion: SDD at mammography benefits from second-look US for analysis of intraductal content's, which often presents benign findings. When intraductal mass was found, the main result was papilloma. We propose that SDD at mammography should be classified as BI-RADS category 0.

B-0085 11:34

Outcome of microcalcifications classified as BI-RADS 3, 4a and 4b in patients with and without a history of breast cancer

V. Bertani¹, M. La Grassa², L. Balestrieri³, N. Berger⁴, M. Urbani³, K. Lang⁵, A. Boss¹, T. Frauenfelder⁴, M. Marcon⁴, ¹Udine/IT, ²Pordenone/IT, ³Aviano/IT, ⁴Zurich/CH, ⁵Malmö/SE (magda.marcon@usz.ch)

Purpose: To compare the outcome of microcalcifications classified as BI-RADS3, 4a and 4b at mammography in patients with a history of breast cancer to that of women undergoing mammography screening.

Methods and Materials: 176 patients (mean age 61 years) with microcalcifications classified as BI-RADS3, 4a and 4b, without sonographic correlation, whom had undergone vacuum-assisted biopsy (VAB) between Oct 2016-Oct 2017 were retrospectively included. The agreement imaging/pathologic result from VAB was verified and for BI-RADS4b lesions and B2 pathologic result excisional biopsy was performed. For each BI-RADS

category, pathologic results from VAB in case of B2 diagnosis and from surgical specimens in all the other cases were compared between patients with a history of breast cancer (group A, n=45) and women undergoing screening (group B, n=131). Positive predictive values (PPVs) were compared using Fisher's exact test.

Results: A total of 73 lesions were classified as BI-RADS3(41.5%), 57 BI-RADS4a(32.4%) and 46 BI-RADS4b(26.1%). The overall PPV for BI-RADS 3, 4a and 4b were 5.5%(4/73), 10.5%(6/57) and 58.7%(27/46). The PPV for BI-RADS3 lesions in group A and B were 13.0%(3/23) and 2.0%(1/50), respectively (p=0.089). The PPV for BI-RADS4a lesions in group A and B were 15.4%(2/13) and 9.1%(4/44), respectively (p=0.611). The PPV for BI-RADS4b lesions in group A and B were 77.8%(7/9) and 54.0%(20/37), respectively (p=0.270).

Conclusion: The likelihood of malignancy in cases of microcalcifications classified as BI-RADS 3, 4a and 4b at mammography tends to be higher in women with a history of breast cancer than in women undergoing screening, the difference was however not statistically significant.

B-0086 11:42

Architectural distortions with microcalcifications: a mammographic malignancy predictor of B3 lesions?

I. De Serio, K. Jerman, V. Londero, C. Zuiani, Udine/IT (Isdeserio@gmail.com)

Purpose: Breast borderline lesions (B3) demonstrates variable (9%-35%) malignancy upgrade rate on surgical excision (SE). Our purpose was to evaluate the existence of a mammographic (Mx) finding able to predict the likelihood of malignancy on SE of Mx only B3 lesions, without US correlate, that underwent tomobiopsy-guided vacuum-assisted biopsy (VAB).

Methods and Materials: Between March 2015-March 2018 we have retrospectively analyzed 88 B3 lesions (10 papillary lesions [PL], 44 radial sclerosing lesions [RSL], 13 atypical ductal hyperplasia [ADH], 21 lobular neoplasia [NL]). Mx findings were divided into 4 categories: microcalcifications (MI), architectural distortions (DA), masses (MA) alone-associated to other Mx findings, and architectural distortions with microcalcifications (DA+MI). The relation between Mx findings and malignancy upgrade rate on SE was evaluated with exact Fisher test.

Results: An overall upgrade rate of 16% (14/88) was observed for presence of malignancy at SE (9 intraductal carcinomas G1-G2, 2 intraductal carcinomas G3, 1 invasive ductal-lobular carcinoma G2 and 2 invasive lobular carcinomas G2). Mx findings were MI on 32 cases (36%), DA on 31 cases (35%), MA on 14 cases (16%) and DA+MI on 11 cases (13%). A statistically significant association was found between malignancy upgrade rate and lesions having DA+MI as Mx finding (p=0.01). None significant association was found in the other Mx findings. Positive predict values were 10% for PL (1/10), 14% for RSL (6/44), 31% for ADH (4/13) and 14% for NL (3/21).

Conclusion: A high statistically significant likelihood of upgrade was found for B3 lesions that Mx present as DA+MI.

B-0087 11:50

False-positive recall in screening mammography: pitfalls of challenging mammogram

F. Leone¹, M.A. Orsi¹, M. Cellina¹, A. Presazzi², D. Mariani¹, G. Oliva¹;
¹Milan/IT, ²Pavia/IT (federica-leone@live.it)

Purpose: to review the most common feature in false positive recall in order to suggest a strategy for assessment of challenging screening mammogram

Methods and Materials: We reviewed a retrospective cohort of 7230 patients involved in Mammogram Screening program between November 2015 and September 2018. We included the false positive recall which at second level exam have been classified as BIRADS 1 or 2. We evaluated two different groups according to agreement recall (AR) or disagreement recall(DR). We compared the differences among tumoral imaging features between the two groups and considering also the overall findings prevalence in screening recall (SR)

Results: We obtained a final cohort of 1157 suspicious findings whose 416(35.9%) have been in AR group and 741(64.1%) in DR group. In the AR group we found, as single or one of multiple features in suspicious lesion, 287(69%) mass, 26 (6.25%) calcifications, 78(18.75%) architectural distortion and 25(6%) asymmetric density; in the DR group we detected 578(78%) mass, 89(12%) architectural distortion, 43(6%) asymmetric density, 31(4%) calcifications. Differences in tumor imaging features between the two groups were statistically significant (p<0.05)

Conclusion: Our results show how mass is the most common feature in false positive recall with no changes between one or two readers. Calcification, when classified as BIRADS 2, is a rare challenging feature, mostly due to the breast radiologist's expertise. Our study proves how Screening Program is a good tool to avoid false positive recall for architectural distortion and asymmetric density, considering the higher prevalence of these findings in recall group

Wavelet parameter maps of perfusion-weighted MRI correlate to tumour vascularity and cell proliferation in glioblastoma

T. Huber¹, L. Rotkopf¹, S. Bette¹, C. Preibisch¹, J. Gempt¹, T. Pyka¹, K. Thierfelder², B. Wiestler¹; ¹Munich/DE, ²Rostock/DE

(Thomas.Huber@med.uni-muenchen.de)

Purpose: Wavelet-based reconstructions of dynamic susceptibility contrast (DSC) perfusion weighted imaging (wavelet-PWI) are a new and elegant way of vascular visualization. Wavelet-PWI yields maps with a clear depiction of hypervascular tumour, as recently shown. The aim of this study was to show if the wavelet-PWI power spectrum signal in tumour tissue is associated with tumour vascularity and cell proliferation in glioblastoma multiforme (GBM).

Methods and Materials: For this IRB-approved study 12 subjects (63.0±/14.9y; 7m) with histologically confirmed GBM were included. Target regions for biopsies were prospectively marked on contrast-enhancing GBM regions as seen on preoperative 3T MRI T1-weighted images. During subsequent neurosurgical tumour resection 27 targeted biopsies were taken intraoperatively from these target regions. All specimens were analysed for the endothelial cell marker CD31 and the proliferation marker MIB-1 and correlated to the wavelet-PWI power spectrum signal derived from dynamic susceptibility contrast (DSC)-MRI.

Results: Wavelet-PWI maps could be successfully calculated in 12/12 patients within less than 3 minutes. There was a strong correlation between wavelet-PWI power spectrum signal (median=4.41) and conventional relative cerebral blood volume (median=5.97 ml/100g) in Spearman's rank-order correlation ($\kappa=0.83$, $p<0.05$). The wavelet-PWI power spectrum signal showed a significant correlation to CD31 dichotomized to no or present staining in a logistic regression model ($p<0.05$) and a significant correlation to MIB-1 in a nonlinear generalized model ($p<0.05$).

Conclusion: The wavelet-PWI power spectrum signal derived from existing DSC-MRI data might be a promising new surrogate for tumour vascularity and cell proliferation in GBM.

Noncontrast ASL-perfusion in pre-surgical differential diagnosis of brain gliomas

A. Batalov, N. Zakharova, E. Pogobekyan, L. Fadeeva, A. Baev, S. Goryaynov, A. Kosyrkova, A. Potapov, I. Pronin; Moscow/RU (batalov89@gmail.com)

Purpose: To assess the tumour blood flow (TBF) in the supratentorial brain gliomas by ASL-perfusion in comparison with the histopathological characteristics and 5-ALA intraoperative fluorescence.

Methods and Materials: The study group included 186 patients (97 female, 89 male, avg. 45 ± 15 years) with primary supratentorial gliomas: 47 - low-grade (LGG) and 139 - high-grade (HGG: 50-grade III, 89-grade IV). Patients were examined on a 3T MR-scanner. The pseudo-continuous ASL (pcASL) technique was used to determine TBF. TBF was normalized regarding to intact white matter (nTBF). In 66 of 186 patients tumour resection was performed using fluorescence-guided technology. All diagnoses were confirmed histopathologically.

Results: TBF and nTBF in the groups of LGG and HGG were significantly different ($p<0.001$). TBF in the group of LGG was 31.55±15.75 ml/100g/min, nTBF was 1.69±0.82. In the group of HGG, the TBF was 154.63±92.86 ml/100g/min, nTBF was 8.36±5.30. The sensitivity and the specificity of ASL in diagnosis of LGG and HGG were 82.7% and 95.7%, accordingly, AUC 0.946, cutoff-64 ml/100g/min. TBF and nTBF in groups of GrIII and GrIV didn't show statistically significant difference ($p=0.08$). Nevertheless, we found a significant difference in TBF and nTBF between fluorescent and non-fluorescent gliomas ($p<0.05$). The sensitivity and specificity of pcASL in predicting fluorescence in gliomas was 77% and 71%, accordingly, AUC-0.722, cutoff-3.3.

Conclusion: pcASL is a reliable quantitative technique for the differential diagnosis between LGG and HGG. pcASL can be used in predicting intraoperative fluorescence in gliomas. The study was supported by RFBR №18-29-01018

Lesion and lesion habitat analysis on magnetic resonance imaging: an imaging biomarker for tumour grade and 1p19q deletion status

A. Alvi¹, F. Mubarak¹, A. Alvi², S. Enam¹, M. Shahzad¹; ¹Karachi/PK, ²Lahore/PK (aamnaalvi@gmail.com)

Purpose: The purpose of the study is to grade gliomas and predict 1p19q deletion status on the basis of MRI characteristics. Hypothesis: low-grade gliomas are more heterogeneous, less well circumscribed, have low mean ADC values, usually in frontal and parietal lobes and are 1p/19q codeleted.

Methods and Materials: Retrospective analysis of 97 patients (53 male, 44 female; age 20-70 years) with oligodendroglioma grade II and anaplastic oligodendroglioma grade III. Associations of 1p/19q deletion status and grading with imaging characteristics were assessed. Multivariable logistic regression models were used to assess the association of grading and 1p/19q deletion with imaging characteristics and results were summarised with odds ratios and 95% confidence intervals. P values of .005 were considered statistically significant. Statistical analysis was done using SPSS® v. 19 (SPSS Inc., Chicago, IL).

Results: Thirty-one of 97 patients had 1p/19q codeleted tumours (21= Grade II, 10= Grade III). They were mostly in frontal and parietal lobes showing heterogeneity, ill-defined margins and low ADC values (mean/SD: 1185.3/283.4). 66 patients did not show 1p/19q codeletion. They had circumscribed borders, mostly in temporal lobe and insula showing homogeneity and relative high ADC values (mean/SD: 1784.2/648.7).

Conclusion: Heterogeneous signal characteristics and less well circumscribed borders on T1, T2 and SWI with lower mean ADC values are features of low-grade gliomas and these are usually 1p19q codeleted tumours. Dealing with gliomas, MRI characteristics can predict tumour grade and 1p19q deletion status. In addition, this evaluation is recommended for better treatment planning and effective patient management and prognostication.

B-0091 11:03

Changes in high-grade gliomas after different kinds of radiation therapy depending on IDH status during chemotherapy in combination with bevacizumab

A.V. Smirnova¹, O.V. Lukina¹, A. Kuzmin¹, A. Tkachev², N. Plakhotina¹, M. Cherkashin¹, M. Anishkin¹; ¹St. Petersburg/RU, ²Volgograd/RU (smirnova_alina@bk.ru)

Purpose: Identification of consistent patterns for accurate MRI-based assessment of recurrence in patients with high-grade gliomas (HGG) treated with radiotherapy, chemotherapy and bevacizumab, taking IDH1 status into account.

Methods and Materials: 31 patients with HGG (Group A included 18 patients with IDH1-mutant tumour, Group B included 13 patients with IDH1-wild-type) treated with radiotherapy, chemotherapy (temozolomide and subsequently irinotecan) in combination with bevacizumab were prospectively studied between 2016 and 2018. Changes on T1CE, T2, flair, PWI and 11C-methionine PET/CT before radiotherapy, and after 4, 8, 12 and 16 months were evaluated. Tumour volume estimation was performed with GammaPlan workstation 10.1.

Results: The earliest features of recurrence were registered at 8 months after radiotherapy for IDH1-wild-type and 12 months for IDH1-mutant tumours during continued systemic therapy, and in 96.8% of cases were in a form of an increase in T2/Flair anomaly with unconvincing methionine uptake (1.4 or less). At the same time, T1CE showed no signs of pathological contrasting and PWI with no increase in CBV also. Only subsequent observations of T2/Flair hyperintense volumes revealed higher methionine uptake values (1.8 to 4.0) and increase in CBV.

Conclusion: Wild-type gliomas are characterized by an earlier onset of progression as opposed to IDH-mutant gliomas. Well-timed identification of recurrence during bevacizumab-containing therapy is challenging due to decrease in contrasting, blood flow and moderate methionine uptake, and can be suspected by T2/Flair. To identify continued tumour growth, it is necessary to take into account all available data to start anti-relapse therapy as early as possible.

B-0092 11:11

Novel imaging signs in detecting the 1p 19q non-co-deleted IDH wild and 1p 19q non-co-deleted IDH mutant lower grade gliomas

A.N. Kamble¹, A. Kamble²; ¹New Delhi/IN, ²Mumbai/IN
(akshaykumar.kamble92@gmail.com)

Purpose: Lower grade glioma are classified based on genetic markers into subgroups, one being 1p19q -co-deletion, this subgroup would include both IDH mutants, IDH wild type of gliomas.

Methods and Materials: Total 330 lower grade glioma cases from cancer imaging archive (TCIA) were analysed 171 from TCGA-LGG collection and 159 from LGG-1p19qDeletion collection. Two signs (Sign A and Sign B) were then applied to the whole collection. Confusion matrices and ROC curves were plotted for Sign A, Sign B and T2-FLAIR mismatch sign using 1p 19q non-codetelion, IDH wild and mutants from TCGA genetic database were taken as a gold standard. These novel signs were validated using LGG-1p19qDeletion collection(n=159 cases).

Results: With TCGA data Sign A had 88.19% sensitivity, 63.56% specificity, 87.5% precision, 81.87% accuracy (p value<0.0001) Sign B had 41.09% sensitivity, 91.11% specificity, 92.98% precision (p value <0.0001), T2-FLAIR mismatch sign had a poor 26.11% sensitivity and 96.77% specificity in detecting 1p 19q non-co-deleted gliomas (p value<0.0001). There was a good intra-observer variability with Sign A ($\kappa=0.669$,) and Sign B ($\kappa= 0.691$) in TCGA-LGG collection. Validation cohort of TCGA-LGG collection showed Sign A had 87.72% sensitivity, 69.61% specificity, 91.03%of NPV (p value <0.0001), while Sign B had sensitivity of 71.93%, specificity of 90.1%, 80.39% precision, 83.54% accuracy (p value<0.0001).

Conclusion: The sign A has good sensitivity and specificity; while sign B has good specificity to identify the 1p 19q non-co-deleted gliomas containing both IDH mutants and IDH wild types of tumour in lower grade gliomas.

B-0093 11:19

Diffusion kurtosis imaging parameters predicting survival in integrated molecular subtypes of diffuse glioma: an observational cohort study

J.-M. Hempel, N.-C. Nüßle, C. Brendle, B. Bender, G. Bier, M. Skardelly, H. Richter, J. Schittenhelm, U. Ernemann, U. Klöse; *Tübingen/DE*
(nils-christoph.nuessle@student.uni-tuebingen.de)

Purpose: To assess the predictive value of preoperatively assessed diffusion kurtosis imaging (DKI) metrics as prognostic factors in the 2016 World Health Organization Classification of Tumors of the Central Nervous System integrated glioma groups.

Methods and Materials: Seventy-seven patients with histopathologically confirmed treatment-naïve glioma were retrospectively assessed between 08/2013 and 10/2017 using mean kurtosis (MK) and mean diffusivity (MD) histogram parameters from DKI, overall and progression-free survival, and relevant prognostic molecular data (isocitrate dehydrogenase [IDH]; alpha-thalassemia/mental retardation syndrome X-linked, [ATRX]; chromosome 1p/19q loss of heterozygosity). The optimal cutoff-values of the metric variables were determined using receiver operating characteristic (ROC) analysis. Univariate survival data were assessed using the Kaplan-Meier method. A multivariate Cox proportional hazards model was performed on significant results from univariate analysis.

Results: There were significant differences in overall and progression-free survival between patient age (p=0.001), resection statuses (p=0.002), WHO glioma grades (p<0.0001), and integrated molecular profiles (p<0.0001). Survival was significantly better in patients with lower MK and higher MD values (p=0.009) in gliomas without chromosome 1p/19q LOH (p<0.0001) and those with retained ATRX expression (p=0.008).

Conclusion: Patient age and MK from DKI from DKI are relevant factors for preoperatively predicting overall and progression-free survival. Regarding the molecular subgroups, they are unfavourable prognostic factors in gliomas without chromosome 1p/19q LOH and those with ATRX retention.

Altered whole brain connectivity as a potential marker of disease burden in glioma patients

S. Stoecklein¹, V. Stöcklein¹, F. Schöppe¹, N. Thon¹, F.-W. Kreth¹, B.B. Erti-Wagner², J.-C. Tonn¹, H. Liu³; ¹Munich/DE, ²Toronto, ON/CA, ³Boston, MA/US (sophia.stoecklein@med.uni-muenchen.de)

Purpose: In glioma patients tumour cells spread far beyond the lesion that is detected by conventional MRI. Assessing non-lesional brain in glioma patients could provide crucial information about disease burden. We developed an individual measure of altered functional connectivity based on resting-state functional MRI (rsfMRI) and related this marker to WHO grade, IDH mutation status, neurocognitive performance and overall survival.

Methods and Materials: 40 patients with suspected de novo glioma were prospectively included and rsfMRI data were obtained. We evaluated the abnormality of functional connectivity by comparing each patient's data to normative data obtained from 1000 healthy individuals. Abnormality was quantified at each voxel, resulting in an individual measure for abnormality (abnormality index, ABI). Statistical analysis was conducted adjusting for tumour volume, age and SNR of rsfMRI data.

Results: ABI maps reflected the macroscopic tumor, but also displayed alterations in non-lesional brain tissue. On a quantitative level, ABI was associated with WHO grade, both when summarized in the lesional and non-lesional hemisphere (<0.01, respectively). ABI was increased in patients with IDH-wildtype gliomas, with strongest effects in the non-lesional hemisphere (p<0.01). Association with neurocognitive performance was strongest in the lesional hemisphere (p<0.005). 8/38 patients died within the follow-up period, showing a trend towards association of overall survival with ABI (p=0.12).

Conclusion: ABI captures widespread connectivity changes in glioma patients on an individual level. ABI reflects tumour biology and correlates with neurocognitive performance and might be associated with overall survival. Individual ABI maps might therefore proof as a useful complement to conventional structural MRI.

B-0095 11:35

GLINT: GlucoCEST in neoplastic tumours at 3T - first-in-man studies of GlucoCEST in glioma patients

T. Lindig¹, M. Zaiss¹, K. Herz¹, A. Deshmane¹, B. Bender¹, X. Golay², K. Scheffler¹; ¹Tübingen/DE, ²London/UK
(tobias.lindig@med.uni-tuebingen.de)

Purpose: Dynamic glucose enhanced (DGE) CEST imaging has almost only been shown at ultra-high field (UHF) due to low effect size. First results in brain tumour patients of a DGE CEST method with fast 3D imaging developed for clinical field strength are shown herein.

Methods and Materials: CEST saturated images at different frequency offsets were acquired at 160 time points before, during and after a glucose injection (0.3 mg/kg) with 6.3s temporal resolution (Total: 16:45 min) to detect accumulation in the brain. Two glioblastoma (IDH wild-type, unmethylated MGMT promoter) patients (1: female, 70y, 2: female, 75y) and 3 healthy controls were scanned at a clinical 3T System. DGE contrast images were analysed by subtracting each image from a pre-injection baseline image: $\Delta DGE(t) = DGE_{baseline} - DGE(t)$.

Results: In the high-grade glioma (1), glucose uptake in the Gadolinium enhancing region could be detected approximately 4 minutes after injection with a maximum increase of $\Delta DGE = 0.51 \pm 0.078$, whereas a contralateral white matter ROI was barely affected ($\Delta DGE = 0.07 \pm 0.085$) at the same time point. The second glioma (2), with the same histology and grading, showed very little gadolinium enhancement as well as no significant detectable DGE effect. Healthy controls did not show any significant DGE contrast.

Conclusion: We demonstrated that stable dynamic glucose enhanced imaging can be accomplished at clinical field strength using optimized saturation and readout parameters. First results are promising, and indicate that glucoCEST corresponds more to the disruptions of the blood-brain-barrier with Gadolinium uptake than to the molecular tumour profile or tumour grading.

B-0096 11:43

Preoperative resectability estimates of non-enhancing glioma by neurosurgeons and a resection probability map

E.J. Hendriks¹, S. Idema¹, A.H. Zwiderman¹, F. Barkhof¹, W.P. Vandertop¹, E. Mandonnet², H. Duffau³, M.S. Berger⁴, P.C. De Witt Hamer¹; ¹Amsterdam/NL, ²Paris/FR, ³Montpellier/FR, ⁴San Francisco, CA/US
(hendriks.eef@gmail.com)

Purpose: Preoperative interpretation of resectability of diffuse non-enhancing glioma is primarily based on individual surgical expertise, to identify patients who benefit most from resective surgery. Here, we compare the agreement between observed resections and preoperative estimates of neurosurgeons and a resection probability map (RPM).

Methods and Materials: 234 consecutive patients were included from two neuro-oncological centres, who had resective surgery with functional mapping between 2006 and 2012 for a supra-tentorial non-enhancing glioma. Extent of resection (EOR) and residual tumour volume (RTV) were segmented and an RPM was constructed in standard brain space. Three junior and three senior neurosurgeons estimated EOR and RTV, blinded for postoperative results. We used Bland-Altman analysis to determine the agreement between the estimations and receiver operating characteristic analysis to calculate the diagnostic accuracy of the neurosurgeons and the RPM to predict observed resections.

Results: Preoperative estimates of resection results by junior and senior neurosurgeons were significantly biased towards overestimation of EOR (4.2% and 11.2%) and underestimation of RTV (4.3 and 9.0 mL), whereas estimates of the RPM were unbiased (-2.6% and -0.2 mL, respectively). The limits of agreement were wide for neurosurgeons and for the RPM. The RPM was

significantly more accurate in identifying patients in whom an EOR>40% was observed than neurosurgeons.

Conclusion: Neurosurgeons estimate preoperative resectability before surgery of a non-enhancing glioma rather accurate - with a small bias, and imprecise - with wide limits of agreement. An RPM provides unbiased resectability estimates, which can be useful for surgical decision-making, planning and education.

B-0097 11:51

Radiomics MRI phenotyping with machine learning to predict the grade of lower grade gliomas: a study focused on non-enhancing tumours

S. [Yoon](#), Y. Park, Y. Choi, S. Ahn, J. Chang, S. Kim, S.-K. Lee; *Seoul/KR*

Purpose: To assess whether radiomics features derived from multiparametric MRI can predict the tumour grade of lower grade gliomas (LGGs; WHO grade II and grade III) and the non-enhancing LGG subgroup.

Methods and Materials: Two-hundred and four patients with LGGs from our institutional cohort were allocated to training (n = 136) and test (n = 68) sets. Postcontrast T1-weighted images, T2-weighted images, and FLAIR images were analysed to extract 250 radiomics features. Various machine learning classifiers were trained using the radiomics features to predict the glioma grade. The trained classifiers were internally validated on the institutional test set, and externally validated on a separate cohort (n = 99) from The Cancer Genome Atlas (TCGA). Classifier performance was assessed by determining the area under the curve (AUC) from receiver operating characteristic analysis. An identical process was performed in the non-enhancing LGG subgroup (institutional training set, n = 73; institutional test set, n = 37; and TCGA cohort, n = 37) to predict the glioma grade.

Results: The performance of the best classifier was good in the internal validation (AUC 0.85) and fair in the external validation (AUC 0.72) to predict the LGG grade. For the non-enhancing LGG subgroup, the performance of the best classifier was good (AUC 0.82) in the internal validation, but poor in the external validation (AUC 0.68).

Conclusion: Radiomics feature-based classifiers may be useful to predict LGG grades. However, radiomics classifiers may have limited value when applied to the non-enhancing LGG subgroup in an external cohort.

Mass casualty incidents: are you ready? An evidenced-based radiology MCI protocol template

J.W. [Ryan](#), P.J. MacMahon, F. Bolster; *Dublin/IE (jamesryannchd@gmail.com)*

Purpose: Mass casualty incidents (MCIs) are increasing in frequency across Europe. Radiology plays a critical role in appropriate patient triage during an MCI. Major incident planning (MIP) can help optimize radiology's response with the goal of improving patient outcomes. Historically, radiology is often underrepresented or excluded from MIP. Our goal was to identify key topics that should be addressed by radiology during MIP, thus promoting MCI awareness and education amongst radiologists.

Methods and Materials: A review of the literature was performed. The advanced search builder on PubMed was utilized. Search terms "radiology" and "mass casualty incident" were used in the primary search filter. External MCI protocols from level 1 trauma centres were obtained on request and reviewed.

Results: 27 relevant studies were identified on the primary search of PubMed and review of references. Trauma guidelines from the Royal College of Radiologists and NICE were also reviewed. Key topics include patient identification strategy, scan ordering, patient tracking, MCI scan protocols, result communication, PACS failure contingencies, scalability of response and individualized radiology staff action cards.

Conclusion: All radiology departments should partake in MIP and in MCI simulation to help maximize patient throughput and improve triage efficiency in the event of an MCI. We have provided an evidenced-based radiology MCI protocol template for use by radiologists during MIP.

B-0099 10:38

Whole-body trauma CT for critical and mass casualty incident patients: how fast can we go

L.F.M. [Beenen](#), M.J. Scheerder, D. Bekebrede-Kauffman, N.H.J. Lobe; *Amsterdam/NL (l.f.beenen@amc.uva.nl)*

Purpose: In trauma, every second counts: time = life. Whole-body computed tomography (WBCT) for trauma patients can achieve both significant time and survival benefits. Faster radiological diagnosis could be lifesaving, particularly for haemodynamically critical or MCI patients. Hence, high efficacy of the scanning workflow is paramount. However, detailed time claims of different scan setups are not known. The aim of our study was to investigate the impact of different WBCT procedures on trauma CT times.

Methods and Materials: Adult anthropomorphic phantoms were used to evaluate 6 different scan protocols in a trauma exercise, with 5 simulation tests for each protocol. Tested workflow settings were: single vs double scout acquisitions, acquisition direction, non-enhanced vs contrast-enhanced, and fixed-delay or bolus triggering contrast administration. Several start and end time points were measured for the complete trauma radiology period: scout acquisitions, CT acquisitions, and reconstruction times, respectively.

Results: Of the total trauma radiology time, up to 83% consisted of non-radiation time. Scout acquisition times claim between 7 and 24% of the examination time. Acquisition times of scouts were close (range 70-93%) to total CT acquisition times. The fastest protocol was a non-enhanced one-stop WBCT protocol, costing in mean only 79 seconds to completion (p<0.001). For contrast-enhanced scans, a fixed delay split bolus protocol could present all axial images 159 seconds after start of imaging.

Conclusion: Scout acquisition and non-acquisition times are significant time-limiting factors in WBCT. Optimising examination times of WBCT protocols can contribute to faster trauma radiology workflow.

B-0100 10:46

Whole-body CT using biphasic injection protocol with adaptive statistical iterative reconstruction-V (ASiR-V) in multi-trauma patients: impact on dose reduction and image quality

A.H. Elmokadem¹, E.A. Ibrahim², W.A. Gouda³, A. Abdel Razek¹; *¹Mansoura/EG, ²Kuwait/KW, ³Menoufia/EG (walaagoda@yahoo.com)*

Purpose: To evaluate dose savings and image quality after implementing adaptive statistical iterative reconstruction-V (ASiR-V) on a revised protocol for whole-body CT (WBCT) for trauma patients.

Methods and Materials: One hundred multi-trauma patients were scanned using a 256-section multidetector CT system (GE Healthcare Revolution system). They were randomized into two groups using two different scanning protocols. Group (A) (n=50, age 32.48±8.09) underwent conventional protocol including unenhanced scan for brain and cervical spines, then a contrast-enhanced arterial-phase of the thorax and abdomen followed by a venous and delayed scans of the abdomen and pelvis. Group (B) (n=50, age 35.94±13.57) underwent biphasic injection protocol including unenhanced scan for brain and cervical spines, followed by a one-step acquisition of the thorax, abdomen, and pelvis following a biphasic injection, the examination was ended by delayed phase for the abdomen and pelvis. All examination were done under 50 % ASiR-V. Image count, radiation dose, total acquisition time, mediastinal artifacts were compared between the groups. Two radiologists independently graded image quality from 1 to 5. In addition, contrast enhancement was measured in the pulmonary artery, aorta, inferior vena cava, portal vein, liver, spleen, and kidneys.

Results: The mean (±SD) dose length product for group (A) was 2202.3 ± 271.8 mGy*cm and markedly higher when compared to group (B) (p < 0.001) which was 1485.8 ± 489.2 mGy*cm. Protocol B gave a dose reduction of 32.5% and 7.7 % time reduction. The HU values of the aorta & liver were significantly higher in group (A) while kidneys values were higher in group (B). There was no significant difference between the image quality scores for both groups, however group (A) scored higher grades.

Conclusion: Implementing ASiR-V algorithm into biphasic CT protocol markedly reduced radiation with maintenance of accuracy and image quality.

B-0101 10:54

Diagnostic performance of CT and the use of GI contrast material for the detection of hollow viscus injury after penetrating abdominal trauma

S. [Thorisdottir](#)¹, G. Oladottir¹, M. Nummela², S. Koskinen³; *¹Stockholm/SE, ²Helsinki/FI, ³Huddinge/SE (sigurveig.thorisdottir@sll.se)*

Purpose: To assess the diagnostic performance of CT regarding hollow viscus injury (HVI) from penetrating abdominal trauma.

Methods and Materials: Retrospective analysis of patients with penetrating abdominal trauma during 2013-2016. Data from Karolinska Trauma Registry, medical records, and from local PACS were reviewed. CT and surgical findings were compared.

Results: Of 636 patients with penetrating trauma, 177 had abdominal trauma (mean age 34 yrs, range 16-88 yrs; M 163, F 14), and 155 (85%, 155/177)

were imaged with CT on arrival. 128 (83%) were stab wounds and 21 (14%) gunshot wounds. 6 patients had miscellaneous trauma mechanisms. Thereof 47 (47/155; 30%) had emergent surgery after CT imaging. Two patients were imaged using oral, rectal and i.v. contrast, 23 with rectal and i.v. contrast, and 22 with i.v. contrast only. Surgery revealed HVI in 26 patients. CT had an overall sensitivity of 69.2%, specificity 90.5%, PPV 90.0% and NPV 70.4%. CT with oral and/or rectal contrast (n = 25) had sensitivity of 66.7%, specificity 71.4%, PPV 85.7% and NPV 45.5%. CT with i.v. contrast only (n = 22) had sensitivity 75.0%, specificity 100%, PPV 100% and NPV 87.5%. Difference in sensitivity between the oral and/or rectal contrast group and i.v. contrast only was not statistically significant (p=1.00).

Conclusion: Stab wounds were the most common cause of penetrating abdominal trauma. The overall sensitivity and specificity of CT in detecting HVI were 69.2% and 90.5%, respectively. The use of oral and/or rectal contrast yielded similar sensitivity to the use of i.v. contrast only.

B-0102 11:02

Evaluation of a CT-based scoring system regarding the prognosis of blunt splenic and liver injuries: a single-centre analysis with 720 patients

D. Morell Hofert, M. Fodor, E. Braunwarth, M. Haselbacher, T. Schmid, M. Blauth, E.-M. Gassner, S. Stättner, F. Primavesi; *Innsbruck/AT (Dagmar.Morell@i-med.ac.at)*

Purpose: Non-operative management (NOM) of blunt splenic and hepatic injuries has been getting increasingly common. Next to clinical parameters, CT-based grading systems are habitually used as screening tools in early management. Usually the AAST classification is used. Shortly, another scoring system, which contemplated contrast-media extravasation, was introduced for spleen injuries (CTSI). This study validates this system for spleen injuries and proposes/validates an adapted classification for liver injuries.

Methods and Materials: Retrospective analysis of patients with traumatic blunt liver/spleen lesions in the MUI from 2000 to 2016. CT imaging on admission was reevaluated by two radiologists, using the AAST and the CTSIs. Both classifications were examined regarding their capability to predict the necessity of operative treatment, the failing of NOM and the in-hospital-mortality.

Results: In total, 720 patients were analysed (median 32; 230 female), 276 with spleen, 364 with liver and 80 with combined injuries. The total mortality was 5.6%. 160 patients had severe (grade 4-5) lesions according to AAST, with a mortality of 6.0%/5.3% (severe/mild liver injuries, p=0.790) and 10.5%/3.2% (spleen injuries, p=0.008). When using CTSI, 33 patients with liver and 87 patients with spleen lesions had severe injuries (≥4a), associated with a higher in-hospital-mortality: 12.1%/4.9% for liver (p=0.095) and 10.3%/3.0% for spleen injuries (p=0.005). Both classifications showed a high-significant tendency (p < 0.001) of severe lesions more often requiring first-hand operative treatment and were equally good for predicting NOM failure.

Conclusion: The CTSI is able to predict in-hospital mortality and proved efficient as a management indication tool and as a predictor for NOM failure. Therefore, it should substitute the AAST classification as the gold standard.

B-0103 11:10

Characteristics and predictive factors of delayed events in patients of blunt splenic trauma designated for non-operative management

Y.-C. Wong, L.-J. Wang, C.-H. Wu; *Taoyuan/TW (ycwong@cgmh.org.tw)*

Purpose: We compared patients with delayed events and immediate events who required splenic angioembolisation (SAE) for salvaging failures of non-operative management (NOM) after blunt splenic trauma.

Methods and Materials: From 2012 to 2017, 161 patients of blunt splenic trauma who were designated for NOM and treated with SAE at our institution were identified. Delayed event occurred at least 4 days after trauma, whereas immediate event occurred within 24 hours. We excluded 11 patients whose events fell between 1 and 4 days. The final inclusion was 150 patients (38 women, 112 men) with median of 33.0 (IQR 21, 47) years. Records were retrospectively reviewed for clinical and CT characteristics. Comparisons between delayed and immediate events as well as predictive factors for delayed events were computed.

Results: Delayed events occurred in 23 (15.3%) patients and were significantly associated with less vascular injuries on CT (3.5% vs. 96.5%), smaller CT score (3.3 vs. 5.2) and smaller hemoperitoneum score (2.9 vs. 4.3). Significant predictive factors for delayed events were CT score, hemoperitoneum score and initial platelet count. Among 23 delayed events, paired T test showed a worse CT score (3.2 vs 4.8; p=0.001) and lower haemoglobin (11.9 to 10.1 g/dL; p=0.004) on follow-up CT examinations and haemograms. Patients with immediate events had a significant longer length of stay after SAE than patients with delayed event, 12.7 days vs. 9.4 days.

Conclusion: Delayed events of blunt splenic trauma were associated with CT findings. The significant predictive factors were CT score, hemoperitoneum score and initial platelet count.

B-0104 11:18

Can MR be useful in the follow-up of blunt liver and spleen injuries: preliminary results

F. Iacobellis, M. Di Serafino, T. Cinque, C. Stavoio, L. Romano; *Naples/IT (iacobellisf@gmail.com)*

Purpose: In haemodynamically stable patients, the standard of care for blunt liver and spleen injuries is the non-operative management. In our Institution, MR was introduced for the follow-up of haemodynamically stable patients with blunt liver and spleen injuries. The aim is to describe the imaging protocol, the main findings and the potentialities in the use of MR in these patients.

Methods and Materials: From May 2018, patients with blunt liver and spleen injuries without MR contraindications, after admission CT, were followed up by MR. The imaging protocol was tailored to each patient. Post-contrast sequences were acquired especially in the early follow-up and in high grade injuries. In suspected biliary complications, MR cholangiographic sequences were added, and hepatobiliary-specific contrast agent (gadobenate dimeglumine) administration with delayed acquisitions was used.

Results: Seventeen patients with spleen (6 pts.) and liver (11 pts.) injuries of low (10 pts.) and high (7 pts.) grade, were followed-up by MR. The signal behaviour of the healing lesions was documented and described. In 4 patients, liver intraparenchymal collections were detected, MR allowed to characterize them and to examine the biliary ducts communication. In 1 case was observed an intraparenchymal pseudoaneurism of the spleen that was subsequently embolized.

Conclusion: MR may constitute a useful alternative to CT to follow-up patients with blunt liver and spleen injuries considering the panoramcity, the high resolution and the lack of ionizing radiation. In this preliminary experience, MR allowed to identify and monitoring, in a less invasive way, vascular and parenchymal liver and spleen injuries.

B-0105 11:26

Repeated imaging work-up in revisiting emergency patients: analysis of clinical and radiological risk factors

Y. Ahn, G.-S. Hong, K. Park, C.W. Lee; *Seoul/KR (foryourmiracle@gmail.com)*

Purpose: To analysis risk factors to cause repeated imaging in revisiting emergency patients.

Methods and Materials: A retrospective review identified 12,357 patients returning to emergency room (ER) within 7 days after performed CT or MRI at the first visit and discharged from the ER between 2005 and 2013. Among them, 1250 patients underwent repeated image workup for the same or different part of the body. The patients were divided into two groups according to the revisiting time after discharge: early revisiting group (≤ 72 hours) and late revisiting group (> 72 hours). The factors to cause re-performing the imaging are classified as follows through medical record and image review: 1) radiological factor (RF) (misdiagnosis vs. inappropriate reporting turn-around time [R-TAT]); 2) non-radiology clinician's factor (CF) (mistriage); and 3) patient's factors (PF) (disease or symptom progression).

Results: The repeated imaging was performed in 10.12% of revisiting patients. The ratios of RF and CF in early revisiting group were significantly higher from those in late revisiting group (13.50% vs. 8.29% and 12.29% vs. 6.76%, respectively) (P < 0.001). In the radiological factors, there was significant difference between early revisiting group (inappropriate R-TAT 64.04%; and misdiagnosis 35.96%) and late revisiting groups (inappropriate R-TAT 30.61%; and misdiagnosis 69.38%) (P < 0.001).

Conclusion: RC and CF are the major causes of repeating imaging in early revisiting group than late revisiting group. In radiological factors, inappropriate R-TAT is the main cause in the early revisiting group and misdiagnosis in the late revisiting group.

B-0106 11:34

Incidental findings in whole-body CT: a retrospective analysis in over 1000 resuscitation room patients

S. Sudarski, T. Henzler, D. Schäfer, T. Viergutz, T. Terboven, S.O. Schönberg, H. Haubenreisser; *Mannheim/DE (sonja.sudarski@medma.uni-heidelberg.de)*

Purpose: Whole-body computed tomography reveals beyond findings related to the suspected diagnosis often additional incidental findings. Aim of this investigation was the assessment of these findings in whole-body CT scans of patients admitted via the resuscitation room after suffering potential major trauma or life-threatening medical conditions.

Methods and Materials: Patients admitted via the resuscitation room were retrospectively included if they had received a whole-body computed tomography scan at admission. The final cohort consisted of 1165 patients (1038 trauma and 127 internal-neurological patients). Whole-body computed tomography reports screened for incidental findings. These findings were then classified as either clinically relevant or not.

Results: 465 incidental findings were reported in a total of 293 patients (25.1%). Relevant incidental findings could be detected in 5.8% of the study patients (68/1165). The group of internal-neurological patients was older than

the trauma patients (61.6 years vs. 45.5 years). The rate of relevant incidental findings in the internal-neurological group was more than twice as high as in the trauma group (11.0% vs. 5.2%). Yet, in the relatively young trauma group one in 20 patients showed an incidental finding classified as clinically relevant as well.

Conclusion: Incidental findings are reported in 1/4 of whole-body CT scans of patients admitted to the resuscitation room. About 6% of all patients had incidental findings being rated as clinically relevant. In the internal-neurological older group of patients the rate of incidental findings was doubled compared to the younger trauma group.

B-0107 11:42

Diagnostic error in emergency studies: an analysis of explanatory variables

F. Facal de Castro¹, R. Mirón Mombiola¹, J. Vucetic¹, J. Mota Martinez², E. Arana Fernandez De Moya¹, D. Dualde Beltran¹; ¹Valencia/ES, ²Barcelona/ES (facalrayos@hotmail.com)

Purpose: To determine the discrepancy rate between the first and second readings. To estimate the clinical significance of errors. To identify latent factors associated with a higher incidence of errors. To discover weak points in the radiological work that can be solved by training or quality control measures.

Methods and Materials: Retrospective observational analysis of diagnostic discrepancies in emergency studies of adult patients from 37 health centres detected after a second reading at the company Iberorad SL from 2014 to 2016.

Results: We found a diagnostic discrepancy rate of 1.4% in emergency studies. The average rate of emergency studies with clinically significant discrepancies is 27.4% of total discrepancies. A statistically significant association was noticed with the diagnostic discrepancy, in decreasing order of magnitude, of the following: availability of previous imaging studies; average level of concordance between area of expertise of the radiologist and modality of the study; insufficient clinical information; non-use of speech recognition systems; low level of concordance between area of expertise of the radiologist and modality of the study; study of high complexity; body studies; use of a single monitor to visualise images; and MSK/spine studies.

Conclusion: The diagnostic discrepancy rate during the period analysed is similar to that reflected in the medical literature. Most discrepancies are not clinically significant. There are multiple factors associated with diagnostic error. The intensity in which each of these is associated with diagnostic error is different and variable determined by the rest of the characteristics present in the diagnostic process.

B-0108 11:50

Would it be safe to have a dog in the MRI scanner before your own examination?

A. Gutzelt¹, J.M. Fröhlich², F. Steffen¹, D.-M. Koh³, C. Orasch¹; ¹Lucerne/CH, ²Zurich/CH, ³Sutton/UK (agutzelt2000@gmail.com)

Purpose: To determine whether it would be hygienic to evaluate dogs and humans on the same MRI scanner.

Methods and Materials: We compared the bacterial load in colony-forming units (CFU) of human pathogenic microorganisms in specimens taken from 18 men and 30 dogs. In addition, we compared the extent of bacterial contamination of an MRI scanner shared by dogs and humans, with two other MRI scanners used exclusively by humans.

Results: Our study shows a significantly higher bacterial load in specimens taken from men's beards compared with dogs' furs ($p = 0.036$). All of the men (18/18) showed high microbial counts, whereas only 23/30 dogs had high microbial counts and 7 dogs moderate microbial counts. Furthermore, human pathogenic microorganisms were more frequently found in human beards (7/18) than in dog fur (4/30), although this difference did not reach statistical significance ($p = 0.074$). More microbes were found in human oral cavities than in dog oral cavities ($p < 0.001$). After MRI of dogs, routine scanner disinfection was undertaken and the CFU found in specimens isolated from the MRI scanning table and receiver coils showed significantly lower bacteria count compared with "human" MRI scanners ($p < 0.05$).

Conclusion: Our study shows that bearded men harbour higher burden of microbes and more human pathogenic strains than dogs. As the MRI scanner used for both dogs and humans was routinely cleaned after animal scanning, there was substantially lower bacterial load compared with scanners used exclusively for humans.

Operator learning curve for transradial liver cancer embolisation: implications for the initiation of a transradial access programme

F. Carchesio, R. Iezzi, A. Posa, G. Veltri, A. Gasbarrini, R. Manfredi; Rome/IT (francesca.carchesio@gmail.com)

Purpose: To analyze transradial approach (TRA) learning curve on patients undergoing hepatic chemoembolization, investigating the relationship between procedural volumes and various benchmarks of procedural success.

Methods and Materials: We enrolled sixty consecutive patients who received two unilobar hepatic chemoembolization within a 4-week interval performed by a single interventional radiologist, highly-trained in conventional transfemoral procedures (TFA), but without any previous practical experience in TRA procedures and with a preliminary 2-days theoretical training only. We divided the study population, prospectively consecutively random-enrolled, into 3 groups: A (case 1 to 20), B (case 21 to 40), and C (case 41 to 60), using all TFA procedures performed by the same operator in the same series of patients as the control group. Primary endpoint was to analyze the relationship between procedure volumes and benchmarks of procedural success, such as safety, and procedural variables, including fluoroscopy time, and radiation dose, to define the optimal procedural learning curve.

Results: Technical success was obtained in all patients, without needing any switch from radial to femoral access. No major complications were registered without significant differences in terms of minor complications between the three subgroups of patients. An association between incremental TRA volume and reduction decreasing of preparation, puncture, fluoroscopy and total examination times was demonstrated, with values significantly higher only for group A (first 20 patients).

Conclusion: TRA is safe and feasible for transarterial hepatic chemoembolization. Operator proficiency improves with greater TRA experience, with a threshold needed to overcome the learning curve represented by 20 cases.

B-0110 10:38

Transarterial chemoembolisation with degradable starch microspheres (DSM-TACE) as second-line treatment in HCC patients dismissing or ineligible for sorafenib

G. Veltri, R. Iezzi, A. Posa, F. Carchesio, A. Gasbarrini, R. Manfredi; Rome/IT (Giuseppeveltri1701@gmail.com)

Purpose: To evaluate safety, feasibility and effectiveness of transarterial chemoembolisation with degradable-starch-microspheres (DSM-TACE) in the treatment of patients with advanced HCC dismissing or ineligible for multikinase-inhibitor chemotherapy administration (Sorafenib) due to unbearable side effects or clinical contraindications.

Methods and Materials: 40 consecutive HCC patients who underwent DSM-TACE via lobar approach were prospectively enrolled. Tumor response was evaluated on MD-CT based on mRECIST criteria. Primary endpoints were safety, tolerance and overall disease control (ODC); secondary endpoints were progression free survival (PFS) and overall survival (OS).

Results: Technical success was achieved in all patients. No intra/procedural death/major complications occurred. No signs of liver failure or systemic toxicity were detected. During the mean follow-up of 18.2 months an ODC of 52.5% was registered. Progression free survival was 6.4 months with a median overall survival of 11.3 months.

Conclusion: DSM-TACE seems to be a safe and effective second-line treatment for HCC patients ineligible for Sorafenib administration or dismissing it due to progressive disease or unbearable side effects.

B-0111 10:46

Same-day workup angiography and Yttrium 90 microsphere radioembolisation: feasibility and efficacy of hepatic flow redistribution

A. Ezponda Casajús, M. Calvo Imirizaldu, M. Morales, I. Vivas Perez, M. De La Torre, M. Rodríguez-Fraile, B. Sangro, J.I. Bilbao Jaureguizar; Pamplona/ES (aezponda@unav.es)

Purpose: To assess the feasibility and efficacy of performing vascular flow redistribution and transarterial radioembolisation with 90Y-microspheres (90YRE) for hepatic malignancies in a single-day session.

Methods and Materials: From November 2015 to September 2018, in 16 patients undergoing same-day workup angiography, cone-beam CT (CBCT), ^{99m}Tc-MAA SPECT-CT and 90YRE, accessory tumour arteries were embolised with microcoils. Perfusion of the lesions in the redistributed and non-redistributed segments was qualitatively compared by assessing the distribution of ^{99m}Tc-MAA. Within 18 hours following treatment, a PET/CT was performed.

Results: Sixteen patients were treated for primary (n=11) and secondary hepatic malignancies (n=5). Flow redistribution was achieved by embolisation of intrahepatic (n=12) and extrahepatic branches (n=4). In most cases, CBCT provided additional information of arterial tumour perfusion. In all patients, the ^{99m}Tc-MAA-SPECT/CT showed uptake in the redistributed tumoural areas. The mean lung shunt fraction (LSF) ratio was 7.10%±0.056. Of the 16 patients, 8 received segmental injections to both lobes, 5 to the right lobe and 3 to the left lobe. The median doses administered to the tumour and normal hepatic tissue were 141Gy (range 29-576Gy) and 40Gy (range 5-315Gy), respectively. The 90Y-PET/CT images showed accumulation of microspheres over the tumoural territory, both in the redistributed and non-redistributed tumoural segments, with a mean 90Y activity of 1.57±0.7 GBq. The mean total procedure time was 392 minutes (range 204-532).

Conclusion: Same-day embolisation of extra and intrahepatic branches (to redistribute intrahepatic flow patterns to the tumour) and 90YRE procedure is feasible and effective.

B-0112 10:54

Locoregional heparinisation for patients with acute deep venous thrombosis of lower extremity: safety and efficacy evaluation

Y.-D. Xiao; Changsha/CN (xiaoyudong222@csu.edu.cn)

Purpose: To assess efficacy and safety of locoregional heparinisation in patients with acute deep venous thrombosis (ADVT) of lower extremity.

Methods and Materials: A total of 10 patients with unilateral ADVT who were contraindicated for thrombolysis and systemic anticoagulation were enrolled in the study. The popliteal vein was punctured, and an 8-F sheath was inserted. After confirming the diagnosis and extent of the DVT, suction thrombectomy was performed, and then, a multiple infusion side-hole catheter was advanced to the iliac vein. Through the infusion catheter, 500 IU/h heparin mixed with normal saline was infused using a micropump. Blood samples were taken every 4 hours from both cubital vein and popliteal vein to measure the activated partial thromboplastin time (aPTT), which was to adjust the heparin dose. The symptoms and the complications of patients were evaluated.

Results: Our results revealed that for the blood sample from the cubital vein, the aPTT maintained at 30s-45s, while for the blood sample from the popliteal vein, the aPTT maintained at 60s-90s. With the dissolution of thrombus, the aPTT from cubital vein and the popliteal vein tended to be converging. One month later, the symptoms related to ADVT were significantly improved in eight patients. Repeat venography showed that vascular completely recanalisation observed in two patients, partial recanalisation in seven patients. No severe complications such as intracranial bleeding occurred.

Conclusion: Locoregional heparinisation is a safe and effective way for patients with ADVT who is contraindicated to thrombolysis and systemic anticoagulation

B-0113 11:02

Response to SIRT (selective internal radiation therapy) in patients affected by unresectable multifocal intra-hepatic cholangiocarcinoma: results of a preliminary study

A. Paladini¹, D. Beomonte Zobel², G.E. Vallati², G. Pizzi², F. Cappelli², A. Borzelli³, E.M. Amodeo²; ¹Novara/IT, ²Rome/IT, ³Naples/IT (andreapaladini1988@gmail.com)

Purpose: The aim of this study is to demonstrate the results in terms of overall survival (OS) and response to treatment in a cohort of 43 patients (pts) affected by unresectable multifocal intra-hepatic cholangiocarcinoma (ICC) and treated with SIRT.

Methods and Materials: Between 2011 and 2018, we treated 43 pts affected by multifocal ICC with SIRT. Response to treatment was evaluated after 2 TC performed at 3 and 6 months.

Results: The 3- and 6-month radiological evaluation was performed on 40 pts with the analysis of complete (CR) or partial (PR) response to treatment, stability (SD) or progression disease (PD). Response to treatment (CR + PR) was 70% according to mRECIST and 60% according to the EASL criteria. The median OS was 17.9 months (range: 14.3-21.4 months). A shorter OS was found in pts treated with medical or surgical therapies before SIRT: 16 versus 52 months of the pts treated only with SIRT. We reported a greater correlation between OS and CR and PR according to the mRECIST and EASL criteria compared to RECIST 1.1 criteria. Treatment was well tolerated and no mortality was seen in the first 30 days post-treatment. No peri-procedural complications were documented.

Conclusion: SIRT documented excellent results in terms of efficacy in pts affected by ICC and portal thrombosis also. It is a safe and repeatable treatment and, therefore, it is a valid loco-regional therapy in pts affected by unresectable ICC.

B-0114 11:10

Locoregional treatments for unresectable early stage HCC in patients with high-risk for intraprocedural bleeding: is single-step combined therapy safe and feasible?

G. Veltri, R. Iezzi, A. Posa, F. Carchesio, A. Gasbarrini, R. Manfredi; Rome/IT (Giusepveltri1701@gmail.com)

Purpose: To assess feasibility and safety of a single-step combined therapy with radiofrequency ablation and transarterial chemoembolization (RFA+TACE) in patients with hepatocellular carcinoma (HCC) and uncontrolled coagulopathy. To compare the effectiveness of this approach with TACE alone performed in a control group.

Methods and Materials: From January 2010 to June 2017, 143 consecutive cirrhotic patients with single HCC < 8 cm were enrolled in an observational prospective single-center study and divided, according to coagulation tests, into 3 groups (A, low risk; B, intermediate and C, high risk of bleeding). Feasibility and safety of a single-step combined treatment (RFA followed by TACE) were evaluated in terms of technical success rate, incidence of periprocedural complications and laboratory values variations. Efficacy was evaluated comparing tumour response on 1 month CT in group C and in a control group, composed by 16 patients with severe coagulopathy and single HCC < 8 cm, underwent TACE in a previous period performed by the same operator.

Results: Technical success was obtained in all patients, without major complications. Incidence of minor complications was significantly higher in group C after RFA, successfully treated with subsequent TACE without differences between pre- and post-procedural laboratory values. The complete response rates on 1-month follow-up were similar in the 3 groups whereas was significantly higher when compared group C with control TACE Group (p<.001).

Conclusion: Single-step RFA plus TACE allows to expand the indication for percutaneous thermal ablation to previously contraindicated cases due to procedural high-risk of bleeding complications improving patient outcome.

B-0115 11:18

Effectiveness and safety transarterial embolisation with bleomycin-loaded PLA/PLGA microspheres for the treatment of vascular malformation using a porcine spleen model

F. Nurili¹, T. Acar², S. Derman², I. Caymaz², S. Özkanlı², A. Bas², I. Yurdaisik², H. Cakiroglu², O. Aras¹; ¹New York, NY/US, ²Istanbul/TR (fuatnurili@gmail.com)

Purpose: To prospectively study the effectiveness and safety of bleomycin-loaded PLA/PLGA microparticles in the porcine spleen model.

Methods and Materials: Bleomycin-loaded PLA/PLGA microspheres were manufactured using the double emulsion solvent evaporation method. The porcine spleen was chosen as a vascular malformation model and eleven pigs were assigned to either the embolisation group (n=7) or control group (n=4). Selective angiography was performed in all animals and bleomycin-loaded PLA/PLGA microspheres (800 -1000 micron in diameter) were administered into the splenic artery in the embolisation group. 0.5mg/kg of bleomycin was used per procedure. After 30 days, porcine spleens were acquired to evaluate for the volumes of organ, presence or absence of microspheres, intraluminal reaction to bleomycin, vessel wall changes and extent of sclerosis.

Results: Newly manufactured microsphere formulations showed sustained long-term in vitro release performance. Transcatheter arterial embolisation was technically successful in all animals. Toxicity monitoring showed no haematologic, pulmonary, hepatic or renal toxicities. Microspheres induced significant shrinkage in volume of spleens. The mean spleen volume after embolisation was significantly (P<0.001) reduced compared with the mean volume for the group control. Pathology showed apoptosis/vasculitis of endothelial cells and disconfiguration of the spleen without systemic side effect in the experimental group.

Conclusion: Embolisation of the spleen with bleomycin-loaded microspheres with slow release properties can induce strong sclerosis of the spleen locally and promote apoptosis and vasculitis of splenic endothelial cells without systemic side effects. This study shows that transcatheter embolisation with bleomycin-loaded microspheres has the potential to be an alternative treatment for vascular malformations in humans.

B-0116 11:26

Low pretreatment neutrophil to lymphocyte ratio predicts better survival in uveal melanoma liver metastases undergoing hepatic chemoperfusion

J.M. Ludwig, O. Drescher, J. Haubold, H. Richly, M. Forsting, Y. Li, A. Wetter, S. Bauer, J. Theyssohn; *Essen/DE* (johannes-maximilian.ludwig@uk-essen.de)

Purpose: To evaluate neutrophil to lymphocyte ratio (NLR) as a pretreatment prognostic factor in patients with unresectable uveal melanoma liver metastases and limited extrahepatic disease undergoing a structured transarterial hepatic chemoperfusion (THC) protocol.

Methods and Materials: 56 patients (44% male; median age: 61 years) first treated between 01/2014-10/2015 were assessed retrospectively. A median of 3 (range: 1-11) THC sessions were performed starting with melphalan which was replaced by Fotemustine when progressing. Pretreatment factors were assessed within 1 month prior to start. Kaplan-Meier for median overall survival in months (OS; 95%CI) and cox proportional hazard model for uni- (UVA) and multivariate (MVA) analyses (hazard ratio; 95%CI) were performed.

Results: Median OS of the study cohort was 7.7 (6.3-10.9) months. Low pretreatment NLR (≤ 3.5) was associated with prolonged OS (11.1;7.1-20.6) versus high NLR (>3.5) (6.5; 3.5-7.8), $p=.0035$. In addition to low NLR (0.4; 0.2-0.75, $p=.0045$) UVA identified serum lactate dehydrogenase (LDH) ≤ 2 upper level of normal (ULN) (0.26; 0.13-0.5, $p<.0001$), gamma-glutamyl transferase (GGT) ≤ 3 ULN (0.3; 0.15-0.6, $p=.0004$), aspartate aminotransferase (0.27; 0.11-0.7, $p=.007$), c-reactive protein \leq ULN (0.31; 0.15-0.59, $p=.0006$), and liver metastasis ≤ 6 cm (0.29; 0.15-0.53, $p=.0002$) as predictors for prolonged OS. MVA confirmed low NLR (0.36; 0.14-0.83, $p=.018$), LDH (0.25; 0.08-0.83, $p=.03$), GGT (0.2; 0.05-0.77, $p=.016$) and liver metastasis ≤ 6 cm (0.15; 0.06-0.37, $p<.0001$) as independent predictors. Absolute NLR change ≤ 1.5 -fold within 1 month prior to first THC was associated a lower hazard ratio (0.4; 0.17-0.85, $p=.018$) in all patients but only proved significant in the low NLR subgroup (12- vs. 6.4-month median OS, $p=.019$).

Conclusion: Low pretreatment NLR is an independent predictor for prolonged OS in patients with uveal melanoma liver metastases treated with THC.

B-0117 11:34

Transvenous pulmonary chemoembolisation (TPCE) for palliative and neoadjuvant treatment of primary lung malignancies

A.I.A. Mekawy¹, A.A. Hassan¹, M. El-Sharkaway¹, H.M. Kamel¹, D.B. Thabet¹, N.-E.A. Nour-Eldin², N.N.N. Naguib², T.J. Vogt²; ¹Asyut/EG, ²Frankfurt a. Main/DE (time_dr@yahoo.com)

Purpose: To assess the response, mean time to progression and mean survival time for patients with primary lung cancer treated with TPCE in palliative and neoadjuvant intent.

Methods and Materials: This study included 56 patients (mean age 61.6 \pm 9 years; 27 females, 29 males) with an unresectable primary lung tumour, who failed or refused systemic chemotherapy, and underwent repetitive TPCE, between 2008 and 2017. Bilateral lung involvement was seen in 39.3% of patients and the median number of lung nodules/patient was 2.5. Regional delivery of the chemotherapeutic agents was performed after catheterization of the tumor-supplying pulmonary artery, followed by embolization with Lipiodol and microspheres. Patients who underwent subsequent ablation represented the neoadjuvant group (n=18). The response according to the revised Response Evaluation Criteria in Solid Tumors (RECIST 1.1) was evaluated and survival parameters were statistically analyzed.

Results: After evaluation of the tumour response; partial response was achieved in 14.3% (n=8), stable disease in 58.9% (n=33) and progressive disease in 26.8% (n=15). The estimated mean survival time and mean time to progression were 15.8 \pm 1.7 and 9 \pm 1.3 months, respectively. The mean survival time was significantly ($P < 0.05$) longer for the neoadjuvant group (22.3 \pm 2.8 months), compared to the palliative group (11.6 \pm 1.8).

Conclusion: TPCE could be a promising palliative treatment with acceptable survival for patients with primary lung cancer who failed or are not eligible for other treatment options. It, also, has a neoadjuvant potential when combined with ablation therapy.

B-0118 11:42

Predictors for refractoriness and survival after transarterial chemoembolisation among hepatocellular cancer patients: outcomes from a novel southeast Asian cohort

R. Kuhn, G. Ignacio, J. Jamiias; *Quezon City/PH* (rudolfvkuhn@yahoo.com)

Purpose: Patients with hepatocellular carcinoma become refractory to repeated sessions of transarterial chemoembolisation. Predictors associated with refractoriness and survival are, however, poorly defined and lack consensus. The aim of this study was to identify predictors associated with overall survival and refractoriness of HCC patients undergoing repetitive TACE. The secondary aim was to validate the ART score, neutrophil-lymphocyte ratio and radiologic response using the mRECIST and CHOI criteria for the first time in a southeast Asian setting.

Methods and Materials: The clinical and laboratory characteristics and radiologic response of 39 patients treated with repetitive conventional TACE from January 2012 to June 2018 were analysed in a retrospective cohort.

Results: The median overall survival of patients was 23.2 months and overall mortality was 36%. Multivariate Cox regression analysis revealed that Child-Pugh score (hazard ratio=3.47, $p=0.044$), AST (HR=7.6, $p=0.021$), tumour size (HR=5.47, $p=0.033$), progressive disease using CHOI criteria (HR = 5.47, CI 1.15 - 25.99, $p = 0.033$), neutrophil-lymphocyte ratio (HR=1.25, $p=0.049$) and nodular enhancement on follow-up CT imaging (HR=1.98, $p=0.034$) were independent risk factors for poor survival. Multivariate analysis also showed that ALT ($p=0.005$), enhancement ($p=0.003$), Child-Pugh score ($p=0.010$), and progressive disease using CHOI criteria ($p=0.022$) were predictive of TACE refractoriness/failure.

Conclusion: Predictors for poorer survival and TACE failure/refractoriness were identified. A rational treatment strategy and the decision to switch therapy should be individualised considering the patient's clinical condition and aforementioned clinical and laboratory parameters and response on radiologic follow-up.

B-0119 11:50

Radiation dose reduction during angiographic adrenal vein sampling using a new imaging technology

C. Spink, M. Avanesov, T. Schmidt, M. Grass, G. Schoen, G. Adam, H. Ittrich, P. Bannas; *Hamburg/DE* (c.spink@uke.de)

Purpose: To compare the patient radiation doses during angiographic adrenal vein sampling (AVS) before and after an imaging processing technology upgrade.

Methods and Materials: In this retrospective single-center-study, cumulative air kerma (AK), cumulative dose area product (DAP), fluoroscopy time and total contrast agent volume were gathered from 70 patients during AVS. 35 procedures were performed before and 35 after an imaging processing technology upgrade from Philips Allura Xper to Philips AlluraClarity. Mean values were calculated and compared using two-tailed t tests. DSA image quality was assessed independently by two blinded readers using a four-rank Likert scale (1=acceptable; 4=excellent) and compared using the Wilcoxon signed-rank test.

Results: Using the new imaging technology a significant reduction in DAP (235.1 vs. 170.1 Gy \cdot cm², $p=0.01$) and a significant reduction in AK (1.7 vs. 1.1 Gy, $p=0.01$) could be achieved. The number of exposure frames (143 vs. 132 frames, $p=0.65$), fluoroscopy time (42.3 vs. 36.5 min, $p=0.47$) and amount of contrast agent (179.5 vs. 198.1 ml, $p=0.31$) did not differ significantly between the two groups. There was no significant difference regarding image quality after the technology upgrade (3.25 vs. 3.32, $p=0.68$).

Conclusion: The new angiographic noise reduction technology significantly reduces radiation dose while maintaining adequate image quality in patients undergoing AVS.

Association of the four international guidelines for thyroid nodule management to surgical and treatment outcomes in patients with small papillary thyroid carcinoma

J. Lee, J. Kwak, E.-K. Kim, H. Moon, V.Y. Park, J. Yoon; *Seoul/KR* (easywg@yuhs.ac)

Purpose: To evaluate the role of four international guidelines for thyroid nodule management in predicting pathologic staging and treatment outcomes for patients with small conventional papillary thyroid carcinoma (PTC).

Methods and Materials: From 2007 to 2015, 775 patients who had been surgically treated for conventional PTC measuring 1-2cm were included. Each nodule was categorized according to the FNA guidelines of the 2015 American Thyroid Association (ATA) guidelines, the Korean Society of Thyroid Radiology

guidelines (K-TIRADS), the European Thyroid Association guidelines (EU-TIRADS), and the American College of Radiology Thyroid Imaging Reporting and Data System (ACR TIRADS). Multivariate regression analysis was used to analyse predictors for central or lateral cervical lymph node (LN) metastasis, and recurrence/persistence or distant metastasis in patients with small thyroid cancer.

Results: Microlobulated or irregular margins, or not parallel shape had higher rates of central lateral LN metastasis (all $P < 0.05$). Presence of microcalcifications had higher rates of central or lateral LN metastasis ($P < 0.05$). FNA indication of the four guidelines was significantly associated with central LN metastasis (all $P < 0.05$). FNA indications of the ATA guidelines, EU-TIRADS, and ACR TIRADS were significantly associated with the presence of lateral LN metastasis (all $P < 0.05$). Size, the presence of central LN metastasis, and the extrathyroidal extension were significantly associated with recurrence/persistence (all $P < 0.05$). FNA indications of the four international guidelines did not show significant association with recurrence/persistence or metastasis (all $P > 0.05$).

Conclusion: FNA indication of the EU-TIRADS and ACR TIRADS can be used in deciding upon surgical extent for patients with small PTC.

B-0121 10:47

Efficiency of biopsy criteria in thyroid nodules: the 2017 European Thyroid Imaging Reporting and Data System vs the 2014 American Thyroid Association management guidelines

V. Perez Riverola, F. Bosch Barragan, M. Prenafeta Moreno, J. Cabero Moyano, I. Capel Flores, F. Guirao Garriga, S. Barcons Vilaplana, A. Rovira Gols; *Sabadell/ES (vperez@tauli.cat)*

Purpose: To determine the diagnostic efficiency and assess malignancy risk stratification of the 2017 European Thyroid Imaging Reporting and Data System (EU-TIRADS) in comparison to the 2014 American Thyroid Association (ATA) management guidelines.

Methods and Materials: Retrospective study reviewing all fine-needle aspiration biopsies (FNAB) of thyroid nodules done following the ATA criteria at our centre from January 2015 to December 2017. We evaluated the ultrasound characteristics of all the nodules and regrouped them according to the EU-TIRADS. The EU-TIRADS criteria for FNAB are more restrictive than those of the ATA criteria in the very low risk (EU-TR2), low-risk (EU-TR3), and intermediate-risk (EU-TR4) groups; the criteria in the high risk (EU-TR-5) is the same in both systems. We analysed FNABs done under the ATA criteria that did not meet the EU-TIRADS criteria and calculated the rate of malignancy for each subgroup in each system.

Results: Of 891 thyroid nodules biopsied, EU-TIRADS criteria for biopsy were unmet in 235 (26.4%): 54 (23%) in EU-TR2, 143 (60.8%) in EU-TR3, and 38 (16.2%) in EU-TR4. FNABs were inconclusive in 39; in the remaining 196, only 4 (2%) were malignant. No EU-TR2 nodules were malignant. Only 1 EU-TR3 nodule was malignant (a noninvasive follicular thyroid neoplasm with papillary-like nuclear features). There were 3 EU-TR4 malignancies: 1 invasive follicular carcinoma, 1 classical papillary carcinoma and 1 follicular variant papillary carcinoma.

Conclusion: Using EU-TIRADS would have decreased the number of FNABs by 26.4%; only 2% of malignant nodules would have been missed.

B-0122 10:55

Radiological-pathological correlation of thyroid nodule ultrasound and cytology using the TIRADS and Bethesda classifications

S. Aslan, S. Ozdemir; *Tokat/TR (serdaraslan28@hotmail.com)*

Purpose: To compare the Thyroid Imaging Reporting and Data System (TIRADS) of classifying thyroid nodules with the findings on fine-needle aspiration cytology (FNAC) reported using the Bethesda System.

Methods and Materials: A prospective analysis of 150 patients was performed comparing thyroid nodule ultrasound findings based on the TIRADS classification to the FNAC report based on the Bethesda Classification. TIRADS 1 and biopsy-proven malignancy were excluded. Benign-appearing nodules were reported as TIRADS 2 and 3. Indeterminate or suspected follicular lesions were reported as TIRADS 4, and malignant-appearing nodules were reported as TIRADS 5. All the nodules were performed FNAC, and TIRADS findings were compared to Bethesda Classification.

Results: Of the 150 patients, 77 were TIRADS 2, 28 were TIRADS 3, 18 were TIRADS 4 and 27 were TIRADS 5. The probability of a malignant FNAC (Bethesda V-VI) in TIRADS 2, 3, 4 and 5 classes were 0%, 7.1%, 16.6% and 81.4%, respectively. The benign FNAC (Bethesda I) in TIRADS 2 was 100%, while for TIRADS 3, 4 and 5 were 75%, 27.7% and 4.6%, respectively. Of the 27 patients that were TIRADS 5, 20 patients had biopsy-proven cancer (74% concordance), but 7 were benign (false-positive sonographic impression). Overall concordance rate with FNAC was 92%, and sensitivity, specificity and negative predictive value were 88%, 90.4% and 95%, respectively.

Conclusion: Our study shows a fairly good correlation of thyroid ultrasound reporting using the TIRADS classification with the Bethesda Classification of FNAC.

B-0123 11:03

Combination of ultrasound elastography with TI-RADS in the diagnosis of small thyroid nodules (<10 mm): a new method to increase the diagnostic performance

Y. Du, C. Ji, Y. Wu, X. Gu; *Shanghai/CN (duyanran44@126.com)*

Purpose: To evaluate the diagnostic performance of a new method of combined ultrasound elastography (UE) and thyroid imaging-reporting and data system (TI-RADS) in the differential diagnosis of small thyroid nodules.

Methods and Materials: Ultrasonography, TI-RADS, elasticity imaging, virtual touch tissue imaging (VTI) and virtual touch tissue quantification (VTQ) features of 142 thyroid nodules (maximum diameter ≤ 10 mm according to conventional ultrasound measurement) confirmed by surgery or FNA were retrospectively analysed. Different elastographic methods in small benign and malignant thyroid nodules were compared. The diagnostic efficiency of three adjustment methods of TI-RADS classification and UE (VTI and/or VTQ) was compared.

Results: There were 70 benign thyroid nodules and 72 malignant thyroid nodules. The differential ability of UE to diagnose the small benign and malignant thyroid nodules alone is not better than that of conventional ultrasound TI-RADS classification. The sensitivity of conventional ultrasound TI-RADS classification was higher than that of VTI and equal to VTQ (91.67% vs 83.33%, 91.67%), while the specificity of VTI was much higher than that of TI-RADS and VTQ (91.43% vs 75.71%, 60.00%). The diagnostic sensitivity and specificity of TI-RADS plus UE (VTI + VTQ) were 94.44% and 87.14%, respectively. TI-RADS classification combined with UE (VTI + VTQ) was the highest diagnostic efficiency.

Conclusion: TI-RADS classification is the basis for the diagnosis of small thyroid nodules. The combination of TI-RADS with VTI and VTQ can significantly improve the differential diagnosis of small benign and malignant thyroid nodules. It may provide a new and reliable method for the clinical diagnosis of small thyroid nodules.

B-0125 11:19

Prediction of Bethesda category of thyroid nodule with specific sonographic findings

F. Kulali, M. Demir, A. Semiz-Oysu, Y. Bukte; *Istanbul/TR (ftkulali@gmail.com)*

Purpose: Our purpose was to depict specific sonographic characteristics of thyroid nodule for each cytological Bethesda category for planning patient management.

Methods and Materials: The Institutional Review Board approved this retrospective study, and informed consent was waived. A total of 1488 patients who had undergone ultrasound guided fine-needle aspiration biopsy (FNAB) were included. There were 1260 women (85%) and 228 men (15%) with a mean age of 49 years (range: 12 - 88 years). Sonographic features (the largest diameter, contour, echogenicity, existence of halo, multiplicity, solid/cystic nature, presence of calcifications, lymphadenopathy and thyroiditis findings) were recorded. The relationship between sonographic findings and cytological results was investigated for each Bethesda category.

Results: A total of 1488 patients were enrolled in our study. Among Bethesda category 2 nodules, ratios of iso-/hyper-echogenicity, well-defined contour, solid plus cystic component, thin halo and multiplicity were higher than those of Bethesda 3, 4, 5 and 6 categories ($p < 0.05$). Nodules with thick halo (7/75, 9.5%) and lymphadenopathy (4/75, 5.5%) were only observed in Bethesda category 6 nodules. Ill-defined/irregular contour was mostly seen in Bethesda category 5 (5/7, 71%) and category 6 (34/75, 45%) nodules (all $p < 0.05$). Solid composition and single nodule were more frequent in Bethesda category 6. There were no statistical difference about the existence of micro-calcification or thyroiditis between Bethesda categories ($p > 0.05$).

Conclusion: Prediction of Bethesda category of nodule with sonographic findings is possible in some Bethesda categories. Specific sonographic findings can decrease the number of unnecessary FNABs.

B-0126 11:27

On-site evaluation microscopic evaluation of unstained slides to assess adequacy of thyroid fine-needle aspiration cytology

N.M.H. Nik-Hussin, M. Robinson, K. Kenyon, M. Brown, P.-T. Diep, M. Atwan; *Lancaster/UK (nik3278@hotmail.com)*

Purpose: On-site evaluation of thyroid fine-needle aspiration cytology (FNAC) on stained slides is a proven way to reduce inadequate samples. However, staining requires additional time, specialist staff and reduces clinic throughput. Our institution utilises a unique approach to evaluating adequacy of FNAC by assessing unstained slides. This study aimed to evaluate our practice of assessing adequacy of ultrasound-guided fine-needle aspiration biopsy of thyroid lesions using contemporaneous microscopy on unstained, air-dried samples.

Methods and Materials: Retrospective review of cytopathology and radiology reports on 139 consecutive patients who had undergone FNAC sampling between September 2015 and August 2016 at a regional clinic for suspected

thyroid cancer. Cytology reports use the Royal College of Pathologist 'Thy' classification system. The samples were obtained and slides prepared by 3 histopathologists and 1 radiologist using a standardised technique. Each operator evaluates the unstained samples for adequacy and performs up to 3 needle passes if no adequate sample was seen on microscopy.

Results: Using our method of assessing unstained thyroid fine-needle aspiration cytology biopsy, our service was able to achieve a collective adequacy rate of 93.9% (range 90-100%). This adequacy rate is higher than that is cited in the literature in studies where on-site evaluation of adequacy is not utilised. Our adequacy rate is comparable to studies evaluate stained fine-needle aspiration samples, but without the time penalty required to stain the samples.

Conclusion: On-site evaluation of thyroid FNAC on unstained slides is a practical and efficient way of achieving a high adequacy rate.

B-0127 11:35

Malignancy risk of thyroid nodules with isolated macrocalcification

H.Y. [Gwon](#), D.G. Na, W. Paik, S.J. Yoon; *Gangneung/KR*

Purpose: This study was performed to investigate the incidence and malignancy risk of thyroid nodules with isolated macrocalcification.

Methods and Materials: From January 2011 to June 2018, a total of 3061 consecutive patients with 3852 thyroid nodules (≥ 1 cm) underwent ultrasonography (US)-guided fine-needle aspiration (FNA). We retrospectively reviewed all US images of those nodules to determine nodules with isolated macrocalcifications. We assessed the incidence, malignancy rate, and size distribution of thyroid nodules with isolated macrocalcifications. The nodule size was categorised as 3 groups (group 1: 1-1.4cm, group 2: 1.5-1.9cm, group 3: ≥ 2 cm).

Results: Isolated macrocalcification was found in 38 (1.2%) of 3061 patients. Among 38 nodules with isolated macrocalcifications, the final diagnosis was achieved in 30 nodules and seven malignant tumours (6 conventional type and 1 follicular variant type papillary carcinomas) were diagnosed by surgery (n=6) and FNA (n=1). The malignancy rate of isolated macrocalcification was 23.3% in 30 nodules with final diagnoses and 18.4% in all nodules. The size of isolated macrocalcifications was group 1 (n=27, 71.1%), group 2 (n=8, 21%), and group 3 (n=3, 7.9%). The mean size of malignant tumours was 1.5 ± 0.4 mm and the tumour size was group 1 (n=3, 43%), group 2 (n=3, 43%), and group 3 (n=1, 14%). Among 6 malignant tumours with surgical pathology diagnoses, the extrathyroidal extension was found in 4 (66.7%) and lymph node metastasis in 2 (33.3%) tumours.

Conclusion: Thyroid nodule with isolated macrocalcification (≥ 1 cm) was found in 1.2% of our cohort patients and showed an intermediate malignancy risk (at least 18.4%).

B-0128 11:43

Role of acoustic radiation force impulse (ARFI) in differentiating benign and malignant thyroid nodules

S.K. [Suganchand Rikabchand](#); *Jodhpur/IN (Sunilmed@gmail.com)*

Purpose: The purpose of the study was to assess the role of shear wave elastography in differentiating benign and malignant thyroid lesions with pathological correlation in Indian population

Methods and Materials: 246 thyroid nodules in 198 patients presenting with thyroid lesions were included in the study. All the patients were subjected to B-mode ultrasound and elastography using shear wave with Virtual Touch Imaging (VTITM) (Siemens Medical Solutions USA, Inc., PA, USA) and Virtual Touch Quantification (VTQTM) (Siemens Medical Solutions USA, Inc., PA, USA) before ultrasound guided Fine Needle Aspiration Cytology was performed. The obtained data was compared and analyzed using an appropriate statistical test to check the validity of elastography in determining the nature of the neoplasm.

Results: Of the 246 thyroid nodules 158 were benign and 88 were malignant as evidenced by FNAC results. VTI was 93.7% sensitive and 90.7% specific in detecting benign thyroid nodules whereas 90.9% sensitive and 94.9% specific in detecting malignant thyroid nodules. VTQ was 92.5% sensitive and 87.4% specific in detecting benign thyroid nodules whereas 89.1% sensitive and 96.1% specific in detecting malignant thyroid nodules.

Conclusion: VTI and VTQ both are very useful tools in diagnosing the nature of thyroid neoplasm. Also VTQ helps in providing quantitative values to differentiate benign and thyroid nodules thus can be used in accurate diagnosis. 2D Ultrasound features with elastography can be used in accurate diagnosis of benign or malignant thyroid nodules thus improving patient compliance by reducing invasive procedures determining the nature of neoplasm.

B-0129 11:51

Thyroid nodules: diagnostic performance of ATA and TIRADS on risk stratification for malignancy

B.C.S. Rabelo, F. Tinoco Alvim de Souza, P. Ramos Botelho Antunes, E. Carvalho de Siqueira, M. Alvares de Campos, L. [Vianna Cancado](#), A. Vianna Cancado, M. Barbosa Alvares; *Belo Horizonte/BR*

Purpose: We aimed to access the performance of Thyroid Imaging Reporting Data System (TIRADS) and 2015 American Thyroid Association (ATA) on malignancy risk stratification, by comparing both ultrasound classification systems with fine needle aspiration (FNA) histologic data.

Methods and Materials: We retrospectively reviewed exams of 190 patients. Thyroid ultrasound images of each patient and nodule were categorized based on TIRADS and ATA. Both classifications systems were initially compared with each other, and then matched with FNA histologic data classified with Bethesda system. Location and size of each nodule were also verified.

Results: Of the 190 evaluated patients (87.4% women), the mean age was 53.7 years (51,12-55,02), the mean size of nodules were 17,87mm (17,07-18,67). More nodules were solid and isoechoic (49.5% and 36.8% respectively). There was a strong correlation between TIRADS and ATA classifications ($r=0,860$ $p<0,0001$). When compared with histological analysis, TIRADS AND ATA had a weak correlation. TIRADS $r=0,179$ $p=0,023$; ATA $r=0,170$ $p=0,031$.

Conclusion: Our study showed that TIRADS and ATA had similar diagnostic accuracy in the evaluation of thyroid nodules ultrasound, but both classifications were shown to overestimate the presence of malignant neoplasms.

Image quality evaluation of ultra-low dose chest CT using six iterative reconstructions

M. [Afadzi](#), K. Fosså, H. Andersen, T.M. Aaløkken, A.C.T. Martinsen; *Oslo/NO (merafa@ous-hf.no)*

Purpose: To assess the effect of six different iterative reconstruction (IR) algorithms on image quality of ultra-low-dose Chest CT using two phantom sizes.

Methods and Materials: A Kyoto Kagaku Lungman phantom (with and without extensions) was scanned on four high-end CT systems using fixed tube voltages (80 or 140 kVp) and the lowest mAs on each scanner, resulting in different CT DIvol of 0.1-0.2 mGy (80 kVp) and 0.3-1 mGy (140 kVp). Images were reconstructed with the IR available on the scanners. Image quality parameters were evaluated for all reconstructions.

Results: All IR algorithms improved quantitative image quality parameters for both phantom sizes with increase in dose. Model-based iterative reconstructions (MBIR) improved contrast-to-noise ratio of lesions more than the statistical algorithms at the same dose level. Hounsfield units measured in the smaller phantom were within acceptable range (≤ 6 HU) for all IR at 140 kVp. All algorithms showed lower noise power spectrum (NPS) peaks at 80 kVp than 140 kVp for the bigger phantom. In comparison with the statistical techniques, MBIR algorithms showed lower NPS peaks at 80 kVp. The FIRST algorithm showed higher ($p \leq 0.004$) noise texture deviations (NTD) at 140 kVp than 80 kVp; however, NTD of IMR was not dose dependent ($p = 0.172$). Lower peak frequencies of NPS and higher NTD values indicate coarser and blotchier noise texture respectively.

Conclusion: MBIR techniques enhanced quantitative image quality parameters at ultra-low doses more than the statistical techniques but affected the image texture to a higher degree.

Evaluating the use of a noise index to identify outliers in CT examinations
A.S.L. Dedulle, S. Rahimzadeh, N. Fitousi, H. Bosmans, J. Jacobs; *Leuven/BE* (niki.fitousi@qaelum.com)

Purpose: To evaluate which outliers would be identified if multi-parameter alerting would be implemented, such as the combined use of patient size, CTDI_{vol} and a noise index for clinical chest CT examinations.

Methods and Materials: Fifty thorax CT examinations (Siemens Somatom Force, Germany) with the same study protocol were used. The water equivalent diameter (WED) of the patients, the CTDI_{vol} of each series and other important parameters (e.g. vertical offset) were extracted by the dose management system DOSE (Qaelum, Belgium). The global noise level (GNL) was calculated for expiration series with the lung (Br59d) kernel (Christianson et al. Medical Physics 2015).

Results: The WED range was 20cm to 32cm and the correlation between WED and CTDI_{vol} was significant ($p < 0.01$). Three outliers were observed. Two of them had a vertical offset of 3cm to 4cm closer to the tube. Literature indicates this leads to a higher CTDI_{vol} by 10% to 30%. The third outlier had a wrong positioning (arms next to body). When the GNL was added as the third dimension, another exam with very high noise was found even though it was not initially identified as outlier. This case had a vertical offset of 4.4cm away from the tube, which caused a decrease of CTDI_{vol}, thus high GNL. The correlation between the WED and GNL was significant ($p < 0.01$), as well as between the CTDI_{vol} and GNL ($p < 0.05$).

Conclusion: Introducing an automated image quality index can detect extra and relevant outliers when compared to a simpler dose versus patient size analysis.

Improved grey-white matter separation by amplitude/power coefficients derived from spectral analysis of dual-energy CT

I. Leichter, B. Fialkoff, Y. Uziel, E. Ben-David, Z. Romman, J. Sosna, J.M. Gomori; *Jerusalem/IL* (gomori@cc.huji.ac.il)

Purpose: In conventional CT there is an overlap in the HU levels of grey matter (GM) and white matter (WM). Our aim was to use dual-energy CT (DECT) to improve GM/WM separation.

Methods and Materials: DECT reconstructs virtual mono-energetic (VME) images, which allow for spectral analysis. Three pairs of regions-of-interest (ROI) in GM and WM were marked in VME images of 33 normal subjects, at different brain locations. Spectral-attenuation curves describing the mean HU versus energy, for series of VME images in the range 40-100keV, were generated for GM-ROIs and WM-ROIs and fitted to power curves. An algorithm was developed to generate for each pixel in the image a spectral-attenuation curve, and calculate the amplitude/power coefficients of the fitted power-curve. Based on the amplitude/power coefficients, the algorithm characterized each pixel as GM or WM and created a GM-WM map by superimposing them in different colors over the original image.

Results: The mean HU of GM-ROIs was higher than for WM-ROIs, but their ranges completely overlapped. In contrast, the resulting amplitude coefficient of the fitted power curve for GM was significantly higher than for WM, with a large separation ($GM_{min} - WM_{max}$) between their ranges. The power coefficient was negative for GM and positive for WM with a substantial separation between them. The significant GM/WM separation was also confirmed visually and allowed creation of more accurate grey/white matter maps.

Conclusion: Amplitude/power coefficients derived from DECT allow better GM/WM separation than conventional CT. The possible clinical applications of this technique need further study.

Changes on noise power spectrum by advanced CT image reconstruction techniques

T. Pan, R. Vikram; *Houston, TX/US* (tpan@mdanderson.org)

Purpose: We use noise power spectrum (NPS) to evaluate noise reduction by ASir and ASir-V of GE, SaFire and Admire of Siemens, and PixelShine of AlgoMedica based on deep learning.

Methods and Materials: The homogeneous module of ACR CT phantom was scanned for NPS. The baseline filtered back-projections (FBP) were from the standard kernel on GE, Hr44f on Force and J40f on AS+. For noise reduction, all ASir, ASir-V, SaFire, Admire, and PixelShine settings were compared. Centroid frequency ratios (CFR) between the NPS centroid frequencies of noise reduction and FBP were compared. A smaller CFR means more image

blurring. Noise magnitude ratios (NMR) between the areas under the NPS curves of noise reduction and FBP were compared. A smaller NMR means more noise reduction. An ideal reconstruction shall maintain CFR of close to 1 and low NMR of close to 0.

Results: For the same noise reduction NMR=0.6, PixelShine (0.97) has the least frequency shift (CFR closer to 1), followed by SaFire (0.95), ASir-V (0.91), Admire (0.88), and ASir (0.86). For the same centroid frequency shift of CFR=0.95, PixelShine (0.44) has the most noise reduction, followed by SaFire (0.60), ASir-V (0.74), Admire (0.78), and ASir (0.82).

Conclusion: PixelShine (noise reduction based on deep learning) has the least centroid frequency shift for the same amount of noise reduction or the most noise reduction for the same amount of centroid frequency shift. For the same centroid frequency shift, ASir-V reduces more noise than ASir; and SaFire reduces more noise than Admire.

Patient size-dependent ultralow-dose data completion scan in a whole-body photon-counting CT scanner

S. Dorn¹, S. Sawall¹, J. Maier¹, C. Polster², S. Faby³, M. Uhrig¹, H.-P. Schlemmer¹, M. Kachelrieß¹; ¹Heidelberg/DE, ²Munich/DE, ³Forchheim/DE (sabrina.dorn@dkfz.de)

Purpose: To find the minimum possible dose of a data completion scan (DCS) on a photon-counting (PC) CT prototype.

Methods and Materials: The SOMATOM Count (Siemens Healthineers, Germany) CT system features a PC detector with 27.5 cm field of measurement (FOM). To correct for truncation artefacts, the additionally available 50-cm FOM conventional detector subsystem can acquire a DCS. Two anthropomorphic phantoms (liver, thorax) of three sizes (small, medium, large) were scanned with 120 kV at 210 mAs_{eff} with the PC subsystem. For each phantom eight DCS were acquired (120 kV) ranging from 200 to 7 mAs_{eff}. To further lower the dose also 100 and 80 kV were used. CT value consistency in PC images after detruncation across DCS dose levels was quantitatively assessed.

Results: Minimum achievable DCS dose was 0.13 mGy (32cm CTDI_{vol}), corresponding to about 0.06 mSv. No significant shift in CT values was observed between PC images with minimum dose DCS and PC images with high-dose DCS for small and medium phantom size. For the large phantom size, we observed a shift for the minimum dose DCS of about -3 HU. Setting tube voltage to 100 kV resulted in a deviation of 0.1 HU. We achieved an 8.7-fold dose reduction compared to previously proposed DCS protocols [JCAT 40(4):663-669, 2016].

Conclusion: DCS settings of 80 kV, 7 mAs_{eff}, are sufficient to provide satisfactory data completion of PC images. With larger patients, the tube voltage needs to be increased. DCS dose is small compared to conventional CT scans.

Optimising CT acquisition parameters for the quantification of lung emphysema

G. Van Gompel, S. Mahmoudi, C.C. Brussaard, J. De Mey, N. Buls; *Brussels/BE* (Gert.vangompel@uzbrussel.be)

Purpose: To optimise image reconstruction settings for improved and reproducible lung emphysema quantification.

Methods and Materials: A dedicated technical phantom was composed using lung tissue equivalent material (Leeds, LN330) in a water-filled cylindrical tank. CT scans of the phantom were acquired on a Philips ICT scanner at 100 kVp and CTDI_{vol} from 0.4-17 mGy. Images were reconstructed with FBP, iDose and IMR with a selection filters, and the noise power spectrum (NPS) and task transfer function (TTF) were calculated. The emphysema quantification efficiency (EQE) is defined as the percentage of correctly identified pixels (emphysema versus no emphysema) in the images after applying a threshold at -950HU. The EQE dependence of hole size in noise-free conditions was investigated by applying the TTF-derived point spread function on a virtual phantom image with increasing hole size.

Results: Image resolution and noise in terms of TTF and NPS improve, and the EQE increases as the complexity of the iterative reconstruction and the hardness of the filter kernel increase, e.g. EQE=96% for IMR sharp plus versus 91% for FBP-B, at 2.2 mGy and 2mm diameter. For decreasing emphysema spot diameters, the EQE has a decreasing trend: e.g. FBP-L EQE=99% at 10mm and EQE=91% at 1mm diameter.

Conclusion: The quantification of lung emphysema is impacted by the spatial resolution and noise properties of the reconstruction methods; advanced iterative reconstruction methods in combination with harder filters are preferred. Moreover, lung emphysema consisting of numerous small spots tends to be underestimated in CT images.

B-0137 11:18

Automated image quality assessment in CT using a 3D printed lung vessel phantom and structural similarity index analysis

I. Hernandez-Giron¹, R. Schippers², J.M. den Harder³, G.J. Streekstra³, W.J.H. Veldkamp¹; ¹Leiden/NL, ²The Hague/NL, ³Amsterdam/NL (irene.debroglie@gmail.com)

Purpose: Image quality is frequently assessed using geometric phantoms and simple image quality metrics such as contrast-to-noise ratio and noise power spectrum. Extrapolating these technical results to patient images is not straightforward. There is a need for metrics to analyze image quality in closer relation to clinical practice, including patient's anatomy and radiologists' clinical tasks. We used a 3D printed anthropomorphic lung vessel phantom combined with a structural similarity index metric to analyze, as proof of principle, the effect of dose on CT image quality.

Methods and Materials: A 3D printed anthropomorphic phantom, mimicking the human lung vessels distribution (8mm diameter ≥ 0.25mm, VisijetEX200 material, 10×15×2.5cm³), inserted in a PMMA thorax-shaped holder (300×200×29mm³) was scanned 10 times (high-resolution-thorax protocol, Aquilion-ONE-Genesis (Canon Medical Systems)), varying dose [CTDI_{vol}=0.2-0.4-0.9-2.6-5.2-10.9 mGy]. Image quality was assessed with the structural similarity index (SSIM:0-1 range, 1 is best), based on the assumption that the human visual system extracts structural image information. Each acquired set was compared to two references: a high dose image volume (39.2 mGy) and the phantom design file.

Results: When the high dose image set was the reference, image quality deteriorated as dose decreased [SSIM:(0.986±0.2%;10.9mGy)-(0.972±0.4%;5.2mGy)-(0.951±0.9%;2.6mGy)-(0.879±1.5%;0.9mGy)-(0.809±3.5%;0.4mGy)-(0.720±2.9%;0.2mGy)]. SSIM values were slightly lower when the phantom design file was used as reference, for all dose levels: [SSIM:(0.915±1.5%;10.9mGy)-(0.907±1.9%;5.2mGy)-(0.891±1.4%;2.6mGy)-(0.835±2.9%;0.9mGy)-(0.777±3.6%;0.4mGy)-(0.706±2.4%;0.2mGy)].

Conclusion: CT image quality can be assessed using a 3D printed anthropomorphic phantom and the structural similarity index, showing image quality improvement (SSIM increase) with increasing dose, as a proof of principle. This approach has the potential to be used in protocol optimization.

Sparse-sampling computed tomography (SpSCT) for the detection of pulmonary embolism

A. Sauter¹, F.K. Kopp¹, J. Dangelmaier¹, D. Deniffel¹, F. Meurer¹, R. Bippus², E.J. Rummeny¹, P.B. Noel¹; ¹Munich/DE, ²Hamburg/DE (andreas.sauter@tum.de)

Purpose: Evaluation of sparse sampling computed tomography (SpSCT) regarding subjective and objective image criteria for the detection of pulmonary embolism (PE) at different dose levels.

Methods and Materials: Computed tomography pulmonary angiography (CTPA) scans of 20 clinical patients were used to obtain simulated low-dose scans (100%-50%-25%-12.5%-6.3%-3.1%). 6 levels with full sampling (FS) resulted. From these data, every second (2-SpSCT) or fourth (4-SpSCT) projection was used to obtain sparse sampling scans. 300 image sets (20 patients, 6/5/4 levels of FS/2-SpSCT/4-SpSCT) resulted and were evaluated by four blinded radiologists regarding subjective image quality and diagnostic performance. Additionally, CNR was evaluated.

Results: Sensitivity was 100% with 2-SpSCT and 4-SpSCT at the 25% and the 12.5% dose level for all localizations of PE (one subgroup 98.5%). SpSCT showed higher values for sensitivity, specificity, accuracy and the area-under-the-curve at all dose levels compared to FS. Subjective image quality (IQ) was significantly higher for 4-SpSCT compared to FS at all dose levels with a mean IQ of 3.8 at the 12.5% dose level (4=good IQ). 4-SpSCT showed significantly higher IQ compared to 2-SpSCT at the 12.5% dose level. No examination was rated as non-diagnostic at this dose level when using 4-SpSCT (2-SpSCT: 0.5; cases FS: 1.5 cases).

Conclusion: Via SpSCT, a significant dose reduction down to a 12.5% dose level (mean effective dose 0.38 mSv in the current study) for CTPA is possible while maintaining full diagnostic confidence. Hereby, 4-SpSCT is superior to 2-SpSCT at lower dose levels.

B-0139 11:34

Application of preset adaptive statistical iterative reconstruction-V in dual-enhanced abdominal CT

Y. Chai; Zhengzhou/CN (chaiyarcy@163.com)

Purpose: To analyse the effect of preset ASIR-V on image quality and radiation dose in dual-enhanced abdominal CT and to investigate the optimal ASIR-V in clinic.

Methods and Materials: 180 patients were collected prospectively. All patients underwent two-phase enhanced abdominal CT (120 kVp, NI 10) and were randomly divided into 6 groups (A-F, n=30 each). In group A-F, 0%-50% preset ASIR-V (10% interval) was applied, respectively. Qualitative parameters (subjective image quality, diagnosis confidence and radiation dose) and quantitative parameters [image noise, CT number and contrast to noise ratio (CNR)] were measured and compared among the groups using ANOVA or Kruskal-Wallis H test.

Results: The CTDI_{vol} decreased with the preset ASIR-V percent increasing. The effective radiation dose had significant difference among groups (P<0.001), and the ED of group B-F dropped by 10.8%, 21.7%, 31.2%, 44.9% and 61.9%, respectively, compared with group A. Group E showed the optimal image quality (all P<0.01) and diagnosis confidence (all P<0.01) in all phases. The image noise and CT number of liver, pancreas and muscle had no difference among groups. The CNRs had no significant difference except liver and portal CNR in PVP.

Conclusion: In abdominal CT, 40% preset ASIR-V can provide the best image quality and reduce radiation dose by 44.9%.

B-0140 11:42

Comparison of 90 and 180 micron resolution cone-beam CT scans in patients with artefact causing root canal filling material

A. Patney, M. Murugavel, V. Mahajan; New Delhi/IN (vidur@mahajanimaging.com)

Purpose: Many dental patients have root-canal filled teeth which cause artefacts on a Cone-beam CT (CBCT) scan. We studied the effect of voxel size on image quality of CBCT scans in presence and absence of root canal filling material.

Methods and Materials: CBCT scans of 30 patients, 15 with (group-1) and 15 without (group-2) root canal filling, having both 90u and 180u voxel size were obtained. In group-1, patient scans had root canal filling material and no other artefact causing material in field of view. In group-2, patient scans had no artefact causing material. In all scans, CNR (contrast-to-noise ratio) was calculated by determining the mean and standard deviation of grey values on DICOM data, adjacent to root canal filling material (group-1)/central region of scan volume (group-2) and also determining the grey values at edge of the scan volume (both groups). CNRs of the scans were analysed by Student's t-test.

Results: Significant difference (paired t-test, p=0.018) was seen in CNR between the 90u and 180u scans of the same patient in group-1. Significant difference (p=0.135) was not seen in CNR between the 90 and 180u scans of the same patient in group-2.

Conclusion: In presence of root canal filling material, the image quality of 90 microns scan is significantly better than that of 180 microns scan. However, in absence of artefact causing material, the image quality is not affected significantly by voxel size, even though it is better in 90 microns scan.

Outcomes of long-term interval rescreening with low-dose CT for lung cancer in different risk cohorts

A. Lam, R. Aggarwal, G. Liu, J. Kavanagh; Toronto, ON/CA (jokavana@tcd.ie)

Purpose: We hypothesize that the incidence of screen-detected lung cancer (LC), in participants with previously negative scans, will be highest in the cohort with the highest baseline risk score.

Methods and Materials: Individuals with negative baseline screening results from the Princess Margaret International Early Lung Cancer Action Program prior to 2009 underwent low-dose CT rescreening from 2015 to 2018.

Individuals were contacted in order of decreasing risk, as determined by the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial's PLCOM 2012 6-year LC risk-prediction model, and then categorized into three risk cohorts according to their baseline risks. The incidence of LC in each risk cohort was determined and compared. Chi-square testing was used for categorical variables and one-way ANOVA on ranks was used for continuous variables.

Results: Of the 1261 participants we attempted to recontact, 359 patients returned for a rescreening scan (mean of 7.6 years between scans). Participants were divided into low- (<2%), moderate- (≥2%<3.5%), and high-baseline risk (≥3.5%) cohorts. On average, those in the high-risk cohort were older (66 vs 62 and 59 years) and had a greater smoking history (54 vs 47 and 29 pack-years) when compared to the moderate and low-risk cohorts, respectively. The incidence of cancer in the high-risk cohort was significantly higher than in the moderate-risk cohort (11% vs 1.7%, p=0.002).

Conclusion: There was a significantly higher incidence of LC in the high-risk cohort than in the moderate-risk cohort. The cut-point between the high and moderate risk was determined to be ≥3.5% 6-year baseline risk.

B-0142 10:38

Applying British Thoracic Society 2015 compared to Fleischner Society 2017 recommendations for lung nodule management leads to different discharge and PET-CT referral rates

L. Royle, M. Anjari, S. Sasikumar, R. SinhaRay, S. Mak, M. Subesinghe, D. Murphy, R. Breen, A. Nair; London/UK (leanne.royle@nhs.net)

Purpose: To compare agreement, and rates of discharge and referral for PET-CT between the British Thoracic Society 2015 (BTS) and Fleischner Society 2017 recommendations (FS) for pulmonary nodule management.

Methods and Materials: In 138 patients [89 (64.5%) ever-smokers] with fully investigated CT-detected incidental pulmonary nodules [median average diameter 7mm, 8 (5.8%) malignant], we retrospectively modelled four management strategies: combined volume- and diameter-based BTS (BTSvol), diameter only-based BTS (BTSdiam), diameter-based FS where ever-smokers were considered high risk (FSsmoking), and diameter-based FS where a Brock model score of ≥5% was considered high risk (FSBrock). We compared agreement using the weighted kappa statistic (k_w) and rates of discharge and referral for PET-CT using McNemar's test.

Results: Agreement between the BTS and FS strategies was good (k_w 0.66-0.72). However, significantly more patients were discharged using BTSvol [35(25.4%)] compared to BTSdiam [14(10.1%), p<0.0001], and FSsmoking [18(13.0%), p=0.0015], but not compared to FSBrock [37(26.8%), p=0.81]. Conversely, significantly more patients were referred for immediate PET-CT using BTSvol [21(15.2%)], compared to FSsmoking [7(5.1%), p=0.0026] and FSBrock [8(5.8%), p=0.0002]. 4/21(19%) nodules referred for immediate PET-CT using BTSvol were malignant, and none were referred for immediate PET-CT using FSsmoking or FSBrock.

Conclusion: Volume-based BTS management can (1) reduce nodule follow-up rates compared to diameter-based BTS and diameter-based, smoking-stratified FS management, and (2) result in higher referral for immediate PET-CT, allowing earlier detection of malignant nodules. However, using risk stratification in the FS with the Brock model, rather than smoking status alone, can yield similar discharge rates to BTS volume-based management.

Low-dose computed tomography (LDCT) screening reduces overall and lung cancer specific mortality beyond five years

U. Pastorino¹, M. Silva², F. Sabia¹, S. Sestini¹, M. Boeri¹, G. Sozzi¹, N. Sverzellati², A.V. Marchiano¹; ¹Milan/IT, ²Parma/IT (alfonso.marchiano@istitutotumori.mi.it)

Purpose: To assess the long-term benefit of lung cancer screening (LCS) by low-dose computed tomography (LDCT), notably the overall and lung cancer (LC) specific mortality beyond 5 years and until 10 years.

Methods and Materials: The Multicenter Italian Lung Detection (MILD) trial prospectively enrolled 4,099 participants, randomised to either LDCT arm (n=2,376) or control arm (n=1,723); 39,293 person-years of follow-up were accumulated between 2005 and June 2018. The primary outcomes were 10-year overall and LC specific mortality. A landmark analysis was used to test the specific long-term effect of LCS beyond 5 years, notably by selective exclusion of events that occurred < 5 years. Cumulative mortality was evaluated using Kaplan-Meier estimator and differences among groups were tested using Log-rank test, adjusted for sex, age and pack-years. The prognostic value of assigned arm in predicting mortality was investigated by Cox's proportional-hazard's regression adjusted for the above variables.

Results: In the whole 10-year LCS, LDCT arm showed a protective non-statistically significant trend for reduction of overall mortality (HR: 0.80, 95% CI 0.62 to 1.03) and a significant 39% reduced risk of LC mortality (HR 0.61, 95% CI 0.39 to 0.95), compared to the control arm. The landmark analysis beyond the 5th year of screening showed significant reduction of mortality in the LDCT arm: 32% reduction of overall mortality (HR: 0.68, 95% CI 0.49 to 0.94), 58% reduced risk of LC mortality (HR 0.42, 95% CI 0.22 to 0.79).

Conclusion: LDCT screening reduces lung cancer mortality and overall mortality, especially in the long-term range between 5 and 10 years.

B-0144 10:54

Lung cancer CT screening performance at a large hospital system in the US: our 5-year experience showcases the need for better systems of care

E.J.M. Barbosa Jr., A. Kolansky¹, X. Sui², J. Jiang¹; ¹Philadelphia, PA/US, ²Beijing/CN (eduardo.mortani@gmail.com)

Purpose: Lung cancer low-dose CT screening (LCS) has been shown to decrease mortality in national trials in the United States and Europe. We assessed performance metrics of our LCS program and patient compliance to screening recommendations.

Methods and Materials: We retrospectively identified all patients who underwent LCS from 2014 to 2018, via our EMR. We recorded patient demographics, lung cancer related and incidental findings, lung-RADS category, outcomes, and compliance with screening recommendations.

Results: 1373 patients were screened during a 5-year interval, of which 260 (18.9%) returned for follow-up scans (87.7% had two, 2.3% had three, and 0.07% had four). Average age was 65.3, (51.5% men, 48.5% women), average smoking history was 51.4 pack-years (SD=19.8). 34/260 (13.1%) had positive scans, of which 22/260 (8.4%) were lung-RADS category 3, 3/260 (1.1%) were 4A, 5/260 (1.9%) were 4B, and 4/260 (1.5%) were 4X. 2/260 were diagnosed with lung cancer on follow-up. Among patients who had multiple scans, only 14.5% obtained follow-up within a month of the recommended time. Of those who also had positive screening scans, 34.4% followed up on time, 43.8% followed up late, and 21.8% were lost to follow-up.

Conclusion: Our rate of positive LCS exams is slightly higher than Lung-RADS prediction (13.1% vs 9%), however most were not confirmed as lung cancers, leading to an estimated false positive rate as high as 94%. Moreover, adherence to LCS recommendations is very low, but increases with positive exams (14.5% vs 34.4%). Healthcare systems should devise strategies to address these problems.

B-0145 11:02

Lesion measurement on a combined "all-in-one" computed tomography window on chest scans: effect on intra- and interobserver variability

A. Snoeckx¹, J. Cant², C. Franck¹, K. Carpentier¹, E. Luyckx¹, S. Nicolay¹, M.J. Spinhoven¹, A. Van Hoyweghen¹, P.M. Parizel¹; ¹Edegem/BE, ²Mortsel/BE (annemie.snoeckx@uza.be)

Purpose: Historically, chest CTs are viewed in several window settings to evaluate specific anatomical structures and regions. A newly developed imaging processing technique fuses these conventional windows into a single "All-In-One" (AIO) window. Previous research has shown that lesion detection on this AIO-window is as good as on conventional window settings. This study aims to evaluate consistency of CT measurement of lesions on this novel AIO-window, compared to conventional window settings.

Methods and Materials: In this retrospective study, 368 measurable lesions of various size, origin and lesion sharpness were measured on CT images by 6 radiologists with 3 different levels of expertise. All lesions were measured twice on both the AIO-window and conventional window settings, with an interval between repeated measurements of at least one week. Intraclass correlation coefficients were used to assess intra- and interobserver variabilities.

Results: Overall intra-observer agreement for the AIO-window and conventional window settings was 0.986 (95% confidence interval (CI): 0.983-0.989) and 0.991 (95%CI 0.989-0.993), respectively. For interobserver agreement this was 0.982 (95%CI 0.979-0.985) (AIO) and 0.979 (95%CI 0.957-0.982) (conventional). Intra- and interobserver agreement differed by size, sharpness and reader experience for both AIO and conventional windows. Measurement variability decreased with increasing lesion size. Regarding sharpness, inter- and intra-observer agreement ranged from 0.986-0.989 (AIO) and 0.985-0.992 (conventional) for well-defined lesions and from 0.978-0.983 (AIO) and 0.974-0.991 (conventional) for ill-defined lesions.

Conclusion: Overall intra- and interobserver variability rates were similar for the AIO-window and conventional windows; lesion measurement on the AIO window seems to be reliable and reproducible.

Comparison of computer-aided semi-automated volumetry with manual volumetry of part-solid pulmonary nodules
S. Werner¹, R. Gast¹, R. Grimmer², M. Hoger¹; ¹Tübingen/DE, ²Forchheim/DE (sebastian.werner@med.uni-tuebingen.de)

Purpose: To test whether computer-aided volumetry (CAV) can compete with manual volumetry performed in part-solid pulmonary nodules.

Methods and Materials: 66 part-solid pulmonary nodules were retrospectively identified in 34 thin-slice unenhanced Chest-CTs of 19 patients. CAV and manual volumetry was carried out for the solid and subsolid part. Smooth and sharp kernels were used for CAV. Manual volumetry was carried out by two radiology residents using the smooth kernel. Ground truth was determined by an experienced radiologist in consensus with one of the residents. Accuracy of CAV and manual volumetry was compared. Consistency of repeated CAV measurements was determined and compared between usage of the soft and hard tissue kernel.

Results: Accuracy of manual volumetry/CAV was 79%-80%/77% for the solid part and 73%-76%/67% for the subsolid part. Consistency of CAV was high for the solid part and low for the subsolid part with >90% and 19 % of measurements lying in the correct ground truth range, respectively. Comparison of CAV consistency between soft and sharp tissue kernel showed slightly better results for the sharp kernel which for the solid part yielded volumetric deviations from the ground truth of <5%/<1% in 48/45 of 54 lesions compared to 46/43 of 54 lesions for the soft kernel.

Conclusion: CAV of part-solid lung nodules delivers comparable and reproducible accuracy for the solid and subsolid component compared to manual volumetry. Measurement consistency of CAV was high for the solid part and poor for the subsolid part showing slight improvement when using a sharp tissue kernel.

Pulmonary nodule size measuring difference: comparison between machine-learning based auto-measurement on CT images and gross specimens through surgery

X. Luo, M. Zhang, J. Ding, M. Chen; Beijing/CN (archaeopteryxdin@163.com)

Purpose: This study was aimed to evaluate the accuracy of machine-learning in measuring the size of pulmonary nodules by comparison between the auto-segmented size with those manually measured from gross specimen in surgery.

Methods and Materials: 73 patients (age: 59.5±9.9 years, F=52, M=21), who underwent preoperative CT-guided pulmonary nodule location, were enrolled. The slice thickness of CT images were 1.0 mm. All the images were analysed through machine-learning model for pulmonary nodules. With auto-segmentation, nodule sizes were measured automatically. Preoperative medical adhesive was injected adjacent to the targeted nodule. In surgery, gross specimen of nodules were measured manually. Paired t test was performed to compare the difference.

Results: (1) 102 nodules were studied, with 61 GGOs, 30 sub-solid and 11 solid nodules; 24 were confirmed benign, including hamartoma, organized pneumonia, fibrosis, granuloma and lymphoid hyperplasia; the rest were 12 AAHs, 21 AIs, 4 MIAs, 12 IACs and 29 nodules with other malignancy. (2) Among all nodules, the average auto-segmented maximum dimension was 10.8±6.2mm; in gross specimen, it was 9.4±5.7mm (p<0.0001). Measurement difference was observed in GGOs (p=0.0001). However, it was not significant in sub-solid and solid nodules (p=0.1962, p=0.0885). (3) Compared according to different pathology, measurement difference was not significant in benign lesions or AAHs (p=0.3099, p=0.2247). While adenocarcinoma-related nodules were showing different (p<0.0001). However, the difference was not significant in MIAs or IACs.

Conclusion: The auto-segmented nodules were measured about 15% larger than those in gross specimens. The causes might connect with nodule's components.

B-0148 11:26

The differential diagnosis of benign and malignant solid pulmonary nodules by CDT-VIBE early dynamic contrast-enhancement of MRI
H. Zhang, L. Xu; Dazhou/CN (zhangheng_DZCH@yahoo.com)

Purpose: The purpose of this study was to assess the imaging characteristics of SPNs (solid pulmonary nodules) by CDT-VIBE early rapid multi-phase dynamic enhanced scanning.

Methods and Materials: In this retrospective, institutional review board-approved study, 20 patients (with d≥1cm and solitary SPN confirmed by pathology or clinical treatment) scanned on a 3.0-T magnetic resonance system (Skyra; Siemens) were divided into benign nodule group (n=9) and malignant nodule group (n=11). The CDT-VIBE (TR = 4.1ms, TE = 1.33ms, Flip angle = 9°, Field of view = 340mm X 255mm, Matrix = 288 X 162) was started

20 seconds after the injection of 0.1 mmol/kg Gd-DTPA. Within 26 seconds, 14 high spatial resolution (1.2 X 1.2 X 3 mm³) data sets were acquired. The CDT-VIBE images were evaluated independently by 2 blinded, experienced radiologists with regard to image quality and measuring signal strength of different points in time.

Results: In all patients, CDT-VIBE measurements were successfully acquired and the image quality was diagnostic (Figure 1). As shown in Figure 2, in the multi-phase rapid scan of 20-46s, the signal intensity values of the malignant nodule group were greater than 250; while the signal intensity values of the benign nodule group were less than 230, the difference between the two groups was statistically significant (p < 0.05).

Conclusion: Compared with the traditional DCE-MRI, CDT-VIBE sequence of the rapid multi-phase dynamic enhanced scan of 20-46s is of great significance in the differential diagnosis of benign and malignant solid pulmonary nodules.

Application of dual-layer detector spectral CT in differentiating benign and malignant lung nodules

Q. Wen, Y. Hou, Y. Ma, Q. Ma, X. Lu; Shenyang/CN (2609579904@qq.com)

Purpose: To quantitatively observe the value of dual-layer detector spectral CT (DLCT) in differentiating malignancy and benignity of solitary pulmonary nodules.

Methods and Materials: Ninety-one patients with solitary pulmonary nodules proved by pathology underwent contrast-enhanced CT scan in artery phase (AP) and venous phase (VP) with DLCT. The patients were classified into two groups (malignant group, n=51; benign group, n=40). The slope of spectral HU curve (λ_{HU}) was calculated from the spectral curve ($\lambda_{HU} = |CT_{40\text{ keV}} - CT_{80\text{ keV}}|/40$). Iodine concentrations (IC) were derived from iodine-based material decomposition CT images and normalized to the IC in the aorta (NIC). Normalized arterial enhancement fraction (NAEF) was calculated by NIC_{AP}/NIC_{VP} . T test was performed to compare quantitative parameters among the two groups. Receiver operating characteristic (ROC) curve analysis was performed to assess the differential diagnosis performance.

Results: NIC, λ_{HU} and NAEF of malignant group were all higher than those of benign group (P<0.05). In the benign and malignant groups, the NIC were 0.09±0.04 and 0.15±0.05, respectively, in the AP, and 0.22±0.06 and 0.36±0.10, respectively, in the VP. The λ_{HU} were 1.17±0.49 and 1.75±0.63, respectively, in the AP and 1.33±0.49 and 2.09±0.63, respectively, in the VP. The NAEF were 0.374±0.126 and 0.374±0.126, respectively. ROC analysis showed that the area under the curve (AUC) of the NIC in VP was largest (AUC_{NIC}=0.90) among all parameters with sensitivity and specificity values were 84.7% and 90.8%, respectively.

Conclusion: DLCT imaging with quantitative parameter provides more promising value for distinguishing malignant nodules from benign ones.

B-0150 11:42

Automated CT texture analysis of lung cancer FDG PET-CT data using a novel software tool: preliminary results

G.M. McDermott¹, M. Hayball², B. Ganeshan², Z. Riaz², A. Scarsbrook³; ¹Leeds/UK, ²Cambridge/UK, ³York/UK (garry.mcdermott@nhs.net)

Purpose: To explore the utility of automated software (TexRAD lung) for extracting texture features from routinely acquired fluorine-18 fluorodeoxyglucose (FDG) positron emission tomography-computed tomography (PET-CT) datasets in lung cancer patients.

Methods and Materials: 107 patients with lung cancer who underwent pre-treatment FDG PET-CT at a single centre were studied. TexRAD lung was applied to all PET-CT datasets with standard settings: 40% fixed threshold for PET region detection, CT region threshold -50 to 150 Hounsfield Units, filter levels (0, 2mm, 3mm) and minimum single slice area of 200mm². Auto-contoured FDG-avid regions were transposed to corresponding CT images. Texture parameters were then extracted from a region of interest encompassing the maximal cross-sectional area of tumour on a single axial CT slice, using a filtration-histogram technique. Kaplan-Meier analysis (Mantel-Cox log-rank) was used to assess correlation between texture parameters and overall survival.

Results: The software was unable to process some cases due to unusual chest anatomy, confluent benign tracer activity adjacent to the tumour or small tumour size which left 74 studies for analysis. The CT texture kurtosis, extracted with a 3-mm filter, was a statistically significant predictor of overall survival (p=0.0255) at an optimised cut-off level (≥0.47512 indicates poor prognosis, median survival of the poor prognostic group was 1.1yrs vs. good prognostic group at 3.03yrs).

Conclusion: Texture features (kurtosis) extracted from routinely acquired FDG PET-CT data using automated software may help predict overall survival of patients with lung cancer. Region extraction methodology warrants further assessment to account for certain patient-specific features.

Can dual-energy CT replace perfusion CT for the diagnosis of the solid pulmonary nodules?

B. [Zhu](#), T. Jiang, P. Peng, M. Li; *Beijing/CN (zhubl2017@163.com)*

Purpose: To determine the correlation and diagnostic value between dual-energy CT (DECT) (70/Sn150) and low-dose volume perfusion CT (VPCT) parameters in patients with solid pulmonary nodule.

Methods and Materials: All patients provided written informed consent. Thirty-three patients (mean age 57 years±7) with solid nodules who underwent same-day DECT and VPCT were enrolled. All CT findings were histologically confirmed. Exploration the correlation and comparison the diagnosis value between VPCT parameters and DECT parameters. According to the ROC analysis of solid pulmonary nodules to determine the optimal diagnostic cut-off value, and pairwise compare the area of ROC curves. The effective radiation doses of the VPCT and DECT scan protocols were recorded. Pearson R, t test and Mann-Whitney U test were used.

Results: The effective radiation dosage of the VPCT and DECT were 3.8 mSv, 0.32±0.10mSv, respectively. Significant correlations were found between iodine concentrate (IC) from DECT and VPCT parameters (P<0.05): blood volume (BV), blood flow (BF), flow extraction product (FED), pulmonary nodule enhancement peak (PPnod) and the ratio of PPnod to the aortic enhancement peak. The sensitivity and specificity of IC were 87.50%, 66.70%, which slightly lower than that of BV (100%, 75.00%), FED (94.12%, 81.25%) and PPnod (100%, 81.25%). The area of ROC from combination of PPnod and IC was significantly higher than those of IC (p=0.038).

Conclusion: Iodine parameters from DECT are significantly correlated with VPCT parameters, IC combine PPnod from VPCT and VPCT parameters are helpful to the differential diagnosis of benign and malignant for SPNS.

The influence of background signal intensity changes on cancer detection in prostate MRI

A.M. [Hötter](#)¹, E. [Dappa](#)², Y. [Mazaheri](#)³, B. [Ehdaie](#)³, J. [Zheng](#)³, M. [Capanu](#)³, H. [Hricak](#)³, O. [Akin](#)³; *Zurich/CH, ²Mainz/DE, ³New York, NY/US (andreas.hoetker@usz.ch)*

Purpose: To develop a scoring system for background signal intensity (BSI) changes on prostate MRI and assess these changes' influence on cancer detection.

Methods and Materials: This IRB-approved, HIPAA-compliant, retrospective study included 418 prostate MRI examinations in 385 men, who subsequently underwent MRI-guided biopsy. The Likert score for the suspicion of cancer assigned by the primary radiologist was extracted from the original report and histopathological workup of the biopsy cores served as the reference standard. Two readers assessed the amount of BSI changes on T2-weighted sequences and assigned a pre-defined BSI score (BSIS) of 1-5 (1=poor, extensive changes; 5=excellent, no changes). The sensitivity and specificity of Likert scores for the detection of prostate cancer and clinically significant cancer (GS ≥ 3+4) were estimated in and compared between subgroups of patients with different BSI scores (BSIS 1-2; BSIS 3; BSIS 4-5).

Results: Inter-reader agreement on BSIS was substantial (kappa: 0.783). Sensitivity for prostate cancer detection increased when BSI scores were better (i.e., higher) (reader 1: 0.412 to 0.714; reader 2: 0.526 to 0.728; p<0.007, both readers). In the detection of significant cancer (Gleason score ≥ 3+4), sensitivity also increased with higher BSI scores (reader 1: 0.5 to 0.824; reader 2: 0.627 to 0.857; p<0.028), though specificity decreased significantly for one reader (0.667 to 0.377; p=0.009).

Conclusion: Background signal intensity changes on T2-weighted images significantly limit prostate cancer detection. The proposed scoring system could improve the standardization of prostate MRI reporting and provide guidance for applying prostate MRI results appropriately in clinical decision-making.

B-0153 10:47

Validation of the PI-RADS 2 size criterion for the prediction of significant prostate carcinomas: are adjustments to the 1.5-cm threshold warranted?

S. [Mahjoub](#)¹, A. [Baur](#)¹, J. [Pfeil](#)¹, C. [Lee](#)², M. [Rudolph](#)¹, M. [Haas](#)¹, H. [Cash](#)¹, B. [Hamm](#)¹, T. [Penzkofer](#)¹; *Berlin/DE, ²Singapore/SG (penzkofer@gmail.com)*

Purpose: To critically evaluate the 1.5-cm size threshold employed in PI-RADS v2.0 between scores 4 and 5 for the prediction of clinically significant (≥3+4) prostate cancers in a large cohort.

Methods and Materials: 293 patients with systematic and MRI/TRUS fusion biopsy and confirmed prostate cancer were evaluated. Histopathology was matched to the MRI images, lesion sizes were measured on all available sequences and tabulated against the Gleason grade. ROC-AUC and Youden Index analyses were performed to assess the size criterion's current performance and potential adjustments.

Results: 311 lesions were matched to histopathologic findings. Separated by initial tumour zone 59 3+3, 52 3+4, 1 3+5, 27 4+3, 64 4+4, 12 4+5, 1 5+3, 5 5+4 and 1 5+5 tumours were analysed in the peripheral zone, and 35 3+3, 20 3+4, 18 4+3, 18 4+4, 3 4+5, 3 5+5 tumours were included from the transition zone, 10 lesions were equivocal with respect to their zone and excluded. AUCs were higher in PZ-lesions (T2: 0.68, DWI: 0.73, ADC: 0.68 and DCE: 0.78) compared to TZ tumours (T2: 0.63, DWI: 0.63, ADC: 0.66 and DCE: 0.48). When optimizing the threshold using the maximum sum of sensitivity/specificity approach (Youden Index), a threshold of 14 mm in the peripheral zone (DWI), and a threshold of 21 mm TZ lesions (T2) yielded the highest separation.

Conclusion: The size criterion had a greater discriminatory power in the PZ than the TZ. Slightly lowering the PZ threshold to 14mm and increasing the TZ threshold to 21mm could potentially lead to a better separation of significant from non-significant tumours.

Prostate cancer risk stratification using biparametric MRI and clinical parameters improves selection of biopsy naïve men for prostate biopsies

L. [Boesen](#)¹, F.B. [Thomsen](#)¹, N. [Nørgaard](#)¹, V. [Logager](#)², R. [Bisbjerg](#)¹, I. [Balslev](#)¹, H. [Jakobsen](#)¹, H.S. [Thomsen](#)¹; *Herlev/DK, ²Copenhagen/DK (lars.boesen@dadlnet.dk)*

Purpose: To develop a novel predictive model based on biparametric (bp) MRI findings and clinical parameters for detection and ruling out significant prostate cancer (sPCa) in biopsy-naïve men using results from modern biopsy techniques as standard reference.

Methods and Materials: 876 biopsy-naïve men with suspicion of PCa (PSA<50, cTstage<T3) underwent pre-biopsy prostate bpMRI (T2W and DWI) followed by 10-core standard biopsy (all men) and MRI-TRUS fusion targeted biopsies of bpMRI-suspicious lesions (score ≥3). Various prediction models based on bpMRI and clinical parameters (age, rectal examination [DRE], prostate-specific-antigen [PSA], prostate_{volume}: PSA_{density}) were conducted and compared using area under the curve (AUC) and decision curve analysis. Reference standard was combined biopsy results and sPCa was any core with Gleason grade group≥2.

Results: Overall, sPCa was detected in 350/876 (40%) men; median [IQR] age and PSA were 65 yrs [60-70] and 7.3 ng/ml [5.5-10.6]. A model that combined bpMRI suspicion scores with age, DRE and PSA_{density} in an advanced imaging model achieved the highest discriminatory power on ROC curve analysis (AUC 0.89) and showed good calibration on internal bootstrap validation. The clinical performance of this model was superior (highest net benefit) on decision curve analysis and a biopsy risk threshold ≥20% for the model reduced 42% of biopsies and 50% of insignificant PCa diagnosis, while missing only 7% of GGG≥2 PCas.

Conclusion: A predictive multivariable model based on bpMRI imaging and clinical parameters significantly improves risk stratification of sPCa in biopsy-naïve men and could be used for clinical decision-making to avoid unnecessary prostate biopsies.

B-0155 11:03

Restriction of diffusion and tumor aggressiveness: a non applicable correlation for transition zone prostate cancer

F. [Cornud](#), A. [Jemal Turki](#), M. [Barral](#), P. [Soyer](#); *Paris/FR (matthiasbarral@gmail.com)*

Purpose: To show that the restriction of diffusion (ADC) and cell differentiation (Gleason score) are not correlated in transition zone prostate cancers

Methods and Materials: 79 patients with an index tumor developed in the transition zone (TZCa, n=37) or peripheral zone (PZCa, n=42) had an MRI at 3T or 1.5T+endorectal probe before biopsy and radical prostatectomy within three months after biopsy. ADC measurement was performed by two independent readers to assess the interreader agreement. A correlation coefficient was calculated between the ADC and the Gleason score according to the zonal origin of the tumour.

Results: Between the two groups, the mean age (67±6 vs 63±5), PSA level (9.3±4 vs 8.9±4ng/ml), prostate volume (41±17 vs 55±26ml) were comparable (p>0.05). The large tumor MRI axis was higher in TZCa (16±7 vs 11±6mm, p=0.0007). The ADC value of Gleason 3+3 tumor score of TZCa was significantly lower than in the PZ (728±52 vs 861±121 10⁻⁶mm²/s, p=0.0014), and was comparable to that of tumors with >3+4 score in both zones (TZ: 647±124 ; PZ : 646±124 10⁻⁶mm²/s). The correlation coefficient between Gleason score and ADC was 0.32 (95%CI[0.01-0.46], p=0.19) in TZCa of 0.45 in PZCa (p=0.0027, 95%CI[0.66-0.17]).

Conclusion: The relationship between restriction of diffusion (ADC) and cell differentiation (Gleason score) cannot be applied for TZCa, given the high epithelial volume of low-grade TZCa. This finding has implications for the interpretation of targeted biopsy Gleason score of a TZCa for treatment selection.

B-0156 11:11

How to improve the equivocal category PIRADS score 3? Quantitative multiparametric MRI assessment of prostate cancer with histopathology correlation

G. Barchetti, R. Campa, M. Pecoraro, F. Barchetti, C. Catalano, V. Panebianco; Rome/IT (giovanni.barchetti2@gmail.com)

Purpose: To evaluate quantitative mpMRI in characterization of "equivocal" lesions according to Prostate Imaging-Reporting and Data System (PI-RADS), using histopathology as a reference standard.

Methods and Materials: Three groups of patients were identified. Group A: 103 patients with mpMRI before radical prostatectomy. Group B: 100 patients with negative mpMRI and follow-up. Group C: 92 patients with mpMRI-targeted biopsy for one or more PI-RADS 3 lesions. All PI-RADS 3 lesions were quantitatively assessed to obtain ADC, normalized ADC (nADC) and Ktrans. Differences in ADC, nADC and Ktrans between PI-RADS 3 lesions and normal tissue or index lesion were evaluated. ROC curves analysis was performed.

Results: 49 PI-RADS 3 lesions in group A were malignant and had lower ADC (5.95E-010 vs 9.98E-010, p < 0,001) and higher Ktrans (0,48 vs 0,24, p < 0,001) compared to normal tissue and similar ADC, nADC and Ktrans compared to the index lesion. 53 PI-RADS 3 lesions were benign: they had higher ADC (8,75E-010 vs 5,38E-010, p < 0,001) and nADC (0,79 vs 0,46, p < 0,001) and lower Ktrans (0,26 vs 0,48, p < 0,001) compared to the index lesion and similar ADC and Ktrans compared to normal tissue. Comparable results were obtained in groups B and C. ADC, nADC and Ktrans had an area under curve of 73%, 90% and 67% in discriminating PI-RADS 3 lesions harbouring clinically significant prostate cancer (csPCa) from benign tissue or non-csPCa.

Conclusion: quantitative mpMRI metrics (ADC, nADC and ktrans) can discriminate csPCa from non-csPCa in PI-RADS 3 lesions.

B-0157 11:19

Predicting clinically significant prostate cancer in PI-RADS 3 lesions: a retrospective high-volume centre study

I. Hermie¹, J. Van Besien¹, P. De Visschere², G. Villeirs¹; ¹Ghent/BE, ²De Haan/BE (isabeauhermie@gmail.com)

Purpose: To investigate which clinical and radiological characteristics can predict clinically significant prostate cancer (csPCa) in PI-RADS (Prostate Imaging Reporting and Data System) 3 lesions on mpMRI (multiparametric prostate MRI).

Methods and Materials: A retrospective study was performed on PI-RADS 3 lesions from the period March 2015 to August 2017 in a single high-volume centre. Clinical data such as PSA and the presence of csPCa (Gleason score >= 3+4) were collected from hospital records. Apparent diffusion coefficient (ADC) of the PI-RADS 3 lesion, the contralateral side of this lesion and the internal obturator muscle was calculated on diffusion-weighted imaging sequences. Univariate and multivariate Cox regression analyses was performed to identify risk factors for csPCa.

Results: One hundred and thirty-one patients with PI-RADS 3 lesions on mpMRI were examined. In 83 patients (63%) biopsies were performed. For peripheral zone lesions, 37.5% of csPCa was detected. In univariate logistic regression analysis, a higher median PSA density (p=0.009) and in multivariate logistic regression a lower median prostate volume (p=0.025) and a lower ratio of ADC of the PI-RADS 3 lesion on ADC of the contralateral prostate (p=0.003) significantly predisposed for csPCa. Depending on the combination of these parameters, a high sensitivity (100%) or a high specificity (96%) for csPCa could be reached but no combination had both high sensitivity and specificity.

Conclusion: PSA density, prostate volume and the ratio of ADC of the PI-RADS 3 lesion on ADC of the contralateral prostate have the potential to predict csPCa in PI-RADS 3 lesions.

B-0158 11:27

Improved diffusion weighted imaging of the prostate: RESOLVE and ZOOMit in comparison to standard EPI sequences

M. Klingebiel, L. Schimmöller, T. Ullrich, M. Quentin, C. Arsov, G. Antoch, H.-J. Wittsack; Düsseldorf/DE

Purpose: This study retrospectively evaluates objective image quality (IQ), subjective IQ, and diagnostic performance of diffusion-weighted imaging (DWI) in prostate MRI at 3T comparing high resolution RESOLVE (REadout Segmentation Of Long Variable Echo trains), ZOOMit (selective field-of-view) and standard EPI DWI sequences within the same patients.

Methods and Materials: Thirty-six consecutive patients (70±8 years; median PSA 9.1 ng/ml; IQR 6.3-13 ng/ml) with multi-parametric MRI at 3T including RESOLVE, ZOOMit, and EPI DWI with b0,500,1,000 plus calculated b1500 and subsequently histopathologically proven prostate cancer (PCA) by targeted and systematic MR/US-fusion biopsy were included from 03/2016 to 12/2017. Signal intensities (SI) of PCA and benign tissue (peripheral and transition zone; PZ, TZ) in ADC, b1000, and b1500 were analyzed for each respective DWI sequence. Endpoints were comparison of signal-to-noise ratios (SNR), contrast-to-noise ratios (CNR), and subjective IQ (5-point scale).

Results: SI and SNR differed significantly for RESOLVE compared to ZOOMit and EPI DWI (p<0.01). CNR was significantly better for RESOLVE for high b values (b1500; p<0.01) and was best in differentiation of PCA from normal tissue in the PZ. CNR of ADC is not significantly different for the three compared DWI sequences (PZ: p=0.34 and TZ: p=0.48). Subjective IQ was significantly better for RESOLVE compared to both ZOOMit and EPI (p<0.01).

Conclusion: RESOLVE was superior to ZOOMit and EPI DWI regarding subjective and objective imaging parameters in depiction of PCA. ZOOMit and EPI are more or less comparable to each other. Thus, RESOLVE improves DWI in mp-MRI and might facilitate PCA detection.

B-0159 11:35

Prostate cancer treated with irreversible electroporation: MRI-based volumetric analysis and oncological outcome

F. Giganti¹, A. Stabile², S. Giona³, C. Orczyk¹, C.M. Moore¹, C. Allen¹, A. Kirkham¹, M. Emberton¹, S. Punwani¹; ¹London/UK, ²Milan/IT, ³Frimley/UK (giganti.fra@gmail.com)

Purpose: To assess multiparametric magnetic resonance imaging (mpMRI) characteristics in prostate cancer (PCa) before and after irreversible electroporation (IRE) and to investigate their correlation with the presence of post-operative recurrence.

Methods and Materials: MpMRI was performed in 30 men with PCa prior to treatment, after 10 days and at 6 months. An additional scan at 1 year was available for 18 men. Two radiologists assessed retrospectively the following parameters by planimetry: tumour volume, necrotic volume (early post-treatment scan) and residual fibrosis. Residual tumour/recurrence were defined as suspicious areas within the treatment field scored ≥ 4 on a 1-to-5 scale. Oncological outcome was also assessed.

Results: Median follow-up was 15.5 months. At early mpMRI, 6 men were undertreated and showed mpMRI recurrence after 6 months. At 1-year, three additional men had recurrence. Overall, 4 men were retreated. Five men did not receive any further treatment. Median time to re-treatment was 15 months. Median pre-treatment lesion volume was 0.65cc, 0.66cc and 0.43cc on the different mpMRI sequences (T2, DWI and DCE). Median necrotic volume was 10.77cc. Median overall residual fibrosis volumes were 0.84cc and 0.95cc at 6-month and 1-year mpMRI. Pre-treatment, necrotic and residual fibrosis volumes were significantly different (p < 0.001). Pre-treatment tumour volumes on diffusion-weighted imaging and necrotic volumes were correlated (r= 0.18; p = 0.02).

Conclusion: MpMRI is a feasible imaging modality to visualise the IRE ablation effects in men with PCa. MpMRI parameters (tumour, necrotic and fibrosis volumes) are promising tools to assess the efficacy of IRE in PCa.

B-0160 11:43

Is DCE useless in early detection of prostate cancer? The analysis of quantitative parameters might help radiologists to decide if findings mildly restricted on ADC map should be sampled

M. Pecoraro, R. Campa, G. Barchetti, V. Salvo, C. Catalano, V. Panebianco; Rome/IT (pecoraro.martina1@gmail.com)

Purpose: The aim is to evaluate whether the DCE can improve tumour detection, applying the quantitative analysis of pharmacokinetic parameters of lesions not having a clearly positive ADC map.

Methods and Materials: Among 1236 men who underwent mpMRI for PCA suspicion from 2015 to 2018, we retrospectively enrolled 86 patients treated with radical prostatectomy and 86 patients suspected of harbouring PCa with

at least one negative systematic prostate biopsy, at least two negative mpMRI exams and a minimum follow-up of 48 months, as "control group" (Group C). Exams were performed at 3T with a PI-RADSV2-compliant protocol. Quantitative analysis was performed, computing both pharmacokinetic parameters (k-trans, k-ep and ve) and ADC values.

Results: Mean ADC value of 82,634mm²/s (95%CI= 77,564 to 88,236), mean k-trans of 0,325min⁻¹ (95%CI= 0,278 to 0,372), mean k-ep of 0,568min⁻¹ (95%CI= 0,466 to 0,640) and mean ve of 0,77 (95%CI= 0,65 to 0,89). Results were stratified into two groups: lesions with a normalised ADC≤0,62 (Group A) 72% and lesions with a nADC>0,6 (Group B) 28%. The difference of Ktrans values of the groups was not significant (p=0,08), however a statistical difference was found comparing the normalised Ktrans (nKtrans) of healthy prostate tissue with the one of PCa lesions, both separately and together (p<0,05).

Conclusion: It seems reasonable to adopt the nKtrans in the decision-making process of performing a prostate biopsy, particularly for those radiologic findings having a nADC>0,6. The omission of DCE would decrease PCa detection, especially when the ADC map cannot be unequivocally interpreted.

B-0161 11:51

Impact of dynamic contrast-enhanced (DCE) MRI on prostate cancer detection: is it worth the effort?

L. Schimmöller, F. Ziavve, N. Laqua, T. Ullrich, M. Klingebiel, M. Quentin, G. Antoch, C. Arsov; *Düsseldorf/DE*

Purpose: While current PIRADS implies a multiparametric (mp) MRI for prostate cancer (PCa) detection many authors discuss DCE only for individual cases. Adverse reactions, additional costs and efforts, and limited value represent main reasons. This study investigates the influence of DCE on PIRADS classification.

Methods and Materials: 66 consecutive patients with verified PCa after mp-MRI from 04-12/2017 have been retrospectively included. PIRADS classifications for T2, DWI and DCE sequences on lesion and patient level have been correlated with histopathological findings. Situations in which DCE could influence the classification were considered: As substitution/aid for non-diagnostic DWI or in peripheral zone (PZ) PCa with a PI-RADS of 3 in DWI so that DCE could upgrade to PI-RADS 4.

Results: Of all 159 PCa-lesions, 128 (81%) were positive on DCE. 29 patients (44%) were classified PIRADS 5 without relevant influence of DCE, 34 were PI-RADS 4, and 3 were PI-RADS 3. 43 lesions (27%) were located in Tz. 15/159 (9.4%) in 6/66 patients (9.1%) or 5/75 PI-RADS 4 lesions (20%) in 6/34 PI-RADS 4 patients (18%) were upgraded due to DCE. Of those, 3 (4.5%) patients had clinically relevant PCA (Gleason score ≥7).

Conclusion: DCE seems to be very useful for confirming PCa, which may help inexperienced readers. However, in a high portion of PIRADS 5 and PI-RADS 4 lesions the benefit of DCE is minor. Only few lesions with clinically relevant PCA would have been missed in consecutive patients without DCE. Therefore, the general application of DCE might be reformed.

Ultrasound as an alternative for plain radiography in the detection of the endotracheal tube position in neonatal intensive care unit patients

R.H. Hashem, R.H. Tomerak, A.M. Tosson, A. Abdelmoneim; *Cairo/EG* (rania.hachem@yahoo.com)

Purpose: To detect the role of ultrasound and its accuracy in the detection of the endotracheal tube position in the neonatal intensive care unit (NICU) and to compare it to the gold standard plain radiography.

Methods and Materials: Totally 100 intubated neonates were enrolled in the study over one-year period in the NICU. They all underwent high-resolution ultrasound using linear probe (5-8 MHz) on the neck and upper chest in LS to determine the tip of the ETT position, 2-point distance from the arch of the aorta was calculated. Plain radiography of chest and lower neck in AP position performed on the same day was collected. The head was kept in the sniffing position during both procedures.

Results: The ultrasound was able to identify the tip of the ETT in 100% of patients. There was statistically significant relation between the ultrasound and the chest radiography to determine the position in the NICU (P value less than 0.001).

Conclusion: Visualization of the ETT tip and its distance of 0.6 to 1.2 cm from the upper border of the arch of the aorta by ultrasound using linear high-frequency probe suggest correct position. So high-resolution ultrasound is helpful in identification of the level of the ETT tip, in neonates in the NICU.

B-0163 10:47

Lung ultrasound, a safe & useful tool for neonatal with respiratory problems monitoring

S. Foutziti, S.P. Dettoreos; *Alexandroupoli/GR* (foutzita@gmail.com)

Purpose: The diagnosis and management of respiratory diseases (RD) is of great importance in Neonatal Intensive Care Unit (NICU). Chest X-Ray (CXR) and computed tomography are usually the appropriate tools for RD diagnosis (but with radiation and neonatal transportation). The safety of lung ultrasound (LUS) led to the increasing use of them in diagnosis and in every day follow-up of RD.

Methods and Materials: 104 consecutive neonates from Neonatal Intensive Care Unit (NICU) with a gestational age from 25 Weeks(Wk)+5 days(d) to 40Wk were included in this study. 29.80% were premature (<29 Wk). Preterm were 45.20%(30-34Wk) and 8.32%(35-37 Wk +6d). 58.65% were reveal respiratory distress syndrome(RDS), 7.7%(from seventeen full-term) transient tachypnea of the new born(TTN), 6.25% pneumothorax and 4.68% bronchopulmonary dysplasia. Used criteria were the presence of A-Lines, "sliding sign", "pleural line" sign, presence of subpleural opacities and the B-lines "density".

Results: According to these: 2 pleural fluids (3.12%), 3 pneumothoraxes (4.68%), 4 neonates with TTN(6.25%) were diagnosed. RDS-severity was estimated by B-Lines density(normal/medium/white lung). LUS follow-up showed improvement in 47(73.43%). With the use of LUS we had a decreased CXRs up to 32,1% in comparison with NICU-CXRs in the same period for the last three years.

Conclusion: CXR remains the method of choice in RD diagnosis with the disadvantage of radiation. LUS is convenient, noninvasive, free of radiation method with the potential to become a tool for bedside dynamic respiratory monitoring. LUS is a useful tool in NICU reliable, easy to use and reproducible method for the follow-up of illness neonate.

B-0165 11:03

Comparison of Iodixanol 320, Iomeprol 350 and Iopromide 370 effectiveness in CT cardiothoracic angiography in infants

M. Pop; *Targu Mures/RO* (pop.marian@gmail.com)

Purpose: To compare the effectiveness of Iodixanol 320, Iomeprol 350 and Iopromide 370 in CT angiography of infants with congenital cardiovascular anomalies.

Methods and Materials: From February 2015 to March 2017, 65 consecutive CT cardiothoracic infants angiographies, performed in a single centre with a 64-slice scanner, using power injector and bolus tracking technique were retrospectively evaluated by an expert radiologist that analysed the axial images to assess the enhancement of great vessels using ROIs placed at the level of main pulmonary artery bifurcation. Age, sex, BMI, clinical indication, contrast medium type, iodine concentration, contrast volume, flow rate, and Hounsfield units of aorta and main pulmonary artery were recorded.

Results: The median patient age was 43 days (IQR 11.5:147.5 days), with a M:F ratio of 0.8 and a median BMI of 12.81 kg (IQR 11.5:14 kg). The average volume of contrast (and average flow) was 8.37 ml (1.04ml/s) for Iodixanol 320, 8.2 ml (0.94ml/s) for Iomeprol 350 and 7.39 ml (0.83ml/s) for Iopromide 370. The average enhancement of aorta was 337 UH when using Iodixanol (320 mg Iodine/ml), 627 UH when using Iomeprol (350mg iodine/ml) and 470 UH when using Iopromide (370 mg Iodine/ml); the difference being statistically significant (p<0.05) when comparing Iodixanol with either of the others. Similar results were obtained when assessing main pulmonary artery enhancement.

Conclusion: In infants undergoing cardiovascular thoracic CT angiography, the contrast volume and flow are inherently limited; however, Iodixanol 320 provides 45 to 28% less great vessel enhancement than other contrast media.

B-0166 11:11

The difference of left ventricular myocardial strain in isolated LVNC and dilated cardiomyopathy with hyper-trabeculation: structure, functional and risk factors analysis

H. Fu, R. Xu, Y. Guo, Z. Yang, H. Liu; *Chengdu/CN* (fuhang66666@163.com)

Purpose: This study was to evaluate the difference of myocardial strain in children and adult patients with iLVNC and dilated cardiomyopathy hyper-trabeculation by CMR tissue tracking, and further to explore the prognosis impact of different degree of hyper-trabeculation.

Methods and Materials: Eighty-nine DCM patients with hyper-trabeculation, 23 LVNC subjects (13 children and 11 adult subjects) and 44 healthy subjects (17 children and 27 adults) and were included. The degree of LV trabeculation was assessed by NC/C ratio for the CMR criterion. The myocardial structure, function and strain were measurement. Tissue-tracking analysis included LV

global peak strain (PS) and peak displacement (PD) in three directions of longitudinal, circumferential and radial. The clinical symptoms and outcome were record.

Results: For the strain of GPS and GPD in three directions of longitudinal, circumferential and radial, children/adult with iLVNC had significantly lower strain compared with healthy subjects, respectively (all $p < 0.0017$); and adult with iLVNC were lower than children. Conversely, no significant difference in strain parameters were observed between adult iLVNC patients and DCM patients with hyper-trabeculation. LV strain parameters were associated with increased indexed LV EDV, ESV, diastolic-mass and decreased EF (absolute R: 0.396-0.908; all $p < 0.05$).

Conclusion: Left ventricular myocardial functional impairment and strain changes were detected in iLVNC patients, especially being already noticeable in the children. With the age growing, the strain of iLVNC patients were lower, but the hyper-trabeculation may have no obviously effect on strain in DCM patients contrast to iLVNC patients.

B-0167 11:19

Radiation exposure of thoracic computed tomography in paediatric patients: can we always achieve a sub-mSv scan in a clinical setting?

K. Bubel¹, K. Altmeyer², J. Pfeifer¹, H. Abdul-Khalik¹, T. Krenn¹, A. Massmann¹, A. Bucker¹, P. Fries¹, ¹Homburg/DE, ²Saarouis/DE (katharina.bubel@gmx.de)

Purpose: To retrospectively analyze radiation exposure of thoracic CTs in pediatric patients in a clinical setting using a third generation dual source scanner (Siemens, Force) and to identify risk factors preventing sub-mSv examinations.

Methods and Materials: In 144 patients (age: mean \pm -SD: 6.1 \pm -5.9yrs; range: 0-18yrs) a total number of 197 examinations of the thorax were performed for different clinical purposes. We acquired a high-pitch protocol using automatic exposure control (CareDose4D, CareKV, Siemens) in the majority of cases. Scans were performed unenhanced, contrast-enhanced (with or without ECG-synchronization) or with tin-filter technique. We retrospectively evaluated dose length product (DLP) and calculated effective doses (E) thereof using age and kV specific conversion factors.

Results: Examinations were performed for cardiovascular (n=114), and non-cardiovascular (n=83) indications (inflammation, tumor and congenital lung disease). Mean \pm -SD radiation exposure for all examinations was E(all)=0.78 \pm -0.72mSv with a range of 0.03-3.85mSv. In 42/197 cases (21%) radiation exposure was above 1mSv. Here, patients were significantly older (11.23 \pm -5.5yrs vs. 3.9 \pm -4.9yrs, $p < 0.001$) potentially resulting in higher kV-settings (n=33/42 with tube voltage > 70 kV). 7 patients presented with metallic implants (pacemaker, stents, coils). 7 scans were performed with retrospective ECG-gating and 3 patients were obese. Radiation exposure was significantly lower in scans with tin-filter technique (0.17 \pm -0.14mSv; $p < 0.001$) as compared to cardiovascular (0.82 \pm -0.68mSv) or non-cardiovascular CTs (0.95 \pm -0.74mSv)

Conclusion: Thoracic CTs in pediatrics can be acquired routinely with a radiation exposure below 1mSv using automated exposure control for a broad spectrum of clinical indications. Risk factors for higher doses include age, metallic implants, obesity and retrospective ECG-gating.

B-0168 11:27

Fontan-operated adolescents have increased hepatic fibrotic markers assessed by ultrasound shear wave elastography and MR T1 mapping

C. de Lange, K. Thrane, K. Thomassen, K. Rydén Suther, L.-S. Ording Müller, O.M. Geier, G. Døhlen, R. Almaas, T. Møller; Oslo/NO (charlotte.delange@medisin.uio.no)

Purpose: To investigate magnetic resonance (MR) T1 mapping with extracellular volume fraction (ECV) and ultrasound shear wave elastography (SWE) in adolescents with Fontan circulation, as a surrogate measure of hepatic fibrosis.

Methods and Materials: Hepatic and splenic native T1 times and ECV were prospectively measured with a modified look-locker inversion recovery sequence and stiffness measured with SWE. Results were compared to a control group and correlated to clinical and haemodynamic information from cardiac catheterization.

Results: Thirty-nine Fontan patients aged 16.7 \pm 0.6 years and 15 controls aged 19.2 \pm 1.2 years were included. Hepatic native T1 times were increased in patients (n=31) 776 \pm 48 ms compared to controls 632 \pm 52 ms ($p < 0.001$) as well as ECV 48.4 \pm 5.7% vs 36.8 \pm 3.7%, respectively ($p < 0.001$). Splenic native T1/ECV was comparable between groups ($p = 0.17$ and $p = 1.0$, respectively). For SWE, liver stiffness/velocity was measured to 1.9 \pm 0.1 m/s in patients (n=38) vs 1.2 \pm 0.1 m/s in controls ($p < 0.001$). SWE correlated only with ECV (R=0.6, $p = 0.001$) in patients, but was without association with T1 and ECV in controls (R=0.3, $p = 0.3$ /R=0.2, $p = 0.4$, respectively). There were no associations between hepatic T1/ECV and SWE with central venous or ventricular pressures or to slightly abnormal liver function.

Conclusion: Fontan patients have elevated MR and SWE biomarkers suggestive of diffuse hepatic fibrosis and/or congestion. However, no hepatic

failure or correlation to central venous pressure was found. MR T1 mapping and SWE revealed only partial correlation thus opposing an interchangeable use of the two techniques in monitoring hepatic fibrosis. Longitudinal studies are required to test the significance of our findings.

B-0169 11:35

Diagnostic utility of 3 Tesla thorax magnetic resonance imaging in HIV-positive children

P. Fana¹, K.S. Sodhi², A. Bhatia², A.K. Saxena², D. Suri², S. Singh²; ¹Dwarka/IN, ²Chandigarh/IN (pratyaksha_25@yahoo.com)

Purpose: To evaluate the role of 3T thorax MRI in HIV-positive children by keeping CT chest as the gold standard.

Methods and Materials: Twenty-five children with confirmed HIV-positive status having pulmonary complaints, and referred for CT chest were included in this prospective study. Thorax MRI was performed in all children using T2 TSE, BTFE, MVXD, mDIXON, STIR and DWI sequences. The images were evaluated for various pulmonary and mediastinal findings. The sensitivity, specificity, PPV, NPV of MRI were calculated. The kappa test of agreement was used to assess the agreement between MRI and CT findings.

Results: Sensitivity, specificity, PPV and NPV of MRI was 100% for detection of nodules > 4 mm, pleural effusion and lymphadenopathy. For consolidation/collapse, sensitivity and specificity was 93.8 and 88.9%, respectively. The sensitivity for detection of bronchiectasis and GGOs was 75%, while specificity was 100% and 94.1%, respectively. Nodules < 4 mm were not well detected on MRI with sensitivity and NPV of 35% and 23.5%, respectively. The kappa test showed perfect agreement (k-1) for detection of nodules > 4 mm, pleural effusion and lymphadenopathy, with almost perfect agreement (k-0.82) for the detection of consolidation/collapse.

Conclusion: Amongst the sequences used, T2 TSE sequence was the best pulse sequence to detect parenchymal and mediastinal abnormalities out of all MR pulse sequences. Diagnostic yield was poor with DWI and STIR sequence as compared to T2 TSE sequence with no additional benefit. Common findings such as consolidation, pleural effusion, nodule > 4 mm and lymphadenopathy were well demonstrated on MRI.

B-0170 11:43

Assessment of lung volume and central airways dimension using MRI in children: a comparison with plethysmography, CT and PFT

Y. Wang¹, C. Yong¹, P. Wielopolski², E.C. van der Wiel-Kooij², H.A. Tiddens², P. Ciet²; ¹Yinchuan/CN, ²Rotterdam/NL (p.ciet@erasmusmc.nl)

Purpose: To test whether MRI measurements of lung volume and central airways dimensions correlate to validated pulmonary function tests parameters in children with cystic fibrosis (CF), asthma and healthy controls, and to assess capacity to detect trapped air (TA).

Methods and Materials: Spirometer-controlled MRI was performed with a breath-hold 3D-SPGR sequence at end-inspiration and expiration using a 3.0 T scanner in 37 subjects, including 12 CF patients (age 11.3 \pm 2.4), 12 asthma patients (12.9 \pm 2.8) and 13 healthy volunteers (12.3 \pm 1.7). We measured lung volume (in ml) and central airways dimensions (area and diameters in trachea and main bronchi every cm). We compared total lung capacity (TLC) and residual volume (RV) measured with MRI and with body plethysmography. We also correlated MRI airway dimensions to forced expiratory flow in 1 sec (FEV1) and TAMRI with TA plethysmography and Forced expiratory flow (FEF25-75). Mixed model analysis was used as statistic.

Results: Lung volume and TA measured with MRI significantly correlated with plethysmography and CT measurements (in CF group ($p = 0.0006$)). TA was significantly higher in CF group ($p = 0.01$) than healthy control, and almost significantly higher in the asthma group ($p = 0.057$). There were no differences in TLC between patients' groups, while RV tended to be higher in CF ($p = 0.058$). No difference in central airways dimensions was detected between the groups. MRI parameters had high correlation with FEV1.

Conclusion: Lung MRI is a feasible method to evaluate lung volume and central airways dimensions in children with respiratory disorders.

Image quality and incidental findings of chest MRI in a large paediatric population-based study

A. Pittaro¹, L. Duijts², P. Wielopolski², M.W. Vernooij², A. Van der Lugt², V.W. Jaddoe², M.M.P.C. Kemner-van de Corput², H.A. Tiddens², P. Ciet²; ¹Padova/IT, ²Rotterdam/NL (p.ciet@erasmusmc.nl)

Purpose: To describe image quality (IQ) and incidental findings (IFs) of chest MRI in children participating in a population-based prospective cohort study.

Methods and Materials: Two end-inspiratory (INSP) and -expiratory (EXP) breath-hold chest-MRI scans were performed in 2498 healthy children using a 3D-SPGR sequence (voxel-resolution=2mm isotropic) in a 3Tesla scanner. IQ was assessed visually using a 5-point scale from poor (score 1) to excellent

(score 5). Imaging artefacts included: motion, wrap, ghosting, low SNR. IFs were classified by trained raters as potentially clinically relevant or non-clinically relevant. Descriptive statistical analysis was used to assess IQ, IFs and artefacts. Significant differences between IQ-INSP and IQ-EXP were assessed with Wilcoxon test.

Results: 47 children had missing data. Final analysis included 2451 children (median age 9.9 years, range 9.5-11.9). Median IQ was good to excellent 4.5 (Interquartile Range, IQR= 4-5). IQ was mostly affected by motion artefact (31.9%), fat ghosting (7.9%) or both (6.3%). 1.7% of the cohort subjects had clinically relevant IFs, 45% had non-clinically relevant IFs. Clinically relevant IFs included pulmonary nodules (diameter>10 mm, 0.04%), severe tracheomalacia (collapse>70%, 0.3%), severe trapped-air (>25% lung lobe volume, 0.9%), atelectasis/consolidation (>10 lung lobe volume, 0.08%) and congenital abnormalities (i.e. sequester, 0.38%). Non-clinically relevant IFs were: mild trapped-air (23.8%), atelectasis (15.4%) and mild tracheomalacia (4.5%).

Conclusion: Chest MRI provides good quality images, and potentially clinical incidental findings are rare. However, trapped-air, atelectasis and mild tracheomalacia are common non-clinically relevant "incidental" findings on chest MRI in healthy children.

Classification of prostate cancer on multiparametric MR imaging using 3D convolutional neural network

N. Aldoj, S. Lukas, M. Dewey, T. Penzkofer; Berlin/DE
(nader.aldoj@charite.de)

Purpose: To present a novel single-pipeline, fully automated approach for prostate cancer classification based on multiparametric magnetic resonance (MR) imaging using a 3D convolutional neural network (CNN).

Methods and Materials: Two hundred patients (provided by PROSTATEx challenge) with a total of 318 lesions for which histological correlation was available were analysed. A novel CNN was designed, trained, and validated simultaneously using three MRI sequences as input (T2-weighted, apparent diffusion coefficient (ADC), and diffusion-weighted images). The network consists of 12 convolutional layers organized in seven blocks with intermittent skip connections of concatenated feature maps and two fully connected and one output layer at the end. The model was trained and validated using 8-fold cross-validation.

Results: In terms of detection of significant prostate cancer defined by biopsy results as the reference standard, the 3D CNN achieved an average area under the curve (AUC) of the receiver operating characteristics of 0.82 with the best model having an AUC of 0.87, 68.9% sensitivity, and 88.8% specificity. This performance is comparable to that reported for experienced radiologists (AUC of 0.83) using the prostate imaging reporting and data system (PI-RADS). Lesion size had no effect on the network's performance.

Conclusion: The diagnostic performance of the 3D CNN in detecting clinically significant prostate cancer is characterized by a good AUC, moderate sensitivity, and high specificity.

B-0173 10:38

Ovarian cancer staging and resectability assessment: prospective comparison between diffusion-weighted MRI and MSCT

A.E. Solopova, A.M. Sdvizhkov, A.D. Makatsaria; Moscow/RU
(dr.solopova@mail.ru)

Purpose: to evaluate the diagnostic potential of diffusion-weighted MRI sequences (DW-MRI) compared with multispiral computed tomography (MSCT) for ovarian cancer (OC) staging.

Methods and Materials: 78 patients with suspected OC underwent preoperative examination, including abdominal/pelvic MSCT and DW-MRI, using a 1.5T scanner with b-factors of 0, 1000 s/mm². Using the obtained data, the peritoneal cancer index (PCI) was calculated and ROC curves for DW-MRI vs MSCT were created. The imaging-based diagnoses were compared with surgical staging and histopathological examination.

Results: The following stages of OC were determined: 6 (7.7%) IV; 37 (47.4%) IIIC; 25 (32%) IIIB; 10 (12.8%) IIIA. DW-MRI was markedly superior to MSCT in detecting of tumor implants in the large intestine mesentery (83.8% and 37.8%, respectively), into the small intestine serosa (79.7% and 31.8%), and the para-aortic lymph nodes (71.4 and 35.7%). The specificity were similar (80.4% - DW-MRI and 81.6% - MSCT). The peritoneal cancer index (PCI) calculated from the DW-MRI results correlated with the surgical staging data better than based on MSCT (r=0.814 for DW-MRI, r=0.625 for MSCT). Based on the obtained data, the ROC curves were plotted to show the AUC of 0.926 and 0.693 for DW-MRI and MSCT, respectively with overall sensitivity for correct staging of 83% for DW-MRI and 61% for MSCT. A decrease in ADC values was found in secondary tumor foci (1.09±0.28 for primary tumor, 0.810±0.26 - omentum, 0.750±0.23 × 10⁻³ mm²/s - peritoneal implants).

Conclusion: For the assessment of ovarian cancer spread, DW-MRI is significantly more sensitive than MSCT.

B-0174 10:46

Multiparametric MRI in prostate cancer: a radiomic study applied to different diffusion and perfusion models

D. Grimaldi, S. Monti, C. Rinaldo, V. Brancato, M. Aiello, G. Di Costanzo, C. Cavaliere, A. Ragozzino, M. Salvatore; Naples/IT
(carlocavaliere1983@yahoo.it)

Purpose: To evaluate radiomics features extracted from 2D region and 3D volume of interests on diffusion weighted imaging (DWI), diffusion kurtosis imaging (DKI), and Tofts modelling (TM) of perfusion maps between prostate cancer (PCa), benign prostatic hyperplasia (BPH), and benign peripheral zone (PZ).

Methods and Materials: 75 foci of PCa, 100 BPH nodules, and 100 benign PZ from 75 patients who underwent multiparametric MRI of prostate were investigated. MRI was performed with a 3T mMR Biograph scanner. DWI was performed using 7 b-values (0-2500), and non-Gaussian diffusion coefficient (D), deviations from normal distribution (K), and classical apparent diffusion coefficient (ADC) maps were generated. DCE-MRI parameters (Ktrans, ve, and kep) were also determined. First-order statistical features were extracted from T2w MRI, DWI, and DCE-MRI maps on both 2D and 3D segmentations. A logistic regression classifier was used to identify features discriminating clinically significant tumours (PIRADS 4-5), and was evaluated by area under the receiver-operating characteristic curve (AUC).

Results: Radiomic features that were identified as useful for PCa detection differentiated PCa from BPH or benign PZ, independently from the segmentation method employed (2D vs 3D). When comparing classification achieved with features extracted from different diffusion and perfusion parameters, a statistical difference was detected only among diffusion features in PCa. When classification was performed using a multivariate model, the classifier identified DKI features as the best predictors for prostate tumour (AUC > 0.85).

Conclusion: A classifier that includes features extracted by DKI significantly improves the accuracy of cancer detection.

B-0175 10:54

Associations between whole tumour histogram analysis parameters derived from ADC maps and expression of EGFR, VEGF, Hif 1-alpha Her-2 and Histone 3 in uterine cervical cancer

H.-J. Meyer, P. Gundermann, A. Höhn, G. Hamerla, A. Surov; Leipzig/DE
(hans-jonas.meyer@medizin.uni-leipzig.de)

Purpose: Diffusion-weighted imaging (DWI) is able to predict microstructure in tissues and can be quantified by apparent diffusion coefficient (ADC). The present study sought to correlate ADC histogram-based parameters with different histopathological parameters in uterine cervix squamous cell carcinoma.

Methods and Materials: 18 female patients (age range 32-79 years) with squamous cell cervical carcinoma were retrospectively enrolled. In all cases, pelvic MRI was performed with a DWI (b values 0 and 1000 s/mm²). Histogram analysis was performed as a whole lesion measurement, calculating several percentile, kurtosis, skewness and entropy. Histopathological parameters included expression of EGFR, VEGF, Hif1-alpha, Her2 and Histone 3. Spearman's correlation coefficient was used to analyse associations between investigated parameters.

Results: The investigated ADC histogram showed a good interreader variability, ranging from 0.705 for entropy to 0.959 for ADCmedian. EGFR expression correlated statistically significant with several histogram parameters. The highest correlation was observed for p75 (p=-0.562, P=0.015). There were several correlations with histone 3, the highest with p25 (p=-0.610, P=0.007).

Conclusion: Histogram analysis showed a good interreader agreement. ADC histogram parameters can reflect expression of EGFR and histone 3 in squamous cell carcinomas of the cervix, but not expression of VEGF, Hif1-alpha and HER 2.

B-0176 11:02

IVIM MRI: a better tool to assess myometrial invasion in endometrial cancer

R. Balaji; Chennai/IN (ravikanthbalaji@gmail.com)

Purpose: Myometrial invasion is a major prognostic factor in endometrial malignancy. The aim of the current study was to investigate diagnostic value of IVIM MRI in peritumoural zone for assessing infiltration of endometrial cancer and comparing with T2 weighted images.

Methods and Materials: 68 patients with biopsy proven endometrial cancer were included in the study. Patients underwent MR imaging on a 1.5 Tesla scanner (Achieva, Philips Healthcare, Best, The Netherlands). Imaging sequences included T1, T2, regular diffusion and IVIM performed with 11 b values (0 to 1200 mm²/s). Regions of Interest (ROI) were drawn in the peritumoural zone where the tumour was in proximity to the myometrium. IVIM derived parameters f (perfusion fraction), D (true diffusion) and D* (pseudo diffusion) were obtained. The signal changes and values were compared with corresponding T2 weighted images.

Results: The primary tumour in the endometrial cavity had high f and low D values. Similar values were obtained in peritumoural zone and points of infiltration. In 24 patients with only breach of junctional zone and no obvious myometrial invasion seen on T2WI, IVIM parameters were altered with increased f values and low D values compared to normal myometrium.

Conclusion: f and D values obtained by IVIM MRI in peritumoural zone could accurately predict depth of myometrial invasion.

Multiparametric reproducibility of DCE-MRI enhancement curves for adnexal masses: quality assurance study for multicentre MROC trial

A.S. Mehdi, S. Islam, N. Bharwani, S. Sudderuddin, A.G. Rockall; London/UK (aia.s.mehdi@gmail.com)

Purpose: Dynamic Contrast Enhanced MRI (DCE-MRI) is a useful tool in characterising ovarian tumours; Semi-quantitative DCE-MRI metrics separate the relative enhancement curves of lesions into 3 types; benign (1), indeterminate (2) and malignant (3), using myometrium as internal reference. This technique is being used in the NIHR-funded multicentre study in ovarian cancer (MROC). The purpose of the current study was to assess the agreement of categorisation of these enhancement curves between different platforms and readers.

Methods and Materials: 58 females (mean age 54 ±16) underwent pelvic DCE-MRI for characterisation of adnexal masses. The inclusion criteria were presence of solid tissue in lesion and a uterus in situ; yielding 26 lesions for final analysis. DCE-MRI relative time intensity curves were generated for each lesion using 3 applications: Olea sphere 3.0, Osirix DCE plugin 2.2 and Mint Lesion. These were generated from regions of interest drawn on the lesion and outer myometrium. Each curve was categorised as type 1, 2 or 3 by three Consultant Radiologists specialising in gynaecological imaging. Inter-observer agreement for each platform and intra-observer agreement was assessed using a Fleiss kappa score.

Results: The inter-observer kappa score ranged from 0.65-0.70 demonstrating strong agreement. The intra-observer kappa score across different platforms ranged from 0.23-0.47 demonstrating fair to moderate agreement.

Conclusion: Semi-quantitative DCE-MRI enhancement curves for adnexal lesions demonstrate good reproducibility between readers for a given platform but are less reproducible across different platforms. This indicates a need to develop robust semi-quantitative parameters that may be validated across different platforms.

B-0178 11:18

Texture analysis of multiparametric MRI and association with tumour grading in cervical cancer

J.A.U. Peruchio, E.Y.P. Lee, R. Du, V. Vardhanabhati, K.W.H. Chiu, E.M.F. Wong; Hong Kong/HK (jperuchio@hku.hk)

Purpose: To explore efficacy and generalizability of texture analysis of multiparametric magnetic resonance imaging (mpMRI) in discriminating histopathological characteristics of cervical cancers in a two-centre setting.

Methods and Materials: 130 cervical cancer patients were retrospectively reviewed for pre-treatment diffusion-weighted (DWI) and standard T2-weighted (T2W) abdominopelvic MRI in two centres (centre 1 n=100; centre 2 n=30). Biopsies of each patient were acquired to determine histological subtype and tumour grading. Volumetric regions of interest (VOI) were placed to encompass the entirety of primary tumours on T2W and DWI parametric maps. 144 texture features were calculated using pyradiomics. Redundancy analysis was used for feature reduction while goodness-of-fit measures were used for feature selection. Logistic regression was used to build predictive models with centre 1 serving as the training set and centre 2 serving as an external testing set.

Results: In the first centre 80 patients had squamous cell carcinoma (SCC) while 20 had adenocarcinoma (ACA), and 42 patients had well or moderately differentiated tumours (G1/G2) while 58 had poorly differentiated tumours (G3). In the second centre, 25 patients had SCC while 5 had ACA, and 14 had G1/G2 tumours while 16 had G3 tumours. Redundancy analysis demonstrated that only 15% of features were independent predictors. In discriminating histological grading, only one texture, T2W_{kurtosis}, achieved reasonable goodness-of-fit and moderate discriminative performance (internal accuracy: 0.64, external accuracy: 0.71). In discriminating histological subtype. Texture features had poor discriminative performance for tumour grading.

Conclusion: T2W_{kurtosis} was moderately discriminative in differentiating tumour grading in cervical cancer.

B-0179 11:26

The utility of histogram analysis of whole tumour apparent diffusion coefficient map and MRI volumetry in differentiating low and high grade endometrial cancer

W.M. Fathallah, M. Habeeb, M.E. Ghanim, M.E. Bandar; Kuwait/KW (waelldr@hotmail.com)

Purpose: To test the diagnostic performance of histogram analysis of apparent diffusion coefficient (ADC) map and tumor volumetry for differentiating low from high grade endometrial cancer.

Methods and Materials: Fifty eight patients with histologically proven endometrial cancer who had preoperative MRI and surgery were retrospectively included in this institutional review board approved study with waiver of informed consent. Histogram data derived from regions of interest (ROIs) manually drawn on all slices of the ADC map including areas of necrosis. Histogram parameters (ADC mean, standard deviation, skewness, kurtosis and 5th-95th percentiles), tumor volume (TV), uterine volume (UV) and tumor/uterine ratio (T/U ratio) were correlated to tumor histological grade.

Results: High grade endometrial cancers demonstrated significantly higher ADC maximum and standard deviation (p<0.001), 75th (p=0.008), 90th and 95th (p<0.001) percentiles values than low grade tumors. T/U ratio and TV were significantly higher for high-grade neoplasms (mean T/U of 0.31 for G3, 0.12 for G2 and 0.07 for G1; p<0.001 for G1 vs G2 and G3). Rest of parameters showed no significant correlation with tumor grade. Cutoff values of T/U of 0.11, TV of 12.9 mL, 95th percentile of 1.334x10⁻³mm²/s, 90th percentile of 1.259x10⁻³mm²/s, 75th percentile of 1.022x10⁻³mm²/s, ADC standard deviation of 0.206x10⁻³mm²/s and ADC maximum of 1.688x10⁻³mm²/s enabled to distinguish G1 from G2-G3 tumors with sensitivity 94.7%, 84.2%, 68.4%, 68.4%, 68.4%, 78.9% and 84.2%, specificity 82.1%, 74.4%, 82.1%, 89.7%, 66.7%, 74.4% and 71.8% and accuracy 86.2%, 77.6%, 77.6%, 82.7%, 67.2%, 75.9% and 75.9% respectively.

Conclusion: Histogram analysis of ADC map and MRI volumetry are useful in differentiating low from high grade endometrial cancer.

B-0180 11:34

Ovarian cancer neoadjuvant treatment response evaluation: value of diffusion-weighted MRI

A.E. Solopova, S.N. Gurov; Moscow/RU (dr.solopova@mail.ru)

Purpose: To evaluate the capability of diffusion MR-sequences (DW-MRI) in the assessment of neoadjuvant chemotherapy treatment (NACT) response of ovarian cancer (OC).

Methods and Materials: 72 zones of interest in 25 patients with disseminated OC, who underwent pelvic and abdominal MRI to clarify the tumor spread, the issue of NACT and after 1 and 3 courses in the evaluation of its effectiveness, were available for analysis after the 3-d course of NACT. MR-study was performed on 1.5 T MRI, using protocol: T2-,T1-, Dynamic 3D FS, DWI with b-factors 0, 200, 400, 600, 1000 m/mm², with apparent diffusion coefficient (ADC) estimation. The basic treatment response evaluation was performed in accordance with RECIST 1.1 criteria.

Results: The average ADC values in the primary tumour before treatment were significantly higher than in omental and peritoneal implants (p=0,024 and p=0,029, respectively). A comparative assessment of ADC before and after treatment revealed significant increase after 3 courses of chemotherapy (p=0,012), while improvement after 1 course in the primary tumour and differences in ADC before and after treatment in the omental and the peritoneal implants are less pronounced and insignificant (p=0,84; 0,71; 0,59 respectively). Information on evaluation of residual tumour and the degree of therapeutic MRI pathomorphosis were: sensitivity - 89,6%, specificity - 81,3%, and accuracy - 87,1%.

Conclusion: MRI DWI is informative adjunct in NACT treatment response evaluation in patients with advanced OC. Significant differences in the mean ADC were obtained for the solid component of the primary tumours, indicating their greater sensitivity to NACT.

MRA vs DSA based models of cerebral aneurysms: how do the corresponding CFD derived flow fields compare?

M. Mantatzis, K. Thanosoulis, A. Theodoridis, J. Mokali, C. Gianniotis, I. Seimenis; Alexandroupoli/GR (mmantatz@med.duth.gr)

Purpose: Computational fluid dynamics (CFD) simulations can be used to study the blood flow dynamics in cerebral aneurysms (CAs). This study aims at comparing the CFD derived flow fields in matching CA models determined by magnetic resonance angiography (MRA) and digital subtracted angiography (DSA).

Methods and Materials: Three-dimensional (3D) models of the same CAs were reconstructed from corresponding MRA and DSA data. Following similar meshing, the two models were used to calculate CA haemodynamic parameters, such as the wall shear stress (WSS) and the static pressure. The flow fields were analyzed computationally using the 3D Navier-Stokes equation for laminar flow of incompressible Newtonian fluid. Various inlet conditions were considered.

Results: The gross morphologies of the CA models reconstructed from DSA and MRA were comparable, although the two respective aspect ratios differed by about 12%. However, the intrinsically high spatial resolution of DSA seems to result in an elaborate and accurate morphological characterization of the CA that requires less user interference. The 3D model determined from DSA resulted in generally higher WSS and static pressure values compared to those obtained with the MRA based model. Minimum WSS values differed by up to 28% in the two models. Nevertheless, local minima were found at the same CA locations.

Conclusion: CFD-derived local values of WSS, a parameter which has been proposed as predictive of the risk for CA rupture, may be dependent on the imaging modality and protocol employed for the reconstruction of the 3D aneurysmal model.

B-0184 10:38

The mechanism of cerebral aneurysms and treatment effect on the genesis

B.-L. Gao; Zhengzhou/CN (browngao@163.com)

Purpose: To investigate the mechanisms of cerebral aneurysms and treatment effect on the mechanisms.

Methods and Materials: 724 patients with cerebral aneurysms were investigated. The angiographic data of 140 patients were processed for computational fluid dynamics (CFD). Different therapies were analysed for their effects on the mechanisms of aneurysms.

Results: 1018 cerebral aneurysms were detected. 717 aneurysms involved a branch (70.4%) and 301 aneurysms were located on a vascular curve (29.6%). On the wall where a cerebral aneurysm was generated, two peak values and one minimal value were demonstrated on the curve of wall shear stress while one peak value was revealed on the total pressure curve. Moreover, cerebral aneurysm occurred on one of the shear stress peaks. Stenting can straighten the arterial bends and change the vascular bifurcation angle, revising the profile of shear stress and total pressure and the distance between two peaks of shear stress and thus making the haemodynamic stresses focused more on the divider of vascular bifurcation. Coiling or surgical clipping alone did not alter the arterial shape and the profile of shear stress and total pressure, without affecting the haemodynamic stresses for aneurysm initiation.

Conclusion: Cerebral aneurysms are initiated at sites with both high wall shear stress and total pressure, and stenting especially Y-shaped stenting can decrease the haemodynamic stresses for aneurysm initiation while coiling alone or surgical clipping do not. Stenting with Y configuration is a better choice of treatment than coiling or surgical clipping in managing the genesis of cerebral aneurysms.

B-0181 11:42

Pre- and post-MRI risk-stratification reduces prostate MRIs, biopsies and overdiagnosis in prior negative biopsy men

F.-J.H. Drost, J.F.M. Verbeek, A.R. Alberts, M.J. Roobol, I.G. Schoots; Rotterdam/NL (i.schoots@erasmusmc.nl)

Purpose: To assess the diagnostic performance of prostate cancer (PCa) detection by incorporating Rotterdam Prostate Cancer Risk Calculator (prostatecancer-riskcalculator.com) in pre- and post-MRI diagnostic setting.

Methods and Materials: In 146 consecutive men with prior negative biopsy, mpMRI with blinded standard biopsies (SBx) and MRI-targeted biopsies (MRI-TBx) to PIRADS ≥ 3 lesions was performed "by default". Various diagnostic strategies w/o MRI(-TBx), SBx, and risk-calculation (pre-MRI and post-MRI) were evaluated to PCa outcomes (Grade Groups [GG]), quantified by detection rates between diagnostic strategies (McNemar-test, $p < 0.05 = *$).

Results: MRI was negative in 63/146 (43%) men, potentially saving 43% biopsies in the MRI-TBx strategy. PI-RADS 3, 4 and 5 coincided with GG ≥ 2 PCa in 4/23 (17%), 18/33 (55%) and 24/26 (92%) men, respectively. MRI-TBx versus default (MRI-TBx+SBx) reduced 23/40 (58%)* GG=1 but missed 4/49 (8%) GG ≥ 2 PCa. Pre-MRI risk-stratification identified 53/146 (36%) men at low-risk, potentially saving 36% MRIs and biopsies. Pre-MRI risk-based MRI-TBx+SBx versus default (MRI-TBx+SBx) reduced 10/40 (25%)* GG=1 PCa but missed 7/49 (14%) GG ≥ 2 PCa. Post-MRI risk-stratification identified 40/146 (27%) men at low-risk, potentially saving 27% biopsies. Post-MRI risk-based MRI-TBx+SBx versus default (MRI-TBx+SBx) reduced 7/40 (18%)* GG=1 and missed none (0%) GG ≥ 2 PCa.

Conclusion: In prior negative biopsy setting, pre-MRI risk-stratification indicating MRI(-TBx) and SBx, may potentially result in saving one-in-three MRIs, with reduced detection of GG1 PCa, at the expense of missing limited GG ≥ 2 PCa. Post-MRI risk-stratification, i.e. (all men undergo MRI) indicating TBx and SBx, may potentially result in saving one-in-four biopsies, not compromising any GG ≥ 2 PCa detection.

B-0182 11:50

DW-MRI can be used to predict complete cytoreduction and survival in colorectal peritoneal carcinomatosis patients using leading predictive models

M.P. Engbersen, I. Van 't Sant, W.J. Van Eden, J.D.R. Velzing, N.F. Kok, D.M. Lambregts, R.G.H. Beets-Tan, A.G. Aalbers, M.J. Lahaye; Amsterdam/NL (m.engbersen@nki.nl)

Purpose: This study demonstrates the performance of diffusion-weighted MRI to predict complete cytoreductive surgery (CRS), disease-free survival and overall survival by using 5 different predictive models for HIPEC candidates with colorectal cancer.

Methods and Materials: Between February 2016 and October 2017, patients with colorectal peritoneal carcinomatosis considered for CRS/HIPEC who underwent DW-MRI for preoperative staging were included. DW-MRI images were evaluated, retrospectively, to determine the PCI. Relevant clinical parameters were obtained from patient files. Five predictive models were used; the Peritoneal Surface Disease Severity Score (PSDSS), Region Count, Simplified Peritoneal Cancer Index (SPCI), Peritoneal Cancer Index (PCI), and the Colorectal Peritoneal Metastases Prognostic Surgical Score (COMPASS). The performance of the predictive models was assessed by receiver operator characteristics (ROC) analysis and Cox-proportional analysis.

Results: Ninety-one patients were included. The mean age was 62.30 (± 10.93) and 49% (45/92) of the patients were female. Fifty-three (58%) patients underwent successful CRS/HIPEC. For 38 patients, CRS/HIPEC was deemed infeasible, mostly due to extensive peritoneal carcinomatosis (23/38). ROC curve analysis for predicting a complete cytoreduction showed AUCs for PSDSS, region count, SPCI, PCI and COMPASS of 0.79, 0.81, 0.82, 0.85 and 0.86, respectively. PSDSS, region count, SPCI, PCI and COMPASS showed significant hazard ratios for overall survival of 1.19, 1.69, 1.22, 1.12 and 1.02. None were found for disease-free survival.

Conclusion: DW-MRI seems to be able to select patients with colorectal peritoneal carcinomatosis eligible for CRS/HIPEC. All five predictive models are predictive of complete cytoreduction and overall survival, not of disease-free survival.

B-0185 10:46

Evaluation of haemodynamic and morphological biomarkers to assess the rupture risk of intracranial aneurysms using magnetic resonance fluid dynamics and computational fluid dynamics

M.G.R.S. *Perera*¹, H. *Isoda*¹, T. *Mizuno*¹, M. *Terada*², T. *Naito*², C. *Tanoi*², T. *Izumi*¹, H. *Sakahara*³, S. *Naganawa*¹; ¹*Nagoya/JP*, ²*Iwata/JP*, ³*Hamamatsu/JP (mg.roshani@d.mbox.nagoya-u.ac.jp)*

Purpose: The purpose of this study was to evaluate in-vivo haemodynamic and morphological biomarkers using magnetic resonance fluid dynamics (MRFD) and computational fluid dynamics (CFD) in order to assess the rupture risk of intracranial aneurysms.

Methods and Materials: 41 intracranial aneurysms (33 unruptured, 8 ruptured) were analyzed using MRFD and patient specific MR-based CFD. Two morphological and ten haemodynamic biomarkers were calculated and evaluated for significance with respect to rupture. Mean values of biomarkers for the ruptured and unruptured groups were compared and the existing correlations between CFD based and MRFD based biomarkers were assessed.

Results: Four haemodynamic biomarkers, average oscillatory shear index (MRFD, $p=0.012$; CFD, $p=0.041$), maximum oscillatory shear index (MRFD, $p=0.027$; CFD, $p=0.016$), average relative residence time (MRFD, $p=0.027$; CFD, $p=0.024$), maximum relative residence time (MRFD, $p=0.045$; CFD, $p=0.024$) were statistically significantly different between the 2 groups with respect to both MRFD and CFD analyses. Inflow concentration index ($p=0.024$) achieved statistical significance in MRFD analysis whereas spatially and time averaged wall shear stress ($p=0.024$) was significantly different in CFD analysis. Receiver operating characteristic analysis revealed AUC values greater than 0.731 for all the significant biomarkers. None of the morphological biomarkers, namely aspect ratio and size ratio exhibited statistically significant differences. Moderate to very strong, positive monotonic correlations were observed between CFD and MRFD with respect to the significantly different biomarkers.

Conclusion: Oscillatory shear index, relative residence time, inflow concentration index and time averaged wall shear stress could be potential haemodynamic biomarkers for intracranial aneurysm rupture risk assessment.

B-0186 10:54

4D CT-angiography as a predictor of growth of intracranial aneurysm

E. *Grigorieva*¹, V. *Krylov*², V. *Lukyanichikov*², N. *Polunina*²; ¹*Fryazino/RU*, ²*Moscow/RU (iara333@yahoo.com)*

Purpose: The prevalence of unruptured aneurysms in population consist of 2.8%, about 30% among them are multiple, giant or partly thrombosed aneurysms, which need more accurate assessment because of high risk of neurological deficit and adverse outcome.

Methods and Materials: In 2012-2017, 4D CT angiography was performed on 16 patients with unruptured aneurysms from 3mm to 35mm, 2 patients with partially thrombosed aneurysms. 4D CT angiography was performed with ECG synchronization followed the reconstruction of the R-R interval resulting in a pulsation video sequence of the aneurysm wall. We considered any asynchronous pulsation of the aneurysmal wall to be haemodynamically significant. All patients were observed during 4 years using CT-angiography.

Results: 11 of 16 patients showed the uniform pulsation of the aneurysmal sack, with the stable size over time. In 3 patients (18,75%) the nonsynchronous pulsation of one wall was noted, with an increase in the size of aneurysms by 1-1.5 mm per year and the formation of diverticula at the level of maximum wall pulsation. In 2 patients with partially thrombosed aneurysms the wall pulsation was too weak to be analyzed.

Conclusion: 4D CT angiography may provide additional functional information not only about aneurysm wall pulsation but about the tendency of hasty growth that is one more factor of risk of aneurysmal rupture.

B-0187 11:02

Risk evaluation of malignant intracranial hypertension development in children with severe traumatic brain injury

I. *Melnikov*, M. *Ublinskiy*, O. *Lukovkina*, M. *Akhlebinina*, T. *Akhadov*; *Moscow/RU (iliamed@inbox.ru)*

Purpose: To determine the potential of DWI in assessing the risk of developing malignant intracranial hypertension in children with severe TBI.

Methods and Materials: We retrospectively evaluated clinical and MRI data of 36 pediatric patients with severe TBI. The severity of clinical condition of each patient was evaluated with the use of the Glasgow Coma Scale (GCS). Parenchymal ICP gauge placement was performed in all patients for adequate ICP monitoring. Patients were categorized into three groups: (1) high ICP managed conservatively; (2) malignant ICP managed with DC; (3) normal ICP. Four pairs of symmetrical ROIs were manually drawn on ADC maps, that were grouped for analysis of deep white matter of frontal, temporal, parietal and occipital lobes. All ROIs excluded areas that appeared abnormal on T2WI.

Results: Average ADC values in the deep white matter of frontal lobes were significantly increased in children with severe TBI with following DC ($851.5 \pm 54.3 \times 10^{-3} \text{ mm}^2/\text{sec}$) compared to those with severe TBI and conservatively controlled ICP ($756.4 \pm 40.5 \times 10^{-3} \text{ mm}^2/\text{sec}$; $p < 0.05$).

Conclusion: Assessment of DWI and ADC values in severe pediatric TBI is a potential tool for evaluating the risk of malignant ICP development. Early identification of children at high risk for this complication may assist in earlier aggressive (surgical) clinical management of pediatric TBI patients.

B-0188 11:10

Association of amygdala volume and markers of cardiovascular disease

S. *Grosu*¹, R. *Lorbeer*², F. *Bamberg*², C.L. *Schlett*³, M. *Heier*¹, S. *Rospleszcz*⁴, A. *Peters*⁴, B.B. *Ertl-Wagner*⁵, S. *Stöcklein*¹; ¹*Munich/DE*, ²*Freiburg/DE*, ³*Heidelberg/DE*, ⁴*Neuherberg/DE*, ⁵*Toronto, ON/CA (sergio.grosu@med.uni-muenchen.de)*

Purpose: Recent publications suggest a link between amygdala activity measured by PET and cardiovascular disease. Data generated from animal models show that stress leads to larger amygdala volumes. Therefore, we investigated the association between amygdala volume determined by magnetic resonance imaging (MRI) and MRI-based surrogate markers for cardiovascular disease.

Methods and Materials: 237 subjects of the KORA study cohort without prior cardiocerebrovascular disease underwent comprehensive 3T MRI assessment to characterize amygdala volume and imaging-based markers of cardiovascular disease (carotid plaque, media wall thickening, myocardial mass, myocardial late gadolinium enhancement, left ventricular function). Amygdala volume was automatically segmented (based on FLAIR images) and corrected for total intracranial volume. Logistic regression analyses of amygdala volume and MR-derived cardiovascular parameters were conducted while controlling for age and sex as well as cardiovascular risk factors, including diabetes, blood cholesterol levels, hypertension, smoking and obesity.

Results: Among 237 subjects (mean age: 56.2 ± 9.1 , 57% males), the average amygdala volume was 3.04 ± 0.24 ml. The prevalence of MR-based markers of cardiovascular disease was moderate (carotid plaque 20.8%, myocardial late gadolinium enhancement 2.9%). Mean media wall thickening was 0.75 ± 0.11 mm, mean myocardial mass was 72.9 ± 15.5 g/m², mean ejection fraction was $69.2 \pm 8.1\%$. Logistic regression analyses showed no significant association of amygdala volume and any of the cardiovascular parameters ($p \gg 0.05$, respectively).

Conclusion: In this reference population, MR-based amygdala volume was not associated with markers of cardiovascular disease, potentially indicating an independent role in risk prediction.

B-0189 11:18

Imaging requests, stroke incidence and contributing factors after open-heart surgery

L. *Melazzini*, M. *Codari*, G.D.E. *Papini*, C. *Beretta*, M. *Ranucci*, F. *Secchi*, F. *Sardanelli*; *Milan/IT (lucamelazzini@yahoo.it)*

Purpose: Stroke is a critical complication of cardiac surgery. In spite of the adoption of neuroprotective strategies, incidence for postoperative stroke remains around 5% for combined cardiac procedures. In this light, we conducted an internal investigation on brain imaging requests, stroke incidence and contributing factors after open-heart surgery at our institution.

Methods and Materials: 1014 adults who underwent open-heart surgery between January 2017 and December 2017 were retrieved from our institutional database. Among them, we identified those who underwent head CT or MRI within 7 days from surgery. Their radiological reports were examined to identify cases of stroke. Demographics, anaesthesiological statistics and clinical data were extracted from patients' records and statistically processed to find contributing factors for stroke.

Results: 55 patients (5.42% of the study sample) had brain imaging performed within one week after cardiac surgery. Among them, 53 patients underwent head CT scans while two had brain MRI scans too. 18 patients (1.78% of the study sample; PPV of brain scans=32.73%) were found to be radiologically positive for stroke. Stroke was deemed as ischaemic in 17 patients, the one remaining being ischaemic with haemorrhagic transformation. Significant correlations were found between stroke occurrence and previous transient ischaemic attack ($p=0.036$), diabetes ($p=0.001$), combined cardiac procedure ($p=0.039$), use of circulatory arrest ($p<0.001$), creatinine ($p=0.029$), extracorporeal circulation time ($p=0.003$) and clamp time ($p=0.007$).

Conclusion: Our results slightly overcome those previously reported in the literature. Given this, stroke persists as a fearsome complication of cardiac surgery, where timely neuroimaging requests play a vital role.

B-0190 11:26

Arterial spin labelling MRI in evaluating perioperative cerebral perfusion of carotid endarterectomy with different post labelling delays: comparison with CT perfusion imaging

H.M. Xu, Y. Liu, H. Yuan; *Beijing/CN (84498843@qq.com)*

Purpose: Taking CT perfusion imaging as a reference standard, to find the appropriate perioperative PLDs which can reflect the accurate cerebral hemodynamics changes after CEA using arterial spin labeling.

Methods and Materials: Fourteen patients diagnosed as carotid artery stenosis and scheduled for CEA were recruited. All patients were scanned with two PLDs 3D-ASL (PLD=1.5s and PLD=2.0s) and CTP about 1 week before and after CEA respectively. CBF values were measured respectively in the same position of surgical side and the other side before and after surgery on CBF maps of 3D-ASL and CTP. To calculate perioperative changes of relative CBF values on CTP and 3 different PLD combinations of ASL: perioperative PLD=2.0s, perioperative PLD=1.5s or preoperative PLD=2.0s and postoperative PLD=1.5s.

Results: The ICC between these three different PLD combinations of ASL (preoperative PLD=2.0s and postoperative PLD=1.5s; both PLD=1.5s; both PLD=2.0s) and CTP were 0.139, 0.875 and 0.856 respectively. It indicates that the consistency of the first set-preoperative PLD=2.0s and postoperative PLD=1.5s-with CTP was poor, and the consistency of the latter two groups with CTP were good and have no statistically difference. While compared to ASL with PLD of 2.0s, ASL with PLD of 1.5s would underestimate the CBF values since the prolonged arterial transient times.

Conclusion: The PLD of arterial spin labeling should be consistent before and after CEA. Compared to ASL with PLD of 1.5, ASL with PLD of 2.0 is a more appropriate to evaluate hemodynamic changes around carotid endarterectomy.

B-0191 11:34

Accuracy of intracerebral haemorrhage volume calculation: comparison between manual volume segmentation, ABC/2 and sABC/2

A.V. Marinescu, R. Radu, E. Terecoasa, A.N. Marinescu, C. Tiu, A. Nicula; *Bucharest/RO (andrei.victor.marinescu@gmail.com)*

Purpose: Accurate estimation of intracerebral haemorrhage (ICH) volume is essential for adequate management decisions. The aim of the study was to determine the accuracy of the ABC/2 and sABC/2 methods relative to manual volume segmentation (MVS) method for estimating ICH volumes.

Methods and Materials: Clinical and neuroimaging data were prospectively collected for 47 patients with ICH. Haematoma volume was measured separately by a single examiner using ABC/2, sABC/2 and Carestream MVS. Agreement between these methods was evaluated using Bland-Altman plots and MVS was considered the reference method.

Results: Mean patient age was 69.7 ± 11.3 years and 55.3% were males. Median ICH volumes assessed with the MVS, ABC/2 and sABC/2 methods were 12.2 mL, 6.9 mL and 10.7 mL respectively. ICH volumes were systematically underestimated by ABC/2 with a mean difference of -7.6 mL (95% CI -10.6 to -4.47 mL) and systematically overestimated by sABC/2 with a mean difference of 3.6 mL (95% CI 0.31 to 6.9 mL). The variability between the methods increased with larger ICH volumes and therefore, we created second Bland-Altman plots using the geometric means, which showed an ABC/2 to MVS ratio of 0.66 and a sABC/2 to MVS ratio of 1.05. In our cohort, ICH volume percentage difference using ABC/2 and sABC/2 is not expected to exceed 33.72% and respectively 16.9% of the MVS volumes.

Conclusion: Absolute haematoma volumes might vary depending on the technique. Further work is needed to identify the most suitable methods for ICH volume measurement and to estimate their clinical impact.

B-0192 11:42

Effect of prolonged acquisition intervals on CT brain perfusion analyses

F. van Ommen, F. Kauw, E. Bennink, J.W. Dankbaar, H.W.A.M. De Jong; *Utrecht/NL (f.vanommen@umcutrecht.nl)*

Purpose: Axial coverage in CT perfusion (CTP) imaging can be increased with toggling table techniques. This, however, prolongs the acquisition interval (AqI) up to 4 seconds. This study investigates the influence of prolonged AqI on quantitative perfusion maps and infarct volumes.

Methods and Materials: Quantitative perfusion values (CBF, CBV and MTT) of 25 CTP scans, with an AqI varying from 2-5 seconds, were compared to the 1-second AqI. A commercial method (ISP) (brain perfusion, singular value decomposition algorithm, Intellispace Portal9, Philips Healthcare) and an academic method (NLR) were used for generation of perfusion maps. Infarct core volumes were determined using a CBV threshold and penumbra volumes using a CBV and relative MTT threshold. All AqI-imaging results were qualitatively compared by visual inspection.

Results: An AqI-dependent bias was observed although not significant for CBV values up to 4 seconds AqI. Regarding MTT and CBF, ISP provided significantly different values for all AqIs, whereas NLR did not. Infarct core volumes were significantly lower (<8%) for ISP and significantly higher (>29%)

for NLR for AqIs of ≥3 seconds. Penumbra volumes were significantly larger (>33%) with ISP for AqIs of ≥3 seconds and for NLR significantly larger (>20%) at AqI of 3 and 4 seconds. Visually, summary maps for ISP and NLR showed minor differences in diagnostic quality up to 4-second interval.

Conclusion: An AqI-dependent bias was observed in the quantitative perfusion parameters. The summary maps with intervals up to 4 seconds are of diagnostic quality, suggesting that CTP imaging with a toggling table is feasible.

Completeness of trauma head computed tomography reports: possibilities for improvement using machine learning

N. Schmidt, I. Nestic, M. Moor, J. Cyriac, D. Zumofen, B. Stieltjes, K. Blackham; *Basle/CH*

Purpose: Regular reevaluation of trauma head CT report quality is of great importance but cannot be performed manually. Here we test a Machine learning (ML) approach for automated completeness detection in reports.

Methods and Materials: Literature and neurosurgical suggestions were combined to establish vital items required in a report: intracranial bleeding (ICB), fracture, signs of hydrocephalus, midline position, and vessel status were selected. All CT reports from the last 8 years were retrieved and labelled. ML model creation was done with Python 3.6 with the scikit library. We applied Support Vector Machines (SVM) for item detection. Positive Predictive value (PPV), Sensitivity and F1-score were calculated in comparison to hand labelled reports.

Results: 1906 reports were retrievable from our RIS. 146 reports had to be excluded due to missing labelling. 100 of the mentioned reports were also analyzed manually for direct comparison. The results of the SVM indicated the presence of a single critical finding ranging from 63.9% (vessel status) to 92.9% (ICB). In the manual analysis, this range was between 67% (midline) and 99% (ICB). The difference between the manual and the automated detection rate was only statistically significant (p<.5) for ICB and vessels.

Conclusion: SVM is suitable for the estimation of level of completeness reports in an automated fashion. It can be implemented as a quality control system and can be trained and applied to any report type. Structured reporting may help to improve the substantial level of incompleteness described here.

Primary stenting of superficial femoral artery in patients with intermittent claudication has durable effects on health-related quality of life at 24 months: results of a randomised controlled trial

H. Lindgren¹, A. Gottsater²; ¹Helsingborg/SE, ²Malmö/SE (2hanslindgren@gmail.com)

Ethics committee approval: Written informed consent was obtained from all patients. The study was approved by the Medical Ethics Committee of Lund University (Dnr 2009/478).

Methods and materials: One hundred patients with stable IC due to SFA disease from seven Swedish hospitals treated with best medical treatment (BMT) were randomised to either the stent (n=48) or the control (n=52) group. Change in HRQoL 24 months after treatment was a primary outcome measure.

Results: Significantly better SF-36 Physical Component Summary (mean difference =5, 1; P=.024) and physical domain scores Physical Function (P=.012), Bodily Pain (P=.002), General Health (P=.037), and EQ5D (P=.010) were reported in intergroup and intragroup comparisons between the stent and the control group.

Limitations: The long inclusion period and large number of screening failures due to the strict inclusion and exclusion criteria might have created a bias in patient selection

Conclusion: In patients with IC caused by lesions in the SFA, primary stenting compared to BMT alone was associated with significant durable improvements in HRQoL, ABI, and walking distance.

Funding for this study: This study was supported by grants from the Gorthons Foundation, the Ernhold Lundström Foundation, Regional research funds and funds at Skåne University Hospital, the Albert Pålsson Foundation, the Hulda Ahlroth Foundation, Mediel AB, and from the Swedish state under the LUA/ALF agreement.

Ultrasound-guided vs computed tomography-guided renal mass biopsy: a prospective randomised study

H.M. Farg, A. Abdelhamid, M. Zakaria, M. El-Ksas, A. El Mahdy, M. Abd El-Hameed, T. El-Diasty; Mansoura/EG (hashim2008_mf@yahoo.com)

Purpose: The purpose of this study was to compare ultrasound (US) vs computed tomography (CT) guidance for renal mass biopsy.

Ethics committee approval: The study was approved by the local ethics committee. Written informed consent was obtained from all participants.

Methods and materials: This was a single-centre prospective randomised trial comparing US vs CT guidance for renal mass biopsy. Between June 2016 and May 2018, eligible patients with renal masses were randomly assigned in a 1:1 ratio to perform either US- or CT-guided biopsy using 18-gauge automated device. The primary outcome was to evaluate the diagnostic success rate in both groups. Secondary outcomes included total procedure time, total punctures, and complications.

Results: A total of 82 patients (men, 57%; mean age, 59.2 years) were included; 41 in each group. The diagnostic success rate was higher in the US group (90%) compared to the CT group (83%); ($p < 0.001$). Four of the patients undergoing US-guided biopsy required re-biopsy compared to 7 patients in CT group; ($p < 0.001$). US significantly shortened the total procedure time (150 seconds) compared to CT group (330 seconds). The complication rate was higher in the CT group (22%) than in the US group (12%). There were no procedure-related deaths in either group.

Limitations: Failed biopsy is not usually related to the image guidance procedure and it may be related to sampling error resulting from tumour haemorrhage or necrosis.

Conclusion: Ultrasound-guided renal mass biopsy has better diagnostic accuracy, less procedural time and lower complication rate than that of CT guidance.

Funding for this study: No funding from industry and/or a funding agency.

Self-compression mammography in clinical practice: a randomised clinical trial compared to standard compression mammography

V. Iotti, M. Guberti, L. Canovi, P. Giorgi Rossi, M. Bertolini, R. Vacondio, P. Pattacini; Reggio Emilia/IT (valentina.iotti@ausl.re.it)

Purpose: Self-compression for mammography may help reaching better compression, with a potential improvement of image quality and reduction of dose. To test the efficacy of a self-compression device, compared to radiographer-lead compression, to reduce the average-glandular-dose without affecting image quality. Secondary outcomes are pain, compression, thickness, time to perform mammography. Here we present preliminary results.

Ethics committee approval: Approved by the provincial Ethical Committee. All participants signed a written informed consent form.

Methods and materials: Women presenting for mammography for breast-cancer follow-up, symptoms, opportunistic screening or familial-risk were asked to participate in this prospective randomised trial and randomised to self-compression or to radiographer-compression. Anxiety was measured before mammography; pain (visual-assessment-scale) and discomfort were measured after. Image quality was assessed blindly by two independent radiologists and two radiographers. Room-in/room-out time has been measured.

Results: From January 2018 to July 2018, 496 women were enrolled, 245 and 251 in self- and radiographer-compression arm, respectively. Image quality (radiologists' judgement $p=0.62$; radiographers' judgement $p=0.34$, slightly better in self-compression for both), dose (0.94 vs. 0.96mGy, $p=0.38$) and pain (3.8 vs. 4.0, $p=0.50$) were similar in the two arms; compression was higher in self- than radiographer-arm (114 vs. 102daN, $p<0.00005$), with a small impact on thickness (46.4 vs. 48.1mm, $p=0.13$). Moderate/severe discomfort was reported by 7.9% vs 9.9% ($p=0.46$). Time was slightly higher 11.5 vs. 10.2m ($p=0.06$). Results were similar in women with higher anxiety level.

Limitations: Screening population was not included.

Conclusion: Self-compression has no impact on dose, pain and discomfort, even if increases compression.

Funding for this study: Sustained by the institutional funds of the Reggio Emilia Local Health Authority-IRCCS.

MRI vs mammography screening for high-risk women: an RCT - the influence of density and effectiveness

A. Geuzing¹, S. Saadatmand¹, E. J. J. Rutgers², R.M. Mann³, D. de Roy van Zuidewijn⁴, H. Zonderland², R. Tollenaar⁵, M.B.I. Lobbes⁶, M. Ausems⁷, M. van 't Riet⁸, M. Hoening¹, I. Mares-Engelberts¹, E. Luiten⁹, E. Heijnsdijk¹, C. Verhoef¹, N. Karssemeijer³, J. Oosterwijk¹⁰, I.-M. Obdeijn¹, H. de Koning¹, M. Tilanus-Linthorst¹; ¹Rotterdam/NL, ²Amsterdam/NL, ³Nijmegen/NL, ⁴Leeuwarden/NL, ⁵Leiden/NL, ⁶Maastricht/NL, ⁷Utrecht/NL, ⁸Delft/NL, ⁹Breda/NL, ¹⁰Groningen/NL (madeleinetilanus@hotmail.com)

Purpose: American guidelines advise women with a familial breast cancer risk MRI-screening, but European mammography. FaMRIsc is the first randomised controlled trial comparing both strategies.

Ethics committee approval: The IRB of ErasmusUniversityMC approved FaMRIsc. All participants gave written informed consent.

Methods and materials: From January 2011 until December 2017, women with a cumulative lifetime risk (CLTR) of $\geq 20\%$ without a BRCA1/2 mutation, aged 30–55 years, were in twelve Dutch centres randomised into two arms: A. yearly MRI-screening, clinical breast examination (CBE), and biennially mammography or B. yearly mammography and CBE. Primary outcomes were number, size and nodal stage of the detected breast cancers. Results were also stratified by mammographic density.

Results: More breast cancers were detected in the MRI-arm (N=675) compared to the Mx-arm (N=680) (41 vs 14, $p<0.001$), after on average 4.3 screening rounds per woman. In the MRI-arm invasive cancers were smaller (median size 8 vs 17 mm, $p=0.006$) and less often node positive (20% vs 71.4%, $p=0.019$). Sensitivity hardly differed (95.1% vs 92.9%, $p=1$), but false positive rate was higher in MRI-arm (160 vs 89.9/1000 woman-year at risk $p<0.001$). All tumours $\geq T2$ were in the two highest density categories. In ACR density A-C MRI detected more small tumours than mammography. Results of incident rounds and cost will be discussed.

Limitations: are discussed

Conclusion: More cancers were detected in the MRI-arm than in the mammography-arm and in a relevantly earlier stage also at low density. We will discuss at what cost.

Funding for this study: This study was supported by ZonMw, The Dutch Cancer Society, A Sisters Hope, Pink Ribbon, Stichting Coolsingel.

Purpose: To determine the variability of positive predictive value (PPV) across centres according to PI-RADS v2 scores.

Ethics committee approval: IRB-approved, HIPPA-compliant study, with waiver of signed informed consent.

Methods and materials: This retrospective included 3,479 men who underwent prostate mpMRI at 26 DFP-member expert centres from several countries and had a lesion classified as PI-RADS ≥ 2 . Exams scored as PI-RADS 1 (i.e. no visible lesion) were not included. MR-targeted biopsy results were the standard of reference. PPV were derived from generalised estimating equations regression to estimate variability across centres.

Gender-specific reference values of thoracic aortic growth

L.R. Bons¹, Z. Sedghi Gamechi¹, K.F. Kofoed², J.H. Pederson², R.P.J. Budde¹, M. de Bruijne¹, J.W. Roos-Hesselink¹, ¹Rotterdam/NL, ²Copenhagen/DK (l.bons@erasmusmc.nl)

Purpose: Longitudinal information about individual aortic growth in the general population is scarce. The aim of this study is to present reference values for thoracic aortic growth among men and women.

Methods and Materials: Participants of the Danish Lung Cancer Screening Trial with two non-contrast computed tomography at least one year apart were included. The study consisted of current and former smokers aged 50-70 years. The diameters of the ascending aorta (AA) and descending aorta (DA) were measured at the pulmonary bifurcation level with an automatic tool. Mean annual aortic growth and 95th percentile (95th) was calculated between the first and last scan during follow-up. Associations between aortic growth and baseline parameters were investigated using multivariable linear regression analysis.

Results: A total of 1987 participants (56% men, mean age 57.4±4.8 years) were included. During a median follow-up of 4.0 years, the AA growth was similar in men (mean 0.12±0.31, 95th 0.47 mm/year) and women (mean 0.11±0.29, 95th 0.42 mm/year). Also the DA growth was not significantly different between men (mean 0.10±0.30, 95th 0.43 mm/year) and women (mean 0.13±0.27, 95th 0.42 mm/year). Larger AA growth was independently associated with increased height, lower weight and smaller AA baseline diameter, while larger DA growth was associated with increased height, absence of antihypertensive medication, larger AA Agatston scores and smaller DA baseline diameter.

Conclusion: This longitudinal population-based study shows that ascending and descending aorta growth is 0.1 mm/year. We found no difference in thoracic aortic growth between men and women.

B-0195 10:47

Aliased flow planimetry by phase-contrast CMR imaging for grading of aortic stenosis

C. Mantini¹, F. Ricci¹, D. Mastrodicasa², D. Rotondo¹, A.R. Cotroneo¹, S. Gallina¹; ¹Chieti/IT, ²Stanford, CA/US (cesare.mantini@gmail.com)

Purpose: The aim of this prospective, observational, cross-sectional study was to: I) test the accuracy and precision of a new, simple, non-invasive CMR technique to measure the effective orifice area (EOA) based on aliased orifice area(AOA) planimetry by low-VENC phase-contrast CMR imaging; II) investigate the relationship and the diagnostic agreement of AOA with: valve area planimetry by bSSFP-CMR images(GOAO_{cmr}), standard EOA obtained with continuity equation by TTE (EOA_{echoc}) and gold standard hybrid EOA.

Methods and Materials: We prospectively enrolled 22 consecutive patients (14 men, mean age 70 ± 9 years)with mild, moderate and severe aortic stenosis(AS) and 6 age- and sex matched healthy controls undergoing TTE and CMR imaging on the same day. We performed a comprehensive analysis of the agreement and correlation among i)AOA planimetry by low-VENC phase-contrast CMR imaging, ii)GOAO valve planimetry by CMR, iii)EOA by TTE(continuity equation method), and iv) multimodality hybrid EOA (EOA_{hybrid}), as obtained by substituting the LVOT area by CMR into the Doppler continuity equation. A phase-contrast slice was prescribed through the tips of aortic valve leaflets, then by setting the VENC value down to40-50 cm/s, with NEX of 5 and free-breathing acquisition, an aliased flow signal was detected.

Results: Across all centres, the PPV for PI-RADS score ≥ 2 was 33.8% (range: 12.9%, 68.6%), for PI-RADS ≥ 3 was 37.5% (range, 14.7%, 68.6%), and for PI-RADS ≥ 4, 48.4% (26.4%, 75.9%). The PPV stratified by PI-RADS scores were as follow: score 2=6.9% (range, 4.2%, 50.0%); score 3=15.3% (3.2%, 54.0%), score 4=38.4% (17.7%, 70.0%), and score 5=71.9% (40.0%, 97.1%).

Limitations: Outcomes based on biopsy modalities that are different and not perfect.

Conclusion: Enormous variation in the PPV exists across expert centres, and the overall PPV among these centres was alarmingly low. Based on the results, a PPV ≥ 50% for PI-RADS v2 score ≥ 4 is proposed as a performance standard, with centres below this benchmark warranting quality improvement efforts. Many of the participating centres did not achieve this threshold.

Funding for this study: University of California San Francisco, Department of Radiology and Biomedical Imaging Seed Grant # 16-43.

Weinberger⁵, J. Yu¹⁸, R.J. Zagoria¹; ¹San Francisco, CA/US, ²New York City, NY/US, ³Philadelphia, PA/US, ⁴Nashville, TN/US, ⁵Chicago, IL/US, ⁶Nijmegen/NL, ⁷Houston TX/US, ⁸Rio de Janeiro/BR, ⁹San Diego, CA/US, ¹⁰Vancouver, BC/CA, ¹¹Portland OR/US, ¹²Albuquerque, NM/US, ¹³Rochester, MN/US, ¹⁴Toronto, ON/CA, ¹⁵Madison, WI/US, ¹⁶Durham, NC/US, ¹⁷Orange, CA/US, ¹⁸Richmond, VA/US, ¹⁹Seoul/KR, ²⁰Aurora, CO/US, ²¹Minneapolis, MN/US, ²²Cincinnati, OH/US (antonio.westphalen@ucsf.edu)

Purpose: To determine if PI-RADS v2 improves the prediction of high Gleason score prostate cancer beyond PSA, PSA density (PSAD), and clinical stage (T1c versus T2/T3).

Ethics committee approval: IRB-approved with waiver for signed consent.

Methods and materials: This retrospective study included 3,479 men who underwent prostate MRI at one of 26 institutions in the USA, Canada, Brazil, South Korea, and Netherlands. Up to 4 lesions/case were classified using PI-RADS. Cognitive, fusion, and in-bore MR-targeted biopsies were performed. Data was collected using REDCap. The impact of PI-RADS on clinical variables was determined using logistic regressions derived area under the ROC curves. Confidence intervals were calculated using cluster-corrected (to account for multiple lesions/person) bootstrapping.

Results: PI-RADS score, logPSA, logPSAD, and palpable nodule were predictors of GS≥3+4 on uni- (all P<0.001) and multivariate analyses (palpable nodule=0.03, others P<0.001). The PI-RADS AU-ROC was 73.9% (72.6%, 75.3%). Adding PI-RADS to the clinical model raised the AU-ROC from 60.7% (59.1%, 62.2%) to 80.8% (79.5%, 82.2%). The differences between the AU-ROC of the PI-RADS and combined model (6.8%; 5.8%, 7.9%), and of the clinical and combined model (20.1%; 19.0%, 21.4%) were statistically significant (P < 0.001).

Limitations: All centres are expert sites, so results may not apply to all locales.

Conclusion: PI-RADS predicts GS≥3+4 prostate cancer better than clinical variables, but its performance may be enhanced by knowledge of PSA, PSAD, and/or presence of palpable nodule.

Funding for this study: UCSF Department of Radiology Seed Grant # 16-43.

Discussant:

E. Rud; Oslo/NO (erikrud@yahoo.no)

Results: We observed excellent pairwise correlation among AOA, EOA_{hybrid}, GOA and EOA ($P < 0.001$), AOA yielding the highest grade of correlation with EOA_{hybrid} ($R^2 = 0.987$, $P < 0.001$). At exploratory reclassification analysis, 2 patients with severe AS by AOA and 3 patients with severe AS by EOA were reclassified downward to moderate AS by EOA_{hybrid}.
Conclusion: AOA planimetry by low-VECT phase-contrast imaging is a simple, reproducible, accurate and precise technique for the grading of AS.

B-0196 10:55

CT as a one stop shop for TAVI-Planning: do we still need an additional invasive coronary angiography?

R.F. Gohmann, C. Kriehoff, P. Seitz, C. Lücke, P. Hartung, M. Abdel-Wahab, D. Holzhey, H. Thiele, M. Gutberlet; *Leipzig/DE*

Purpose: To evaluate the suitability of CT coronary angiography (cCTA) to exclude significant CAD during pre-TAVI-evaluation.

Methods and Materials: Two-hundred consecutive patients undergoing pre-TAVI-evaluation (97 female; mean-age 79.6±7.4 years) were retrospectively included. All patients were examined with a standard protocol consisting of a retrospectively gated CT scan of the heart, immediately followed by a high-pitch scan of the vascular access route utilizing a single bolus of 70 ml iodinated contrast-medium. No beta-blockers or nitrates were applied. Heart-rate and heart-rate-variability during the scan were 73.2±19.3 and 22.6±32.8 beats-per-minute; attenuation at the ascending was 456.6±142.5 HU. Images were evaluated for significant CAD (stenosis ≥50%); examinations where stenoses could not be excluded were read as positive. Routinely all patients received invasive coronary angiography (ICA) 79.5% (159/200), which was omitted if renal function was impaired significantly and no significant stenosis could be identified on cCTA.

Results: cCTA was negative for significant CAD in 44.0% (88/200). Sensitivity, specificity, NPV, PPV and accuracy were 96.3%, 62.0%, 94.2%, 72.0%, 79.3%, respectively. The significant stenoses additionally identified on ICA were either located in side-branches (2/3) or the distal LAD; 2/3 had no identifiable plaque on cCTA.

Conclusion: cCTA and pre-TAVI-evaluation can be performed jointly with no need for additional contrast medium or medication. cCTA is able to exclude significant CAD in a relatively high proportion of this high-risk collective. Thereby cCTA can reduce the number of ICA and total amount of contrast-medium applied, making pre-procedural-evaluation for TAVI-Planning safer for elderly patients with a high incidence of nephropathy.

B-0197 11:03

Reduced dose, reduced contrast single-acquisition TAVI imaging using novel contrast protocol and spectral low-mono-energetic imaging: a proof of concept study

P.A. Ball; *Belfast/UK (peterandrewball@me.com)*

Purpose: To investigate whether a low-dose low-contrast protocol can still produce excellent diagnostic images with spectral CT

Methods and Materials: 20 sequential patient referred for pre-TAVI-gated CT planning were imaged using a novel protocol. 50ml Ioversol 300mg/ml was initially injected at 5ml/s using linear bolus reduction (reducing to 4.2ml/s). A delay of 2 seconds was built in to the protocol prior to a second injection of 20ml of contrast at 4ml/s. The initial gated CTCA was performed using a retrospective acquisition protocol with reconstructions at both 40 and 75% (systolic and mid-diastolic phase). Run off was assessed using mono-energy reconstructions of the aorta iliac and femoral vessels. Doses and contrast administration volume were compared with the previous acquisition protocol along with image quality and reproducibility (patients were compared on a like-for-like basis for patient habits, length of scan, etc.).

Results: There was a significant dose reduction from an average of 1750 DLP to an average of 460DLP ($p < 0.01$) This is primarily due to the avoidance of overlapping low-pitch acquisition of the abdominal structures. The image quality of the gated study for annular measurement and run off was assessed by a 5-point Likert scale by two experienced cardiothoracic radiologists. There was an excellent level of agreement of image quality (k 0.76).

Conclusion: The protocol using low-mono-energetic CT images provides excellent image quality with a significantly reduced radiation and contrast dose in high-risk patients undergoing TAVI.

B-0198 11:11

Low iodine, fast kV switching dual energy thoraco-abdominal CT angiography for planning of transcatheter aortic valve implantation (TAVI): a pilot feasibility study

L. Faggioni, M. Gabelloni, M. Bianchi, E. Neri, D. Caramella; *Pisa/IT (lfaggioni@sirm.org)*

Purpose: To evaluate the image quality of thoraco-abdominal fast kV switching dual energy CT angiography (DE-CTA) examinations performed for TAVI planning using a low iodine protocol and reconstructed at different monochromatic energy levels.

Methods and Materials: Forty nonobese patients with severe aortic stenosis candidate to TAVI underwent thoraco-abdominal DE-CTA for preprocedural assessment of vascular access routes on a high definition, 64-row fast kV switching DECT scanner. All patients received an average volume of 35mL (30-40mL) of an iso-osmolar, moderate concentration (320mg/mL) iodinated contrast medium. Intra-arterial density was measured on 40keV, 50keV, 60keV, 70keV and 80keV monochromatic images at the same levels inside the ascending thoracic and infrarenal abdominal aorta. The monochromatic dataset with the best overall visual image quality was generated, and the occurrence of extravascular incidental findings was recorded.

Results: Intra-arterial density and signal-to-noise ratio increased monotonically with decreasing energy levels, ranging from 150±38 HU and 6.10±1.78 at 80keV to 620±164 HU and 9.97±3.70 at 40keV, respectively. Image noise was highest at 40keV (66±16 HU) and lowest at 70keV (24±6 HU). Monochromatic datasets between 50keV and 60keV yielded an intra-arterial density consistently above 200HU (217-576 HU), along with the best balance among vascular enhancement, noise, and blooming artefacts from densely calcified plaques. Incidental findings occurred in 17/40 patients (42.5%), of which 4 (3 advanced cancers, 1 pulmonary embolism) significantly altered patient management.

Conclusion: Pre-TAVI thoraco-abdominal DE-CTA is feasible using a low iodine, fast kV switching approach. 50keV to 60keV reconstructed monochromatic images provide the best overall diagnostic quality.

B-0199 11:19

Psoas muscle cross-sectional areas and aortic valve calcification in patients enrolled for transcatheter aortic valve implantation (TAVI)

G. Spadarella, L. Bonomo, C.B. Monti, F. Sardaneli, F. Secchi; *Milan/IT (gaia.spadarella@gmail.com)*

Purpose: To evaluate the correlation between psoas muscle cross-sectional areas (PCSA) as a marker of central sarcopenia and aortic valve calcification.

Methods and Materials: 77 patients from 2015 to 2017 were retrospectively collected from our pre TAVI registry. In the abdominopelvic CT scan, the right and left PCSA was calculated as well as the ratio between the mean cross-sectional area of the psoas muscles and the L4 vertebral body immediately below the origin of the posterior elements. In the thoracic ECG-trigger CT scan aortic valve and anulus calcification (AC) were measured as calcium in mm² (ACmm) or as Agatston score (ACA). Spearman test was used to test the correlation between these two variables.

Results: Of the 77 patients the mean age was 81±8.2 years (82±7.5 in female and 79±8.61 in males). PCSA was 0.71±0.20 overall and 0.79±0.22 in males and 0.63±0.13 in females ($p < 0.01$). ACmm was 1869±1419 overall and 1999±1171 in males and 1736±1640 in females ($p = 0.12$). Similarly, as expected, ACA was 2404±1777 overall and 2544±1395 in males and 2261±1109 in females ($p = 0.07$). No significant correlation was found between PCSA and ACmm and ACA for all patients ($r = -0.154$ $p = 0.19$; $r = -0.148$ $p = 0.215$ respectively). A significant negative correlation was found in male patients between PCSA and ACmm and ACA ($r = -0.341$ $p = 0.04$; $r = -0.351$ $p = 0.03$). No correlation was observed in female patients for PCSA and ACmm and ACA ($r = -0.27$ $p = 0.11$; $r = -0.29$ $p = 0.09$).

Conclusion: PCSA can be a useful tool to evaluate cardiovascular risk in male patients undergoing TAVI procedures.

B-0200 11:27

Radiation dose and the repeatability of measurements of dimensions of the aortic valve in multidetector computed tomography performed routinely in the qualification procedure for TAVI

B. Kedziński, P. Gac, M. Glosna, R. Poreba, K. Pawlas; *Wroclaw/PL (bkedziński@wp.pl)*

Purpose: The purpose of the study was to evaluate the relationships between the radiation dose and the repeatability of aortic valve dimensions measurements in multidetector computed tomography (MDCT) performer in the qualification for transcatheter aortic valve implantation (TAVI).

Methods and Materials: The study was conducted on a group of 60 patients who underwent the MDCT examination in the qualification for TAVI. The radiation dose was expressed using the computed tomography dose index volume (CTDIvol) and the dose length product (DLP). The coefficient of variation (CV) of each aortic valve dimensions measurement was defined as standard deviation of measurements/average value of measurements *100%, based on the measurements performed independently by two radiologists.

Results: The highest CV of measurement occurred for the distance between the outlet of the left coronary artery and the aortic ring (9.24±5.17%). The lowest CV of measurement was observed for the aortic bulb average dimension (2.39±1.72%). A significant negative correlation was observed between DLP and CV of the aortic ring minimum dimension measurement ($r = -0.25$, $p < 0.05$). Regression analysis showed that lower doses of DLP are an independent factor associated with a higher CV of measurement of the minimum dimension of the aortic ring.

Conclusion: Due to the demonstrated some relationships between the radiation dose in the MDCT examination performed in the qualification for TAVI and the repeatability of aortic valve dimensions measurements, it is postulated that attempts to perform examination using lower radiation doses should be followed by a subsequent control of the repeatability of aortic valve dimensions measurements.

B-0201 11:35

Dysfunction and thrombosis of aortic valve prostheses in patients after TAVR in computed tomography

L. Lehmkuhl¹, J. Grimm², I. Diamantis³, M. Wutschke², K. Lenk², M. Franz², C. Schulze², U.K. Teichgräber²; ¹Bad Neustadt/DE, ²Jena/DE, ³Weimar/DE (lukas.lehmkuhl@campus-nes.de)

Purpose: Aim of the study was to determine the incidence of dysfunction and thrombosis of aortic valve prosthesis in patients after TAVR and to systematically evaluate the prosthesis position and deployment in CT.

Methods and Materials: A total of 60 consecutive patients after TAVR (33 Edwards Sapien 3, 22 CoreValve EvolutR and 5 ACURATEneo) were included. All patients received echocardiography and cardiac CT during the 30-day follow-up. The post-TAVR CT protocol included multiphase cardiac CT (256 Slice GE Revolution, ECG triggering). For image analysis, MPRs were prepared parallel to the aortic valve prosthesis and LVOT axis in cine mode. The following parameters were assessed: Degree of prosthesis deployment (min./max. Diameter, ≥ 0.9 = circular deployment), prosthesis position in relation to aortic annulus and coronary ostia, motility of the cusps and cusp thrombosis.

Results: One third of the prostheses (20/60) were not circularly deployed, the mean degree of development was 0.91 ± 0.06 (0.75-0.99). In 18/60 cases (30%) there was a partial overlap of the left and right coronary ostium, of which both ostia were affected in 8/18 cases. Limited motility of the cusps as well as partial thrombosis could be observed in 6/60 cases (10%), motility restrictions without thrombosis did not occur. The cups thromboses had not previously been detected in echocardiography.

Conclusion: In addition to echocardiography, post-TAVR-CT detects a high incidence of motility restriction and partial thrombosis of the prosthesis. Moreover, prosthesis deployment and position deviates in a relevant percentage from the theoretically optimal implantation result.

B-0202 11:43

Biological versus mechanical aortic valve prostheses: an in vitro 4D flow MRI comparison of haemodynamics

T.H. Oechtering, A. Panagiotopoulos, M. Sieren, M. Scharfschwerdt, B. Fujita, S. Ensminger, H.-H. Sievers, J. Barkhausen, A. Frydrychowicz; Lübeck/DE (thekla.oechtering@uksh.de)

Purpose: In vitro 4D flow MRI evaluation of haemodynamics distal to mechanical and biological aortic valves.

Methods and Materials: Five valve prostheses with 21mm outer diameter [BV= biological valves: Perimount Magna Ease (Carpentier-Edwards), Trifecta valve (Abbott), Tribio (prototype); MV= mechanical valves: trileaflet valve (prototype), On-X (CryoLife)] were scanned at 3T in a flexible silicone aortic phantom. A home-built piston pump pumped blood mimicking fluid at physiological pressure settings with 60bpm. Quantitative haemodynamic parameters were analysed using GTFLOW (v.3.1.13, GyroTools, CH), average results $\pm 2SD$ from twelve healthy volunteers (VOL, 55 \pm 6 years) served as normal reference values. Semi-quantitative grading of visualized secondary flow patterns was achieved on a 0-3 scale.

Results: Absolute stroke volumes in MV and BV were within normal limits (VOL=105 \pm 25ml, MV=99 \pm 11ml, BV=111 \pm 3ml) confirming near-physiologic settings in the phantom setup. In contrast to VOL and MV, there was a pronounced central ejection jet distal to BV that hit the outer curvature of the ascending aorta where peak velocities were higher in BV=170 \pm 22cm/s compared to VOL=91 \pm 13 cm/s and MV=90 \pm 24cm/s. MV had more pronounced sinus vortices while there were no sinus vortices distal to BV (median[25%/75%]: VOL=1[1,2], MV=3[3,3], BV=0[0,0]). While VOL and MV developed few or no secondary flow patterns, respectively, there were large secondary helices and vortices distal to all BV.

Conclusion: Biological valves showed disturbed flow with the ejection jet colliding with the outer curvature. Whether this increases the risk of aneurysm formation through wall shear stress changes remains speculative. In contrast, mechanical valves' haemodynamics resembled those of healthy volunteers.

Aortic valve bypass surgery in severe aortic valve stenosis: insights from cardiac and brain magnetic resonance imaging

C. Mantini¹, M. Caulo¹, D. Mastrodicasa², D. Marinelli¹, A. Tartaro¹, A.R. Cotroneo¹, G. Di Giammarco¹; ¹Chieti/IT, ²Stanford, CA/US (cesare.mantini@gmail.com)

Purpose: To investigate and describe the distribution of aortic and cerebral blood flow (CBF) in patients with severe valvular aortic stenosis (AS) before and after aortic valve bypass (AVB) surgery.

Methods and Materials: We enrolled 10 consecutive patients who underwent AVB surgery for severe AS. Cardiovascular magnetic resonance imaging (CMR) and brain magnetic resonance imaging were performed as baseline before surgery and twice after surgery. Quantitative flow measurements were obtained using 1.5-T magnetic resonance imaging (MRI) scanner phase-contrast images of the ascending aorta, descending thoracic aorta (3 cm proximally and distally from the conduit-to-aorta anastomosis), and ventricular outflow portion of the conduit. The evaluation of CBF was performed using 3.0-T MRI scanner arterial spin labelling (ASL) through sequences acquired at the gray matter, dorsal default-mode network, and sensorimotor levels.

Results: Conduit flow, expressed as the percentage of total antegrade flow through the conduit, was $63.5 \pm 8\%$ and $67.8 \pm 7\%$ on early and mid-term postoperative CMR, respectively ($P < .05$). Retrograde perfusion from the level of the conduit insertion in the descending thoracic aorta toward the aortic arch accounted for 6.9% of total cardiac output and 11% of total conduit flow. No differences were observed between preoperative and postoperative CBF at the gray matter, dorsal default-mode network, and sensorimotor levels ($P = .394$).

Conclusion: After AVB surgery in patients with severe AS, cardiac output is split between the native left ventricular outflow tract and the apico-aortic bypass, with two-thirds of the total antegrade flow passing through the latter and one-third passing through the former. In our experience, CBF assessment confirms that the flow redistribution does not jeopardize cerebral blood supply.

Correlation between T2WI texture features of primary tumour and nodal metastasis in rectal cancer

I. Yang, B. Wu; Chengdu/CN (lqyang95@163.com)

Purpose: To explore the potential relationship between nodal metastasis state and the texture parameters of T2WI in primary rectal cancer.

Methods and Materials: 69 rectal cancers which directly received radical surgeries between July 2017 and June 2018 were enrolled retrospectively. Axial T2WI were loaded into the texture analysis software, and whole-tumour ROIs were manually drawn by two radiologists independently, then texture parameters were automatically generated. Pathological results of nodal stage were the reference standard. Interobserver agreement was evaluated. The difference of texture parameters between nodal positive (N+) and negative (N-) groups were compared, diagnostic performance and the correlation with nodal state were analysed.

Results: The interobserver agreement was moderate to excellent for texture parameters (ICC = 0.555-0.998). The kurtosis ($P = 0.002$), skewness ($P < 0.001$) and energy ($P = 0.009$) of primary tumour were significantly higher in N- group ($n = 47$), and the entropy ($P = 0.041$) was higher in the N+ group ($n = 22$). The respective AUCs of kurtosis, skewness, energy and entropy in diagnosing nodal metastasis was 0.732, 0.78, 0.652 and 0.636. Both kurtosis and skewness showed better diagnostic performance than energy and entropy (all $P < 0.05$). With a cut-off value of 1.97 and 1.148 of kurtosis and skewness, they revealed sensitivities of 68.2% and 95.5%, specificities of 76.6% and 51.1%, respectively. Both kurtosis and skewness had significant negative correlations with nodal state ($r_s = -0.375$ and -0.453 , respectively).

Conclusion: Kurtosis and skewness of primary tumour on T2WI correlated with nodal state in rectal cancer. Texture analysis of T2WI may give additional information on assessing the nodal metastasis in rectal cancer.

Quantitative elastography of rectal lesions: the value of shear-wave elastography (SWE) in identifying benign and malignant rectal lesions
T. Li; Chengdu/CN (635598031@qq.com)

Purpose: We evaluated the diagnostic value of shear-wave elastography (SWE) in identifying benign and malignant rectal lesions.

Methods and Materials: Reviewed of 96 lesions, endorectal ultrasound (ERUS) and SWE examination were performed prior to operation. Elasticity parameters including mean elastographic index (Emean), maximum elastographic index (Emax), minimum elastographic index (Emin) were analysed. Correlation between elastographic parameters and histopathological results were studied. Interobserver and intraobserver agreements were analysed.

Results: Of the 96 rectal lesions, 72 were malignant and 24 were benign lesions. Compared with ERUS, ERUS with SWE achieved higher sensitivity (93.0% vs. 88.9%), specificity (83.3% vs. 79.2%), PPV (94.4% vs. 92.7%), NPV (80.0% vs. 70.4%), and overall accuracy (90.6% vs. 86.4%). In ROC curve analysis, Emean and Emax achieved larger the area under the curve (AUC), 0.92 for Emean and 0.91 for Emax, respectively. The optimal cut-off value was 61.3KPa for Emean (sensitivity, 88.9%; specificity, 87.5%), 63.4KPa for Emax (sensitivity, 94.4%; specificity, 83.3%). We found a kappa value of 0.83 (95% CI:0.72-0.95) for ERUS and 0.90 (0.81-0.99) for ERUS with SWE of differential diagnosis in two observers. The intraclass correlation coefficient for the intraobserver variability of Emean in malignant lesion, benign lesion, surrounding normal rectal wall in malignant and normal rectal wall in benign were 0.91 (0.86-0.94), 0.94 (0.88-0.97), 0.92 (0.88-0.95) and 0.89 (0.77-0.95), respectively.

Conclusion: SWE is a promising tool that yields additional valuable quantitative data to ERUS examination in rectal lesions. The cut-off value 61.3KPa for Emean may serve as a complementary tool for diagnosis of rectal lesions.

MRI texture analysis in predicting lymph nodal yield after neoadjuvant chemoradiotherapy in locally advanced rectal cancer (LARC)

M. Panzeri, A. Di Chiara, A. Palmisano, A. Esposito, P. Passoni, A. Del Maschio, F. De Cobelli; Milan/IT (panzeri.marta@hsr.it)

Purpose: Overall survival in patients treated with neoadjuvant chemotherapy has been proved to be significantly influenced by nodal status, but all imaging techniques have low accuracy in prediction of the lymph node involvement. Aim of our study was to assess the value of MRI-derived lymph node texture features in the prediction of lymph nodal yield after chemotherapy.

Methods and Materials: 58 pts with locally advanced rectal cancer underwent 1.5T MRI before the beginning of CRT (preMRI) and at the end of CRT (postMRI). Multiplanar high-resolution axial-T2w sequences and DWI sequences were acquired. A mean number of 8 pathologic lymph nodes (range 3-19) per patients was found at MRI and a total of 174 lymph nodes were segmented on T2w (VT2) and b:1000 (Vb1000) images. A volumetric histogram analysis of T2 and ADC was performed. Pathological lymph nodal status after chemotherapy was evaluated on surgical sample.

Results: At histopathology, 43 patients were pN0 after neoadjuvant chemotherapy, 7 pts were pN1 and 8 pts were pN2. At univariate analysis a significant difference was found between the standard deviation (SD) of T2 values at pretreatment MRI of pN0 patients vs N+ (p<0.01). At multivariate analysis, SD of T2 at preMRI was associated with pN0 (p<0.034).

Conclusion: The evaluation of lymph node heterogeneity at pre-treatment assessed through texture analysis-derived T2-SD may increase MR accuracy in the prediction of nodal involvement at final histology.

B-0208 10:54

Multislice spiral CT images combined with CEA, lymphocyte and neutrophil ratio predict recurrence and metastasis postoperative of rectal cancer

D.H. Yuan; Kunming/CN (921574199@qq.com)

Purpose: To exploring the earlier predictors of postoperative recurrence and metastasis of rectal cancer and make a model.

Methods and Materials: Retrospective collection patients with rectal cancer underwent surgical resection and pathological diagnosis of 400's from September 2013 to September 2014. The patients have had imaging examination(CT), serum tumour markers, blood routine follow-up for 3 years at least. Statistics in patients with preoperative CT examination in the lesion size, postoperative 3, 6, 12 month serum carcinoembryonic antigen (CEA), CA242, CA199, peripheral blood lymphocyte and granulocyte ratio of conventional. Using Cox proportional hazards model , X-tile software combining Kaplan - Meier curves are stratified analysis to set up normogram model and use ROC curve detected this model.

Results: Preoperative CT imaging lesion size (P = 0.000, HR = 0.000, 95% CI: 1.015 1.033), postoperative 1 year lymphocyte by neutrophils ratio (P = 0.028, HR = 0.028, 95% CI: 0.917 3.832), postoperative 1 year CEA value (P = 0.000, HR = 0.000, 95% CI: 1.002 1.005) and as a significant biomarker to predicting recurrence and/or metastasis of postoperative rectal cancer, The stratified threshold of the lesion size Cut-Point in CT images of patients with rectal cancer was 18.75 cm³, and the CEA Cut-Point after surgery was 16.97 ng/ml. Normogram model predict recurrence and metastasis postoperative of rectal cancer AUC is 0.939.

Conclusion: Preoperative CT images in the lesion size and the preoperative 1 years CEA values can predict postoperative recurrence and metastasis of rectal cancer.

The value of MRI in the evaluation of peri-anal fistula

A.M.J. Al-Mosawe, M.A.K. Al-Jiboori; Baghdad/IQ (Drammaralmosawe@gmail.com)

Purpose: To study MRI role in evaluating perianal fistula and the value of using intravenous gadolinium in the determination of precise tract pathway, extensions and other associated pathologies.

Methods and Materials: Cross-sectional analytic study was conducted on 32 patients in the MRI department of AL-Imamain AL-Kadhmain medical city, Baghdad, from November 2015 to December 2016. Axial and coronal T2 WI with and without fat suppression and T1 FS before and after contrast administration were performed. The type of fistula, location of internal opening, associated abscesses or sinus tracts were all evaluated. Significance and diagnostic accuracy of each sequence were documented in relation to surgical results.

Results: The most common type of fistula encountered was the intersphincteric type, seen in 21 patients (66%); of those, 16 fistulas (50%) were grade I and 5 fistulas (16%) were grade II. Transsphincteric fistulas were seen in 9 patients (28%), 2 of them (6%) were grade III and 7 fistulas (22%) were grade IV. Two patients (6%) had extra-sphincteric type. T2 TSE, T2 TSE FS and T1-weighted FS post-contrast sequences all show significant correlation with surgical results (p value less than 0.05) while the highest significance was obtained by the post-contrast sequence (p value of 0.00001). The highest accuracy was with the use of T1-enhanced FS sequence (98.8%) followed by 87% for the T2FS and only 57% for the T2 TSE.

Conclusion: Axial and coronal enhanced fat-suppressed T1 provides the highest accuracy and significance with surgical data, therefore, decreasing the incidence of postoperative complications.

B-0210 11:10

Structured vs narrative reporting of pelvic MRI in perianal fistulising disease: impact on clarity, completeness, and surgical planning

O. Tuncyurek, A. Garces-Descovich, E.E. Duran, T.E. Cataldo, V.Y. Poylin, K.J. Morteale; Boston, MA/US (ozum.tuncyurek@gmail.com)

Purpose: To evaluate clarity and usefulness of MRI reporting of perianal fistulising disease using a structured disease-specific template versus narrative reporting for planning of disease treatment by colorectal surgeons.

Methods and Materials: In this HIPAA-compliant, IRB-approved study with waiver of informed consent, a structured reporting (SR) template for perianal fistulising disease MRIs was developed in collaboration between colorectal surgeons and abdominal radiologists. The study included 45 consecutive patients who underwent pelvic MRI for perianal fistulising disease prior to implementation of SR, and 60 consecutive patients who underwent pelvic MRI for perianal fistulising disease after implementation of SR. Objective evaluation of the reports for the presence of 12 key features was performed, as also subjective evaluation regarding the clarity and completeness of reports, and impact on treatment.

Results: More key features were absent in narrative reports [mean: 6.3±1.8 (range 3-11)] than in structured reports [mean: 0.3±0.9 (range 1-5)], (p=<0.001). The use of SR also increased the percentage of completeness (72.5% to 88.3% for surgeon 1, and 61.2% to 81.3% for surgeon 2; p=0.05 and 0.03, respectively), helpfulness in surgical planning (7.1±1.5 to 7.6±1.5 for surgeon 1, and 5.8±1.4 to 7.1±1.1 for surgeon 2; p=0.05 and p<0.001, respectively), and clarity (7.6±1.3 to 8.3±1.1 for surgeon 1, and 5.2±1.4 to 7.1±1.3 for surgeon 2; p=0.006 and p<0.001, respectively) of the reports.

Conclusion: Structured MRI reports in patients with perianal fistulising disease miss fewer key features than narrative reports. Moreover, SRs were described as more complete and clear, and more helpful for treatment planning.

MR fistulography with percutaneous instillation of ultrasound gel and its role in the preoperative mapping: our experience

G. Fontanella, M. Mancinelli, S. De Lucia, A. Festa, R. Villanacci, C. Manganiello; Benevento/IT (giovanni.fontanella@hotmail.com)

Purpose: The aim of this study is to show the role of MR fistulography (MRF), performed after percutaneous instillation of ultrasound gel, in the preoperative mapping of perianal fistula, underlying its various advantages.

Methods and Materials: 68 patients were selected from September 2017 until September 2018 for pre-operative fistular mapping among those with viable percutaneous orifices. After a basal scan (22 min), we instilled 3-10 cc of ultrasound gel per orifice, then re-scanned using a T2w, fsT2w and DWI protocol. Each case was reviewed through standard reporting by experienced radiologists, comparing either standard MR or MRF reports with the surgical findings. Surgeons in our institution are currently operating on the basis of MRF reports.

Results: MRF has shown to be a well-tolerated, faster technique (mean scan time 16 mins), superior to standard MR, allowing the detection of 94 tracts (versus 82 of basal MR). MRF is highly congruous with surgical findings, with specificity and sensitivity in the definition of fistular grade close to 100%, thus resulting in a significant drop of fistular relapses in one year: 2.89% vs 22.43% (from Sept 2016 to Sept 2017). Specificity, sensitivity and accuracy of detection of internal openings range between 90 and 97.5%, data comparable to basal MR.

Conclusion: MRF with percutaneous instillation of ultrasound gel is a more accurate, well-tolerated, faster technique for pre-operative mapping, allowing better depiction of lesser tracts and, in our institution, significant drop in fistular relapses.

B-0212 11:26

Introducing 3D modelling of MRI in preoperative mapping of perianal fistula: how it could help the surgeons?

M.S. Roman, M.Y. Awadallah, A.F. Ahmed, F.S. Fawzi, H.A.S. Shawali, R.F. Elsayed; Cairo/EG (drmarysalah@yahoo.com)

Purpose: To study the merits of 3D modelling MRI in enhancing preoperative interpretation of perianal fistulous tracts by the surgeons.

Methods and Materials: Fifty patients underwent 2D MRI fistulography and reported by an experienced radiologist of 20 years to assure accuracy. Based on 2D report, 3D model was achieved by manual segmentation and 3D reconstruction. A second radiologist and a surgeon both were blinded to 2D MRI findings, were asked to report on internal opening, side branches, abscess collections and supralelevator extensions. The data of the 2nd radiologist and the surgeon were compared individually to the 2D MRI findings by the expert radiologist to detect the degree of diagnostic agreement.

Results: Comparing 3D MRI findings by the surgeon to 2D findings, the highest and lowest sensitivities were the supralelevator extension (100%) and abscess collection (50%), respectively. The highest specificity were internal opening, supralelevator extension, abscess collection (100%), the lowest was side branches (88.57%). The highest diagnostic agreement was supralelevator extension (100%), the least was internal opening and side branches detection (80%). Comparing second radiologist report to the 2D findings, the highest sensitivity was supralelevator extension, abscess collections (100%), the lowest was internal opening (76.32%). The highest specificity was internal opening, supralelevator extension (100%). The lowest was side branches (91.43%). The highest and least diagnostic agreements were supralelevator extension (100%) and internal opening (80%), respectively.

Conclusion: 3D model MRI yielded the highest detection rate for the supralelevator extension, an important cause of postoperative recurrence, followed by abscess collection.

B-0213 11:34

Perianal fistula mapping at 3T: volumetric vs conventional MR sequences

M. Çerit, A.Y. Oner, A. Yildiz, E. Cindil, H.N. Sendur, S. Leventoglu; Ankara/TR (mahinurp@yahoo.com)

Purpose: To evaluate volumetric 3DSPACE T1, 3DVIBE T1 sequences with conventional 2D T1 and T2 FSE sequences in assessing perianal fistulas.

Methods and Materials: 23 patients with perianal fistula were included in this prospective study and underwent pelvic MR at 3T including contrast-enhanced fat suppressed 3DSPACE T1W, 3DVIBE T1W, axial and coronal 2DT1W together with 2DT2W sequences in the axial and coronal planes. Acquisition times were recorded. Results were compared with postsurgical findings defined as the gold standard. Performance of each sequence was evaluated in terms of image quality, presence of artefacts, lesion conspicuity, fistula type, presence of abscess, visibility of internal opening and number of internal opening.

Results: Both 3D VIBE-3D SPACE turned out to be the best sequence to determine the fistula type and the best performer in terms of image quality, artefacts, determining locations of internal orifices. Number of internal opening

were correctly detected in 23 (100%) patients for 3D SPACE and VIBE sequences, in 17(73,9%) patients on CE-T1WI and in 7(30,4%) patients on T2WI. When combined, T2 and T1W sequences correctly detected internal openings in 17(73,9%). The lesion conspicuity was higher for 3D SPACE and 3DVIBE sequences compared to other 2D sequences (P<0,05). Overall acquisition time for each 3D sequences were shorter compared to 2D sequences combined.

Conclusion: 3D SPACE and VIBE sequences offer better diagnostic accuracy, in a shorter scanning time in perianal fistula evaluation when compared to T1WI and T2WI sequences.

B-0214 11:42

Anal fistula: the role of MR imaging in preoperative evaluation

D.T. Vo, C.C. Phan, L.T.T. Nguyen, H.M.D. Le, T.T. Nguyen; Ho Chi Minh City/VN (duc.vt@ump.edu.vn)

Purpose: To describe the MR imaging features of anal fistula and evaluate the role of T2W TSE and post-contrast FS T1W TSE gadolinium sequences in detecting the characteristics of the fistula tract.

Methods and Materials: 367 patients with anal fistulas, diagnosed and treated at HCMC-UMC between 1/1/2016 and 1/31/2018, were included in this study. This study was a retrospective analysis. We compared the imaging features with the surgical findings.

Results: The mean age was 39.3 years (range, 12 - 84 years), male/female=9/1. A total of 411 fistulas were found at surgery. Agreement between the surgical findings and MR imaging for the classification of the primary track, detecting secondary track was very good with $\kappa = 0.89$ (0.84, 0.93), 0.94 (0.90, 0.97), respectively. The sensitivity and specificity of MR imaging in correctly detecting internal openings were found to be 99% and 85.2%, respectively; for abscess, it was 100% and 100%, respectively. Post-contrast FS T1W was very good in detecting abscess; differentiating between abscess and inflammation, active inflammatory components with scars.

Conclusion: MRI was highly accurate in the assessment of surgically important parameters of anal fistula. With the very good agreement between the surgical findings and MR imaging for characterisation of perianal fistulas, MR imaging was considered the reliable technique for establishing preoperative fistula map.

Branching pattern of the cerebral arterial tree

J. Helthuis¹, T. van Doormaal¹, B. Hillen², R. Bleys¹, A. Hartevelde¹, J. Hendrikse¹, A. van der Toorn¹, J.J. Zwanenburg¹, A. van der Zwan¹; ¹Utrecht/NL, ²Nijmegen/NL

Purpose: Quantitative data on branching patterns of the human cerebral arterial tree are lacking in the 1.0-0.1 mm radius range. We aimed to collect quantitative data in this range, and to study if the cerebral artery tree complies with the principle of minimal work (Law of Murray).

Methods and Materials: To enable easy quantification of branching patterns a semi-automatic method was employed to measure 1294 bifurcations and 2031 segments on 7T-MRI scans of two corrosion casts embedded in a gel. Additionally, to measure segments with a radius smaller than 0.1 mm, 9.4T-MRI was used on a small cast section to characterize 1147 bifurcations and 1150 segments. Besides MRI, traditional methods were employed. 733 bifurcations were manually measured on a corrosion cast and 1808 bifurcations and 1799 segment lengths were manually measured on a fresh dissected cerebral arterial tree.

Results: Data showed a large variation in branching pattern parameters (asymmetry-ratio, area-ratio, length-radius-ratio, tapering). Part of the variation may be explained by the variation in measurement techniques, number of measurements and location of measurement in the vascular tree.

Conclusion: This study confirms that the cerebral arterial tree complies with the principle of minimum work. These data are essential in the future development of more accurate mathematical blood flow models.

High-resolution MR image of intracranial blood vessels wall using 3D VISTA sequence

L. Zheng, Q. Wang, Z. Wang; *Shanghai/CN*

Purpose: To introduce the technique of using high-resolution three-dimensional volumetric isotropic Tse acquisition (HR-3D-VISTA) for magnetic resonance (MR) imaging of intracranial blood vessel wall.

Methods and Materials: Institutional review board approved this study. From November 1, 2015 to December 31, 2016, 143 cases underwent 3D VISTA MR image of intracranial blood vessels wall using PHILIPS INGENIA 3Tesla MR Scanner. The scan parameters are as follows: TE 21ms, TR 425 ms, matrix 332x332, and voxel 0.6x0.6 x 0.8, and number of slices 120. Then image qualities of non-contrast and contrast-enhanced 3D VISTA (CE-3D-VISTA) images were evaluated and lesion type were analysed. Additionally, 3D-VISTA images were compared with conventional time of flight MR angiography (TOF MRA) and digital subtraction angiography (DSA).

Results: The techniques of HR-3D-VISTA finished intracranial blood vessels wall imaging in six minutes for one case. The images of HR-3D-VISTA can well show normal and lesion features of vessels wall. The CE-3D-VISTA image has high image quality than those images of non-contrast 3D-VISTA. 3D VISTA image provide more information for either positive or negative cases with TOF MRA and DSA examination.

Conclusion: 3D VISTA MR image of vascular wall technique is a suitable method for intracranial blood vessels, and can play an important role in suspicious cases with vascular diseases by combination with TOF MRA and DSA in clinical practice.

B-0217 14:16

Development and validation of prediction model based on hemodynamic derived from computed tomography angiography for rupture risk of small unruptured intracranial aneurysms

Z. Shi, G. Chen, C. Zhou, G. Lu, L. Zhang; *Nanjing/CN (fmrishiz@126.com)*

Purpose: The risk factors of small intracranial aneurysms (sIAs) ($\leq 5\text{mm}$) rupture remain unclear and this study aimed at determining the risk factors and developing a prediction model of rupture risk of unruptured sIAs.

Methods and Materials: The patients with sIA diagnosed by both computed tomography angiography and invasive cerebral angiography were included from January 2010 to December 2016 and were randomly separated into training and validation cohort. A model was developed based on patient characteristics, anatomical characteristics and hemodynamics information by multivariable analysis. The area under ROC curve (AUC) was used to present the diagnosis performance and the model was further assessed in the validation cohort which was randomly selected from the entire dataset and the procedure repeated for 4 times. Random forests were implemented for features selection.

Results: The ratio of training cohort to validation cohort was 3 and age, sex, location, HBP, cvWSS, cvOSI, inflowconcentration, flowimpingement and flowstability (all $p < 0.05$) were independently associated with rupture status in multivariate logistic regression in the four groups. The mean AUC of the models was 0.918 and application of the model in the validation cohorts still performed excellently with the mean AUC of 0.898. Ten variables passed the feature selection and comprised cvOSI, flowimpingement, size and so on.

Conclusion: sIAs have distinct risk factors of rupture, and age, location, OSI, and inflowconcentration et al. were independently associated with sIAs rupture status. We demonstrated that our model can provide reliable quantitative individual risk assessments for sIAs and may help choose the optimum management.

B-0218 14:24

One-stop coronary CTA combined with carotid and cerebrovascular CTA using wide-detector CT: comparison with conventional protocol

P. Han, W. Li, Z.-G. Yang, K. Diao, R. Shi, Z. Li; *Chengdu/CN (peilhan@foxmail.com)*

Purpose: To determine the value of "one-stop" coronary CT angiography (CCTA) combined with carotid and cerebrovascular CT angiography (CCCTA) in single contrast injection using 16 cm wide-detector CT.

Methods and Materials: Fifty-six patients with suspected coronary, carotid and cerebrovascular disease were prospectively and randomly divided into Group A (n=36, combined CTAs) and Group B (n=20, conventional protocol: CCTA, followed by CCCTA after contrast re-injection). CTA examinations were performed with contrast dose at 0.7 ml/kg. We compared the contrast dose, CT examination time and contrast-to-noise ratio (CNR), as well as the CT values

and standard deviations (SD) of atherosclerotic plaques and arteries between groups A and B.

Results: The contrast dose was significantly smaller in group A than in group B ($44.6 \pm 5.9\text{ml}$ vs. $91.9 \pm 11.8\text{ml}$, $p < 0.001$), while examination time was significantly reduced in group A than in group B (6 min vs. 13 min). Both groups achieved satisfied image quality at all examined vessels (no significant difference in CT values at all regions between the two groups) and were available for diagnosis, despite the CNR of coronary arteries were higher in group B (28.34 ± 6.21 vs. 35.95 ± 8.53 , $p < 0.001$). Nevertheless, group B also demonstrated a prominently higher mean SD than group A.

Conclusion: Combined cerebral, carotid and coronary CTA could save scan time and reduce contrast dose, without impairing image quality. It provides a promising simplified work-flow in clinical practice.

B-0219 14:32

Curved surface reformations - diagnostic accuracy and time-efficiency of a new peripheral CTA reformation technique

D. Toth, J. Kittinger, K. Lampichler, C. Loewe, R. Scherthaner; *Vienna/AT (daniel.toth@meduniwien.ac.at)*

Purpose: Peripheral CTA has evolved into an accurate modality for the assessment of peripheral arterial occlusive disease (PAOD). However, due to the limitations of available angiogram-like reformations such as Maximum Intensity Projections, the evaluation of axial and coronal multiplanar reformations (MPRs) is still required to reach sufficient accuracy. Recently, a centerline-based reformation technique called curved surface reformation (CSR) was developed. The purpose of this pilot trial was to assess the diagnostic accuracy and time efficiency of CSRs compared to standard MPR for peripheral CTA, with intra-procedural DSA as the standard of reference.

Methods and Materials: 21 consecutive patients (7 females, mean age 67 years), who underwent peripheral CTA prior to endovascular treatment of PAOD, were retrospectively included. 21 arterial segments were defined in each leg; for each segment, the presence of haemodynamically relevant stenosis ($\geq 70\%$) was assessed on CSRs and MPRs independently, with DSA as gold standard. Time for image analysis was recorded.

Results: 395 out of 882 arterial segments were depicted with DSA and available for analysis. Using MPRs, CTA yielded a sensitivity of 88%, a specificity of 94% and an accuracy of 93%. Using CSRs, sensitivity, specificity and accuracy increased to 95%, respectively ($p < 0.01$, $p = 0.84$ and $p = 0.09$, respectively). The mean reading time decreased significantly from $8'44''$ to $3'15''$ ($p < 0.01$).

Conclusion: CSR is a new centerline-based CTA reformation technique that seems to allow accurate and fast assessment of PAOD without the necessity to review MPRs. Further studies with larger cohorts and several readers are required to confirm this finding.

B-0220 14:40

TSH suppressive therapy aggravates arterial inflammation: an ^{18}F -FDG PET study in thyroid carcinoma patients

E. Boswijk, K.J.C. Sanders, E. Broeders, M. de Ligt, W.D. Vanmarckenlichterbelt, F. Mottaghy, P. Schrauwen, J.E. Wildberger, J. Bucerius; *Maastricht/NL (eboswijk@gmail.com)*

Purpose: We aimed to investigate the influence of hypothyroidism and TSH-suppressive therapy on arterial inflammation *in vivo*, using ^{18}F -fluorodeoxyglucose (FDG) positron emission tomography (PET)/CT.

Methods and Materials: Ten well-differentiated thyroid carcinoma patients underwent an ^{18}F -FDG PET/CT during post-thyroidectomy hypothyroidism and during TSH-suppressive therapy after ^{131}I (radioiodine) ablation therapy. We analysed ^{18}F -FDG uptake in the carotids, aortic arch, ascending, descending, and abdominal aorta. Target-to-background ratios (TBRs) corrected for blood pool activity were established for all arterial territories. Additionally, we measured ^{18}F -FDG uptake in the spleen, bone marrow and multiple adipose tissues. The Wilcoxon sign rank test was used to compare TBRs between hypothyroidism and TSH-suppression. TBRs from both periods were further compared to that of historic control subjects without known thyroid disease with a Mann-Whitney U test.

Results: There was a trend towards higher arterial TBRs during TSH-suppressive therapy than during hypothyroidism ($\text{TBR}_{\text{max,all vessels}} = 1.8$ and 1.6 , respectively, $p = 0.058$). In concurrence with this, we found increased CRP levels after levothyroxine treatment (CRP = 4.8 and 2.9 mg/L during TSH-suppressive therapy and hypothyroidism, respectively; $p = 0.005$) and increased activity in the bone marrow ($\text{TBR}_{\text{max,2.0}}$ and 1.7 during TSH-suppressive therapy and hypothyroidism, respectively; $p = 0.014$). An exploratory comparison with controls without known thyroid disease also showed a trend towards higher arterial TBRs during TSH-suppressive therapy ($\text{TBR}_{\text{max,all vessels}} = 1.8$ and 1.6 for TSH suppressive therapy and euthyroidism, respectively; $p = 0.055$).

Conclusion: Arterial inflammation is increased in patients during TSH-suppressive therapy. This could indicate that TSH-suppression renders patients at an increased risk of atherosclerotic disease.

B-0221 14:48

Comprehensive validation of two accelerated 4D-flow MR sequences at 3T: a phantom study

S. Ebel¹, L. Hübner¹, B. Köhler², S. Kropf², B. Preim², B. Jung³, M. Grothoff¹, M. Gutberlet¹; ¹Leipzig/DE, ²Magdeburg/DE, ³Bern/CH (sebastian.ebel@icloud.com)

Purpose: To assess for the first time 4D-flow measurement accuracy (flow volume and peak velocity) of different accelerated MR sequences using a constant and pulsatile flow phantom at 3T in comparison to a standard 2D-flow MR sequence.

Methods and Materials: The two accelerated 4D-flow MR sequences (GRAPPA2- and k-t-GRAPPA5) were evaluated regarding accuracy of calculated flow volumes, flow velocities, reproducibility, dependency on proper planning of the measuring plane and the encoded velocity (V_{enc}). The calculated flow volumes and peak velocities of the phantom were used as the standard of reference. The MR-flow analysis was performed using the custom-made software "Bloodline".

Results: No significant differences were found between the 2D- and both accelerated 4D-flow MR sequences and the pump reference regarding flow volumes and flow velocities in continuous and pulsatile flow. An excellent correlation ($r=0.99-1.0$) to the standard of reference and excellent reproducibility of measurements ($r=0.99$) could be achieved in all used sequences. An up to two-and-a-half-times overestimated V_{enc} had no impact on the accuracy of flow measurements. However, misaligned measuring planes led to dramatically reduced 2D-flow accuracy while both 4D-flow measurements were not affected by any misalignment.

Conclusion: Both accelerated 4D-flow MR sequences demonstrated equal accuracy compared to 2D-flow measurements and better accuracy in any case of plane misalignment. The highly accelerated, faster k-t-GRAPPA5-sequence revealed comparable results to the GRAPPA2 and should, therefore, be used preferentially whenever possible.

Validation of CT imaging characteristics to differentiate intimal from medial calcifications in peripheral vessels and its application in a non-vascular cohort

L.C.D. Konijn¹, P.A. de Jong², H. van Overhagen¹, W.P. Mali²; ¹The Hague/NL, ²Utrecht/NL (l.konijn@hagaziekenhuis.nl)

Purpose: Recently, histologic studies showed that calcifications in the wall of peripheral vessels are not only caused by atherosclerosis in the intimal wall, but also by medial wall calcifications. This might play a role in the development of critical limb ischemia. The aim of this study was to validate a CT imaging score to differentiate intimal from medial wall calcifications in the peripheral vascular beds of this non-vascular cohort.

Methods and Materials: A recently developed histologically validated CT scoring system was used to assess calcifications in eight different vascular beds.

Results: 204 patients were included (age 61 (range 22-90; male 52%). A high overall prevalence was seen (abdominal aorta 69.1%, iliac 65.2%, femoro-popliteal 52.5%, crural 42.2%). However, calcifications in the upper extremity were scarce (brachial arteries 2.9%, radio-ulnar 1.5%).

Overall, we could see that clusters of CT characteristics that have been validated for intimal (dotted, thick and patchy) or medial calcifications (circular, thin and continuous) indeed correlate strongly between each other. The highest correlation coefficients were found in the crural arteries (medial 0.79, 0.85, 0.76; intimal 0.39, 0.88, 0.76) and slightly less strong correlations for the femoro-popliteal arteries (medial 0.51, 0.78, 0.66; intimal 0.49, 0.58, 0.62).

Conclusion: This study strongly suggests that there is indeed a medial and intimal pattern that can be differentiated on CT scan, especially in the leg, with both a different pattern of development. Further studies are needed to explore the on-going process of calcification and how this plays a role in (peripheral) arterial disease.

B-0223 15:04

Virtual monochromatic images in low-tube current dual-energy spectral imaging combined with adaptive statistical iterative reconstruction V in head CT angiography

T. Song, Z. Li; Chengdu/CN (407145908@qq.com)

Purpose: To analyse the value of combining the VMS image and ASiR-V in low-tube current dual-energy spectral imaging in head CTA.

Methods and Materials: An anthropomorphic angiographic head phantom and 40 patients were examined on a revolution CT with spectral imaging mode at two different tube currents. Images of different energy levels in the low-tube current group were reconstructed with the combination of filtered back projection (FBP), 20%, 40%, 60% and 80% ASiR-V; VMS images at 70keV in the routine tube current group were reconstructed with FBP only.

Results: VMS images at 40-55keV yielded a higher CNR compared with 70keV and the subjective scores at 55keV and 60keV were higher than others ($P<0.05$). The SNR and CNR in the low-tube current group with ASiR-V60% and ASiR-V80% were higher than that of the FBP, ASiR-V20% and ASiR-V40% images in the same group ($P<0.05$). The SNR and CNR of the simulated cerebral vessels and subjective scores in the patients' groups of 55keV VMS images in the low-tube current group with ASiR-V60% and ASiR-V80% were higher than that of the 70keV FBP images in the routine tube current group ($P<0.05$). The radiation dose in the low-tube current group was 39% lower than in the routine tube current group.

Conclusion: VMS images in low-tube current spectral imaging combined with ASiR-V can significantly reduce radiation dose and ensure image quality in head CTA. The 55 keV VMS images with ASiR-V60% and 80% provide higher image quality.

B-0224 15:12

Comparing the diagnostic accuracy of ¹⁸F-FDG-PET/CT, contrast-enhanced CT and combined imaging in patients with suspected vascular graft infections

L. Husmann, M.W. Huellner, B. Ledergerber, A. Anagnostopoulos, P. Stolzmann, B.-R. Sah, I.A. Burger, Z. Rancic, B. Hasse; Zurich/CH (lars.husmann@usz.ch)

Purpose: To evaluate the diagnostic accuracy of positron emission tomography/computed tomography with ¹⁸F-fluorodeoxyglucose (PET/CT), contrast-enhanced CT (CE-CT), and a combined imaging approach (CE-PET/CT) in patients with suspected vascular graft infection (VGI).

Methods and Materials: PET/CT and CE-CT were performed prospectively in 23 patients with suspected VGI. Diagnostic accuracy for PET/CT was assessed using previously suggested cut-off points for maximum standardized uptake values (SUV_{max}). Using a new 4-point scale for visual grading, two readers independently assessed the diagnostic accuracy of CE-CT and combined CE-PET/CT. Microbiological culture, obtained after open biopsy or graft explantation, and clinical follow-up of the patients served as the standard of reference.

Results: Sensitivity, specificity, negative predictive value (NPV), positive predictive value (PPV), and accuracy of PET/CT for the diagnosis of VGI were 100%, 50%, 100%, 72.2%, and 78.3%, respectively. Respective values for CE-CT were 100%, 50%, 100%, 72.2%, and 78.3% for reader 1, and 92.3%, 80%, 88.9%, 85.7%, and 86.9% for reader 2; while respective values for combined CE-PET/CT were 100%, 70%, 100%, 81.3%, and 86.9% for reader 1, and 100%, 80%, 100%, 86.7%, and 91.3% for reader 2.

Conclusion: The diagnostic accuracy of combined CE-PET/CT in patients with suspected VGI is very high. The combination of the high sensitivity of PET/CT in detecting metabolically active foci in infection and the high specificity of CE-CT in detecting anatomic alterations appears to be the reason why combined imaging outperforms stand-alone imaging in diagnosing VGI and may be supportive in future decision-making of difficult cases of suspected VGI.

B-0225 15:20

Inter-scanner and inter-software comparison of quantitative 4D flow MRI

T.H. Oechtering¹, A. Nowak¹, M. Sieren¹, J. Graessner², H. Kooijman-Kurfer², J. Barkhausen¹, A. Frydrychowicz¹; ¹Lübeck/DE, ²Hamburg/DE (thekla.oechtering@uksh.de)

Purpose: To compare quantitative 4D flow MRI of healthy volunteers acquired on scanners of different vendors and evaluated with two commercially available software solutions to underline the technique's applicability.

Methods and Materials: Thoracic aortic 4D flow MRI was conducted in five healthy volunteers (27±3 years, 1 female) on 3T MRI scanners (MRI₁=Ingenia, Philips; MRI₂=Skyra, Siemens) using identical scan parameters per guideline recommendations. The ten datasets were evaluated with software SW₁=GtFlow (v3.1.13, Gyrotools, CH) and SW₂=cvi42 (v5.9.2, Circle Cardiovascular Imaging, CAN) for net stroke volume (SV_{net}), peak flow ($Flow_{max}$), maximum velocity (Vel_{max}), and maximum area ($Area_{max}$) on six predefined contours. For these parameters, mean absolute and relative errors with SD and Bland-Altman plots were calculated. Inter-scanner comparison was performed for SW₁ and SW₂ separately. Inter-software comparison was independent of scanner type.

Results: Inter-scanner comparison: acquisitions were performed in 14±2min (MRI₁) and 17±7min (MRI₂; $p=0.69$). Average differences were small for SV_{net} (SW₁: 0±10ml; SW₂: -1±10ml). MRI₂ underestimated $Flow_{max}$ by 4±12% (SW₁: 24±52ml/s; SW₂: 27±56ml/s), Vel_{max} by 18±20cm/s (SW₁) and 8±20cm/s (SW₂), and $Area_{max}$ by 53±142mm² (SW₁) and 41±320mm² (SW₂). Inter-software comparison: SW₂ was underestimating SV_{net} by 8±8ml, $Flow_{max}$ by 37±28ml/s (=9±6%), and Vel_{max} by 10±16cm/s (=7±11%) compared to SW₁. In contrast, SW₂ overestimated $Area_{max}$ by 100±227mm² compared to SW₁. Differences in $Area_{max}$ were smaller when excluding the blurry aortic bulb contour.

Conclusion: Quantitative 4D flow MRI results, especially SV, seem comparable between different 3T scanners. However, it is important to focus on one software because inter-software variability was higher than inter-scanner variability.

Modulation of PSMA expression by androgen deprivation therapy (ADT): serial PSMA PET in men with hormone sensitive and castrate resistant prostate cancer commencing androgen blockade

C. Yin¹, A. Joshua¹, M. Crumbaker¹, L. Emmett², ¹Darlinghurst/AU, ²Sydney/AU (charlotte.yin@gmail.com)

Purpose: Prostate specific membrane antigen (PSMA) can be effectively targeted for both PET and therapy purposes in the management of prostate cancer (PCa). We aim to evaluate the effect on PSMA PET of androgen blockade (AB) in men with measurable metastatic disease commencing ADT (hormone sensitive cohort) or a novel antiandrogen (enzalutamide or abiraterone) in the castrate resistant state.

Methods and Materials: 15 men underwent serial PSMA PET scans at baseline, Day 9, 18 and 28. COHORT 1: 8 men commencing ADT with LHRH agonists. COHORT 2: 7 men commencing novel antiandrogen. Visual and quantitative image analyses was performed using MIM® software.

Results: **Cohort 1:** A mean 25% reduction in SUVmax by Day 9 with an associated marked PSA response in 100% of men. Subsequent rise in PSMA intensity at some sites of metastatic disease at days 18 and 28 in subset of men. **Cohort 2:** All men demonstrated an increase in intensity of uptake by Day 9 unrelated to change in PSA. Relatively homogeneous responses at Day 9 in all men but subsequent heterogeneity in treatment response on Day 18 and 28 scans. This was most marked in Cohort 1, where there was an increase in SUVmax in individual lesions despite an overall reduction in tumour volume. This suggests PSMA-PET may be able to identify phenotypes of early castrate resistance prior to PSA, predictive biomarker potential.

Conclusion: PSMA is a manipulable receptor with rapid dichotomous in vivo response to AB dependent on PCa phenotype.

B-0227 14:08

68 GA PSMA vs whole body diffusion weighted MR imaging in staging of high risk prostate cancer

M. Logudoss, A. Chellathurai; Chennai/IN (drlmkmdrd@gmail.com)

Purpose: The purpose of the study is to compare the sensitivity and specificity of 68 GA PSMA and whole body diffusion weighted MR imaging in staging of high risk prostate cancer.

Methods and Materials: 68 patients with high-risk prostate cancer were included in the study. Inclusion criteria included biopsy proven prostate cancer with PSA more than 20 ng/ml and Gleason score more than 7. All patients underwent 68 GA PSMA and whole body diffusion weighted imaging within 1 week duration. Two radiologists read the modalities independently and the results were compared for staging of nodal and distant metastases.

Results: The mean age of the patients was 63 years and the mean PSA value was 15 ng/ml. The median Gleason score was 8. Regional nodal metastases were detected by 68 GA PSMA in 48 patients and by DWI in 45 patients. Non-regional nodal metastases were detected in 18 patients by 68GA PSMA and in 17 patients in DWI. Skeletal metastases were detected in 24 patients by both modalities. Both detected hepatic metastasis in one patient. Additionally 68GA PSMA detected pulmonary metastasis in one patient, which was missed by DWI. Statistically it was found that the efficacy of whole body diffusion weighted imaging was almost equal to that of 68GA PSMA (p<0.05).

Conclusion: Whole body diffusion weighted imaging has sensitivity and specificity almost equal to 68GA PSMA in the detection of nodal and distant metastases and can be used with Multiparametric imaging of the prostate for complete TNM staging of prostate cancers.

B-0228 14:16

Performance of ⁶⁸Ga-PSMA-11-PET/MRI guided biopsy to detect significant prostate cancer

I.A. Burger, D.A. Ferraro, J. Müller, U. Mühlematter, M. Messerli, P. Stolzmann, N.J. Rupp, O.F. Donati, D. Eberli; Zurich/CH (irene.burger@usz.ch)

Purpose: MRI guided biopsy significantly improved the detection rate of prostate cancer (PCa) in patients with elevated PSA compared to transrectal biopsy. However, still around 22% of patients with significant PCa will not be detected with multiparametric MRI. We investigated if ⁶⁸Ga-PSMA-11-PET/MRI could be used for targeted biopsy.

Methods and Materials: We performed an interim analysis of the first 25 patients from a prospective trial. Patients with an elevated PSA were referred to ⁶⁸Ga-PSMA-11-PET/MRI before template and image targeted biopsy using the BiopSee® system. All cancer lesions with a Gleason Score (GS) of 3+3 or more were assessed. ⁶⁸Ga-PSMA-11 accumulation was quantified in the cancer area using SUV_{max}. Significant PCa was considered any GS 4+3 or more, or 3+4 with more than 6 mm core length. Correlation between GS and ⁶⁸Ga-PSMA-11 uptake was evaluated using Pearson-Correlation.

Results: 17 of 25 (68%) patients had significant PCa on template biopsy. ⁶⁸Ga-PSMA-11-PET scans were positive in 16 of them with a median SUV_{max} of 7.8 (range 5.2-19.3). The single PET negative lesion had a GS 3+4, with a core length of 6 mm. Two areas were considered suspicious for cancer on PET with mild ⁶⁸Ga-PSMA-11 uptake (SUV_{max} 5.5 and 5.1). The patient based positive predictive value was 89%, with a sensitivity of 94%. There was a significant correlation between GS and SUV_{max} (C=0.64, p=0.001).

Conclusion: ⁶⁸Ga-PSMA-11-PET/MRI has the potential to detect significant PCa and can be used for image fusion based biopsy guidance, with the potential to decrease the number of biopsies and associated complications.

B-0229 14:24

PSMA expression heterogeneity of the primary tumour on IHC correlates with the detection rate of ⁶⁸Ga-PSMA-11-PET in patients with biochemical recurrence

D.A. Ferraro, J.H. Rüschoff, J. Müller, U. Mühlematter, M. Messerli, M. Hüllner, D. Eberli, N.J. Rupp, I.A. Burger; Zurich/CH (daniela.ferraro@usz.ch)

Purpose: Around 10% of prostate cancers (PCA) have no increased PSMA expression, therefore a small fraction of patients have negative PSMA-PET scans, despite high PSA values. Currently it is not possible to discriminate those patients before the PET scan. We aimed to investigate if the PSMA expression of the primary tumour predicts PSMA-PET detection.

Methods and Materials: 36 patients underwent radical prostatectomy between 2007-2016 and were referred to ⁶⁸Ga-PSMA-11-PET for biochemical recurrence, with up to two scans if the first was negative. Lesions suspicious for PCA recurrence were quantified using SUV_{max}. The dominant tumour on prostatectomy samples was stained for PSMA. PSMA expression on immunohistochemistry was quantified using a three-tiered system (1+weak, 2+moderate, 3+strong) and the percentage of PSMA negative tumour area. Differences between positive and negative exams were assessed with a t-test.

Results: 43 ⁶⁸Ga-PSMA-11-PET scans were available, median PSA value of 1.69 ng/ml (range 0.05-405.7ng/ml). 30 (69%) PET exams were positive with a median PSMA uptake of SUV_{max} 9.55 (range 2.6-128). Comparing the positive and negative ⁶⁸Ga-PSMA-11-PET scans with immunohistochemistry results: the mean membranous PSMA expression was 2.5±0.5 for the positive and 2.2±0.7 for the negative scans (p=0.101), while the negative tumour area showed a significant difference with mean 9%±17% and 34%±38% (p<0.001) for positive and negative scans, respectively. All three cases with a PSA value above 2ng/ml and negative PET examinations had PSMA-negative tumour areas of 80%.

Conclusion: Tumour negative areas on PSMA immunohistochemistry of the primary tumour could predict negative ⁶⁸Ga-PSMA-11 PET scans.

Influence of segmentation techniques on volumetric and textural metabolic parameters of primary tumours on 18F-FDG PET-CT imaging

M. Novikov, T. Babkina; Kiev/UA (nicknovi@gmail.com)

Purpose: To evaluate the dependence of metabolic volumetric parameters and metabolic textural indices of primary malignant tumour on image segmentation techniques in 18F-FDG PET/CT imaging in order to select more stable or robust parameters.

Methods and Materials: Metabolic PET/CT images were retrospectively analyzed in 50 patients with head and neck and cervical carcinomas. Four different segmentation techniques (fixed SUV2.5 threshold, liver pool threshold, 41% SUVmax threshold and ITK-SNAP algorithm) were utilized to segment primary tumour metabolic volumes with consequent computation of volumetric (SUVmean, MTV and TLG) parameters and textural indices (GLCM Homogeneity, GLCM Entropy, GLRLM SRE, GLRLM SRE, GLZLM HGZE, GLZLM LGZE, Skewness, Kurtosis, Entropy, Energy, Sphericity and Compacity) inside generated volumes.

Results: Among computed parameters only two textural indices (GLCM Homogeneity and GLRLM SRE) showed no statistically significant difference, depending on segmentation technique ($p < 0.05$), analyzing both head and neck and cervical carcinomas groups independently and whole study population, with all other indices, especially volumetric, showing significant dependence on segmentation technique used. Additionally, one of the stable textural indices (GLCLM Homogeneity) showed an ability to differentiate high grade (Grade 3) poorly-differentiated tumours from Grade 1+2 tumours with relatively high specificity (84.4%) but low sensitivity (44.4%) according to ROC analysis.

Conclusion: Metabolic image segmentation technique influence significantly volumetric metabolic indices, unlike selected textural indices, which also show an ability to represent tumour biologic characteristics, providing an opportunity to further investigate them as a potential prognostic biomarker, more stable or robust, compared to volumetric metabolic parameters.

B-0231 14:40

Inflammation focus search with 18F-FDG-PET/MRI: comparative or additive value of PET and MRI

A. Örnek¹, L. Umutlu¹, J. Kirchner², B. Reichardt¹, K. Herrmann¹, V. Rühlmann¹; ¹Essen/DE, ²Düsseldorf/DE (ahmet.ornek@uk-essen.de)

Purpose: To evaluate the comparative or additive value of 18F-FDG PET and MRI for identifying the aetiology of inflammation of unknown origin.

Methods and Materials: A total of 24 patients (13 m, 11 w, age 42±23 [8-82] y) with suspicion of an inflammation focus due to laboratory inflammation markers (increased CRP, leukocytes) or fever and up to now non-leading conventional imaging underwent a whole-body PET/MRI. Image analyses included the detection and localization of pathologically (focal) increased tracer uptake in PET including determination of SUVmax using VOI technique and evaluation of the contrast enhancement and diffusion restriction (ADC values) of abnormal lesions in MRI. Descriptive analysis included mean values, standard deviation and range. PET/CT, clinical, and radiological follow-up as well as histopathology served as standards of reference.

Results: In 21/22 patients in accordance to the reference standard the PET/MRI contributed to the diagnosis of a (focal) pathological aetiology of the inflammatory disease. In PET all pathological foci showed a moderately to significantly increased FDG uptake (SUVmax 5.5 ± 3.3, range 1.4-14.2). The MRI satisfactorily allows the localization of the findings, but only in 16/21 a corresponding contrast-enhancement and in 9/21 a corresponding diffusion restriction could be found. 2/21 patients showed neither a contrast-enhancement nor a diffusion restriction, but only an increased FDG uptake.

Conclusion: Integrated 18F-FDG-PET/MRI shows high potential in identifying the aetiology of inflammation of unknown origin. The MRI satisfactorily allows the localization of the findings, but a significant higher detection rate could be found in PET compared to MRI.

B-0232 14:48

Is PET MRI valuable in inflammation or fever of unknown aetiology?

T. Rohan, T. Andrasina, A. Litavcova, T. Juza, J. Zavadil, S. Richter, V. Valek; Brno/CZ (rohan.tomas@fnbrno.cz)

Purpose: To evaluate the benefit of PET/MR imaging in diagnostic process of patients with inflammatory disease of unknown aetiology.

Methods and Materials: 51 patients were selected for PET/MR imaging due to inflammation of unknown aetiology, these represent 2.5% of all PET/MR examinations (total of 2056 examinations, Signa, GE) acquired in tertiary referral hospital since 7/2016. All patients underwent intensive investigation lasting at least 20 days (screening x-rays, abdominal ultrasound, dedicated CT or MRI focused in clinical suspect). Clinical (fever, artralgia, weight loss, night sweating) and laboratory (CRP, leukocytes) were monitored and correlated with PET/MR findings. Based on suspected aetiology patients were divided into 3 groups - fever of unknown origin (26), unknown infection (13) and rheumatic disease (12). Patients were followed up until the aetiology was diagnosed or symptoms faded away.

Results: In 26 (51%) patients diagnosis was proved, in 22 (43%) patients symptoms disappeared, in 3 patients symptoms persisted without explanation. PET/MR strongly supported or changed the diagnosis in 42% of cases (70% in subgroup of rheumatoid infections). As most important marker of conclusive PET/MR was shown artralgia and elevated level of CRP at the time of examination, which were present in 54% of diagnosed cases. PET/MR proved diagnosis of rheumatoid disease in 18 patients (50% without any clinical suspicion), overall sensitivity was up to 89% and specificity 100%, negative

predictive value was 85%.

Conclusion: PET-MRI is a useful tool in the evaluation of inflammatory disease of unknown aetiology especially in patients with suspected rheumatoid disease.

B-0233 14:56

Role of 18 F FDG PET-CT in documenting the disease burden in brain, spinal and lymph node tuberculosis

K.B.K. Rangan, S. Gambhir; Lucknow/IN (kasturi.rangan123@gmail.com)

Purpose: Demonstrating the potential use of F18 FDG-PET/CT in documenting disease burden in Brain, Spinal, Lymphnodal Tuberculosis. Also, to monitoring follow up and to establish a therapeutic end point.

Methods and Materials: Total of 67 patients (~46years), of which 29 Spinal tuberculosis and 23 Brain tuberculosis and rest were lymph nodal TB. Standard [18F]FDG- PET/CT imaging was done at baseline and its results with compared with site specific MRI. On follow up only [18F]FDG-PET/CT was done at 2, 6 months. Based on the metabolic response in the follow up scans, subjects were categorized as progressive disease(PD), stable disease(SD), partial(PR) or complete metabolic response(CMR).

Results: Baseline 18F-FDG PET/CT revealed good agreement between the two modalities (Kappa-0.809) and also revealed additional findings like diffuse spinal uptake(4), lymph nodes(18), lung lesions(19), psoas abscess(8), some special cases such as aortic arch aneurysm and osteomyelitis. In Follow-up study, 30 subjects underwent 2nd scan, among which 7 had CMR, 20 had PR and 3 with PD. Third follow up was done in 8, among which 4 had CMR, 2 had PR and 2 with PD.

Conclusion: 18-F-FDG-PET/CT can be one stop modality in assessing the disease burden at the start of the treatment, can play pivotal role in individualizing management, monitoring disease status and help in guiding the physicians to reach therapeutic end point. Optimising PET/CT paediatric imaging for patient dose reduction

H. Kertész, T. Traub-Weidinger, I. Rausch, T. Beyer, J. Cal-Gonzalez; Vienna/AT (honor.kertesz@meduniwien.ac.at)

Purpose: To evaluate the potential effective dose (ED) reduction by using advanced image reconstruction methods in pediatric imaging with [18F]FDG PET/CT.

Methods and Materials: Data from fifteen pediatric patients with epilepsy were collected. Patients underwent [18F]FDG-PET/CT examination with injected activities of 4.2±1.9 MBq/kg. The patient ED was estimated from the CT and PET acquisitions. The ED_{CT} was defined as the product of the Dose-Length Product (DLP) and CT dose conversion factor (k_{CT}). The DLP was derived from the scan length and CT Dose Index (CTDI_{vol}). The ED_{PET} was calculated as the injected activity and PET dose conversion factor (k_{PET}). The k_{CT} and k_{PET} were obtained from the ICRP-103 publication. The reduced PET injected activity was simulated with reducing the number of counts to 75%, 50%, 35%, 20% and 10% of the total counts. Reconstructions were performed applying OSEM, Maximum-A-Posteriori (MAP) reconstruction with median-root prior (MAP-MRP) and MAP with quadratic prior (MAP-QP). As figure of merit the target-to-background ratio, noise in the uniform region were calculated.

Results: The ED_{total} was 5.0±1.3 mSv (ED_{PET}=4.7 mSv, ED_{CT}=0.3 mSv). Relative deviations below 10% were obtained for count reductions down to 50% applying the reconstruction methods OSEM+4mm filter and MAP-MRP. Using 50% of counts ED for PET could be reduced from 4.7 to 2.4 mSv. This results in a reduction of the total ED up to 53%.

Conclusion: A potential reduction of the injected PET activity up to 50% can be achieved without compromising the selected image quality parameters by applying a suitable reconstruction method.

First report from breath-holding high-resolution high-sensitivity SiPM PET/CT: are lung nodules getting more active?

M. Jreige, M. Meyer, G. Allenbach, M. Pappou, M. Nicod Lalonde, N. Schaefer, J.O. Prior; Lausanne/CH (mario.jreige@chuv.ch)

Purpose: Accurate pulmonary nodules characterization is highly important considering its impact on management and prognosis. The latest PET/CT scanners combining ultra-dynamic range Silicon-photomultiplier detector technology (SiPM), faster time-of-flight and breath-holding (BH) maneuver may allow better visualization and uptake quantification of smaller lesions. Herein, we investigate the feasibility of 20-second-BH-PET/CT acquisition as compared to the standard free-breathing (FB) and its effects on morphologic and metabolic lung nodule characterization.

Methods and Materials: We retrospectively analyzed all PET/CT examinations from 06-10/2018 acquired on a Siemens Biograph Vision 600 with a lung dedicated BH-acquisition in addition to standard FB-acquisition. Only nodules considered highly suspicious for malignancy were included and

characterized morphologically (size) and metabolically (presence/absence of uptake, SUVmax, SUVmean, MTV and TLG) on both acquisitions.

Results: From the 22 reviewed studies, 11 nodules reported as highly suspicious in nine patients were included. The mean nodule size(mm), SUVmax(g/ml), SUVmean(g/ml), MTV(cm3) and TLG(g*cm3/ml) were 11±4.3, 4.5±3.4, 2.5±1.8, 0.7±1.1 and 2.6±4.9 in FB and 11.6±3.9, 7.7±5.7, 3.3±2, 1±1.2 and 4±7.3 in BH, respectively. Only 72% of the nodules were visible on FB-acquisition compared to 100% on BH, with a trend for a statistically significant difference (p=0.062). Concordance analysis showed a statistically significant increase of 68% of the SUVmax value in BH compared to FB.

Conclusion: BH with high-resolution, high-sensitivity PET/CT allowed to detect higher metabolic activity in lung nodules categorized as highly suspicious, in comparison to FB. This increased accuracy in activity detection may help to increase the sensitivity and specificity of malignant nodule characterization.

B-0236 15:20

PET/CT imaging of the novel molecular probe ¹¹C-aminoglycerol for the diagnosis of liver fibrosis

X. Chen, J. Xin; *Shenyang/CN (986107759@qq.com)*

Purpose: In this study, we utilized amino glycerol as the precursor to synthesize a novel molecular probe [¹¹C]AR, which the preclinical performance of liver fibrosis diagnosis was evaluated with in vivo PET/CT imaging.

Methods and Materials: We developed a fully automatic synthesis procedure for the preparation of [¹¹C]AR with improved synthesis efficiency and radiochemical purity. The distribution of [¹¹C]AR was investigated on PET/CT scanner using a rat model. The dynamic PET/CT scans were performed on the control group (n=6) and model group (n=29), which the model group was divided into three stages (S1, S2+S3, S4) according to the stages of liver fibrosis. The images were reconstructed and the region of interest (ROI) in the liver area was selected within 20 mm². One-way analysis of variance and independent sample t test were used to analyse the difference of SUVmax among the groups in a series of scanning time points.

Results: The fully automatic synthesis of [¹¹C]AR was successfully achieved with a radiochemical purity and a synthesis efficiency at least 98% and 50%, respectively. The uptake of [¹¹C]AR in the model group was significantly lower than that in the control group at all the time points (P<0.05). There were significant differences in the SUVmax between the S1 and S4 groups at 150s, 5min, 10min, 15min and 25min (P<0.01).

Conclusion: We demonstrated a new C-11 radiolabeled amino glycerol PET/CT imaging probe [¹¹C]AR for diagnosing and determining liver fibrosis stages, which shows potential clinical implications for noninvasive diagnosis of liver fibrosis.

Ultra-high-field MR microscopy of the upper extremity of the chicken in vivo throughout the in ovo period

M. Jäschke, K. Thierfelder, B. Kwaan, T. Stahnke, T. Lindner, A. Wree, M.-A. Weber, S. Langner; *Rostock/DE (malte.jaeschke@med.uni-rostock.de)*

Purpose: Ultra-high-field MRI (UHF-MRI) with an in-plane spatial resolution of less than 100 µm is known as MR microscopy (MRM). This technique provides highly resolved non-invasive anatomical images and allows longitudinal assessment of embryonic avian development. The aim of the present study was to evaluate the feasibility of in vivo anatomical MRI assessment of the developing upper extremity of the chicken in ovo.

Methods and Materials: Thirty-eight fertilised chicken eggs were examined at 7 Tesla (ClinScan, Bruker BioSpin, Germany) acquiring high-resolution T2-weighted anatomical images with an in-plane resolution of 78 x 78 µm. To reduce motion artefacts, the eggs were moderately cooled before and during MR imaging. Two eggs were imaged daily for the entire developmental period, and 36 eggs were examined pairwise at only one time point of the embryonic period. Development of the upper extremity was anatomically and quantitatively assessed. Chondrification on MRI was correlated with histological examination.

Results: MRM allowed identification from embryonic stage D5 onwards. First chondrification of the upper extremity was visible at stage D7 and differentiation of the forearm was possible from stage D9 with excellent correlation to histology. Repeated cooling and MRM had no influence on the development of the chicken.

Conclusion: MRM allows in vivo assessment of embryonic development of the upper extremity of the chicken in ovo without affecting normal development. The method provides non-invasive anatomical information supplemented by quantitative evaluation. With increasing availability of ultrahigh-field MR systems, this technique may provide a noninvasive complementary tool in experimental musculoskeletal radiology.

MR quantification of the fatty fraction from IDEAL IQ sequence in the assessment of muscle atrophy in rotator cuff tears

O. Seraydarmanour, Z. Taher Rakei; *Tehran/IR (mansour.omid@yahoo.com)*

Purpose: To assess the degree of muscle atrophy and fatty infiltration within supraspinatus muscle in patients with full-thickness rotator cuff tears using a T2*-corrected IDEAL IQ sequence.

Methods and Materials: Among the patients who were referred to our imaging centre for shoulder MRI, 45 patients with full-thickness rotator cuff tears were included in group A and 21 normal patients were included in group B. The mean age of the patients was 63 years (age range, 82-41 years). Necessary information for our study including age, sex, weight, the time of trauma and the type of work and physical activity was identified through questionnaires. All MRI examinations were performed with a 1.5 Tesla MRI unit (Explorer, GE Healthcare) using a four-channel coil. All subjects underwent the standard shoulder MRI protocol including proton density fat-saturated fast spin echo in the oblique coronal, axial and sagittal planes. T1-weighted fast spin echo in the oblique coronal and sagittal planes. We also performed T2* correction IDEAL IQ sequence in the oblique sagittal plane. Fat-signal fraction from the mapping images was measured by drawing a circular ROI on the cross section of supraspinatus muscle belly on the Y-view.

Results: Fat-signal fraction from the T2*-corrected IDEAL IQ sequence was significantly higher in group A than group B.

Conclusion: MRI quantification of fat fraction by using a T2* corrected IDEAL IQ sequence is a valuable method for detecting the fat infiltration in supraspinatus muscle after tearing the rotator cuff.

B-0239 14:25

Evaluation of glenoid labral tears: comparison between dual-energy CT arthrography and MR arthrography of the shoulder

G. Foti¹, M. Catania², A. Beltramello¹, G. Carbognin¹; ¹Negrar/IT, ²Verona/IT (gfoti81@yahoo.it)

Purpose: To compare the diagnostic accuracy of dual-energy computed tomography (DECT) arthrography and magnetic resonance arthrography (MRA) of the shoulder in depicting glenoid labral tears.

Methods and Materials: This prospective study included 26 consecutive patients studied with DECT (80 kV and tin filter 150 kV) and MR arthrography. DECT data were postprocessed on a dedicated offline workstation (SyngoVia®) using a three-material decomposition algorithm. Two experienced radiologists, blinded to surgical data, evaluated the presence of labral tears on DECT maps and on MRA. Surgical findings served as standard of reference. Diagnostic accuracy values of the DECT and of the MRA and inter-observer and intra-observer agreements were assessed. A value of p<0.05 was considered statistically significant.

Results: MRI revealed the presence of labral tear in 19/26 patients (73.1%), with 8 tears of antero-inferior labrum, 10 tears of superior labrum and 1 tear of posterior labrum. The sensitivity, specificity, PPV and NPV and accuracy of DECT arthrography and MRA were 89.5, 100, 100, 77.7 and 92.3%, and 94.7, 85.7, 94.7, 85.7 and 92.3%, respectively. Using McNemar's test, the difference of accuracy between DECT arthrography and MRA was not significant (p=0.45). The inter-observer and intra-observer agreements were near perfect (k=0.82 and k=0.86, respectively).

Conclusion: DECT represents a reliable imaging tool for demonstration of glenoid labrum tears.

B-0240 14:33

Value of 3D-multi-echo-data-image-combination (MEDIC) for evaluation of SLAP lesions at 3T-MRI of the shoulder with arthroscopic correlation

F. Wuennemann, C. Rehnitz; *Heidelberg/DE (felix.wuennemann@med.uni-heidelberg.de)*

Purpose: To prospectively evaluate the ability of 3D-Multi-Echo-Data-Image-Combination (MEDIC) compared to high resolution 2D-proton-density weighted fat-saturated (PDFs) sequence at 3T-MRI in detecting superior labral anterior to posterior (SLAP) lesions using arthroscopy as gold standard.

Methods and Materials: 17 consecutive patients (mean age 51.6±14.8 years, 11 men) with shoulder pain underwent 3T-MRI including 3D-MEDIC and 2D-PDFs followed by arthroscopy. Presence or absence of SLAP lesions were evaluated using both sequences by two independent raters with 3 and 14 years of experience in musculoskeletal MRI. During arthroscopy SLAP lesions were classified according to Snyder by an orthopaedic shoulder surgeon. Sensitivity and specificity of 3D-MEDIC and 2D-PDFs for detection of SLAP lesions were calculated using arthroscopy as gold standard.

Results: Arthroscopy revealed SLAP lesions in 13/17 patients. Using 3D-MEDIC SLAP lesion were diagnosed in 14/17 patients by rater 1 and in 13/17 patients by rater 2. Using 2D-PDFs SLAP lesions were present in 11/17 and 12/17 patients for rater 1 and 2, respectively. Sensitivity/specificity of 3D-MEDIC was 100%/50% for rater 1 and 100%/67% for rater 2, respectively. Using 2D-PDFs sensitivity/specificity was 91%/83% for rater 1 and 100%/83% for rater 2, respectively. The combination of 2D-PDFs and 3D-MEDIC increased specificity from 50% to 83% for rater 1 and from 67% to 100% for rater 2.

Conclusion: Using arthroscopy as reference, 3D-MEDIC exhibits high sensitivities in detection of SLAP lesions with moderate specificity. The combination of 3D-MEDIC and 2D-PDFs markedly increased specificity and may therefore be recommended for shoulder imaging with respect to SLAP lesions.

B-0241 14:41

Evaluation of bone loss in shoulder instability using on track/off track method: value of 3D MR arthrography in standard and ABER position

C. [Gianneramo](#), F. Bruno, E. Cannizzaro, P. Palumbo, S. Iafrate, S. Mariani, F. Arrigoni, A. Barile, C. Masciocchi; *L'Aquila/IT (camillagianneramo@gmail.com)*

Purpose: To evaluate the value of the 3D MR Arthrography (MRA) in standard and ABER (Abduction-External Rotation) position in identifying engaging lesions in patients with anterior shoulder instability.

Methods and Materials: We retrospectively evaluated 28 patients (17 men and 11 women mean ages 28.3 years range 19-43) with anterior shoulder instability and standard MRI evidence of glenoid bone loss and/or Hill Sacks lesion. All patients were submitted to 3D-CT of the shoulder and 3T-MR Arthrography using a three-dimensional (3D) isotropic PD sequence performed in standard and ABER position. Two double-blind radiologists calculated for each patient the glenoid track and Hill Sacks interval using the "on track/off track" method to identify "engaging" and "non engaging" lesions on CT and MRA exams. The intra and inter-observer agreement were calculated. Results were also compared to arthroscopic findings.

Results: Using the "on track/off track" method, 19 bone loss were identified as "non-engaging" lesion and 9 were classified as "engaging" lesions with an "almost perfect" inter-observer concordance both for glenoid track and Hill Sacks interval measured on CT and MRA. Intra-observer agreement was 0.906 for 3D-CT and 0.713 for MRA. ABER position showed weak positive predictive value but strong negative predicted value to detected engaging lesions.

Conclusion: MRA has an excellent diagnostic accuracy in identifying engaging lesions. The ABER position could represent an added value in evaluation of engaging and non engaging lesions on patients with anterior shoulder instability.

B-0242 14:49

Ability of T2 mapping at 3T MRI for biochemical assessment of normal and damaged glenoid cartilage of the shoulder: an arthroscopy controlled prospective study

C. [Rehnitz](#), F. Wuennemann; *Heidelberg/DE (Christoph.Rehnitz@med.uni-heidelberg.de)*

Purpose: To prospectively evaluate T2 mapping at 3T MRI of the shoulder regarding its ability to assess healthy glenoid cartilage and focal cartilage damage using arthroscopy as the gold standard.

Methods and Materials: 18 consecutive patients (mean age 52.4±14.72 years, 12 men) with shoulder pain underwent T2 mapping at 3T MRI with subsequent shoulder arthroscopy. Cartilage-sensitive morphologic sequences were used to detect normal cartilage and focal cartilage lesions. Then T2 values of normal and damaged cartilage were assessed using region-of-interest analyses by two independent raters. Interrater and intrarater correlation coefficients (ICCs) were calculated. Cut-off values and their sensitivities/specificities including 95% confidence intervals (CI) for the detection of cartilage damage were assessed using arthroscopy as reference. P<0.05 was considered significant.

Results: Mean T2 value of arthroscopically proven healthy cartilage was 23.9±5.99 ms. In 5 patients, a focal cartilage damage was present exhibiting significantly higher (p<0.01) T2 values of 44.7±3.7 ms. A complete data separation was present as the maximum T2 value for normal cartilage (27.3) was lower than the minimum value in damaged cartilage (40.7). Therefore, all cut-off values between 27.3 and 40.7 ms resulted in a sensitivity and specificity of 100% (95%CI: 47.8%-100.0%). Interrater agreement was almost perfect

(ICC 0.94-0.95) with moderate intrarater agreement (ICC 0.37-0.67).

Conclusion: Using arthroscopy as the gold standard, T2 mapping was able to detect and quantify healthy and damaged glenoid cartilage. The presented cut-off values allowed for a perfect discrimination. T2 mapping may be used as an additional tool to evaluate the biochemical cartilage integrity at the shoulder.

B-0243 14:57

Extremity cone-beam CT of forearm and hand: evaluation of image quality, metal artefacts and radiation dose

C. [Polkowski](#), I. Yel, M.C. Langenbach, B. Kaltenbach, T.J. Vogl, K. Eichler; *Frankfurt a. Main/DE*

Purpose: To investigate the impact of different scan protocols in latest generation cone beam CT on image quality, metal artefacts and radiation dose.

Methods and Materials: In a prospective study scans of the same cadaver forearm and hand with a distal radius plate were performed to achieve highest intra-individual comparability. 55 consecutive scans were performed on a latest generation cone beam CT scanner for extremity imaging using different combinations of tube voltage and tube current-exposure time product. Effective radiation dose was calculated on the basis of measurements of seven dosimeters in and on the arm. Image quality and metal artefacts were rated by five different readers independently in a blinded evaluation using a 5-point Likert scale (from 1 indicating non-diagnostic to 5 for excellent image quality).

Results: The calculated effective dose for various settings ranged from 0.011 mSv (manufacturer's suggested protocol: 90 kV, 5.0 mA) with an average overall subjective rating of 4.3 and a subjective rating with focus on metal artefacts of 3.8 to 0.003 mSv (70 kV, 2.0 mA) with an average subjective rating of 3.5 and a rating of 3.2 focusing on metal artefacts.

Conclusion: Subjective image quality, especially focusing on metal artefacts, is maintained at a moderate to good level despite the use of protocols with significant dose reduction compared to manufacturer's suggested standard protocol.

B-0244 15:05

Physal changes in youth gymnasts: a three-dimensional assessment of stress-related volume increase of the distal radial physis using magnetic resonance imaging

R.B.J. [Kraan](#), L. Kox, M. Mens, M. Maas; *Amsterdam/NL (r.b.kraan@amc.uva.nl)*

Purpose: Gymnasts are prone to injuries of the distal radial physis as a result of excessive stress applied to the wrist during gymnastics. This can cause damage to the metaphyseal vascularisation and absent or delayed endochondral calcification, with subsequent widening of the cartilaginous part of the physis. This study aims to evaluate stress-related volume changes of the distal radial physis in symptomatic gymnasts, asymptomatic gymnasts and non-gymnasts.

Methods and Materials: Symptomatic gymnasts with suspected distal radial physeal injury, asymptomatic gymnasts and non-gymnasts (all <18 years) were included. Volume measurements were performed by creating three-dimensional reconstructions of the distal radial physis on coronal three-dimensional water-selective cartilage MRI images.

Results: Between June 2015 and August 2018, 27 symptomatic gymnasts, 18 asymptomatic gymnasts and 24 non-gymnasts were included. No significant difference in median skeletal-age was found (13.1, 11.9 and 13.3 years for symptomatic-, asymptomatic- and non-gymnasts). Median physeal volume was significantly increased in symptomatic (971 mm³, IQR 787-1237) and asymptomatic gymnasts (951 mm³, IQR 871-1004) compared to non-gymnasts (646 mm³, IQR 538-795). Inter- and intrarater reliability of volume measurements were excellent. Of the 10 participants with the highest physeal volumes, nine were symptomatic gymnasts.

Conclusion: Increased volume of the distal radial physis is a sign of physeal stress and can be present in both symptomatic and asymptomatic gymnasts. Especially gymnasts with suspected physeal injury showed more extreme volume increases. Volume assessment of the distal radial physis may, therefore, be a valuable addition in the (early) diagnostic workup and follow-up of suspected physeal stress injuries.

B-0245 15:13

Dual-energy CT in the diagnosis of occult acute scaphoid injury: a direct comparison with MRI

C. [Xie](#), S. Ather, R. Mansour, F. Gleeson, R. Chowdhury; *Oxford/UK (chengxie@doctors.org.uk)*

Purpose: Suspected occult scaphoid injuries are a common clinical issue and they require further imaging (CT/MRI) for diagnosis. We investigating the use of dual-energy computed tomography (DECT) for the detection of acute bone marrow oedema/fracture of the scaphoid compared to MRI.

Methods and Materials: Prospective study of 17 adult patients who presented acutely (without prior injury) to the emergency department with clinically suspected occult scaphoid fracture and had MRI of the wrist were recruited to

have DECT (GE Revolution CT). Two experienced musculoskeletal radiologists independently reviewed the DECTs (blinded from MRI results) for acute bone oedema on the GE AW2.0 Analysis Station using the calcium/water filters. The statistical difference of MRI and reviewers' detection of acute bone oedema (1= present, 0= absent) was performed using Friedman test.

Results: MRI showed acute scaphoid fracture/oedema in 11/17 patients. Reviewer A identified acute oedema in 10/11 patients, and Reviewer B identified 7/11 patients that were positive on MRI. On DECT, both reviews did not identify the mild oedema seen on MRI. However, there was no statistically significant difference in oedema detection on MRI and the reviewers on DECT (p-value 0.73). In addition, the reviewers identified more cortical fractures (7 fractures associated with the acute scaphoid oedema) than the MRI.

Conclusion: DECT has the capability to detect acute scaphoid oedema and more cortical fractures compared to MRI. However DECT was less sensitive in the detection of mild acute scaphoid oedema, and this was the main limitation of the calcium/water filters.

B-0246 15:21

Trapezium ridge fractures: an underappreciated cause of post-traumatic wrist pain with normal initial radiographs.

B. Gibney, M.C. Murphy, D. Ahern, A. Moughty, E. Kavanagh, D. Hynes, P.J. MacMahon; *Dublin/IE (bgibney1@gmail.com)*

Purpose: Fractures of the trapezium are rarely diagnosed on plain radiographs after acute wrist trauma. High-resolution cross-sectional imaging identifies fractures of the trapezium as the most common radiographically occult carpal bone fracture. We review the fracture frequency, mechanisms and patterns of trapezium fractures.

Methods and Materials: Cone-beam CT was performed in patients with suspected radiographically occult radiocarpal fracture following acute injury. The frequency of carpal bone fractures was assessed and compared.

Results: 67 radiographically occult wrist fractures were identified with CBCT in 117 patients with acute trauma and negative radiographs. The trapezium was the most frequently fractured carpal bone, making up 29% of carpal fractures. 79% of trapezium fractures involved the volar ridge.

Conclusion: Fractures of the trapezium in acute wrist trauma are much more common than described in the literature. Awareness of the types and mechanisms of fracture is important. Cross-sectional imaging should be considered in all cases of post-traumatic wrist pain with negative radiographs.

Digital breast tomosynthesis (DBT) in the assessment of false positive recalls in a single-centre breast screening programme

M. Orsi, F. Leone, M. Cellina, G. Oliva; *Milan/IT (m.orsi83@gmail.com)*

Purpose: To evaluate the power of DBT in revealing false positive mammographic findings in a single centre 2D-mammography-based screening programme.

Methods and Materials: Between September 2015 and February 2018, 843 consecutive recalled cases diagnosed BI-RADS 1 or 2 after clinical examination, DBT and ultrasound at second level screening, were retrospectively evaluated by a breast radiologist to assess whether the DBT taken alone was able to exclude with certainty the suspicious findings pointed out at first level screening mammography.

Results: We analyzed 843 cases: in 64% (537) DBT alone was enough for the diagnosis, without the need to perform ultrasound, in 30% (254) ultrasound was needed for the diagnosis; in 6% (52) DBT was considered not helpful or misleading.

Conclusion: Our results demonstrate that DBT is an effective tool for the correct interpretation of false positive mammographic findings at second level screening in 94% cases and DBT alone is enough for the diagnosis in more than a half cases; moreover, our results indirectly confirm that the implementation of DBT in the first level should reduce unnecessary recalls. DBT is a powerful tool to reveal false positive mammographic finding and should be increasingly used in the screening setting to reduce false positive recalls.

Stratifying tomosynthesis screening results by age groups and by first or subsequent screening

G. Romanucci¹, F. Caumo², M. Zorzi², P. Bricolo¹, L. Cugola¹, S. Brunelli³, R. Mariotto¹, S.A. Montemezzi¹, F. Fornasa¹; ¹Verona/IT, ²Padua/IT, ³Peschiera/IT (giovitta@libero.it)

Purpose: To examine the outcomes of a breast cancer screening program based on digital breast tomosynthesis (DBT) plus synthesized two-dimensional (2D) mammography stratified by age groups.

Methods and Materials: from April 2017 to March 2018, 22906 women (50-74 years) underwent DBT + synth2D as a screening test. The results - stratified by age groups and by first or subsequent screening - were examined by calculating the proportions associated with each outcome.

Results: the detection rate (DR) was 9.17% (210/22906) for total screening, significantly lower at the subsequent screening (6.85% (110/16065)) than at the first screening (14.6% (100/6841)) (p<0.001). Regarding the results stratified by age groups, the DR was 6.1% (36/5901) in the 50-54 age group, 6.6% (25/4378) in the 55-59 age group, 9.3% (45/4838) in the 60-64 age group, 12.1% (56/4638) in the 65-69 age group, and 14.0% (44/3150) in the 70-74 age group. The decrement in cancer DR was highest in the 70-74 age group (from 14.6% at the first screening to 9.8% at subsequent screening). Furthermore, the positive predictive value at recall was significantly higher for the 70-74 age group (31.0%, 44/142) vs. all the other age groups (14.9%, 166/1113) (p>0.001).

Conclusion: the DR for cancer of DBT increases with increasing age; our results also highlight the effectiveness of DBT in terms of cancer detection for women older than 70 years.

B-0249 14:16

Stratifying tomosynthesis screening results by breast density

G. Romanucci¹, S.A. Montemezzi¹, S. Brunelli², P. Bricolo¹, L. Cugola¹, F. Caumo³; ¹Verona/IT, ²Peschiera/IT, ³Padua/IT (giovitta@libero.it)

Purpose: To assess the highest detection rate (DR) of tomosynthesis (DBT) compared to digital mammography (FFDM) in a screening population, with better performance in dense breasts.

Methods and Materials: from April 2015 to March 2017, 34071 women (50-69 years) underwent DBT + synth2D as a screening test. The results - stratified by breast density, age groups and radiological features - were compared with those of a historical court that in the previous two years (April 2013 - March 2015) performed the screening test with FFDM, through a retrospective analysis.

Results: DR was 9.2 / 1000 (315/34071) in the study group versus 5.2 / 1000 (152/29360) in the historical court (95% CI 4.4-6.1) with an incremental cancer DR of 4.0 / 1000 (95% CI 2.7 to 5.4), P <0.001. Regarding the results stratified by breast density: in non-dense breasts, DR was 8.7 / 1000 (247/28390) for the study group versus 5.1 / 1000 (122/23860) in the historical court; in high density breasts, DR was 12/1000 (68/5681) for the study group versus 5.6 / 1000 (31/5500) for the historical court. The incremental cancer DR was higher in high density breasts with a difference of 6.4 / 1000 (95% CI: 2.7 to 5.4) and improved detection of opacities (72.2% for DBT + synt2D versus 55.1% for FFDM).

Conclusion: DBT is more sensitive than FFDM in both adipose and dense breasts with more than double detection in the latter group.

B-0250 14:24

Cancer detection rate, ductal carcinomas in situ and advanced breast cancers in the 2nd round of a population-based screening with tomosynthesis and synthetic mammography

F. Caumo¹, G. Gennaro¹, G. Romanucci², M. Zorzi¹, C. Fedato³, S.A. Montemezzi²; ¹Padua/IT, ²Verona/IT, ³Venice/IT (francesca.caumo@iov.veneto.it)

Purpose: To compare cancer detection rate and rates of ductal carcinomas in situ (DCIS) and advanced breast cancers (T2+) found in the first and second rounds of a population-based screening with tomosynthesis (DBT) and synthetic mammography (SM).

Methods and Materials: 16,666 women were recruited between Apr 2015 and Mar 2016 for screening with (DBT+SM) in the Verona screening program. 16,065 of them were rescreened two years later for a second round with the same screening test. Cancer detection rate (CDR), rate of DCIS, and rate of T2+ cancers were compared in the two groups. A P value below 0.05 was considered statistically significant.

Results: 155 cancers were found in the first round and 117 in the second, leading to a CDR of 9.3/1000 versus 7.3/1000. The decrease of CDR was statistically significant ($P = 0.045$). DCIS were 19 and 17 in the two rounds, while T2+ cancers were 19 and 13, respectively. DCIS rates were comparable in the two rounds (1.14/1000 vs. 1.10/1000, $P = 0.82$). T2+ rate decreased from 1.14/1000 in the first round to 0.81/1000 in the second round, but the difference was not significant ($P = 0.34$). Finally, the invasive cancer rate moved from 8.2/1000 to 6.3/1000, producing a statistically significant difference ($P = 0.039$).

Conclusion: There was no significant change in detection rates of both DCIS and advanced breast cancers. The reduction in cancer detection rate at the second screening round confirmed that screening with tomosynthesis early detected small, invasive breast cancers.

B-0251 14:32

Does breast tomosynthesis increase cancer detection in a screening population with clinically elevated breast cancer risk?

M. Keupers¹, S. Woussen¹, S. Postema², H. Westerlinck³, G. Zhang¹, L. Cockmartin¹, H. Bosmans¹, C. Van Ongeval¹; ¹Leuven/BE, ²The Hague/NL, ³Heverlee/BE (sofie.woussen@gmail.com)

Purpose: Adding digital breast tomosynthesis (DBT) to full-field digital mammography (FFDM) increases breast cancer (BC) detection rate (BCDR) in population screening. This trial investigates the impact of adding DBT to FFDM in screening women with clinically elevated BC-risk.

Methods and Materials: This prospective single-institution study included 431 asymptomatic women, aged 40-69, with clinically elevated BC risk who underwent screening with 4-view FFDM + DBT in a single compression (Hologic Selenia dimensions) and additional ultrasound and MRI if IBIS risk score >30%. Four radiologists evaluated density, BIRADS, lesion type and localisation, first for FFDM and second for FFDM+ DBT.

Results: Breast density C/D was found in 85% of the women. BCDR (invasive + in situ) was 9.3/1000 for both FFDM and FFDM+DBT. No additional cancers were found by adding DBT nor any of the detected cancers in FFDM were missed with FFDM+DBT. Moderate inter-reader agreement for BIRADS was found for both study arms (ICC FFDM: 0.43 and ICC FFDM+DBT: 0.45). Further analysis with recall majority vote of the 4 readers showed no significant differences in recall rate (McNemar $p=1$) when adding DBT. Additional US and MRI resulted in a higher BCDR (18.6/1000) with detection of occult invasive cancer, papillary DCIS and non-calcified DCIS, suggesting that non-x-ray or contrast techniques are necessary for BC-detection in this subgroup of patients.

Conclusion: In contradiction to screening trials, addition of DBT to FFDM did not increase BCDR for this clinically elevated BC risk screening subgroup; other modalities (i.e. ultrasound, MRI) were necessary to find additional cancers.

B-0252 14:40

Efficiency of mammography, tomosynthesis and breast MRI in detecting malignant extension to the nipple area complex in patients with multifocal or extensive breast DCIS

R. Capocci¹, V. Tacher², R. Bosc¹, J.-L. Totobenzara¹, H. Kobeiter¹, A. Luciani¹, E. Meyblum², T.H. Dao¹; ¹Créteil/FR, ²Paris/FR (romain.capocci@gmail.com)

Purpose: Ductal carcinomas in-situ (DCIS) are frequent breast cancers with many indications for mastectomy. Cosmetic results are important in this oncological population, increasing conservative surgeries (skin-sparing (SSM) and nipple-sparing mastectomies (NSM)). Our objective was to evaluate the efficiency of digital mammography (DM), tomosynthesis (TS) and breast magnetic resonance imaging (MRI) in detecting tumor extension to the nipple-areolar-complex (NAC) in patients with multifocal or extensive breast DCIS.

Methods and Materials: Thirty-four DCIS patients, retrospectively included between May 2011 and November 2017, underwent either SSM or NSM. Two radiologists (one junior, one senior) independently measured the minimal tumor-to-NAC distances, on available prior-to-surgery DM (front, oblique or side views), TS and subtracted post-injection T1-MRI sequences for inter-rater kappa correlation calculation. Measurements were compared to distances evaluated on the surgical specimen (NAC invasion was considered if this distance was under 10mm).

Results: Nineteen (56%) SSM and 15 (44%) NSM were performed, with pathological invasion of the NAC in five NSM patients (26%) and ten SSM patients (67%). Using the minimal tumor-to-NAC distance (on DM, TS and MRI), sensibility and specificity for NAC-invasion detection were 67% (IC:95-[0.62-0.71]) and 58% (IC:95-[0.53-0.63]), respectively (cut-off of 10 mm). Using MRI (cut-off of 10mm), sensibility and specificity were 58% (IC: 95-[0.53-0.63]) and 46% (IC:95-[0.41-0.61]), respectively. The inter-reader correlation was 0.76 using the minimal tumor-to-NAC distance based on all available images, and 0.60 using only MRI.

Conclusion: Our study suggests that the minimal tumor-to-NAC distance in DCIS could be predicted on multimodality image analysis.

B-0253 14:48

Comparison between rapid unenhanced MRI protocol (RU-MRI) and digital breast tomosynthesis (DBT) in detecting breast cancer in a screening-like population

V. Marconi, M. Lorenzon, R. Girometti, L. Di Mico, F. Bondini, A. Bracciani, C. Zuiani; Udine/IT (vale.marconi27@gmail.com)

Purpose: To compare the accuracy of RU-MRI and DBT, in a simulated breast-cancer screening scenario.

Methods and Materials: A retrospective analysis was performed on patients who underwent DBT and 1.5T-MRI over 2016-2017 in our Institution. Cancer beyond T1-stage, previous breast surgery and examinations after neoadjuvant chemotherapy were exclusion criteria. Four readers, blinded to clinical history and histology-pathology, reviewed first DBT, then RU-MRI (including only DWI and T1-w sequences) in separate reading sections, reporting lesions using BI-RADS score. Cases with BI-RADS ≥ 3 assignment were considered as "Screening Recall" (SR). Pathology and negative follow-up served as reference standard. Receiver operating characteristics analysis and k-statistic were used to assess the accuracy of both methods and interobserver agreement in assessing cases as SR. P-values <0.05 were considered statistically significant. A "per-breast" evaluation was performed.

Results: A total of 118 breasts (patient's age: range 31-79; mean 57) were included. Prevalence of disease was 32% (38/118). Readers showed 89.5%, 92.1%, 84.2%, 84.2% sensitivity for DBT, and 92.1%, 84.2%, 92.1%, 84.2% for RU-MRI; the specificity was 81.2%, 78.7%, 90%, 72.5% for DBT, and 92.1, 84.2, 92.1, 84.2% for RU-MRI. The differences between AUCs for two methods, for all readers, were not significant ($p>0.05$), despite a slight improvement in specificity with RU-MRI. Interobserver agreement was good for RU-MRI (range 0.618-0.783), and moderate to good for DBT (range 0.452-0.718).

Conclusion: RU-MRI and DBT are comparably accurate in detecting cancer in screening-like scenario, with acceptable interobserver agreement. Both methods might be the subject for further research in a screening population.

B-0254 14:56

Synthesized mammography: is it as good as digital mammography to find microcalcification?

V.L.N. Omura; Sao Paulo/BR (vivinakamura@yahoo.com.br)

Purpose: To compare synthesized mammography (SM) plus digital breast tomosynthesis (DBT) versus conventional full-field digital mammography (DM) alone for detection of microcalcification.

Methods and Materials: This prospective multireader study included 119 cases: 94 consecutive diagnostic mammography cases that were submitted to stereotaxic biopsies for suspicious microcalcifications, from July 2017 to January 2018, and 25 additional screening mammograms without microcalcifications (controls). All cases had DM, SM and DBT images. The images were randomly analyzed by two independent radiologists that reported the presence of suspicious microcalcification, using the BI-RADS lexicon. Sensitivity, specificity, positive and negative predictive values were calculated for SM plus DBT and for DM alone. Interreader agreement was calculated with Cohen's kappa values. Receiver operator curve analysis was performed.

Results: Agreement between SM plus DBT and DM was substantial (Cohen's k-coefficient = 0.78 ± 0.09). When comparing DM versus SM plus DBT prevalence, sensitivity, specificity, positive (PPV) and negative predictive values (NPV) and area under roc curve (AUC) was 74.0%, 93.8%, 85.5%, 94.8%, 82.8%, 0.896, respectively. When comparing SM plus DBT versus DM, prevalence, sensitivity, specificity, PPV, NPV and AUC was respectively 73.0%, 94.8%, 82.8%, 93.8%, 85.5%, 0.888. And finally, when comparing radiologist A versus radiologist B, and radiologista B versus radiologista A, prevalence, sensitivity, specificity, PPV, NPV and AUC was, respectively, 75.0%, 94.9%, 95.0%, 98.3%, 86.4%, 0.950 and 72.0%, 98.3%, 86.4%, 94.9%, 95.0%, 0.923.

Conclusion: Synthesized mammography plus DBT showed similar performance to digital mammography for the detection of microcalcification, confirming its potential as an alternative to digital mammography.

B-0255 15:04

A new Fourier-based model observer for image quality evaluation in the central slice of simulated breast tomosynthesis images

C. Balta¹, I. Sechopoulos¹, R. Van Engen¹, M. Broeders¹, W.J.H. Veldkamp², I. Reiser²; ¹Nijmegen/NL, ²Leiden/NL, ³Chicago, IL/US (c.balta@lrcc.nl)

Purpose: To investigate the appropriateness of using a novel Fourier-based prewhitening 2D model observer (FPMO) to quantify image quality in a simulated small-scale breast-structure phantom.

Methods and Materials: An *in silico* breast tissue model based on mammographic power-law noise was used to generate 1000 virtual 3D volumes of 256^3 voxels representing breast-like structures. Soft-edged spherical masses with diameters of 4 mm and 16 mm were inserted at the center of the volumes, with different contrast levels. The central slice of each

volume was scored by the FPMO by computing a test statistic using a pre-whitened signal template. This template was computed in the Fourier domain and incorporated the mammographic noise-power spectrum of the breast-like background. The decision variable from the signal-present and signal-absent images was used to estimate the detectability index (d').

Results: d' varied between 0.43-2.21 for the 4 mm mass and between 0.66-3.41 for the 16 mm mass. In both cases, d' increased linearly with contrast ($R^2 = 0.9938$ and $R^2 = 0.9985$, respectively) for signal amplitude varying between 2 and 10.

Conclusion: As expected, the detectability of masses increased with signal size and linearly with the contrast of the spherical masses. However, being Fourier-based, this FPMO can be expanded to any signal shape, making it possible to use just one MO in image quality assessment of multiple tasks. After further validation, this proposed FPMO could be valuable in assessing clinical image quality objectively in 2D mammography images and potentially in tomosynthesis image stacks.

Digital breast tomosynthesis with photon-counting technology: preliminary data from a clinical comparison study

E. Venturini¹, C. Losio, M. Rodighiero, S. Tacchini, M. Panzeri, S. Ravelli, E. Schiani, P. Panizza; *Milan/IT (venturini.elena@hsr.it)*

Purpose: To compare the image quality and the Average Glandular Dose (AGD) of a new Photon-Counting (PC) tomosynthesis prototype with a commercially available tomosynthesis system.

Methods and Materials: After informed consent, women older than 40 years with highly suspicious breast finding at clinical/imaging evaluation (BIRADS 4c/5) underwent bilateral 2-view tomosynthesis with a conventional system and the PC prototype, before breast biopsy. Three readers with different experience in breast imaging independently compared the 3D and the synthesized 2D (s2D) images giving clinical (BIRADS) and conspicuity scores. The density was evaluated according to the ACR classification. The AGDs of the 2 systems were compared.

Results: Between 12/2016 and 10/2017 17 women (mean age 71 years) were enrolled. The density score was A-B for 9 women, C-D for the other 8 women. In 15 exams, at least one suspicious finding was detectable by both systems: 11 masses, 1 focus of microcalcifications, 3 foci of microcalcifications with associated mass, 2 distortions. Two exams were negative in both systems due to high breast density and small cancer size. All findings were confirmed as malignant. Comparing the 3D images, the conspicuity of findings was scored as equal or better for PC respectively in 95% observations, while comparing the s2D images the conspicuity of findings were scored as equal or better for PC respectively in 85% observation. The mean AGD of PC tomosynthesis was 50% lower than the other system.

Conclusion: PC tomosynthesis performs as well as a conventional system with a drastic reduction of the AGD.

Affirm Prone Biopsy System 2D/3D™: tomosynthesis in the vacuum-assisted prone stereotactic biopsy

C. Depretto¹, D. Baldari², F. Cartia¹, C. Ferranti¹, G. Scaperrotta¹; ¹Milan/IT, ²Naples/IT (gianfranco.scaperrotta@istitutotumori.mi.it)

Purpose: To assess the diagnostic accuracy in terms of detection rate, methodology and dose of Affirm Prone Biopsy System™ (3D stereotactic biopsy) compared to the traditional 2D prone stereotactic biopsy system MultiCare™ (Hologic Inc).

Methods and Materials: In our prospective observational study, we enrolled 270 consecutive patients over 2 years who undergo stereotactic needle biopsies. 135 procedures were performed with a traditional 2D approach (control arm) and 135 procedures were performed in 3D tomosynthesis (study arm). All samples were taken with the Eviva® 9G vacuum-assisted system. Thanks to tomosynthesis technology, it was possible to biopsy 10 parenchymal distortions (7.5%) not clearly visible in 2D, otherwise destined for surgical excisional biopsy.

Results: The total number of exposures per procedure, total duration and mean glandular dose (AGD) were compared. The procedure performed with the MultiCare™ system involves 10 exposures while with the Affirm only 7, since scouting and targeting (+15°/-15°) take place in a single acquisition. The reduction in the number of exposures allows a reduction of the average procedure time of about 25% and also a reduction of the AGD by about 50%.

Conclusion: Affirm Prone Biopsy System™ has enabled us to accurately manage all lesions highlighted in tomosynthesis, particularly parenchymal distortions. We observed a reduction in the number of exposures (30%), in the total duration of the procedure (25%) and in the AGD (50%), which make this system more performing and accurate compared to a traditional 2D prone system.

Validation of automated ASPECTS software for detection of early ischaemic brain changes on non-contrast CT scans

L. Wolff¹, O. Berkhemer², A. van Es¹, T. van Walsum¹, W. Van Zwam³, D.W. Dippel¹, C.B. Majorie², A. Van der Lugt¹; ¹Rotterdam/NL, ²Amsterdam/NL, ³Maastricht/NL (l.wolff.1@erasmusmc.nl)

Purpose: In the Alberta Stroke Program Early Computed Tomography Score (ASPECTS), 10 brain regions are dichotomously scored on presence of ischaemic stroke damage. However, considerable inter- and intra-reader variability exists, even for expert readers. We evaluated computed ASPECTS (c-ASPECTS 2.0.1, Frontier, Siemens Healthineers, Forchheim, Germany) in comparison to expert readers.

Methods and Materials: Each included baseline non-contrast CT-scan (5.0 mm slice thickness) from the MR CLEAN trial (n=446) was evaluated by three expert readers for manual ASPECTS. 2 observer agreement for ASPECTS-regions (normal/abnormal) were used as ground truth for training (20%) and testing (80%). A c-ASPECTS region score specificity of $\geq 90\%$ was used to determine the software threshold (relative density difference between affected and contralateral region). Sensitivity, specificity and receiver-operating characteristic curves were calculated. Thereafter, we calculated ICC[1,1], agreement per region and trichotomized ASPECTS (0-4, 5-7, 8-10) between c-ASPECTS and expert readers, and between the expert readers in the test set.
