Results: A subset (n=442/446) was included. In the training set (n=88), a threshold of 5.6-7.3% was found for a specificity of $\geq 90\%$, resulting in a sensitivity and area under the curve of 47-51% and 0.794-0.809. In the test set (n=354) the corresponding results were 90-93%, 42-51% and 0.794-0.811, respectively. Interobserver analysis resulted in an ICC of 0.486, regional agreement of 78-86% and trichotomized ASPECTS agreement of 58-77%. Comparison of c-ASPECTS with expert readers resulted in an ICC of 0.485, regional agreement of 70-77% and trichotomized ASPECTS agreement of 55-77%.

Conclusion: The performance of c-ASPECTS is similar to expert readers.

Non-contrast ASPECTS region density predicts final infarction in acute ischaemic stroke

W.G. Kunz¹, L.T. Rotkopf¹, D. Pühr-Westerheide¹, F. Dorn¹, S. Tiedt¹, F.A. Wollenweber¹, K.M. Thierfelder², A. Kemmling³, P. Reidler¹; ¹Munich/DE, ²Rostock/DE, ³Münster/DE (wolfgang.kunz@med.lmu.de)

Purpose: To determine if automated non-contrast CT (NCCT) density measurements in acute ischaemic stroke provide information on the development of final infarction.

Methods and Materials: We selected 121 patients with middle cerebral artery stroke due to large vessel occlusion out of a consecutive cohort. Densities in Alberta Stroke Program Early CT Score (ASPECTS) regions were quantified as average Hounsfield Unit (HU) values using automated segmentation. Relative HU (rHU) values were calculated dividing absolute regional densities of ischaemic by non-ischaemic hemispheres. Final infarction was defined visually per ASPECTS region in a dichotomised fashion and as total volume. A composite-rHU-score incorporating values from all ASPECTS regions weighted by regional relevance was calculated. Receiver-operating-characteristic curve (ROC) analysis was performed to calculate area-under-the-curve (AUC) values. Linear regression analysis was used for multivariable adjustment.

Results: Median visual ASPECTS on NCCT was 8 (interquartile range: 6-9). Automated density measurements were feasible in all 121 patients. rHU values yielded significant regional classification of final infarction in ROC analyses for all ASPECTS regions except M3 and M6. Best classifications were achieved for lentiform (AUC=0.810, $p<0.001$), caudate (AUC=0.777, $p<0.001$), and insula (AUC=0.764, $p<0.001$). The composite-rHU-score was independently associated with final infarction volume ($\beta=-0.353$, $p<0.001$), outperforming visual ASPECTS assessment ($\beta=-0.190$, $p=0.062$) in regression analysis. The regression coefficients indicating the effect size were most pronounced in patients that received no reperfusion therapy ($\beta=-0.582$, $p<0.001$).

Conclusion: Automated NCCT density measurements identify ASPECTS regions that develop final infarction after stroke. The composite-rHU-score outperformed visual ASPECTS interpretation in the prediction of final infarction volumes.

Accuracy of virtual monochromatic images for the detection of early brain ischaemia on dual-energy CT

D. [Dodig](#)¹, N. Bartolović¹, S. Kovacic¹, D. Miletic¹, Z. Rumboldt²; ¹Rijeka/HR, ²Charleston, SC/US (doris_5na5@yahoo.com)

Purpose: Reconstructing virtual monochromatic images (VMI) on dual-energy CT (DECT) influences tissue contrast-to-noise ratio and artefacts. The sensitivity of standard head CT for acute brain infarct is in the range of 30-70%. We hypothesised that VMI would allow for a more sensitive and accurate detection of early brain ischaemia.

Methods and Materials: Consecutive patients presenting with acute stroke 1-4.5 hours after symptom onset were scanned with DECT. VMI ranging from 40 to 190 keV with a 10 keV increment were reconstructed on a dedicated workstation. Two readers jointly evaluated presence of ischaemic lesions on polychromatic images (representing standard CT) and all VMI reconstructions. The level of detectability between polychromatic and best VMI reconstruction was then compared for each lesion. Follow-up imaging served as the standard of reference. McNemar's group of tests was used for statistical analysis.

Results: So far sixteen patients have been included in the study. VMI was more sensitive (63-94%) compared to polychromatic reconstruction (44-81%), however the observed difference was not statistically significant in this small sample. One brainstem infarct was seen on VMI only and one lesion was not detected at all. Eighty percent of the ischaemic lesions were better delineated on VMI reconstructions ($p=0.0015$). The study is ongoing and these preliminary results are currently being tested on a larger cohort.

Conclusion: Detection of early ischaemic stroke appears to be more accurate with VMI than with standard head CT.

B-0261 14:33

Added value of susceptibility-weighted imaging for the prediction of hemorrhagic transformation in patients with acute ischaemic stroke treated by mechanical thrombectomy

N. [Ben Daamer](#), A. Benaissa, J.P. Le Faucheur, F. Faugeras, S. Benadjouid, E. Kalsoum, T. Tuillier, H. Hosseini, J. Hodel; *Paris/FR*

Purpose: Using susceptibility-weighted imaging (SWI), we aimed at assessing the correlation between the prominence of cerebral veins (PCV) and the occurrence of hemorrhagic transformation (HT) in a cohort of consecutive patients with acute ischaemic stroke (AIS) treated by mechanical thrombectomy (MT).

Methods and Materials: 75 patients with AIS treated by MT underwent MRI at 3T including SWI. The presence of HT was systematically assessed using a dual-energy CT (DECT) scan 48 hours after MT. Using SWI, two blinded neuroradiologists analyzed independently: (i) the number of microbleeds (MBs), (ii) the presence of PCV. The extent of PCV was evaluated using a three-point scale: "1": 33% or less, "2": 66% or "3": the entire middle cerebral artery (MCA) territory. Modified Rankin scale (mRS) at three months was available for all patients.

Results: According to DECT, HT was observed in 22/75 patients. Inter-observer agreement for the presence and extent of PCV was good (respectively $\kappa=0.83$ and $\kappa=0.79$); excellent for the number of MBs ($\kappa=0.86$). No correlation was found between the number of MBs and HT ($p=0.85$). The occurrence of HT was significantly associated with a small extent of PCV (rated "1": 33% or less of MCA territory) on SWI ($p=0.019$). There was no correlation between the SWI findings (i.e. PCV and MBs) and mRS ($p>0.30$).

Conclusion: Evaluation of PCV extent on SWI may potentially help to predict the occurrence of HT in patients with AIS treated by MT.

B-0262 14:41

Incremental value of CT perfusion for outcome prediction in acute cerebellar stroke

M.P. [Fabritius](#)¹, P. Reidler¹, K. Thierfelder², M.F. Froelich¹, L. Rotkopf¹, D. Pühr-Westerheide¹, W.G. Kunz¹; ¹Munich/DE, ²Rostock/DE (matthias.fabritius@med.uni-muenchen.de)

Purpose: The clinical diagnosis of cerebellar stroke is challenging. Most frequently applied CT imaging lacks diagnostic sensitivity and fails to provide reliable prognostic information. We aimed to identify imaging parameters that predict outcome in cerebellar stroke patients using multiparametric CT including whole-brain CT perfusion (WB-CTP).

Methods and Materials: We selected all subjects with cerebellar WB-CTP perfusion deficits and follow-up-confirmed infarction from a cohort of 3,648 consecutive patients with suspected stroke who underwent WB-CTP. Posterior circulation Acute Stroke Prognosis Early-CT Score (pc-ASPECTS) was determined to assess ischaemic changes on non-contrast CT (NCCT), CT angiography source images (CTA-SI), and on parametric WB-CTP maps. Cerebral blood flow (CBF) deficit volume on WB-CTP imaging as well as the final infarction volume (FIV) on follow-up imaging were quantified. Discharge modified Rankin Scale (mRS) scores were assessed. Regression analyses were performed.

Results: 60 patients fulfilled the inclusion criteria. NCCT parameters showed no significant association with FIV. CTA-SI imaging and CBF deficit volume was significantly associated with FIV in univariate linear regression analysis. Only the association of CBF deficit volume was confirmed in a multivariate model adjusted for age, sex, pc-ASPECTS on NCCT and CTA-SI and admission National Institutes of Health Stroke Scale (NIHSS) score (β , 0.706; $p<0.001$). Univariate logistic regression showed an association between CBF deficit volume and discharge mRS ≤ 2 (odds ratio [OR], 0.941; $p=0.017$). This association was not significant after multivariate adjustment, outperformed by NIHSS (OR, 0.776; $p=0.009$).

Conclusion: In contrast to traditional CT imaging parameters, WB-CTP contains prognostic information for morphologic outcome prediction in patients with acute ischaemic cerebellar stroke.

B-0263 14:49

Clinical outcome after thrombectomy in stroke patients with pre-morbid modified Rankin scale scores of 3 and 4: a cohort study with 136 patients

F. [Seker](#), J. Pfaff, S. Schönenberger, C. Herweh, S. Nagel, P.A. Ringleb, M. Bendzus, M.A. Möhlenbruch; *Heidelberg/DE*

Purpose: In this study, we aimed to analyse clinical outcome after mechanical thrombectomy (MT) in patients with pre-morbid mRS 3 and 4, because there is currently no data on this patient group.

Methods and Materials: Between January 2009 and November 2017, all patients with pre-morbid mRS 3 or 4 undergoing MT due to anterior circulation stroke were selected. Good outcome was defined as a clinical recovery to the status before stroke onset, i.e. equal pre-morbid mRS and mRS at 90 days. Besides, mortality at discharge and at 90 days was analysed.

Results: 136 patients were included, of which 81.6% presented with pre-morbid mRS 3 and 18.4% with pre-morbid mRS 4. 24.0% of patients with pre-morbid mRS 4 achieved clinical recovery compared to 20.7% of patients with pre-morbid mRS 3 ($P = .788$). However, proportion of hospital mortality and mortality at 90 days was non-significantly, but markedly higher in patients with pre-morbid mRS 4. Multivariate analysis identified low NIHSS (OR 0.92, 95% CI 0.85 - 0.99, $P = .040$), high ASPECTS (OR 1.45, 95% CI 1.02 - 2.16, $P = .049$) and TIC1 2b-3 (OR 7.11, 95% CI 1.73 - 49.90, $P = .017$) as independent predictors of good outcome.

Conclusion: Good outcome in patients with pre-morbid mRS 3 and 4 is less frequent compared to pre-morbid mRS 0-2. Nevertheless, about 20% of the patients return to their pre-morbid mRS, which may justify endovascular treatment. Most important predictor of good outcome is successful recanalization.

B-0264 14:57

Collateral blood supply role in acute stroke outcomes

M. [Radzina](#); *Riga/LV* (mradzina@gmail.com)

Purpose: Collateral blood supply status is an independent determinant of the clinical outcome, good collateral flow is a factor for favourable clinical outcome and its deficit is considered to be an adverse factor. Early multimodal computed tomography (CT) imaging gives us an insight in various patterns of this parameter and can provide correlation between CT brain perfusion and collateral flow.

Methods and Materials: All 105 patients underwent prospective multimodal imaging (CT, CTA, CT perfusion) with pretreatment imaging for evaluation of collaterals on CTA and brain perfusion by CT perfusion imaging in acute stroke patients within 6-8h after onset. 45 patients showed good collateral pattern while 40 patients showed poor collateral pattern and 10 patients showed absent collateral pattern. All patients were treated by mechanical thrombectomy.

Results: There was statistically significant difference among collateral groups in outcomes by mRS 0-2 in 90 days ($p=0.0001$). As well as the difference maintained unchanged in significance in the actively treated group by mechanical thrombectomy vs bridging treatment group ($p=0.0001$). Strong correlation was seen in the size of the lesion (CT perfusion ASPECTS scoring) and collaterals ($p=0.001$) with 3.2 times better chance for good outcome if 2 factors were combined.

Conclusion: Collaterals can be used as imaging biomarker in prediction of acute stroke outcome independently from treatment selection. Size of the lesion and collaterals should be used as combined set of parameters in prediction of outcome.

B-0265 15:05

Drip, ship, retrieve and leave: a national experience in the management of patients within regional hospitals post endovascular thrombectomy for acute large vessel ischaemic stroke

E. Griffin, M. Sheehan, D. Brennan, S. Looby, S. Power, A. O'Hare, P. Brennan, J. Thornton; *Dublin/IE (emma.griffin.2@ucdconnect.ie)*

Purpose: To report the experiences, outcomes and complications post thrombectomy for patients transferred from and repatriated back to non-endovascular centres with acute large vessel ischaemic stroke. This protocol is known as Drip, Ship, Retrieve and Leave.

Methods and Materials: A retrospective review of a prospectively maintained database was performed to identify all patients who were transferred from an outside institution and followed this model from January 2016-December 2017. Key parameters recorded included the presenting National Institute of Health Stroke Score (NIHSS), the location of large vessel occlusion, the administration of intravenous thrombolysis, the degree of reperfusion achieved (Thrombolysis In Cerebral Infarction (TICI) score) and the 90 day modified Rankin Scale (mRS). We recorded any complications encountered.

Results: A total of 357 patients were deemed eligible for inclusion with a median age of 69 years (20-96). The median NIHSS at presentation was 15 (1-43). All participants had an occlusion confirmed on CT angiography with 92.4% ($n=330$) in the anterior circulation and 7.6% ($n=27$) in the posterior circulation. IV thrombolysis was administered in 200/357 patients (56%). Reperfusion was deemed successful in 91% ($n=325$) with a TICI score of 2a-3, with only complete failure of reperfusion (TICI 0) in 5% ($n=17$). The median 90 day mRS was 3 with 45% ($n=159$) of patients having a mRS of ≤ 2 . The 90 day mortality (mRS=6) for this cohort was 21% ($n=72$).

Conclusion: This model is an effective means at managing patients within a national stroke service. It doesn't negatively affect patient morbidity or mortality rates.

B-0266 15:13

Circle of Willis anatomy does not influence the results of mechanical thrombectomy with balloon guide catheter

A. Velasco González, N. Münich, T. Rusche, B. Buerke, D. Görllich, C. Sauerland, W. Heindel; *Münster/DE (Aglae.VelascoGonzalez@ukmuenster.de)*

Purpose: It has been hypothesised that the suction power through the balloon guide catheter (BGC) might be influenced by the presence of communicant arteries. Our aim was to analyse their effect on the recanalisation rates and the duration of mechanical thrombectomy (MT) performed with a BGC.

Methods and Materials: A total of 200 consecutive patients treated with MT through a BGC for acute ischaemic stroke in the anterior circulation were included in this analysis. The anatomy of the ipsilateral circle of Willis (CoW) was determined from the ipsilateral angiographic images and correlated with the features in the CTA. The duration of the procedure, degree of recanalisation, number of passes, and type of SR used were recorded. In the same way, the assumption of clot migration during MT necessitated retrospective evaluation of the CTA.

Results: The most common anatomical variation of the CoW was the presence of an anterior communicating artery (ACoA, 76.5%, 153/200). An ipsilateral complete CoW was observed in 22.5% of cases (45/200). A mTICI3 was achieved in 64% of cases (128/200) and mTICI3/2b in 87.5% of cases (175/200). Communicant arteries did not have any effect on the angiographic results. Migration into a new territory occurred in six cases. The presence of the ACoA was an independent factor for protection against migration into a new territory (OR, 0.050, 95%CI, 0.004-10.667).

Conclusion: The effectivity of the BGC for MT is not altered by the presence of communicant arteries. Inverted flow through the ACoA could be a factor to prevent migrations.

B-0267 15:21

External referrals for endovascular thrombectomy: our experience in a regional stroke centre and insights into service improvements

E. Griffin, N.C. Adams, R. Motyer, T. Farrell, A. O'Hare, S. Looby, S. Power, P. Brennan, J. Thornton; *Dublin/IE (emma.griffin.2@ucdconnect.ie)*

Purpose: To report experiences at a regional/acute stroke centre of external referrals for endovascular thrombectomy (EVT) in patients with suspected large vessel occlusion (LVO).

Methods and Materials: We accept referrals from 24 external centres throughout the Republic of Ireland. Data was prospectively collected on consecutive referrals for EVT during two separate 4 month periods in 2017 and 2018. Several data points were collected at the time of referral including NIHSS scale, IV thrombolysis, imaging time, ASPECTS score and occlusion site. Reasons for not transferring patients and reasons for not performing EVT were recorded.

Results: 262 phone referrals were made during the study period. 159 patients (61%) were transferred to our institution and 136 patients had EVT (52%). Twenty-three patients were unsuitable for EVT on arrival due to vessel recanalisation (35%), poor ASPECTS score (30%), no intracranial occlusion (13%), clinical improvement (13%) or haemorrhage on repeat imaging (9%). 103 patients (39%) were deemed ineligible for EVT. Reasons for not accepting patients for EVT included lack of intracranial occlusion (59%), ASPECTS ≤ 5 (23%), mild or improving symptoms (11%), distal occlusion (4%), and poor baseline (3%). Median NIHSS was significantly lower in the not transferred group (14v7). Median door to imaging times and onset to arrival times were longer in the not transferred group.

Conclusion: These data provide valuable insights into the service provision of a comprehensive stroke network with low rates of futile transfer. Access to Neuroradiology and specialised stroke assessment is crucial to optimising patient selection and stroke services.

A comparative study 2007-2015 on acute appendicitis: evolution in use by diagnostic imaging techniques

M.A. Depetris, L. Ibañez Sanz, E. Martínez Chamorro, S. Borrueal Nacenta; *Madrid/ES (marinadepetris1976@gmail.com)*

Purpose: To analyse the evolution in the use by diagnostic imaging techniques in acute appendicitis and its impact in the quality of diagnosis process, as negative appendectomy rate is a health care quality indicator.

Methods and Materials: This is a retrospective study that included all patients in whom appendectomies had been performed in 2007 and 2015. The data were obtained from pathology reports, surgical protocols and radiology reports. They were compared between the two periods, by assessing imaging test that were performed and their diagnostic quality.

Results: The previous data of 2007 were assessed and compared with 2015. Both samples included 394 patients (2007) and 280 (2015). In 120 (30%) patients 2007 vs. 37 (13%) patients 2015, any imaging test was done. There was a drop in the negative appendectomy rate from (38) 9.6% to (11) 3.92%. Gangrenous appendicitis rate showed an increased from (46) 11% to 21%(61). There was an increase of abdominal ultrasonography performed (78.5% vs 54.6%), and also ultrasonography (US)+computer tomography (CT) performed (9% vs. 4.8%). There was just one case in which only TC was done at 2015, whereas in 40 patients (10%) in 2007. Ultrasonography predictive positive value (PPV) showed a slight increase from 92 to 97% and ultrasonography and TC together showed a PPV of 100%. Average hospital stay decreases from 4.6 to 2.8 days.

Conclusion: The use of imaging techniques in acute appendicitis has increased, and there was an improvement in health care quality indicators. However, perforated appendicitis does not decrease.

B-0269 14:17

Acute appendicitis: appendicecal angle, morphological variations detected on CT imaging

S. [Evrimler](mailto:Evrimler.H.Aydin@isparta.tr), H. Aydin; *Isparta/TR (drsehna@gmail.com)*

Purpose: We aimed to investigate whether there was an association between appendicecal angle, localisation, length of the appendix and acute appendicitis. To the best of our knowledge, there has been no study investigating the relationship between appendicecal angle and appendicitis development.

Methods and Materials: 226 Abdomen CT scans, (n=116 normal, and n=110 histopathologically proven appendicitis) performed for prediagnosis of acute appendicitis between 2016-2018, were evaluated retrospectively. Diameter-length-localisation of the appendix, appendicecal angle, contrast enhancement, mesenteric stranding, peritoneal thickening, lymphadenopathy, appendicolith, complication, primary/secondary classification were evaluated. Localisation of appendix was classified in 8 groups, as follows; 1:pre-ileal, 2: post-ileal, 3: promontoric, 4: pelvic, 5: subcecal, 6: prececal/paracolic, 7: retrocecal, 8: subhepatic.

Results: Contrast enhancement (%100), and mesenteric stranding (94.5%) were the most observed parameters. There was no significant relationship between appendicitis and the length (p=0.885) or the localisation of appendix. (p=0.231) Pelvic was the most common localisation. Mean of the appendicecal angle for appendicitis group, and normal group was 98.19±41.89, and 85.45±43.31, respectively. There was significant difference for appendicecal angle between appendicitis and normal group(p= 0.028). ROC analysis showed cut-off value of 104.5°, AUC=0.585 (0.510-0.659); p=0.017) (sensitivity 45.45%, specificity 69.82%, accuracy 57.96%). We didn't observe a significant difference for appendicecal angle in complication development. Localisation showed significance only for pre-ileal localisation (p=0.030). On the other hand, length was significantly shorter in complicated cases (p=0.024).

Conclusion: Appendicecal angle is the only significant factor amongst angle, length and localisation of the appendix, and can be an aetiological factor in appendicitis development.

B-0270 14:25

Conditional CT strategy effectiveness in diagnosing acute appendicitis

R. [Luksaite](mailto:Luksaite@gmail.com), R. Kliokyte, A. Samuliis, T. Poskus; *Vilnius/LT (rluksaite@gmail.com)*

Purpose: To present the results of two retrospective studies done in University Hospital Santaros Klinikos analyzing diagnostic accuracy results before and after the application conditional CT strategy and to compare their diagnostic accuracy.

Methods and Materials: Two retrospective analyses of adult patients who were admitted in Emergency room at University Hospital Santaros Clinics with suspected acute appendicitis were done: first study analysed group of 554 patients who from 2008 to 2013 underwent operation for suspected acute appendicitis and the second study included group of 459 patients who underwent operation for suspected acute appendicitis from 2016 to 2018 after implementation of conditional CT algorithm. The results of both algorithms were compared and the positive and negative effects of new diagnostic algorithm were evaluated.

Results: In the first study negative appendectomy (NA) rate was as high as 22.9 %. In Conditional CT strategy group the amount of NA was 0.8%. Increase in usage of imaging was noticed: ultrasound from 75 % up to 97 % and CT from 3.4% up to 25 %. Ultrasonography detected inflamed appendix in 67.5% of these cases, CT scan detected acute appendicitis in 30%. The sensitivity and specificity of ultrasound and CT scan was.

Conclusion: Although applying conditional CT strategy in acute appendicitis diagnostic protocol reduces the amount of negative appendectomies, it increases exposure to ionising radiation, and unnecessary CT scans rate. Taking in to account that potential patient population includes mostly young adults, some new alternatives could be a field for a further search.

B-0271 14:33

Accuracy of grey-scale ultrasound in correctly identifying acute appendicitis in comparison with surgical outcome

K.M.B. [Hassan](mailto:Hassan1@okara.pk)¹, A.U. Slehria¹, T. Baqir Hassan²; ¹Rawalpindi/PK, ²Okara/PK (baqar78@hotmail.com)

Purpose: To validate ultrasonographic diagnosis of acute appendicitis using surgical outcome as the gold standard.

Methods and Materials: Cross-sectional validations setting and duration: Radiology Department, AFIRI Rawalpindi from 1st March 2013 to 31st August 2013. All the patients were referred to the sonography section of Emergency Radiology Department for suspected diagnosis of acute appendicitis. All patients of suspected appendicitis had ultrasound of abdomen. The sampling technique used was consecutive non-probability. Sonographically suspected cases of acute appendicitis resulted in appendectomy of the patient. Patients

were operated by conventional method of appendectomy. Results regarding appendix by ultrasonography and surgical outcome were recorded on the proforma. Data entry and analysis was done using SPSS v21.

Results: A total of 160 patients were included in the study. Mean age of patients was 21.39±4.332 years. There were 77 (48.1%) male and 83 (51.9%) female patients. Clinically, there were 126 (79%) patients positive for appendicitis and on ultrasound findings 121(76%) patients had appendicitis. Surgical outcome showed 125 (78%) patients as positive. Sensitivity and specificity of ultrasound for the diagnosis of appendix was 87.20% and 65.71%. While positive predictive value and negative predictive value of ultrasonography was 90.80% and 58.97%, respectively. Overall diagnostic accuracy of ultrasound was 78.12%.

Conclusion: In patients who present with clinically suspected acute appendicitis, imaging is vital and ultrasound can be a good, cheap, readily available and preferred imaging technique to confirm or support the clinical diagnosis and avoid unnecessary and erroneous surgeries especially in females.

B-0272 14:41

Diagnostic performance of abdominal ultrasound in right-sided acute colonic diverticulitis

F. [Pellegrino](mailto:Pellegrino07@gmail.com), G. Tralli, G. Di Stefano, C. Tartari, S. Tartari, M. Giganti; *Ferrara/IT (fabiopellegrino07@gmail.com)*

Purpose: To assess value of abdominal ultrasound in patients with suspected right-sided acute symptomatic diverticulitis in comparison with supplementary CT.

Methods and Materials: We retrospectively analysed 124 patients from Emergency Department (mean age of 66 ± 18 years) with final diagnosis of acute diverticulitis at discharge. For each patient were registered diagnostic-therapeutic pathway, elective pain location and simple or complicated diverticulitis features with sonography and CT, assessing value of initial US through head-to-head comparison with CT results.

Results: Of the 124 patients with diverticulitis 30 underwent directly to CT and were excluded. Among 94 patients with initial sonography and subsequent CT examination within 24 hours, US was positive in 45/94 patients (true positive) and negative in 49/94 (false negative), with diagnostic accuracy of 48%. Sonography diagnosed correctly 15/32 cases of uncomplicated diverticulitis and 30/62 complicated diverticulitis with diagnostic accuracy respectively of 47% and 48%. Regarding location of pain, US was positive in 12/35 patients with right lower quadrant pain and in 33/59 with left lower quadrant pain showing diagnostic accuracy of 34% and 56%.

Conclusion: Our data show that US in emergency setting is less reliable for diagnosing right-sided colonic diverticulitis in patients with RLQ pain.

B-0273 14:49

Clinical significance of bedside ultrasonography and second-look ultrasonography in pediatric ileocolic intussusception

M. [Park](mailto:Park1102@gmail.com), C. Lee, G.-S. Hong; *Seoul/KR (lpk1102@gmail.com)*

Purpose: The purpose of this study is to identify the performance characteristics of bedside ultrasonography which is performed by clinicians (B-USG), and the clinical significance of the second-look ultrasonography performed by radiologists (R-USG) for the diagnosis of pediatric ileocolic intussusception.

Methods and Materials: From October 2013 to December 2017, the patients who visited pediatric emergency department (PED) and underwent ultrasonography by radiologists for evaluating intussusception were included. The included patients were divided into two groups: group A, the patients in whom first-line B-USG were performed at PED, followed by second-look R-USG; and group B, the patients in whom R-USG were performed without B-USG. We compared the ratio of confirmed ileocolic intussusception between the two groups. The sensitivity and positive predictive value of B-USG were calculated using the result of R-USG as the gold standard.

Results: A total of 262 patients (mean age, 4.3 years old) were included: 108 patients in group A; and, 154 patients in group B. The ratios of the patients in whom ileocolic intussusception were confirmed were significantly different between group A (47.2 %, 51/108) and group B (28.6 %, 44/154) (p < 0.05). In group A, the sensitivity and positive predictive value were 98.0 % (50/51) and 58.8 % (50/85), respectively.

Conclusion: The B-USG is highly sensitive for the diagnosis of pediatric ileocolic intussusception. However, due to its low positive predictive value, the second-look ultrasonography by radiologists can improve the diagnostic accuracy, thus reduce unnecessary radiation exposure caused by fluoroscopic reduction.

B-0274 14:57

Is it possible to establish a clinical prediction rule for computed tomography assessment in suspected bowel obstruction at the emergency department?

R.E. Pacios Blanco, A. Vicente Bártulos, B. Manuel Fernández, E. Cobo Reinoso, A. Muriel García, A. López-Frías López-Jurado, N.A. Almeida, J.I. Gallego Rivera, L. Gorospe Sarasua; *Madrid/ES*

Purpose: Bowel obstruction accounts for 5%-15% of hospital admissions for the evaluation of acute abdominal pain at the emergency department. Mortality rates can be significant without early surgical management. Computed tomography (CT) is currently the most sensitive imaging method for the diagnosis. The main objective of this study is to establish a clinical prediction rule to improve the adequacy of CT requests in suspected acute bowel obstruction.

Methods and Materials: Scientific evidence to better match the CT requests to the suspicion of acute bowel obstruction was evaluated in the previous multicentre trial MAPAC/FIS13/00896-FIS13/01183/ERDF (European Regional Development Fund), in which an algorithm-based radiological approach was developed for clinical use. We reviewed medical records of 422 patients with abdominal CT scan performed between September 2016 and March 2018 requested under suspected bowel obstruction using the previous algorithm. A prediction rule was developed by use of recursive partitioning based on significant factors after univariate analysis.

Results: Abdominal pain was the most reported symptom (91.9%). 50.1% of abdominal CT scans were positive for bowel obstruction and 23.1% revealed other acute diseases. Significant factors to predict bowel obstruction were constipation ($p=0.018$); abolished bowel sounds ($p=0.009$) and personal history of cancer ($p=0.046$). The prediction rule could rule out bowel obstruction with a sensitivity of 80.1% (95% CI, 75.3-84.4 %) using the factors previously mentioned.

Conclusion: We developed a prediction rule for CT assessment in suspected bowel obstruction based on significant clinical and radiological features. Prospective validation is needed in other settings. To the best of our knowledge, no clinical prediction rule on this issue has been published.

B-0275 15:05

Fast track CT in patients that referred to emergency major abdominal surgery

C. Huang¹, C.A. Mardal², L.T. Tengberg², M. Bay-Nielsen², B.B. Bertelsen²; ¹Slagelse/DK, ²Hvidovre/DK (chenxihuang@msn.com)

Purpose: Patients with abdominal pain that referred to emergency major abdominal surgery have a high risk of mortality. To improve the postoperative survival, a standardised, multidisciplinary consultant-led perioperative protocol was introduced at Hvidovre Hospital, including fast track CT diagnostics and surgery. The effort of this showed almost 30 % reduction of 30-day mortality. The present study reports the feasibility of fast track CT and its diagnostic accuracy compared to the intra-operative findings.

Methods and Materials: Single-centre intervention study in an unselected consecutive cohort. We included adult patients with the suspicion of (non-traumatic) major abdominal pathology requiring immediate surgery. All patients were included from Hvidovre Hospital (Denmark) from 2013 to 2015, by senior surgeons at the emergency department. In this multidisciplinary effort, the radiological contribution consisted of a fast track abdominal CT scan (predominantly with IV contrast) and rapid reporting within 2 hours of inclusion. Clinical interventions include surgery within 4 hours and perioperative optimization by anaesthesiologists.

Results: A total of 371 patients were included. Rapid reporting were achieved for all patients. The CT scans detected a high proportion of the pathologies found at the subsequent surgery with an overall accuracy of 90%, including detection of bowel obstruction and perforated hollow organs at accuracy of 93% and 94%, respectively.

Conclusion: The fast and accurate diagnosis provided by CT scan enabled the clinicians to make immediate and educated decisions. The significant reduction of 30-day mortality supports the important role of CT scans and rapid reporting in this multidisciplinary cooperation.

Comparing emergency department disposition of abdominal tomogram to abdominal x-ray

J.Y. Lee, S. Sabbah, P. Rogalla; *Toronto, ON/CA* (Jason.Lee2@uhn.ca)

Purpose: The aim of this study was to analyze the impact of replacing abdominal x-rays (AXR) with abdominal tomograms (AT, ultra-low dose abdominal CT) in the emergency department (ED) with respect to ED length of stay (EDLOS), time-to-ED disposition (TEDD) and time-to-inpatient bed (TIPB).

Methods and Materials: A new protocol at our institution has replaced AXR in the ED with AT. All patients with non-traumatic acute abdominal pain in ED referred to AXR were automatically converted to AT. A total of 581 AT patients between 2/1/2017-5/31/2017 and 471 AXR patients between 2/1/2016-

5/31/2016 were available for analysis. Duplicate entries of 52 for AT and 99 for AXR were excluded. Thus, a total of 529 AT and 372 AXR patients were analyzed. The TEDD was defined as triage time-to-patient disposition where patient may be admitted or discharged from ED, and TIPD was the time from patient disposition to inpatient bed. EDLOS was defined as the sum of TEDD and TIPD. Timestamps were extracted from the hospital's electronic patient record database.

Results: Between the AT and AXR groups, there was no statistical difference between gender (47% vs. 46% male, $p=0.8$) and age (64.7 vs. 63.3, $p=0.5$). Statistical difference was not seen with respect to EDLOS (16.3h vs.17.3h, $p=0.3$), TEDD (8.2h vs. 8.2h, $p=0.9$) and TIPB (14.0h vs. 11.9h, $p=0.06$)

Conclusion: The conversion of abdominal x-rays to abdominal tomogram for non-trauma emergency department indications did not significantly alter the emergency department length of stay, time to emergency department disposition or time to inpatient bed.

Initial results of management for acute ischaemic stroke due to large vessel occlusion by direct aspiration first-pass technique at Cho-ray hospital

T.H.N. Nguyen, P.V. Le; *Ho Chi Minh City/VN* (drtuainnr@gmail.com)

Purpose: The development of new revascularization devices has improved recanalization rates, time and clinical outcomes. A direct aspiration first-pass technique (ADAPT) has been introduced as a simple and fast method for achieving good recanalization and clinical outcomes using large bore aspiration catheter for the treatment of acute ischaemic stroke (AIS) due to large vessel occlusion.

Methods and Materials: Retrospective analysis of a database of patients undergoing stroke with ADAPT technique at Cho-ray Hospital, from January 2017 to June 2018. Variants evaluating the efficacy and safety evolved: recanalization rates (thrombolysis in cerebral infarction (TICI) score), time to recanalization, complications and clinical outcomes (modified Rankin scale (mRS) score) at the 90-day follow-up.

Results: Forty-three patients suffering an AIS treated with ADAPT had initial mean NIHSS score of 17.2 and improved to a mean NIHSS score of 8.7 at discharge. TICI 2b/3 recanalization was achieved in 36/43 (83.7%) patients. The average time to recanalization was 31.7 minutes. 55.8% patients (24/43) presented good clinical outcomes (mRS 0-2), and mRS 3-5 was reported in 13/43 (30.2%) patients. The mortality rate was 6/43 (14%) during follow-up.

Conclusion: The ADAPT technique is a fast, simple, safe and effective method with high recanalization rates and good clinical outcomes for management of acute ischaemic stroke with the latest generation of large bore aspiration catheters.

B-0279 14:08

Double aspiration thrombectomy in endovascular recanalisation of acute ischaemic stroke patients

M. Voormolen, T. van der Zijden, O. D'Archangeau, F. Van den Bergh, A. Mondelaers, C. Loos, P. Vanacker, I. Baar, L. Yperzeele; *Antwerp/BE* (maurits.voormolen@uza.be)

Purpose: Endovascular recanalisation by thrombectomy in patients with acute ischaemic stroke is effective and safe. To improve procedure and clinical outcomes, combination of stent-retriever thrombectomy and catheter thrombo-aspiration might increase first-pass recanalisation rate with more complete recanalisation. Our goal was to assess efficacy of endovascular recanalisation by catheter thrombo-aspiration (TA) combined with stent-retriever thrombectomy with simultaneous aspiration on TA catheter and balloon guiding catheter (double aspiration thrombectomy (DAT)) in patients with acute intracranial thrombo-embolic occlusions.

Methods and Materials: Between January and August 2018, in our hospital 37 DAT endovascular recanalisation procedures as first-pass attempt were performed in patients with acute ischaemic stroke of anterior circulation, involving 16 female (43%) and 21 male patients. Mean patient age was 71 years (range 38-92). Mean NIHSS was 17 (6-25). Occluded arteries were distal internal carotid (27%), M1 (57%), M2/M3 (5%) and tandem lesion (11%).

Results: Recanalisation by DAT was achieved in 34 procedures (92%). First-pass recanalisation rate was 65%. Mean number of passages was 1.4 (range 1-3). Complete recanalisation (TICI 3) was seen in 65%, near complete (TICI 2B) in 27%, fair recanalisation (TICI 2A) in 3% and no recanalisation (TICI 0) in 5%. Median time from groin puncture to recanalisation was 33 minutes (16-120). No major procedure-related complication occurred. Median NIHSS at 24 hours was 4 (1-20). Median mRS at 3 months after stroke was 2 (0-6).

Conclusion: First results of double aspiration thrombectomy in patients with acute ischaemic stroke suggest high rates of complete first-pass recanalisation.

B-0280 14:16

Haemorrhagic transformation after stroke: interrater and intrarater agreement

A. Guenego¹, M. Plotin², R. Blanc², R. Fahed²; ¹Toulouse/FR, ²Paris/FR (adrienguenego@gmail.com)

Purpose: Haemorrhagic transformation (HT) is a complication of stroke that can occur spontaneously or after treatment. We aimed to assess the interrater and intrarater reliability of HT diagnosis.

Methods and Materials: Studies assessing the reliability of the European Cooperative Acute Stroke Study (ECASS) classification of HT or of the presence (yes/no) of HT were systematically reviewed. Eighteen raters independently examined 30 post-thrombectomy computed tomography scans selected from the aspiration vs. stentriever (ASTER) trial. They were asked whether there was HT (yes/no), what the ECASS classification of the particular scan (0/HI1/HI2/PH1/PH2) was and whether they would prescribe an antiplatelet agent if it was otherwise indicated. Agreement was measured with Fleiss' and Cohen's kappa statistics.

Results: The systematic review yielded 4 studies involving few (≤ 3) raters with heterogeneous results. In our 18-rater study, agreement for the presence of HT was moderate ($\kappa=0.55$, 95%CI [0.41-0.68]). Agreement for ECASS classification was only fair for all 5 categories, but agreement improved to substantial ($\kappa=0.72$, 95%CI [0.69-0.75]) after dichotomising ECASS into 0/HI1/HI2/PH1 versus PH2. The interrater agreement for the decision to reintroduce antiplatelet therapy was moderate for all raters, but substantial among vascular neurologists ($\kappa=0.70$ [0.57-0.84]).

Conclusion: The ECASS classification may involve too many categories and the diagnosis of HT may not be easily replicable, except in the presence of a large parenchymal haematoma.

B-0281 14:24

Endovascular treatment of patients with acute ischaemic stroke in posterior circulation: single-centre experience

A. Klepanec, J. Harsany, M. Mako, M. Hoferica, J. Cisar, M. Cabukova, M. Rusina, G. Krastev; Trnava/SK (andrej.klepanec@gmail.com)

Purpose: To evaluate the safety and efficacy of endovascular treatment of patients with acute ischaemic stroke in posterior circulation.

Methods and Materials: During the study period from October 2015 till January 2018, 248 patients with acute ischaemic stroke and large vessel occlusion were treated with endovascular thrombectomy in comprehensive stroke centre, of whom, 42 patients were endovascularly treated for acute ischaemic stroke in posterior vertebrobasilar circulation.

Results: Median age of patients was 72 years (44-86) and NIHSS 15 points (3-36). Median door to image was 16 minutes (0-63), door to needle 49 minutes (25-85), door to puncture 137 minutes (50-310), puncture to start of revascularisation 15 minutes (5-45), puncture to revascularisation 33 minutes (9-135) and onset to puncture 280 minutes (58 - 1130). After the procedure, successful revascularisation TICI 2b/3 was achieved in 80% of patients. Symptomatic intracranial haemorrhage was present in 2 patients. At 3-month follow-up, favorable outcome with mRS 0-2 was in 37.5% patients, mRS 3-5 in 20% and mRS 6 in 42.5%.

Conclusion: Endovascular treatment of patients with acute ischaemic stroke in posterior vertebrobasilar circulation is a safe and effective treatment.

B-0282 14:32

Comparison of mechanical thrombectomy in single- vs. biplane angiosuites

A. Guenego¹, R. Fahed², M. Plotin², R. Blanc², F. Bonneville¹, P. Mosimann³, C. Cognard¹; ¹Toulouse/FR, ²Paris/FR, ³Essen/DE (adrienguenego@gmail.com)

Purpose: To assess differences in radiation, contrast exposures, procedure duration and outcomes between cerebrovascular mechanical thrombectomy (MT) procedures performed in single-plane (SP) or biplane (BP) angiosuites.

Methods and Materials: Consecutive patients treated by MT from four centres between January 2014 and May 2017 were included. Patients and MT characteristics (including type of the angiosuite [SP/BP], recanalisation score, modified Rankin Scale at 3 months, complications, scopy duration, procedure duration, dose-area product (DAP), kerma and contrast load) were assessed.

Multivariate analysis were performed (with Bonferroni correction) to compare angiosuites regarding MT efficacy and safety, patient radiation and contrast exposure, and fluoroscopy duration.

Results: Within four centres, 906 patients underwent a MT (576 on a biplane angiosuite, 330 on a single plane). After multivariate analysis, BP angiosuites significantly decreased contrast load (100 vs 200mL, 50% lower, relative effect 0.75 (CI: 0.67-0.84), $p<0.0001$) and fluoroscopy duration (22 vs 27min, 19% lower, relative effect 0.83 (CI: 0.74-0.94), $p=0.0001$) compared with SP angiosuites. There was no difference regarding procedure duration, radiation doses, rate of successful recanalisation, outcome or procedural complications. Interestingly, performing a pre-intervention diagnostic cerebral angiogram before MT significantly increased procedure duration (46 vs 40min, 15% increase, $p=0.05$), DAP (161 vs 122 Gy.cm², 33% increase, $p<0.0001$), and contrast load (180 vs 80mL, 125% increase, $p<0.0001$).

Conclusion: Our study shows that BP angiosuites significantly decreased iodine contrast exposition. Furthermore, decision to realise a pre-intervention diagnostic cerebral angiogram before a MT should be clinically motivated to avoid any useless increase in radiation, contrast load and procedure duration.

B-0283 14:40

Impact of haemoglobin levels and anaemic state in the prognosis of patients at three months after mechanical thrombectomy for acute ischaemic stroke

J.N. Pinto Ramos¹, J. Silva², P. Calvão-Pires¹, I. Gil¹, J.P. Marto¹, S. Calado¹, C. Branco¹, J.T.C. Baptista¹, G. Branco¹; ¹Lisbon/PT, ²Covilhã/PT (joanpramos@gmail.com)

Purpose: Those anemic and with lower levels of hemoglobin at admission seem to fare worse in the long-term when compared to non-anemic patients regarding acute ischemic stroke (AIS). We hypothesize hemoglobin and anemia play a lesser role in AIS patients treated with endovascular treatment, potentially reflecting a selection bias.

Methods and Materials: Electronic health records were used to collect clinical data as a retrospective analysis of consecutive cases of patients (n=72) that underwent mechanical thrombectomy as part of the acute phase treatment for AIS, in Centro Hospitalar Lisboa Ocidental from 01-01-2016 to 30-06-2018. Good prognosis at 3 months was defined as modified Rankin score (mRs) 0-2 (vs mRs 3-6). We performed 2 logistic regressions: one using the numerical value of hemoglobin at admission; another with anemia at admission as a condition, as defined per the World Health Organization criteria. Dependent variable was defined as good prognosis at 3 months, with adjustment for age, sex, NIHSS at admission, thrombolysis, clinic-to-groin-puncture time and variable of interest.

Results: 44.4% of patients had good prognosis at 3 months. Mean value of hemoglobin was 13.34 ± 1.69 g/dL, and 22.2% of patients were anemic. Neither hemoglobin (OR 1.045 [0.747;1.472], $p=0.796$) nor anemic condition (OR 0.831 [0.227;2.921], $p=0.774$) seemed to have a significant impact in good prognosis at 3 months.

Conclusion: Contrary to most literature regarding AIS in general, hemoglobin levels and anemic condition do not seem to be independent predictors of good prognosis at 3 months in patients with AIS that have undergone mechanical thrombectomy.

B-0284 14:48

Direct puncture of the carotid artery for thrombectomy in acute stroke patients: a single centre experience

M. Baptista, C. Pinheiro, I. Ribeiro Fragata, R. Carvalho, J. Pamplona, A.P. Nunes, J. Reis; Lisbon/PT (marianabah@gmail.com)

Purpose: In the late twenties, Egas Moniz introduced cerebral angiography by injecting a radio-opaque medium directly in the cervical carotid artery. The femoral Seldinger technique later replaced direct carotid access. We aimed to prove that in particularly difficult anatomical configurations of the aortic arch, percutaneous access through the carotid artery may be justified.

Methods and Materials: Retrospective review of clinical and imaging data of stroke patients, submitted to Digital Subtraction Angiography (DSA) at Hospital São José by direct carotid artery puncture, between January 2014 and September 2018.

Results: A total of 9 patients, referred to our hospital for large vessel occlusion stroke, were submitted to DSA by direct carotid artery puncture. Significant arterial tortuosity and difficult anatomy did not allow selective catheterization through femoral access. Mechanical thrombectomy with aspiration was performed in 6 of them, with successful recanalization (TICI 3). In one patient, by the time the vessel was reached, spontaneous recanalization had occurred. In one patient, by the time the vessel was reached, spontaneous recanalization had occurred. In two patients it was not possible to reach the occluded vessel. Four of these patients were also submitted to intravenous thrombolysis. No major complications occurred.

Conclusion: At a time when endovascular treatment is part of the guidelines for the treatment of large vessel occlusion strokes, direct carotid artery puncture may offer patients with no femoral access or difficult anatomy a safe alternative to achieve timely recanalization.

B-0285 14:56

Computational fluid dynamics in patients treated with flow-diverter devices

T. [Baptista](mailto:jtbaptista@gmail.com); Lisbon/PT (jtbaptista@gmail.com)

Purpose: To simulate, using computational fluid dynamics (CDF), the haemodynamic conditions in pretreatment aneurysms and to identify if flow characteristics are of assistance in predicting whether a specific aneurysm is more prone to thrombosis after flow-diverter (FD) placement, and if there are any haemodynamic indices that correlate with the regions which thrombose first.

Methods and Materials: Seven internal carotid artery aneurysms were modelled from 3D pretreatment angiographic studies. Patients were treated using FD and were followed up by digital subtraction angiography and contrast-enhanced 3D time of flight magnetic resonance angiography during 2 to 12 months. Images were segmented using Amira 5.3.3 and @neuFuse 7.3TS software and flow was simulated using ANSYS CFX 13.0 software.

Results: Follow-up showed that a smaller (paraophthalmic) aneurysm was still patent at 6-month follow-up imaging whilst in the same vessel a giant cavernous lesion had already been excluded. CFD analysis demonstrated that the paraophthalmic aneurysm was under higher values of wall shear stress (WSS) and that a substantial portion of flow coming from the larger aneurysm was producing a flow impingement area with high values of WSS, low values of oscillatory shear index (OSI) and positive values of aneurysm formation indicator (AFI). Thrombus formation within the aneurysm sac initiated in regions of high OSI and negative values of mAFI.

Conclusion: In this study, we observe that CFD may be able to help distinguish between those aneurysms likely to occlude more rapidly and those that may undergo delayed occlusion. Initial regions of thrombosis may also be predicted.

B-0286 15:04

Endovascular treatment of intracranial carotid sidewall aneurysms by flow diversion: a single centre's experience and comparison of Fred and Pipeline stents

C.A. [Gundogmus](mailto:cagundogmus@gmail.com); D. Tureli, R. Asadov, S. Sabet, N. Andac, F. Baltacioglu; Istanbul/TR (cagundogmus@gmail.com)

Purpose: To retrospectively evaluate feasibility and efficacy of FRED and Pipeline stents in endovascular treatment of challenging intracranial carotid sidewall aneurysms.

Methods and Materials: One hundred and seventeen patients with a total of 151 sidewall aneurysms were included. Patients received either dual anti-platelet therapy (Aspirin and Clopidogrel) or Prasugrel as monotherapy. Patient follow-up was done by DSA.

Results: Mean patient age was 50 (ranged 29-76). Eighty-three (54.9%) aneurysms were treated with FRED and 68(45.1%) were treated with Pipeline stents. 3 cases were bleeding aneurysms (2 FRED, 1 Pipeline). Stent deployment failure occurred with both Pipeline(n=2) and FRED(n=4) stents; which in turn were corrected by removal and stent replacement (FRED n=2, Pipeline n=1), balloon dilatation (FRED n=2) . In one case no further action was needed due to adequate contralateral supply via anterior communicating artery. Acute in-stent thrombosis was seen in 4 patients(FRED n=2, Pipeline n=2); 2 treated with Tirofiban and additional stenting, 2 treated with Tirofiban only; no long term sequelae were seen. One patient with giant aneurysm treated with FRED and fully packing with coils haemorrhaged post-intervention and died 10 days later. Follow-up periods ranged between 6 and 63 months (average 36 months). Four patients were lost to follow-up. Complete occlusion was observed in 89.4% of aneurysms (FRED n=68, 88.3%; and Pipeline n=58, 90.6%).

Conclusion: Treatment of challenging intracranial carotid sidewall aneurysms with flow diversion using FRED and Pipeline stents is feasible and effective with both stents showing comparable and promising results in short, mid and long-term follow up.

B-0287 15:12

Flow diverters in the treatment of intracranial aneurysms: experience at our institution

I. [Andres Cano](mailto:ignacioanca@gmail.com); Cadiz/ES (ignacioanca@gmail.com)

Purpose: Endovascular treatment of intracranial aneurysms has become an alternative to surgical clip ligation. Flow diverters induce disruption of flow near the aneurysm neck, inducing thrombosis into the aneurysmal sac while preserving physiological flow in the parent vessel and adjacent branches.

Our goal is to study the demographics, indications of treatment and the outcomes of the patients who were under the procedure with the experience of our institution.

Methods and Materials: Retrospective study aiming to identify patients treated with flow diverters between 2007 and 2018 in our hospital.

Results: We identified 22 patients (17 females) and 24 aneurysms. The average age of the patients was 51 ± 13.4 years (range 11-71). Ten aneurysms were located on the left, four aneurysms were in the midline and the remaining 10 aneurysms were on the right. There were three complications, one of which led to death. Four of the aneurysms presented with mass effect symptoms and the remaining were incidental.

Conclusion: Flow diverters were placed in large and complex intracranial aneurysms. Flow diversion was a safe and highly effective technique for treatment of aneurysms of the anterior and posterior circulation. Only 1 of the 22 patients was discharged with poor outcomes and another one died. 90% of our patients (20 out of 22) were discharged asymptomatic. At follow-up, a high proportion of aneurysms treated with flow diverters achieved complete obliteration.

B-0288 15:20

Balloon-assisted coil embolisation and large stent delivery for cerebral aneurysms with a new generation of dual-lumen balloons

A. [Guenego](mailto:adianguenego@gmail.com)¹, J.-B. Zerlauth², R. Meuli², R. Chapot³, P. Mosimann³; ¹Toulouse/FR, ²Lausanne/CH, ³Essen/DE (adianguenego@gmail.com)

Purpose: Dual-coaxial lumen balloon micro-catheters that can serve as a remodeling device and through which small stents can be delivered. We report a series of a new dual-lumen balloon catheter with parallel lumens enabling enhanced inflation and deflation properties and through which larger stents may be deployed, including flow diverters (FD).

Methods and Materials: All aneurysms that were treated with a Copernic2L (COP2L) dual-lumen balloon catheter at a single institution between February 2014 and December 2016 were assessed. Patient, aneurysm, procedural characteristics, clinical and angiographic follow-up.

Results: A total of 18 aneurysms in sixteen patients (14 women) were treated with the COP2L. Mean aneurysm height x width and neck size were 1.1 (min 0.5; max 2.1) and 3.3 mm (min 1; max 6.3), respectively. The COP2L was used for balloon-remodeled coiling exclusively in two aneurysms; coiling and FD stenting in eight; coiling and braided stent delivery in three; coiling, braided and FD stenting in one and for FD stenting without coiling in four (stenting alone). There were three technical complications (3/16, 18.7%), including a perforation and two thromboembolic asymptomatic events that were rapidly controlled with the COP2L. There was no immediate or delayed morbidity or mortality.

Conclusion: According to our initial experience, the COP2L is a new type of dual-lumen balloon catheter that appears to be safe and effective for balloon or stent-assisted coiling of cerebral aneurysms and may be used to optimise stent-wall apposition.

Comparison of lesion detection and image quality between non-EPI diffusion weighted imaging and multi-shot EPI diffusion weighted imaging of cholesteatoma

M. [Wiesmüller](mailto:marco.wiesmueller@uk-erlangen.de), W. Wuest, R. Heiß, M.S. May, M. Uder, F. Laun; Erlangen/DE (marco.wiesmueller@uk-erlangen.de)

Purpose: Recently introduced multi-shot echo planar (MS-EPI) diffusion weighted imaging (DWI) techniques can provide high resolution images with low geometric distortion. Non-echo planar imaging techniques (Non-EPI) are known to have a very high sensitivity and specificity in the diagnosis of cholesteatoma. Our aim was to evaluate the diagnostic performance of a MS-EPI DWI sequence and to compare it with a Non-EPI DWI sequence.

Methods and Materials: We prospectively included 30 patients for examination on a 1.5 T MRI using a dedicated study protocol consisting of a Non-EPI sequence (HASTE, hDWI) and a MS-EPI sequence (readout-segmented sequence, rsDWI). In 25 patients diagnosis of cholesteatoma was histopathologically confirmed. Each dataset was independently evaluated by two radiologists. Sensitivity and specificity were calculated for hDWI and rsDWI. Image quality was rated as overall image quality, presence of artefacts, lesion visibility and subjective diagnostic confidence on five point Likert scales.

Results: Sensitivity and specificity, lesion visibility and subjective diagnostic confidence were significantly higher in hDWI. Presence of artefacts, not affecting the accuracy of diagnosis, was comparable between hDWI and rsDWI. Slightly higher overall image quality was found in rsDWI.

Conclusion: MS-EPI sequences provide high overall image quality and low artefacts. However, non-EPI DWI sequences showed superior diagnostic accuracy for cholesteatomas.

B-0290 14:08

Value of four stage vestibular hydrops grading and asymmetric perilymphatic enhancement in the diagnosis of Ménière's disease on MRI

A. Bernaerts¹, R. Vanspauwen¹, C. Blaivie¹, J. van Dinther¹, A. Zarowski¹, F. Wuyts¹, F.E. Offeciers¹, J.W. Casselman², B. de Foer¹; ¹Antwerp/BE, ²Bruges/BE (Anja.Bernaerts@gza.be)

Purpose: There is still a clinical-radiologic discrepancy in patients with Ménière's disease (MD). Therefore, the purpose of this study was to investigate the reliability of current MRI endolymphatic hydrops (EH) criteria according to Baráth in a larger study population and the clinical utility of new imaging signs such as a supplementary fourth low-grade vestibular EH, the degree of perilymphatic enhancement (PE) and endolymphatic sac enhancement (ESE) in patients with Ménière's disease (MD).

Methods and Materials: This retrospective study included 148 patients with probable or definite MD according to the 2015 Barany criteria who underwent a 4-hour delayed intravenous Gd-enhanced 3D-FLAIR MRI between January 2015 and December 2016. Vestibular EH, vestibular PE, cochlear EH, cochlear PE, and ESE were reviewed twice by 3 experienced readers. Cohen's Kappa and multivariate logistic regression were used for analysis.

Results: The intra- and inter-reader reliability for the grading of vestibular-cochlear EH and PE was excellent ($0.7 < \text{kappa} < 0.9$) except for the ESE ($\text{kappa} 0.5$). The 2 most distinctive characteristics to identify MD are cochlear PE and vestibular EH which combined gave a sensitivity and specificity of 79.5% and 93.6%. By addition of a lower grade vestibular EH, the sensitivity improved to 84.6% without losing specificity (92.3%). Neither ESE, cochlear EH or vestibular PE showed added value.

Conclusion: MRI using vestibular-cochlear EH and PE grading system is a reliable technique. Cochlear PE assessment in combination with a 4-stage vestibular EH grading system gives the best diagnostic accuracy to detect MD.

B-0291 14:16

Teaching temporal bone anatomy CT scan as a psychomotor skill: a quasi-experimental study

S. Sefidbakht¹, B. Bijan², P. Keshavarz¹, M. Amini¹, R. Jalli¹, F. Zarei¹, H.R. Abbasi¹, P. Iranpour¹; ¹Shiraz/IR, ²Sacramento, CA/US (keshavarz.p2390@gmail.com)

Purpose: To present a teaching method for the radiology residents the cross-sectional anatomy of the temporal bone as a psychomotor skill using predetermined points of transition between orthogonal planes as a roadmap.

Methods and Materials: 21 radiology residents entered the study. We provided a teaching scheme based on the Gagne's theory which consisted of 6 steps; gaining attention, informing the learner of the objective, stimulating recall, presenting the stimulus material, providing learning guidance, eliciting performance, providing feedback, assessing performance, enhancing retention and transfer. For the main teaching session, the conceptualization, visualization, verbalization steps of teaching psychomotor skills was employed by guiding the residents systematically using the 3D cursor to move and transit between orthogonal planes for the predetermined anatomical points. The residents were evaluated before and after the training sessions using objective structured clinical examination (OSCE), resident satisfaction and educational goal achievement questionnaires.

Results: Mean age was 27.9 ± 8.6 (range from 26-38) years, 14 (66.6%) men and 7 (33.4%) women. We observed that the OSCE score improved significantly after the twenty-minute session (2.57 ± 1.62 vs. 8.02 ± 2.43 ; $p < 0.001$). Mean resident satisfaction score measured by standardized questionnaires was $7.63 \pm 2.86/10$. Subjectively the residents assessed their ability to identify the anatomical learning objectives after the mini-sessions to have significantly increased (4.33 ± 1.22 vs. 8.27 ± 2.46 ; $p = 0.021$).

Conclusion: Interpretation of cross-sectional images as a psychomotor skill, may be an effective teaching method. Using a standardized approach and defining predetermined transition points moving between orthogonal planes enhances learning.

Ultra-high-resolution CT for temporal bone imaging: a comparison to cone-beam CT

T. Yamashiro, M. Tsubakimoto, Y. Xu, Y. Morita, H. Tomita, S. Murayama; Okinawa/JP (clatsune@yahoo.co.jp)

Purpose: Ultra-high-resolution CT (U-HRCT) scanners, equipped with an advanced detector that receives X-ray signals at 0.25 mm resolution in all three

directions can provide more detailed imaging findings than conventional CT scanners. The purpose of this study was to compare the image quality of U-HRCT scans to cone-beam CT (CBCT) scans for temporal bone imaging.

Methods and Materials: Fifteen subjects (age range, 18-70 years) underwent both U-HRCT and CBCT on different dates to assess various unilateral ear diseases. It was confirmed that no diseases existed in the contralateral (normal) ear. On the axial and coronal views of the U-HRCT scans (pixel size, 0.16 mm; slice thickness, 0.25 mm for axial and 0.16 mm for coronal views) and the CBCT scans (pixel size, 0.13 mm; thickness, 0.5 mm), the image quality of small structures in the normal ear, such as the tendon of the stapedius muscle and the crura of the stapes, were assessed by three radiologists using a 5-point scale. Comparisons of the scores between the U-HRCT and CBCT were made by Wilcoxon matched-pair test.

Results: For all 8 small structures, the scores of the U-HRCT were significantly higher than those of the CBCT ($P < 0.001$). Particularly, the visibility of the crura of the stapes, the chorda tympani, and the tendon of the tensor tympani muscle was significantly better on the U-HRCT than the CBCT.

Conclusion: The U-HRCT can provide more precise anatomical information of small structures in the temporal bone than the CBCT.

Visualisation and image quality of the chorda tympani nerve in temporal bone: comparison with conventional CT and ultra-high-resolution CT

M. Fujiwara¹, Y. Watanabe¹, T. Fujiwara², C. Matsuo², H. Takahashi¹, H. Tanaka², Y. Ohta¹, T. Imai¹, N. Tomiyama²; ¹Osaka/JP, ²Suita/JP (m-fujiwara@radiol.med.osaka-u.ac.jp)

Purpose: The aim of this study was to compare visualization and image quality of the chorda tympani nerve (CTN) between conventional CT (c-CT) and ultra-high-resolution CT (u-HRCT).

Methods and Materials: Retrospective visual assessment of 23 CTNs from consecutive 22 patients who underwent both u-HRCT and c-CT for follow-up. U-HRCT scan was performed by a u-HRCT scanner (Aquilion Precision, Canon Medical Systems, Japan). C-CT was reconstructed separately on the left and the right using the following parameters: FOV120mm, 512 matrix sizes, in-plane resolution 0.23mm, slice thickness 0.50 or 0.625mm, and bone kernel. U-HRCT was also reconstructed separately on one side with FOV120mm, 1024 matrix sizes, in-plane resolution 0.12mm, slice thickness 0.25mm and we used two kinds of kernels (FC80(bone), FC15(soft tissue)). Two neuroradiologists evaluated three portions of CTN (posterior canaliculus, tympanic segment, and anterior canaliculus) and scored them on a 4-point scale (1 = no visible, 4 = entire clearly visible).

Results: The visual score of the posterior portion was 3.4 ± 0.7 with c-CT and 3.9 ± 0.4 , 3.9 ± 0.4 with u-HRCT (FC80 and FC15) and statistically significant difference between c-CT and u-HRCT was observed ($p = 0.044$). The tympanic segment of CTN was 1.7 ± 0.6 with c-CT and 2.6 ± 0.5 , 2.6 ± 0.5 , respectively, with u-HRCT (FC80 and FC15). This segment is significantly more clearly visualized with u-HRCT than c-CT ($p < 0.01$). The anterior portion of CTN was 3.1 ± 0.7 with c-CT and 3.4 ± 0.6 , 3.4 ± 0.6 , respectively, with u-HRCT (FC80 and FC15) and significant difference was also observed ($p = 0.018$).

Conclusion: U-HRCT delineates CTN more clearly than c-CT.

Comparison between high-resolution 3D-REAL-IR and 3D-FLAIR sequences in the assessment of endolymphatic hydrops in 3 Tesla

V.M. Suarez Vega¹, F.M. Caballeros Lam¹, P. Domínguez Echávarri², R. Garcia de Eulate², G. Gallardo Madueno¹, A. Alonso-Burgos¹, C. Sobrido³, B. Alvarez de Sierra¹, N. Perez²; ¹Madrid/ES, ²Pamplona/ES, ³Vigo/ES (proksua1@hotmail.com)

Purpose: Describe the two sequences used in the assessment of endolymphatic hydrops (EH): 3D-REAL-IR and 3D-FLAIR. Compare the sequences in terms of the imaging findings to best determine their application in clinical practice.

Methods and Materials: Fifteen patients (5 females, 10 males) diagnosed of probable or definite Ménière's disease (MD) -according to the Amended 2015 Criteria of the American Academy of Otolaryngology- underwent 3 Tesla MR imaging 4 hours after the intravenous injection of Gadolinium. Items such as affected side's inner ear, hearing loss and/or vertigo were collected. The presence of vestibular and/or cochlear EH was assessed in both 3D-REAL-IR and 3D-FLAIR sequences. A neuroradiologist, blind for the final diagnosis and clinical data, evaluated the images.

Results: All six patients diagnosed with definite MD showed signs of EH in 100% of affected ears and in 4 out of 6 (66%) not affected ears. In the remaining 9 patients with probable MD, 3 of them showed no signs of EH in

any sequence and 3 of them signs of EH only in 3D-REAL-IR sequence. Vestibular EH detection rates were 58,6% in 3D-REAL-IR sequence and 40,7% in 3D-FLAIR sequence, and cochlear EH detection rates were 24% and 11% respectively. In 6 patients both sequences matched the same result, suggesting the 3D-REAL-IR sequence greater degree of severity.

Conclusion: Both sequences are suitable in the assessment of EH. However, 3D-REAL-IR has higher detection rates in both vestibular and cochlear EH. We suggest that 3D-REAL-IR might be superior in the diagnosis of MD.

B-0295 14:48

Measurement of the depth of facial nerve at the level of stylomastoid foramen using MR imaging in Bell's palsy

H. Karaca¹, L. Soydan², F. Baskak², A. Sever², ¹Elazig/TR, ²Istanbul/TR (fulyabaskak@hotmail.com)

Purpose: To investigate whether the depth of the facial nerve from the skin surface as it exits the stylomastoid foramen differs between paralyzed and unaffected sides in patients with Bell's palsy.

Methods and Materials: Forty-three patients (23 females, 20 males; mean age 43.8±15.2 years) diagnosed with Bell's palsy between January 2014 and June 2017 were retrospectively reviewed and those who had a cranial MR imaging performed within 10 days upon admission to hospital were included in the study. The axial postcontrast CUBE sequence was utilized for measurement of the facial nerve depth. Age, gender, and body mass index (BMI) as well as concomitant chronic diseases, were also noted. The severity of facial paralysis was graded using the House-Brackmann (HB) scoring system.

Results: The facial nerve depth was significantly lower on the paralytic side compared to the unaffected side (32.9±5.4 mm vs. 36.9±5.1 mm, respectively; p=0.001). The facial nerve depth on the paralytic side was also lower in female patients than the male patients (31.2±4.6 mm vs. 34.7±5.7 mm, respectively; p=0.03). However, the facial nerve depth on the paralytic side was not correlated with patients' age (r=0.288; p=0.610), BMI (r=0.215, p=0.166), and HB scores (r=0.031; p>0.05).

Conclusion: In study cohort of patients with Bell's palsy, the facial nerve in the paralytic side is located more superficially as it exits the stylomastoid foramen when compared to the contralateral side. Therefore, the depth of facial nerve may potentially play a key role in the etiology of Bell's palsy, which should be further evaluated.

B-0296 14:56

Mastoid pneumatization in children before CI: a risk factor for complications?

I. Burck, M. Goldenko, M.H. Albrecht, A. Lehn, T. Stöver, M. Harth, J.L. Wichmann, B. Kaltenbach, T.J. Vogl; Frankfurt a. Main/DE (iris.burck@kgu.de)

Purpose: To evaluate preoperative mastoid air cells (MAC) pneumatization calculated by 3D-CT volumetry in correlation with complication rate after cochlear implantation (CI) in infants and children.

Methods and Materials: MAC volume of 105 patients (mean age 10.41mo±11.36; 37 female, 41 male) with a total of 186 CI was evaluated by CT-based volumetry. Thresholds were defined to determine 3 different parts of MAC volume: osseous, aerated and soft tissue opacification. 8 groups were classified by varying patient age at CT evaluation: 0-3, 4-6, 7-9, 10-12, 13-24, 25-36, 37-48, 49-60mo. Postsurgical follow-up time was set for 2 years.

Results: 80 patients were evaluated after exclusion of 25 patients because follow-up time was exceeded. Randomized one implanted ear per patient was evaluated. No significant difference was found between right and left MAC volume (p=0.74), as well as between sexes (p=0.30). 12 patients had complications in follow-up. Group 2 (n =40) showed the highest absolute complication rate (n=7). Complications occurred in groups 1, 2 and 7. No significant correlation was seen between volume-impaired MAC and increased complication rate in total (p=0.79). There was no significant correlation between insufficient aerated MAC and complication rate. 17 patients showed opacified MAC, but without significant correlation with increased complication rate (p=0.27). Patient's age at surgery showed significant impact on complication rate (p=0.049), more complications occurred in younger children.

Conclusion: Analysis of preoperative data to identify potential risk factors may reduce post-CI complications. But insufficient MAC pneumatization seems not to be a potential risk factor for complications.

Research software in cochlear duct length estimation, Greenwood frequency mapping and electrode array length selection

A. Dhanasingh; Innsbruck/AT (anandhan.dhanasingh@medel.com)

Purpose: Cochlear size varies among the population bringing the necessity for electrode arrays available in various lengths. This research software helps in the estimation of the patient's cochlear duct length (CDL) which is then used for the selection of the correct length electrode array matching the patient's cochlear size and as well in getting the patient-specific cochlear frequency map.

Methods and Materials: Visual Studio Express 2012 for Windows Desktop is used in the architecture of this research software. The basal turn diameter of the cochlea ("A" value) is retrieved from the pre-operative CT image of the temporal bone. "A" will be taken as the input for the CDL equations proposed by Alexiades et al. for estimating CDL for various insertion depths. Greenwood's equation is used in combination with the CDL for the full length of the cochlea in getting patient-specific frequency map.

Results: This research software with the help of the "A" value as input, with button clicks, provides patient-specific CDL for various insertion depths and Greenwood's frequency map. Users have the choice to select any electrode array of their choice and place it under the frequency map to see how good it fits to that particular patient's cochlea along with the possibility to drag and move electrode array mimicking post-operative actual electrode insertion depth.

Conclusion: This research software simplifies the overall process of CDL estimation and in getting the patient-specific cochlear frequency map.

B-0298 15:12

MRI in unilateral Meniere's disease: the value of post-contrast cochlear perilymph signal intensity

L.M.H. de Pont¹, J. van Steekelenburg¹, A. van Weijnen¹, O.D. Vijlbrief², H.M. Blom¹, S. Hammer¹; ¹The Hague/NL, ²Almelo/NL (l.depont@hagaziekenhuis.nl)

Purpose: Meniere's disease (MD) is characterized by endolymphatic hydrops (EH), although the diagnosis relies on clinical criteria. MR imaging recently became available to detect EH in vivo. However, not all patients with definite MD show EH on MR imaging. The purpose of this study was to evaluate additional value of cochlear perilymph signal intensity ratio (SIR) in patients with suspected MD.

Methods and Materials: 3T MR imaging was performed in patients with definite MD, probable MD and patients with other vertigo-associated inner ear disorders. Delayed contrast-enhanced 3D high-resolution FLAIR images of the inner ear were obtained. SIR was calculated based on ROI measurements in the basal cochlear turn. Data were compared using paired t tests.

Results: 420 ears of definite MD patients, 54 ears of probable MD patients, and 134 ears from patients with other inner ear disorders were included. EH was present in symptomatic ears in 94%, 45% and 6%, respectively. The affected ears in unilateral definite and probable MD showed higher SIR compared with their asymptomatic side (both P<0.001). No significant differences were detected in patients with other inner ear disorders. Six (5%) patients with unilateral definite MD showed no EH on MRI, whereas the SIR was higher in affected ears (P<0.05). In unilateral probable MD, 11 patients (41%) were classified as having no hydrops and showed no significant SIR asymmetry.

Conclusion: Cochlear SIR asymmetry can be used as an additional parameter in discriminating MD from non-MD, which is particularly of value in clinical probable MD.

B-0299 15:20

Double-center study on textural differences between cholesteatoma and middle ear inflammation in non-enhanced high-resolution computed tomography

C.T. Arendt¹, D. Leithner¹, M.E. Mayerhöfer², L. Lengua¹, C. Czerny², I. Burck¹, T.J. Vogl¹, R. Scherthaner²; ¹Frankfurt a. Main/DE, ²Vienna/AT (crt.arendt@gmail.com)

Purpose: To investigate whether radiomic features extracted from non-enhanced CT can be utilized for differentiation between cholesteatoma and middle ear inflammation (MEI), and to compare CT data from two different centers/scanner in that regard.

Methods and Materials: Ninety-five patients (45 with cholesteatoma and 50 with MEI) were included retrospectively. At center A, 45 patients (20 with cholesteatoma, and 25 with MEI) were examined using a 512x512 matrix; whereas at center B, 50 patients (25 with cholesteatoma, and 25 with MEI) were scanned using a 768x768 matrix. Radiomic features (histogram, co-occurrence and run-length matrix, absolute gradient, autoregressive model, Haar wavelet transform) were extracted from axial CT sections using manually defined regions of interest. POE+ACC (probability of error and average correlation) coefficients were used to select subsets of the 10 best radiomic

features for differentiation between cholesteatoma and MEI. Linear discriminant analysis followed by k-nearest neighbor classification (using leave-one-out cross-validation) was used for classification, with histology obtained from surgery specimens serving as the reference standard.

Results: Using pooled data from both centers, only 59/95 cases were correctly classified (accuracy, 62.11%). Separately for data from center A, 31/45 cases (accuracy, 68.9%) were correctly classified, whereas separately for data from center B, 42/50 cases (accuracy, 84.0%) were correctly classified.

Conclusion: Radiomic features extracted from unenhanced CT may be useful for differentiation between cholesteatoma and middle ear inflammation when high-resolution CT data are utilized. Pooling of radiomic data extracted from CT datasets with different resolutions does not appear to be meaningful without further post-processing.

Deep learning reconstruction for calcium scoring reduces radiation dose while maintaining accuracy of Agatston scores

C. Steveson¹, J. Schuzer², T. Acharya³, K. Bronson³, S. Rollison³, W. Bandettini², S. Shanbhag³, M.Y. Chen^{3,1}, Kanagawa/JP,
²Vernon Hills, IL/US, ³Bethesda, MD/US (chloe.steveson@medical.canon)

Purpose: Assessing coronary artery calcium (CAC) is a valuable tool in individualizing cardiac risk assessment. Deep convolutional neural network image reconstruction can reduce image noise and enable radiation dose reductions. The aim of this study is to investigate whether the use of a deep learning reconstruction algorithm allows for reduced radiation dose CAC scanning.

Methods and Materials: With institutional ethics approval, 40 consecutive patients underwent EKG-gated coronary calcium score scans (120kV, 0.275s rotation speed) with 1) standard clinical dose with filtered back projection (FBP) and 2) reduced radiation dose levels with deep learning reconstruction. Agatston score was calculated on a per patient basis using standard techniques and 130 HU threshold and interpreted by 2 independent readers blinded to clinical data and reconstruction techniques. Signal-to-noise was calculated for each reconstruction. Data was analyzed using linear regression.

Results: Patients averaged 63 ± 15 years old, 45% were male, and the median Agatston score was 61.7 (interquartile range 0-315, entire range 0-4121). The median radiation exposure was 93% lower for the reduced (0.05 mSv, interquartile range 0.03-0.08) versus standard dose scans (0.88 mSv, interquartile range 0.63-1.22). There was excellent agreement (R=0.99) between deep learning reconstruction applied to low radiation dose images and standard dose clinical FBP Agatston scores. Signal-to-noise for low dose deep learning images was comparable to standard dose FBP images (2.16 vs. 2.45, respectively).

Conclusion: Deep learning reconstruction in conjunction with 93% radiation reduction has an excellent correlation with standard conventional coronary artery calcium scoring.

Coronary CT angiography derived plaque quantification with artificial intelligence CT fractional flow reserve for the identification of lesion-specific ischaemia

P. von Knebel Doeberitz¹, T. Pannell¹, M. van Assen², M.H. Albrecht³, C.N. De Cecco¹, T. Duguay¹, R.R. Bayer¹, C. Tesche⁴, U.J. Schoepf¹;
¹Charleston, SC/US, ²Groningen/NL, ³Frankfurt a. Main/DE, ⁴Munich/DE (p_knebel@hotmail.de)

Purpose: We sought to investigate the diagnostic performance of coronary CT angiography (cCTA)-derived plaque markers combined with deep machine learning-based fractional flow reserve (CT-FFR) to identify lesion-specific ischaemia using invasive FFR as the reference standard.

Methods and Materials: 84 patients (61±10 years, 65% male) who had undergone cCTA followed by invasive FFR were included in this single-center retrospective, IRB-approved, HIPAA-compliant study. Various plaque markers were derived from cCTA using a semi-automatic software prototype and deep machine-learning based CT-FFR. The discriminatory value of plaque markers and CT-FFR to identify lesion-specific ischaemia on a per-vessel basis was evaluated using invasive FFR as the reference standard.

Results: 103 lesion-containing vessels were investigated. 32 / 103 lesions were haemodynamically significant by invasive FFR. In a multivariate analysis (adjusted for Framingham risk score), the following markers showed predictive value for lesion-specific ischaemia (odds ratio [OR]); lesion length (OR 1.15, p=0.037), non-calcified plaque volume (OR 1.02, p=0.007), Napkin ring sign (OR 5.97, p=0.014), and CT-FFR (OR 0.81, p<0.0001). A receiver-operating characteristics analysis showed the benefit of identifying plaque markers over cCTA stenosis grading alone, with AUCs increasing from 0.61 with ≥50% stenosis to 0.83 with addition of plaque markers to detect lesion-specific ischaemia. Further incremental benefit was realized with the addition of CT-FFR (AUC 0.93).

Conclusion: Coronary CTA-derived plaque markers portend predictive value to identify lesion-specific ischaemia when compared to cCTA stenosis grading alone. The addition of CT-FFR to plaque markers shows incremental discriminatory power.

DeformationNet: unsupervised deep learning co-registration for ventricular segmentation of MR images

B. Norman¹, M. Simonovsky², F. Lau¹, S. Sall¹, D. Golden¹, A. Hsiao³;
¹San Francisco, CA/US, ²Dobris/CZ, ³San Diego, CA/US (berk.norman@arterys.com)

Purpose: We propose a deep learning framework, DeformationNet, which allows for unsupervised image co-registration of perfusion MR images and semi-supervised ventricular segmentation capable of transferring across multiple time points.

Methods and Materials: Using a previously trained ventricular segmentation network that was trained on cine SSFP images, inference is first run on all time points in a perfusion scan. A heuristic based on the inferred segmentation probability maps is then used to select the perfusion image with the "best" target segmentation mask. DeformationNet is trained to predict dense deformation fields (DDF) between two perfusion MR images in order to register the moving image onto a fixed image. The predicted DDFs are then used to warp the best target ventricular segmentation of the moving image onto all other timepoints (the fixed images).

Results: Median Dice values on the test set were 0.855 (IQR values: 0.698-0.899) for LV endo and 0.879 (IQR values: 0.715-0.925) for LV epi. Average computation for calculating the DDFs for an entire perfusion volume was approximately 7 seconds on a Nvidia P100 GPU (compared to traditional iterative co-registration methods which can take in excess of one hour).

Conclusion: We propose DeformationNet, an approach using unsupervised neural networks that can quickly produce deformation fields between new sets of images. These can be leveraged to perform image co-registration and transferring of segmentation masks or anatomical landmarks across multiple image frames. This approach may be faster and more accurate than iterative registration methods and can improve the workflow of perfusion analysis.

Radiomic analysis of coronary CT angiography images can identify invasive and radionuclide imaging markers of coronary plaque vulnerability

M. Kolossvary¹, J. Park², J.-I. Bang², J. Zhang², J. Lee², J. Paeng², T. Kubo³, B.-K. Koo², P. Horvat-Maurovich¹; ¹Budapest/HU, ²Seoul/KR, ³Wakayama/JP (marton.kolossvary@gmail.com)

Purpose: Identification of invasive and radionuclide imaging markers of coronary plaque vulnerability by a single, widely available non-invasive technique may provide the opportunity to identify vulnerable plaques and vulnerable patients in broad populations. Radiomics extracts quantitative metrics from radiological images which describe the heterogeneity and spatial complexity of lesions to create big-data datasets. Our aim was to assess

whether radiomic analysis of coronary CT angiography images outperforms conventional clinical assessment to identify invasive and radionuclide imaging markers of plaque vulnerability.

Methods and Materials: We assessed seven conventional plaque features and 935 radiomic parameters from coronary CT angiography (CTA) images of stable angina patients who in addition underwent sodium fluoride positron emission tomography (NaF¹⁸-PET), intravascular ultrasound (IVUS) and optical coherence tomography (OCT). For diagnostic accuracy, area under the receiver operating characteristics curve (AUC) was calculated using 5-fold cross-validation with 1000 repeats. We calculated the two-sided Wilcoxon signed-rank test to compare the distribution of AUC values resulting from the repeated cross-validations.

Results: In total, we analysed 44 plaques in 25 patients with all modalities. Radiomic analysis of coronary CTA images outperformed conventional qualitative and quantitative metrics to identify attenuated plaque by IVUS; thin-cap fibroatheroma by OCT and metabolically active plaques on NaF¹⁸-PET (AUC: 0.72 vs. 0.59; 0.80 vs. 0.66; 0.87 vs. 0.65; p<0.001 all; respectively).

Conclusion: Radiomic analysis of coronary CTA images identified invasive and radionuclide imaging markers with good to excellent diagnostic accuracy. Radiomic analysis of coronary CTA images may provide an inexpensive, widely available non-invasive solution to identify vulnerable plaques and, therefore, improve cardiovascular risk stratification.

Prediction of the clinical outcome of chest ground glass area using a radiomic approach

N. D'Amico, G. Valbusa, E. Grossi, D. Fazzini, A. Malasevski, F. Rigioli, S. Papa; Milan/IT (NataschaClaudia.D'Amico@cdi.it)

Purpose: The purpose of the study is to analyse chest CT images with a first occasional finding of ground glass (gg) and predict, through a radiomic approach, the evolution of the gg area after at least one year.

Methods and Materials: 79 patients with a first occasional report of gg in chest CT and a CT image acquired after one year were included in the study. Images were acquired on 64-slice dual source CT (Siemens Somatom) with 3 mm slice thickness. A semi-automatic segmentation of the gg areas was carried out by a resident radiologist and controlled by two expert radiologists, using 3DSlicer image analysis software. For every patient, 696 features were extracted and calculated using the IBEX platform. Clinical data, such as age and gender, were added and analysed with a machine learning (ML) algorithm based on an evolutionary optimization to build a prognostic model of the gg areas.

Results: After one year, out of the 79 patients, 19 showed a size increase, and 60 patients were completely negative, i.e. gg areas naturally disappeared (45%) or remained stable (55%). Histological information has confirmed the malignancy of 15 of the 19 suspicious patients. The ML algorithm selected 82 features out of 699 including intensity and texture-based features. A KNN classifier based on the 82 features was identified as the best performing ML approach and showed sensitivity and specificity of 89.4% and 91%, respectively.

Conclusion: This study demonstrated the feasibility to predict clinical evolution of a gg area, with 90% accuracy.

Image quality comparison between iterative reconstruction methods and AI-based reconstruction for CT chest

P. Rogalla¹, B.E. Hoppel², M. Masakazu³, J. Zhou³, C. Farrell¹, S. Kandel⁴; ¹Toronto, ON/CA, ²Delafield, WI/US, ³Vernon Hills, IL/US, ⁴Berlin/DE (Patrik.Rogalla@uhn.ca)

Purpose: To evaluate a new artificial intelligence reconstruction method based on convolutional neural network to improve image quality in thoracic CT compared to two standard of care reconstruction methods, which use iterative reconstruction.

Methods and Materials: Under ethical approval, 48 projection datasets from a lung screening trial (120kV, 50mA, 0.5s rotation time, 0.5°80 collimation; Canon Aquilion Genesis) were reconstructed in 5 series: hybrid-iterative IR (AIDR) and forward-projection based IR (FIRST), both with body and lung settings, and AI. All images were reconstructed with 1 mm slice thickness and presented as 5 on 1 (random order, no image annotation) on a 4K monitor. By using forced ranking, 2 readers evaluated the series in the categories: conspicuity, thoracic noise texture, mediastinum quality, mediastinal texture, artefacts, and overall appeal. Overall image quality was graded on a Likert scale (1=excellent, 10=low quality).

Results: AI reconstruction was overwhelmingly preferred over all other reconstructions by readers in all patients and in all categories (p<0.001) except for artefacts where AI ranked 2nd behind AIDR body with an average rank of AIDR body/AI in was 2.21/1.70 p>0.05. The average overall appeal ranking/Likert score for AIDR body, lung, FIRST body, lung and AI was 3.88/5.71, 3.11/4.84, 4.91/7.04, 2.15/3.56 , 1.00/1.91 respectively, p<0.001. Kappa for forced ranking k=0.90 and Likert score k=0.78.

Conclusion: AI reconstruction shows improved image quality in thoracic CT for lungs and mediastinum when compared to both clinically established iterative methods and may eliminate the need for separate reconstructions for lungs and soft tissues.

Unsupervised machine learning for the identification of CT imaging markers of progression in idiopathic pulmonary fibrosis

J. Pan¹, J. Hofmanner¹, S. Röhrich¹, F. Prayer¹, M. Holzer¹, N. Sverzellati², M. Weber¹, H. Prosch¹, G. Langs¹; ¹Vienna/AT, ²Parma/IT (jeanny.pan@meduniwien.ac.at)

Purpose: To identify imaging markers of progression in chest CT scans of patients with idiopathic pulmonary fibrosis (IPF) and compare the performance of the algorithm to chest radiology experts.

Methods and Materials: 228 chest CT scans of 80 IPF patients were divided into 114 pairs consisting of two examinations of the same patient at different points in time (T1 baseline and T2 follow-up). Non-rigid registration was performed and lungs were segmented automatically. Unsupervised machine learning was used for textural feature extraction and generation of 20 stable lung pattern clusters. Each voxel was assigned to one cluster, volume differences between T1 and T2 were calculated for each cluster. Results were used to train a Random Forest Classifier to predict the sequence of scans. For evaluation leave-one-out cross-validation was performed and global volume fraction change of each cluster per scan was analysed, with a subsequent comparison of two radiologists' performance.

Results: Six out of 20 clusters were identified as predictor of disease progression, used by the classifier to accurately determine the sequence of CT scans in 87 out of 114 pairs (76%). The performance of the classifier was comparable to the expert radiologists (E1: 83% and E2: 67%). The overlap of computational model errors with instances of expert errors were 25.92% (E1) and 66.67% (E2).

Conclusion: By applying an unsupervised machine learning approach, we were able to identify six stable CT-patterns predicting disease progression in patients with IPF. The resulting algorithm showed similar accuracy to two chest radiology experts.

Imaging biomarkers for the differentiation of benign and malignant small solitary pulmonary nodules smaller than 1 cm based on CT texture analysis

J. Ji¹, M. Chen¹, X. Hu¹, W. Ye¹, C. Chen¹, P. Pang², C. Lu¹, Q. Weng¹, H. Wang¹; ¹Lishui/CN, ²Hangzhou/CN (lschrjjs@163.com)

Purpose: To investigate the potential imaging biomarkers for predicting the benign and malignant small pulmonary nodules (PNs) (≤1cm) based on CT texture analysis.

Methods and Materials: 89 PNs (≤1cm) from 89 cases were included, 51 nodules were diagnosed with adenocarcinoma, and 38 had benign PNs diagnosed with inflammation or infections. The AK (Analysis Kit, GE Healthcare) software was used to manually delineate the volume of interest of the lesions and extract a total of 396 quantitative texture parameters. The statistical analysis was performed with R software. The PNs were randomly divided into training set (n=59) and validation set (n=30). All pre-normalized (Z-score) feature values were dimension reduction by LASSO algorithm and selected the most useful features in training set. The selected imaging features were then combined into Rad-score, which was further tested by the ROC curve in training set and validation set.

Results: Four characteristic parameters (ClusterShade_AllDirection_offset4_SD, ShortRunEmphasis_angle45_offset1, Maximum 3DDiameter, SurfaceVolumeRatio) were further selected by LASSO (p<0.05). The above four parameters as a cluster of imaging biomarkers were used to form the Rad-score, the area under the ROC curve in the training set was 0.792 (95% CI: 0.671, 0.913), and the sensitivity and specificity were 86.10% and 65.20%. The area under the ROC curve in the validation set was 72.9% (95% CI: 0.545, 0.913), and the sensitivity and specificity were 86.70% and 60%.

Conclusion: The cluster of imaging biomarkers can reliably predict benign and malignant small solitary pulmonary nodules (PNs) (≤1cm).

Detectability of small coronary calcifications: a comparison between dual-layer and spectral photon-counting CT

N.R. van der Werf¹, M. Vonder², R.W. van Hamersvelt¹, M. Greuter², S.A. Si-Mohamed³, P. Douek⁴, L. Bousse³, T. Leiner¹, M.J. Willemink⁵; ¹Utrecht/NL, ²Groningen/NL, ³Bron/FR, ⁴Lyon/FR, ⁵Menlo Park/NL (nrvdwerf@gmail.com)

Purpose: For spectral photon-counting computed tomography (SPCCT), small detector elements are necessary to reduce pile-up effects, which result in a substantial increase in spatial resolution. We hypothesize that SPCCT will, therefore, improve detectability of small structures, such as small calcifications in the coronary arteries. The objective of this study was to compare detectability of small calcifications between dual-layer computed tomography (DLCT) and SPCCT.

Methods and Materials: A cylindrical phantom containing 100 small cylindrical calcifications (0.5 - 2.0 mm; 90 - 540 mg HA/cm³) was scanned on a clinical DLCT and a prototype SPCCT system. Raw data were acquired at 120 kVp with 147 and 100 mAs for DLCT and SPCCT, respectively, with five repetitions. The smallest available slice thickness was used, 0.67 mm and 0.25 mm for DLCT and SPCCT, respectively. Pixel spacing was 0.49 mm for DLCT and 0.25 mm for SPCCT. Detectability was defined as voxels with ≥ 130 Hounsfield units (HU) in at least three acquisitions using ImageJ.

Results: For SPCCT, 85% of the calcifications were detectable, while only 31% of the calcifications were detected with DLCT. Calcifications measuring 0.5 mm and with a density of ≥ 190 mg HA/cm³ were all visible with SPCCT while the calcifications smaller than 1.0 mm were not detectable with DLCT, independent of their density.

Conclusion: SPCCT is superior in the detection of small calcifications with an increase in detectability of 174% in comparison to DLCT, notably for the calcifications of 0.5 mm with a density of 190 mg HA/cm³ or more.

B-0312 14:08

Stack transition artefact removal (STAR) in cardiac CT with automatic parameter selection

S. Lebedev¹, E. Fournie², K. Stierstorfer², M. Kachelrieß¹; ¹Heidelberg/DE, ²Forchheim/DE (marc.kachelriess@dkfz.de)

Purpose: To remove stack transition artefacts, i.e. misalignments between sub-volumes (stacks), in cardiac CT reconstructions.

Methods and Materials: Phase-correlated reconstructions, e.g. from prospectively/retrospectively gated data, may be affected by stack transition artefacts if the heart is imaged in multiple steps while irregular motion (e.g. cardiac arrhythmia, breathing) is present. The stacks overlap longitudinally by a few mm. However, the consistency in the overlap region may suffer from stack-to-stack heart motion. The redundant information in the overlap region can be used to determine deformation vector fields (DVF) between stacks. We developed a symmetric Demons algorithm that applies deformations symmetrically in both overlapping stacks. The DVF is expanded to non-redundant areas via interpolation. The DVF smoothness is controlled with one parameter. The registration is initially applied with minimal DVF smoothing to estimate the required deformation magnitudes. Based on the latter, a proper smoothing parameter is set, ensuring a realistic DVF that does not introduce distortions. Five retrospectively gated cardiac, patient data sets acquired with a Somatom Definition AS+ (Siemens Healthineers, Forchheim, Germany) and standard partial scan reconstructions were used to evaluate STAR.

Results: STAR considerably improved image quality. Discontinuities, e.g. cuts/breaks in coronary arteries and cardiac valves, were removed or considerably reduced. The automatic parameter selection adjusted the DVF smoothing for individual registrations and overall yielded better results compared to selecting one constant parameter.

Conclusion: STAR is able to consistently remove stack transition artefacts. The adaptive parameter selection prevents the introduction of unnatural distortions, therefore improving the robustness of the new algorithm.

Multi-parametric radiomics in low-dose CT for discrimination between emphysematous and non-emphysematous lung tissue

Y. Nagaraj, M.D. Dorrius, M. Rook, Q. Li, J. Guo, R. Vliegenthart, M. Oudkerk, P.M.A. van Ooijen; Groningen/NL (y.nagaraj@umcg.nl)

Purpose: Emphysema is part of the Chronic Obstructive Pulmonary Disease (COPD) spectrum and known for its high prevalence and mortality rate worldwide. The appearing lung tissue destruction can be detected on Low-Dose Computed Tomography (LDCT) as decreased lung density and architectural changes. However, the latter is difficult to quantify so far. In this study, we evaluated radiomics features using Generalized Matrix Learning Vector Quantization (GMLVQ) to discriminate between emphysema and non-emphysematous lung tissue using a relevance feature ranking classifier.

Methods and Materials: 64 LDCT scans were randomly selected from a large lung cancer screening trial. Independently, three radiologists selected a total of 419 free form Regions of Interest (ROI) from these scans. Every ROI consisted of three consecutive non-overlapping 2D slices. 300 ROIs were classified as emphysematous. ROIs were used to extract radiomics features, which were ranked based on relevance factors from GMLVQ. We used feature selection techniques to decrease redundancy between features before classification.

Results: We extracted 1008 features including Gray-Level Co-Occurrence Matrix (GLCM), Gray-Level Run-length Matrix (GLRL), first order histogram features, shape descriptors and image filters. Relevance feature ranking from GMLVQ, which can be related to pairwise correlations between features, resulted in a maximal area under the curve of 0.95 for discrimination between emphysematous and non-emphysematous lung tissue.

Conclusion: Multi-parametric radiomics with GMLVQ methods can discriminate between lung tissue with and without emphysema. Potentially, it can be a valuable tool for characterization of emphysema.

Evaluation of a novel fully automatic, artificial intelligence-based diameter measurement algorithm for the thoracic aorta

M. Pradella¹, T.J. Weikert¹, S. Rapaka², R. Kärgel³, G. Sommer¹, A.W. Sauter¹, J. Bremerich¹, B. Stieltjes¹, P. Brantner¹; ¹Basel/CH, ²Princeton, NJ/US, ³Forchheim/DE (maurice.pradella@usb.ch)

Purpose: Thoracic aortic dilatation can only be detected by imaging and is an important risk factor for potential dissection/rupture. Manual diameter measurements are time consuming and error prone. We compared the performance of a novel, fully-automatic, artificial intelligence-based radiology assistant (AI-RA) with radiologists' performance.

Methods and Materials: 20 patients with suspected aortic dilatation with ECG-gated, contrast-enhanced CT of the thoracic aorta were analysed retrospectively. Three radiologists (experience: 2, 4.5, 8 years) performed centerline-based measurements of maximum diameters twice at multiple levels according to current ESC guidelines (including aortic sinus (AS), ascending aorta (AA)) using syngo.via (Siemens Healthineers, Germany). Measurement time was recorded. The AI-RA (Siemens Healthineers, Germany) applies multiscale deep reinforcement learning for landmark detection and a deep, convolutional image-to-image network for segmentation. Resulting diameter measurements of the aorta were compared to manual assessment.

Results: Average time for manual full aortic measurement was 4.49min \pm 1.55min. The mean average difference of absolute diameter measurements (radiologists vs. AI-RA) at AS and AA was +2.2mm and -1.4mm, respectively. Standard deviation (SD) of radiologists was \pm 1.6mm (AS) and \pm 1.5mm (AA) and 0.0mm at both locations for AI-RA. Within-subject coefficient of variation (WSV) for radiologists was 5.0-38.0% (AS) and 2.6-17.1% (AA). WSV of the AI-RA measurements was 0%.

Conclusion: The current version of the AI-RA finds plausible diameters comparable to the absolute value and variance range of manual measurements, with neither manual interaction nor introduction of user-based variance. The promising results of this initial study will be fortified in a larger scale study to evaluate solution stability.

Accurate non-invasive assessment of carotid in-stent restenosis by dual-layer spectral CT

I. Leichter, E. Ben-David, J. Menat, A. Peretz, Z. Romman, J.M. Gomori, J. Sosna; *Jerusalem/IL (gomori@cc.huji.ac.il)*

Purpose: Beam-hardening artefacts in CT imaging of metallic carotid stents reduce visibility of plaque. Our aim was to accurately assess, non-invasively, in-stent stenosis, using iodine imaging by spectral-detector CT (SDCT).

Methods and Materials: Virtual mono-energetic images containing iodine solutions were reconstructed at 65keV and 200keV, using SDCT. A spectral map was generated reflecting the relationship between gray-level values of iodine solutions in the two mono-energetic images. An iodine imaging algorithm was developed to mark all pixels fulfilling the spectral map equation and to accurately highlight the contrast-filled lumen. The algorithm was tested on a water-equivalent phantom with plastic tubes containing an iodine solution and surrounded by metallic conichrome stents of 0.2 mm thickness. The tubes of 1.5 mm and 0.75 mm wall thickness mimicked moderate (61%) and mild (34%) in-stent stenosis. The algorithm was used, retrospectively, to quantify restenosis in 2 patients, one with facial numbness, and the other with symptoms of a left CVA.

Results: In conventional images of the phantom, due to beam hardening, mild restenosis could not be visualised, and the moderate restenosis was overestimated by 8%. Iodine imaging demonstrated and quantified the mild and moderate restenosis more accurately with deviations of 5.9% and 0.6%, respectively. In the patient with facial numbness, the algorithm measured a restenosis of 79%. In the other patient, interpreted by a radiologist with moderate stenosis, the measured restenosis was 48%.

Conclusion: Carotid in-stent stenosis in high-attenuation metallic stents can be more accurately evaluated using iodine imaging produced by spectral dual-layer detector CT.

Quantification of metal artefacts in CT imaging: methodological comparison of different techniques and correlation to visual perception

N. Grosse Hokamp¹, B. Eck², J. Holz³, F. Siedek⁴, D. Pinto Dos Santos⁵, D. Maintz¹, S. Haneder¹; ¹Cologne/DE, ²Cleveland, OH/US (nils.grosse-hokamp@uk-koeln.de)

Purpose: Several techniques aiming to reduce metal artefacts in CT imaging (MAR) have been proposed. To quantify MAR, numerous quantification techniques have been suggested (MAR-QT). We compared available MAR-QT to visual perception of artefacts to establish a standard for artefact quantification in CT imaging.

Methods and Materials: 5- and 10-mm Titanium rods were examined in a rectangular water phantom with 25 different scanning and image reconstruction parameters to get a reference database of different types and extents of artefacts. MAR-QT have been identified in the literature, including HU measurements, computation of percent integrity uniformity (PIU) and techniques in the frequency domain (FFT). In total, 38 MAR-QT were implemented in the Matlab environment. To establish a reference ranking, 4 radiologists separately evaluated every image against each other twice using an in-house developed software (2400 comparisons = 2 x 4 readers x 300 comparisons). Rankings were combined to obtain a reference ranking reaching from best to worst image. Intraclass-correlation coefficients (ICC) indicated intra-/inter-reader agreement. The reference ranking was compared to MAR-QT results to identify suited and less suited approaches. Kappa-statistics were used to evaluate agreement between quantitative methods and visual perception.

Results: Intra-/inter-reader agreement of visual artefact perception were excellent (ICC 0.85-0.92). No quantitative method was able to depict the exact ranking of visually perceived artefacts. The methods that showed best correspondence were PIU and FFT based.

Conclusion: Artefact quantification in CT is challenging. We propose two methods that show best correlation with visual artefact perception and suggest using these to allow comparison between studies.

Influence of iterative model reconstruction level for measurement accuracy of the coronary stenosis caused by non-calcified plaques using low-dose CCTA: a phantom study

L. Gao, Y. Hou, Y. Ma, L. Yang, X. Lu; *Shenyang/CN (1242179174@qq.com)*

Purpose: To evaluate the accuracy of low-dose CCTA with different iterative model reconstruction (IMR) levels in quantitative assessment of the coronary stenosis caused by non-calcified plaques using a pulsatile phantom of coronary arteries.

Methods and Materials: A pulsating cardiac phantom mounted with 4 different inter-diameter (2.5, 3.0, 3.5, 4.0 mm) artificial vessels were performed low-dose scan (100 kV, automated tube current modulation; Dose Right Index 13) on 256-slice CT with prospective ECG-gated mode. For each diameter artificial vessels, there were three stenosis degrees (75%, 50% and 25%) with non-calcified plaques (CT value is 20 HU) scanned at heart rate of 60 bpm. For each vessel, the material was arranged ladder like in the iodine-enhanced lumen (350±5 HU in 100 kV) to simulate different stenosis severity. Images were reconstructed with IMR (cardiac-routine IMR-1, IMR-2, IMR-3). The stenosis degree was calculated [1-(luminal stenotic diameter/luminal normal diameter)] and compared with the actual values.

Results: For the measured stenosis degrees of non-calcified plaques, there was statistical difference among different IMR levels and the actual value (P<0.05), and the measured values were smaller than the actual value. The stenosis degree with IMR-1 was closer to the actual value than those with IMR-2 and IMR-3. At the same IMR level, the measured stenosis degrees had no significant difference among different vessel diameters (P>0.05). For severe artery stenosis, the degree of underestimation was larger.

Conclusion: Different IMR levels with low-dose CCTA tend to underestimate stenosis despite of the diameters, IMR level 1 can better estimate the stenosis rate. The severity of the stenosis had a significant effect on the underestimation rate.

B-0316 14:40

Iodine quantification accuracy in dual-source dual-energy CT using default parameters and patient-specific calibrations

S. Dorn, S. Sawall, J. Maier, M. Kachelrieß; *Heidelberg/DE*

Purpose: To evaluate the influence of the relative contrast media ratio (RelCM) on iodine quantification accuracy in dual-source dual-energy CT (DS-DECT).

Methods and Materials: The ratio of high and low iodine contrast is denoted as RelCM and is an input parameter to the standard iodine map algorithm. To evaluate the influence of default vs manual RelCM calibrations on iodine quantification accuracy, two anthropomorphic phantoms (liver, thorax) of three phantom sizes (small, medium, large) are equipped with vials of iodine concentrations between 2.5 and 30 mg/mL and measured with a DS-DECT (SOMATOM Definition Flash, Siemens Healthineers, Germany). Acquisitions are performed using the tube voltage combination 80 kV/140 kV+Sn. A default value for RelCM_{def} of 3.01 is used as preconfigured by the vendor. The patient-specific RelCM_{pat} is obtained by manually placing calibration ROIs inside the vials.

Results: The patient-specific RelCM_{pat} is on average 5.9% (small), 5.0% (medium) and 11.5% (large) smaller compared to RelCM_{def} for both phantoms. Using RelCM_{pat}, the relative error of measured to true iodine concentrations is minimized from 16.9% to 7.4%, 16.8% to 9.9% and 13.7% to 7.6% for the liver phantom and from 7.0% to 2.4%, 6.7% to 4.5% and 8.3% to 2.4% for the thorax phantom. We achieve an accuracy improvement of 64.6%, 50.4% and 60.6% across all concentrations.

Conclusion: Manual calibrations result in a smaller RelCM and also in more accurate iodine concentrations. Therefore, a prior-based automatic calibration might be useful to increase iodine quantification accuracy while keeping manual user interactions at a minimum.

B-0317 14:48

Effect of dose and iterative reconstruction on coronary calcium scores at different heart rates for dual-layer CT

N.R. van der Werf¹, M. Vonder², R.W. van Hamersvelt¹, M.J. Willeminck³, M. Greuter², T. Leiner¹; ¹Utrecht/NL, ²Groningen/NL, ³Menlo Park/NL (nrvdwerf@gmail.com)

Purpose: For a novel dual-layer CT (DLCT) conventional data are acquired by combining the output of both detector layers. The purpose of the current study is to systematically assess the influence of hybrid and model-based IR in combination with radiation dose reduction on coronary calcium score (CCS) in DLCT.

Methods and Materials: In the centre of an anthropomorphic thorax phantom an artificial coronary artery (38.5 mg mgHA - 196±3 mgHA/cm³) was translated (0 to 30 mm/s or 0 to 75 bpm). A routine clinical calcium scoring protocol was used, with three repetitions per HR. Radiation dose was reduced by decreasing mAs by 38% and 75% from the baseline value. Raw data were reconstructed with hybrid iDose (levels 0 to 7) and model-based IMR (levels 1 to 3). CCS was quantified as mean and standard deviation Agatston score (AS).

Results: At reference dose with iDose level 0, AS was 113±9, 105±10, 101±23, and 59±9 for 0 to 75 bpm, respectively. AS increased at decreased radiation dose and decreased for increased HR. For all HR at reference dose, AS decreased up to -17% for iDose, while they increased up to 24% for IMR. At 75%-reduced radiation dose, AS decreased for both iDose and IMR levels.

Conclusion: Application of different types and levels of IR substantially influenced the CCS. Overall, AS decreased with increased IR levels and HR. A trend of increased CCS was found for IMR at reference dose, and reduced CCS at low dose, regardless of HR.

B-0318 14:56

Characterisation of iodine quantification for a fast-kVp switching dual energy CT system

F. [Emiro](#), P. De Marco, D. Origgi; Milan/IT (francesca.emiro@ieo.it)

Purpose: To assess the accuracy of iodine quantification in a GE Discovery 750HD CT.

Methods and Materials: A PMMA CTDI oval phantom (inserts: 1 center-4 periphery), and a homemade phantom with 6 inserts of different diameters (15-to-6 mm) placed in a NEMA IEC PET body phantom filled with water, were used. Phantoms with inserts filled at different iodine Ultravist® concentrations (3.7-7.4-11.1 mg/ml) were scanned at 3 different dose levels (12-21-32 mGy) and images were reconstructed as iodine density maps with FBP and 5 different Iterative Reconstruction levels (ASiR 20-40-60-80-100%) with 2.5 mm slice thickness. For each reconstruction 10 slices were analyzed with ImageJ and statistical analysis was performed with ANOVA.

Results: Iodine concentration measured at the center was significantly lower ($p < 0.05$) than at the periphery (differences ranged from 0.4 to 0.8 mg/ml). Passing from 12 to 21 mGy, iodine quantification was significantly higher: 35%-27%-22%, corresponding to an absolute variation in the range 1.3-2.4 mg/ml, for 3.7-7.4-11.1 mg/ml, respectively ($p < 0.05$). Conversely, no significant differences were observed from 21 to 32 mGy. For all dose and concentration levels, iodine quantification was higher for higher diameters: relative variations were in the range 10-30%, corresponding to absolute variations in the range 0.9-3.3 mg/ml, depending on dose level and iodine concentration. While iodine quantification shows dependence on position, dose and insert's diameter, no impact for the reconstruction choice (Iterative vs FBP) was observed.

Conclusion: Iodine quantification should be assessed carefully in clinical practice, especially in studies that aim to evaluate possible threshold between healthy and pathological tissues.

B-0319 15:04

Does iodine CNR improve when switching from today's energy integrating CT to tomorrow's photon-counting CT?

S. [Sawall](#)¹, S. Dorn¹, J. Maier¹, S. Faby², M. Uhrig¹, H.-P. Schlemmer¹, M. Kachelrieß¹; ¹Heidelberg/DE, ²Forchheim/DE (stefan.sawall@dkfz.de)

Purpose: To measure the iodine contrast-to-noise-ratio (CNR) improvement obtained with whole body photon-counting (PC) CT compared to a conventional energy-integrating (EI) CT detector as a function of patient size and tube voltage.

Methods and Materials: Images of two anthropomorphic phantoms (thorax, liver) of different sizes (small, medium, large) equipped with vials containing different iodine concentrations were acquired at the SOMATOM Count (Siemens Healthineers, Germany) CT system using tube voltages of 80 kV, 100 kV, 120 kV, and 140 kV. CNR is evaluated in reconstructions obtained using the EI detector, the PC detector using a single bin [20, max] keV and in reconstructions obtained by statistically optimally weighting acquisitions with two bins. The bins were equidistantly placed in the spectrum, e.g. [20, 50] keV and [50, 80] keV for a tube voltage of 80 kV. Iodine CNR improvement factors, i.e. CNR of the PC relative to the CNR of the EI measurement, are reported.

Results: In general, iodine improvement factors increase with increasing tube voltage for all patient sizes. In particular, if only one bin is used the improvement is up to 23% (small: 6%-12%, medium: 5%-23%, large: 4%-23%) and up to 37% if an optimal weighting of two bins is performed (small: 9%-16%, medium: 11%-29%, large: 8%-37%).

Conclusion: We find an improved iodine CNR of PC compared to EI. In particular, medium and large sized patient acquired at higher tube voltages benefit from PC and a possible dose reduction.

High concentration contrast medium injection protocol in combination with monochromatic imaging for dose reduction in spectral coronary CT angiography

P. [Liu](#), Y. Wang, Z. Jin, J. Cao, L. Lin, Y. Yi; Beijing/CN (liupeijun_yu@163.com)

Purpose: To evaluate the feasibility of high concentration contrast media (HCCM) combined with monochromatic images to reduce contrast medium dose in CCTA.

Methods and Materials: 56 patients with suspected coronary artery disease were randomly separated into two groups. All patients were scanned with dual-layer detector CT (IQon CT, Philips). Patients were either injected with 18 ml HCCM (400mg/ml) at 2ml/s (group A) or 45 ml contrast medium (370mg/ml)

at 4ml/s (group B). Monoenergetic images (40 to 100 keV with 10 keV increment) were reconstructed for group A, conventional polyenergetic images was reconstructed for group B. Region of interest was placed on aorta root, LM, distant segment of LAD, LCX and RCA to measure the attenuation and noise, SNR and CNR were calculated. Image quality was assessed by two reviewers independently with a 4-point scale.

Results: In group A, the CT Value, SNR and CNR on 40keV were significantly higher than those on other monochromatic images sets and conventional images ($P < 0.01$), which also were superior to group B (738.95±184.70HU vs 408.95 ± 57.92HU; 23.32±7.32vs11.30 ± 2.33 and 29.29±8.00 vs 14.41 ± 2.56) (each $P < 0.01$). In group A, the image noise on 40keV monochromatic images was significantly higher than the other keV set ($P < 0.01$), which also were superior to group B (32.70 ± 6.64 vs 36.96±4.52, $P < 0.05$). The subjective image quality score of 40 keV in group A was better than that in group B ($P < 0.05$). The CTDI, DLP and ED had no significant difference between two groups (each $P > 0.05$).

Conclusion: 40 keV monochromatic images combined with HCCM is feasible in CCTA study.

B-0321 15:20

Optimal iodine CNR in a whole body photon-counting CT scanner

S. [Sawall](#)¹, S. Dorn¹, J. Maier¹, S. Faby², M. Uhrig¹, H.-P. Schlemmer¹, M. Kachelrieß¹; ¹Heidelberg/DE, ²Forchheim/DE (stefan.sawall@dkfz.de)

Purpose: To evaluate the iodine CNR improvements obtained with photon-counting (PC) CT compared to using a conventional energy-integrating (EI) CT detector.

Methods and Materials: Images of two anthropomorphic phantoms (thorax, liver) of different sizes (small, medium, large) equipped with vials containing different iodine concentrations were acquired at the SOMATOM Count (Siemens Healthineers, Germany) CT system, a prototype DSCT scanner housing an EI and a PC detector. mAs-matched acquisitions were performed at 120 kV with effective mAs-values ranging from 75 to 400 mAs using the EI detector, the PC detector with one bin [20, 120] keV, and the PC detector with two bins [20, 70] keV and [70, 120] keV with statistically optimal bin weighting. Image noise and iodine-water contrast is measured and CNR is evaluated.

Results: PC with one bin shows an increased CNR of up to 30% compared to EI (small 19%, medium 30%, large 17%). Comparing the optimally weighted two-bin PC images with EI shows an increased CNR of up to 37% (small 27%, medium 37%, large 25%). In comparison to EI acquisitions, this corresponds to a dose reduction of up to 41% for standard PC acquisitions (small 30%, medium 41%, large 26%) and 47% if an optimal bin weighting is used (small 38%, medium 47%, large 36%).

Conclusion: Iodine CNR using a PC detector is significantly higher compared to measurements acquired with an EI detector. If acquisitions with two energy bins are performed, CNR can be further increased.

Multi-parametric MRI in patients with low-to-moderate risk of prostate cancer for the differentiation of adenocarcinoma and prostatitis

S. Ken, E. [Lacroix](#), D. Portalez, R. Aziza, J. Gilhodes, T. Brun; Toulouse/FR (lacroixemmanuel31@hotmail.fr)

Purpose: To distinguish between biopsy-confirmed prostatic adenocarcinoma (PCa) and prostatitis (PT) with imaging biomarkers derived from multi-parametric MRI.

Methods and Materials: Nineteen patients with low-to-moderate risk of prostate cancer underwent mpMRI on a 1.5T scan. Anatomical T2-weighted, diffusion (11b values 0-800s/mm²) and T1-weighted perfusion series were acquired. Regions of interest (ROI) were contoured on computed b2000 maps and reported on Ktrans, D and ADC modalities. Distributions of voxel values inside the ROIs were compared to contralateral normal-appearing tissue (NT). Volume repartitions according to quartiles were compared between the biopsy-confirmed groups of PCa (N=12) and PT (N=7).

Results: PCa group: median ADC and D parameters (10⁻³mm²/s) inside the ROIs were significantly lower than in the NT: 1.2[0.7-1.6] vs 1.5[1.2-1.7] ($p = 0.0022$) and 1.0[0.6-1.5] vs 1.3[1.0-1.6] ($p = 0.0022$), respectively. Median

voxel intensity of computed b2000 (s/mm^2) was significantly higher: 38.2[31.9-87.1] vs 27.6[18.9-77.8] ($p=0.0037$). Ktrans values were not significantly different between ROIs and NT. PT group: median ADC and D were significantly lower: 1.3[1.0-1.5] vs 1.5[1.2-1.6] ($p=0.0280$) and 1.1[0.8-1.3] vs 1.3[0.9-1.5] ($p=0.0180$), respectively. Median b2000 and Ktrans values were significantly higher inside the ROIs: 46.5[27.3-83.8] vs 38.7[21.6-70.2] ($p=0.0425$) and 0.3[0.1-1.2] vs 0.2[0.1-0.5] ($p=0.0280$), respectively. Volume of ADC values in the 1st-3rd quartiles range was significantly lower in the PCa group compared to the PT group: 0.1%[0.0-0.4] vs 0.3%[0.1-0.4] ($p=0.0312$). Volume of low Ktrans (<1st quartile) was significantly higher in the PCa group: 0.3%[0.1-0.5] vs 0.1%[0.0-0.2] ($p=0.0075$).

Conclusion: Percentage volume distribution of ADC and Ktrans was able to distinguish between adenocarcinoma and prostatitis.

B-0323 14:08

Prostate cancer and benign tissue response to hypofractionated SBRT monitored by multi-parametric MRI

M.J. Zelefsky, K. Zakian, A.G. Wibmer, N. Tyagi, M. Kollmeier, M. Hunt, E. Sala, H. Mejias Vargas; *New York, NY/US (zelefskm@mskcc.org)*

Purpose: To explore the role of serial mp-MRI for evaluation of tumour response after stereotactic radiosurgery (SBRT) for localized prostate cancer (PC).

Methods and Materials: 30 patients with organ-confined PC with dominant lesions ≥ 0.5 cm on MRI were enrolled on a prospective IRB-approved study. All patients received 40 Gy in 5 fractions of SBRT. A baseline MRI was performed and post-treatment MRIs at 3, 6, 12, 18 and 24 months. At 24 months a repeat prostate biopsy was performed to assess local control and correlate with imaging response. A 3.0 Tesla Philips Ingenia was used with a MRI protocol using standard anatomical T₁ and T₂-weighted imaging as well as DCE MRI multi-b-value diffusion-weighted imaging for additional quantitative imaging. Tumour Region of Interest (ROI) identification was obtained by two GU expert radiologists who contoured tumour, peripheral zone, transition zone (TZ).

Results: In all cases perfusion and diffusion-related parameters changed with time and tended to converge with benign tissue values no later than at 12 months. On T2-weighted images the dominant nodule demonstrated significant tumour shrinkage by 3 months and disappearance in >90% of cases by 6 months. Diffusion coefficients significantly decreased post-SBRT providing earlier information than the post-treatment PSA status which continued to decline during the 2-year post-treatment period.

Conclusion: mp-MRI assessment after SBRT demonstrated significant tumour responses at 3 months after treatment far earlier than standard assessment tools such as PSA. Longer follow up will be needed to determine whether MRI initial responses could predict long-term local treatment failures.

B-0324 14:16

Evaluation of dynamic contrast enhancement in PIRADSV2: a report from the Gothenburg 2 screening study for prostate cancer

J. Wallström, K. Geterud, K. Kohestani, R. Godtman, A. Socratous, M. Hellström, J. Hugosson; *Göteborg/SE (jonas@wallstromdiagnostik.se)*

Purpose: In the prostate imaging reporting and data system (PIRADSV2) dynamic contrast enhancement (DCE) has the limited role of upgrading peripheral zone lesions from PIRADS 3 to PIRADS 4 in case of positive DCE. The effect of applying or omitting the upgrading is assessed for PIRADS 3-5 in the Gothenburg2 screening study for prostate cancer (PC).

Methods and Materials: The Gothenburg 2 is a long term study inviting 40000 men to PSA-testing followed by multiparametric prostate MRI at 3T in case of elevated PSA. MRI:s from 1,010 men were prospectively classified according to PIRADSV2. All men with PIRADS 3-5 had prostate biopsies. The detection rates of all tumors and Gleason score (GS) ≥ 7 tumors respectively were calculated for PIRADS 3-5 and PIRADS 4-5 with and without DCE-upgrading.

Results: A total of 371 MRI:s were scored PIRADS 3-5 with positive biopsies in 188 men (51%) including 85 GS ≥ 7 tumors (23%). With DCE-upgrading 262 men were scored PIRADS 4-5 and 162 of these had positive biopsies (62%) including 79 GS ≥ 7 -tumors (30%). Omitting DCE-upgrading a total of 190 MRI:s were scored PIRADS 4-5 and out of these 128 men had positive biopsies (67%) including 73 GS ≥ 7 -tumors (38%).

Conclusion: Applying the PIRADSV2 criteria for DCE resulted in a lesser proportion of GS ≥ 7 PC in PIRADS 4-5 but a slightly higher total number of GS ≥ 7 tumors. With DCE-upgrading and a biopsy indication cut off at PIRADS 4 the number of biopsies would be reduced by 29% however missing 7 % of GS ≥ 7 tumors.

B-0325 14:24

Predicting clinically significant prostate cancer of the transition zone using multiparametric MRI and quantitative radiomic analysis

M. Pecoraro, S. Cipollari, R. Campa, G. Barchetti, C. Catalano, V. Panebianco; *Rome/IT (pecoraro.martina1@gmail.com)*

Purpose: To implement a quantitative radiomic approach to develop a machine learning classifier based on multiparametric MRI (mpMRI) images of the prostate, capable of distinguishing clinically significant and non-clinically significant prostate cancer (PCa) of the transition zone.

Methods and Materials: Ninety-two patients with elevated PSA who underwent mpMRI were included in the study. Inclusion criteria were: PI-RADS score assessment of 3 or higher for lesions within the transition zone, a subsequent TRUS-MRI targeted fusion biopsy and no prostate biopsies or interventions in the previous 6 months. Lesions within the transition zone were manually segmented by a trained urogenital radiologist on the T2-weighted images and on the ADC maps using 3D Slicer, yielding a Volume of Interest (VOI) for each lesion. A radiomic approach was implemented in Python to extract features from the VOIs that correlated with the presence of histologically-proven clinically significant PCa. Extracted features were then selected on univariate analysis and subsequently fed to a machine learning random forest classifier using the R statistical software package. Statistical analyses, including sensitivity, specificity, accuracy and ROC analysis, were performed on the trained classifier.

Results: Of the 92 patients 39 (42%) were positive for clinically significant PCa at histopathology. Radiomic analysis calculated 368 quantitative features for each VOIs. A predictive model using the features selected on univariate analysis achieved a sensitivity of 0.74, specificity of 0.68 and overall accuracy of 0.71.

Conclusion: The machine learning classifier based on mpMRI radiomic analysis showed higher accuracy than radiologist assessment in detecting clinically significant PCa.

B-0326 14:32

Radiological prediction of the chance of post-RALP urinary continence on preoperative MR prostate imaging can substantially alter patients' choice of treatment

S. Heijmink, E. van Muilekom, C. Tillier, N. Grivas, H. van der Poel; *Amsterdam/NL (sweheijmink@live.com)*

Purpose: Prostate cancer patients are often presented with treatment choices that are equal in oncological outcome but different considerably in morbidity, such as the risk of post-treatment urinary incontinence. The purpose of the study was to examine the influence of the preoperative radiological assessment of the chance of urinary continence after robot-assisted laparoscopic radical prostatectomy (RARP) by means of MRI on the patients' choice of treatment.

Methods and Materials: Prospectively, a total of 65 patients with prostate cancer that had preoperative MRI and were referred for RARP were included in the study. In all patients the membranous urethral length and interlevator distance were prospectively assessed. From this, the chance of urinary continence after RARP (continence prediction, Cpred) could be estimated by a previously published prediction model (Grivas et al. *Neurourol and Urodyn* 2018). Patients were subsequently counselled about the surgery and the predicted chance of continence was presented to them. Their final treatment decision was recorded.

Results: Of the 65 patients, 14 (21%) decided to change their preferred choice of treatment from RARP and instead opted for radiation therapy. The average Cpred for the patients that kept RARP with their preferred treatment and those that changed their preferred treatment into radiation therapy was 63% and 42%, respectively ($p=0.02$).

Conclusion: The patients' choice of whether or not to undergo RARP for prostate cancer appeared to be influenced by the predicted chance of urinary continence based on preoperative MRI. This tool may aid patients in better treatment decision making and avoid morbidity.

B-0327 14:40

Value of dynamic contrast enhanced (DCE) MR imaging in PI-RADS 4 patients

L. Schimmöller, F. Ziaee, T. Ullrich, N. Laqua, G. Antoch, P. Albers, C. Arsov; *Düsseldorf/DE*

Purpose: To assess the impact of dynamic contrast-enhanced imaging (DCE) in mp-MRI on prostate cancer (PCa) detection in a large patient cohort assigned to PI-RADS category 4.

Methods and Materials: This prospective, single centre cohort study includes 193 consecutive patients with PI-RADS assessment category 4 after mp-MRI (T2WI, DWI, DCE) at 3T with targeted and systematic biopsy as reference standard. Prostate cancer detection rates were compared either in a multiparametric setting or without the effect of DCE in a biparametric setting.

Results: PCa detection rate was 62% (119/193) including 48% (92/193) clinically significant PCa (csPCa; Gleason score $\geq 3+4=7$). 38 of these 193 patients (20%) had peripheral lesions upgraded from DWI PI-RADS category 3 to an overall PI-RADS category 4 due to positive DCE findings. Of these 38 patients 18 had PCa including 14 with a GS ≥ 7 . Thus 15% (18/119) of the patients with any cancer and 15% (14/92) of the patients with a GS ≥ 7 PCa were detected only based on additional DCE Information.

Conclusion: DCE allows detection of a significant number of mostly csPCa that would have been missed with a biparametric protocol. The current PI-RADS decision rules regarding upgrading PI-RADS-3-lesions to overall category 4 due to positive DCE imaging are useful for PCa detection.

B-0328 14:48

Evaluation of periprostatic neurovascular fibres before and after radical prostatectomy by means of 1.5 T MRI diffusion tensor imaging

V. Di Paola¹, L. Russo¹, M. Miccò¹, M. Sbarra¹, R. Pozzi Mucelli², R. Manfredi¹, ¹Rome/IT, ²Verona/IT (lucarusso.md@gmail.com)

Purpose: To evaluate if diffusion tensor imaging (DTI) is able to detect changes of periprostatic neurovascular fibres (PNFs) before and after radical prostatectomy (RP), and their relationship with post-surgical urinary incontinence and erectile dysfunction.

Methods and Materials: 22 patients (mean age 62.6 years) with biopsy-proven prostate cancer underwent 1.5T DTI before and after RP. The number, fractional anisotropy (FA) values and length of PNFs before and after RP were compared using Student's t-test. Each patient filled out two questionnaires before and after RP, one for the evaluation of urinary continence (ICIQ-SF) and one for the evaluation of erectile function (IIEF-5). The number ratios, FA values and length of PNFs before and after RP (DTI B-A RATIOS) and ratios between scores obtained before and after RP for both ICIQ-SF and IIEF-2 (ICIQ-SF B-A RATIOS and IIEF-2 B-A RATIOS) were calculated to perform Kendall's τ -test between them.

Results: There was statistically significant decrease of the number of PNFs after RP at base, midgland, and apex ($p < 0.01$) and of FA values at midgland ($p < 0.05$), with positive statistically significant correlation between the DTI B-A RATIOS of the number of PNFs and IIEF-2 B-A RATIOS ($p < 0.05$, $\rho = 0.47$).

Conclusion: DTI was able to detect that the decrease of the number of the PNFs after RP was statistically related to post-surgical erectile dysfunction ($p < 0.05$). This study demonstrates that 1.5T MRI DTI is a reproducible technique in detecting the changes of the PNFs induced by RP, with high interobserver agreement.

B-0329 14:56

Calculation of total kidney volume (TKV) in autosomal dominant polycystic kidney disease (ADPKD): comparison of 3 different methods

S. Paolicelli¹, R. Virelli², L. Coi¹, S. Matino¹, M. Telegrafo³, A. Stabile Ianora¹, L. Gesualdo¹, V. Bevilacqua¹, M. Moschetta¹, ¹Bari/IT, ²Matera/IT, ³Triggiano/IT (simonapaolicelli@gmail.com)

Purpose: TKV in ADPKD represents an important biomarkers of disease progression, consequently its correct measurement is crucial. The aim of our study is to compare 3 methods of measuring TKV using MR images to identify the most efficient one. -mTKV: manual method. Kidney's contour was manually traced by free-hand on all slices and then the sum of the values of the respective each slice area is multiplied by the slice thickness used. -TKVel: ellipsoid method. TKV was estimated using the ellipsoid formula (Vol = Length x Width x Depth x $\pi / 6$). -TKV3D: three-dimensional method. TKV is computed using a software that allows automatic calculation of renal volume (VitreaFX software).

Methods and Materials: 50 patients with ADPKD underwent MR examination and obtained a series of images according to axial and coronal planes acquisition. The TKV was calculated using mTKV, TKVel and TKV3D by 2 radiologists. Accuracy, time required, inter- and intra- rater agreement were evaluated comparing different methods.

Results: TKV3D method is very reliable if compared with TKVel (RMSE%= 4,1%vs14,2%), showed excellent inter (CV= 1,7% and 2,2% vs 7,8% and 6,4%) and intra (CV= 2,6%vs14,2%) rater agreement with a time required only slightly greater (7 min vs 4 min).

Conclusion: The use of the Vitrea FX software for the measurement of TKV represents a good alternative to the ellipsoid method because, even if the time required is only slightly higher, it should be preferred for its reliability and less variability between the two operators.

B-0330 15:04

Development of a CT diagnostic prediction model for diagnosis of pyonephrosis

L.H.Q. Chin, K.H. Lee, H. Ng, M. Cheung, Y.L. Li, H.T. Lau, D. Tse; Hong Kong/HK (chin.leanne@gmail.com)

Purpose: Pyonephrosis is a urological emergency necessitating prompt recognition and intervention. Often clinically nonspecific especially in elderly or

immunocompromised patients, mimickers such as pyelonephritis with non-obstructive hydronephrosis also have overlapping features on computed tomographic (CT) imaging. We aim to develop a CT scoring system to diagnose pyonephrosis accurately.

Methods and Materials: This is a retrospective review of 63 patients (22 diseases, 41 controls) who underwent CT within 1 week prior to percutaneous nephrostomy (PCN) from 2008-2015. Imaging parameters included attenuation of renal pelvis and parenchyma (HU), pelvic wall thickness, perinephric strand extent, perinephric strands and renal fascia thicknesses, obstructing stone, fluid-debris level and degree of hydronephrosis. Scores were validated with 42 patients (18 diseases, 24 control) requiring PCN from 2016-2018. Independent predictors defined using multivariate binary logistic regression for development of scoring system and Youden's index (J) for cut-off.

Results: Pelvic wall thickness, renal fascia thickness, attenuation of pelvic content and parenchyma were significant independent predictors and selected for scoring system 0 to 13 (pelvic wall thickness: 4 points; parenchymal attenuation >30HU: 4 points; pelvic content attenuation >15HU: 2 points; renal fascia thickness >3mm: 3 points.) Receiver operating characteristic (ROC) analysis revealed area under curve (AUC) 0.87 (95% CI, 0.77-0.98). Scores 6 or lower had 82.6% (95% CI 66.2-92.0%) negative predictive value (NPV), and score 7 or higher had 73.7% (95% CI 55.27-86.4%) positive predictive value in diagnosing pyonephrosis.

Conclusion: Combined CT imaging parameters can be used to distinguish pyonephrosis from mimickers, facilitating patient triage for emergency intervention.

B-0331 15:12

Correlation between single-kidney glomerular filtration rate (GFR) with ultra-low-dose CT perfusion and 99mTc-DTPA renal scan in healthy and tumour-bearing kidney

F. Wang, Q. Wang; Jinan/CN (200062001264@sdu.edu.cn)

Purpose: To validate a method for calculating single-kidney GFR based on ultra-low-dose renal volume perfusion CT (VPCT).

Methods and Materials: Thirteen patients with unilateral renal tumour were scanned for VPCT, using a MDCT. The dynamic perfusion scan of the whole kidney was initiated with a 5-s delay after contrast agent was given intravenously, consisting of 36 acquisitions with a total scan time of 117s. For 0-30s, 30-90s, and 90-117s, the acquisition interval was 1.5s, 4.5s and 9s, respectively, with tube voltage 80 kVp and current 70 mAs. CT-GFR=Vol(excr) \times HU(excr)-Vol(precontrast) \times HU(precontrast), then divided by (area under aortic TDC), then multiplied by (1-hematocrit). The single-kidney CT-GFR and 99mTc-DTPA-GFR were compared with paired t test and Pearson correlation analysis was performed. Renal function is classified as normal, mild, moderate and severe impairment in two groups and agreement was evaluated by kappa test.

Results: There was no statistically significant difference between CT-GFR and 99Tcm-DTPA-GFR ($t = -1.533$, $P = 0.151$; $t = -1.791$, $P = 0.099$; $z = -0.33$, $P = 0.741$) in 13 tumour-bearing kidneys, 13 healthy and all 26 kidneys. Between two groups, a moderate correlation ($r = 0.402$, $P = 0.324$) in 13 healthy kidneys and strong correlation ($r = 0.790$, $P = 0.062$; $r = 0.614$, $P = 0.019$) in 13 tumour-bearing and all 26 kidneys were found. CT-GFR and 99Tcm-DTPA-GFR were normal in 18 kidneys, of moderate impairment in 1 kidney, mild impairment in 5 and 4 kidneys, respectively, and 99Tcm-DTPA-GFR was severe impairment in 1 kidney. A fair agreement was revealed between two groups ($k = 0.49$). Effective radiation dose of CT-GFR was only 14.17 \pm 0 mSv.

Conclusion: CT-GFR bears the potential as a functional assessment tool in kidney, especially in tumour-bearing kidney.

B-0332 15:20

CT urography for examining the upper urinary tract in case of haematuria: time to reconsider?

E. Rud, T. Flatabø, E. Baco, G. Sandbækk; Oslo/NO (erik.rud@ous-hf.no)

Purpose: Three-phase CT urography (CTU) is the gold standard for evaluating the upper urinary tract in patients with haematuria. The aim of this study was to evaluate the detection rate of upper urinary tract cancer, and second to determine the visibility of tumour on each phase constituting a CTU.

Methods and Materials: This quality control analysis included all patients referred to CTU after a negative cystoscopy during 2016 and 2017. The CTU results were dichotomized as negative or positive and follow up biopsy results were used as reference standard. Two reviewers retrospectively evaluated the tumour visibility of each CT sequence.

Results: Three hundred and seventy-six CTUs were performed in 376 patients with haematuria after a negative cystoscopy. The mean age was 62 years (95% CI: 60-64, range 18-96), 67% (253) were males and 33% (123) were females. Macroscopic and microscopic haematuria occurred in 87% (327) and 13% (49), respectively. Eleven cases of upper urinary tract cancer were detected in 10 patients (2.7%), all found in patients with macroscopic haematuria. Transitional cell carcinomas were found in the renal pelvis and ureter in three (0.8%) and four (1.1%) patients, respectively. Renal cell

carcinomas were detected in four patients (1.1%). All cases of upper urinary tract cancer were visible on the nephrographic phase for both reviewers.

Conclusion: The prevalence of upper urinary tract cancer in patients with haematuria is low, and all cases were seen on the nephrographic phase. This suggests that the CTU protocol may be simplified without reducing the diagnostic accuracy.

Imaging follow-up in patients with biliary atresia after Kasai portoenterostomy

R. Cuocolo, M. Caruso, F. Di Dato, C. Mollica, V. Romeo, G. Vallone, M. Petretta, R. Iorio, S. Maurea; *Naples/IT (renato.cuocolo@gmail.com)*

Purpose: Biliary atresia (BA) is a congenital, progressive fibro-obliteration of the biliary tree, usually treated surgically with Kasai porto-enterostomy (KP). Clinical status and laboratory values influence patient long-term prognosis; furthermore, prognostic value of patient age at time of KP is currently debated. Aim of our study was assessing imaging findings at follow-up ultrasound (US) and magnetic resonance (MRI) in relation to clinically expected patient prognosis and age at the time of KP.

Methods and Materials: Retrospectively, 25 patients treated for BA with KP with post-operative US and MRI exams were enrolled, divided into two groups based on clinical and laboratory parameters which correlated with a better (group A, n=15) or worse expected prognosis (group B, n=10). Uni- and multi-variate statistical analyses were used to evaluate imaging findings in both groups and in relation to the age of each patient at the time of KP.

Results: Splenomegaly and enlarged portal vein diameter, on US and MRI, as well as irregular hepatic margins on US were significant ($p < 0.05$) predictors of clinical prognostic grouping. At multi-variate analysis, splenomegaly resulted the only significant variable. None of the imaging parameters was significantly different in relation to patient age at the time of KP.

Conclusion: Imaging follow-up by US and/or MRI may contribute to assess BA patients treated with KP in agreement with the clinical outcome status; conversely, patient age at the time of KP did not influence clinical outcome status nor imaging findings, suggesting a limited value of this prognostic parameter.

B-0334 14:08

Usefulness of mono-, bi-, and stretched-exponential model diffusion-weighted imaging for the differentiation of biliary atresia and non-biliary atresia in liver MRI

J. Kim, M.-J. Kim, M.-J. Lee, H. Yoon, H. Shin; *Seoul/KR (jisoo0714@yuhs.ac)*

Purpose: To know the usefulness of mono-, bi-, and stretched-exponential diffusion-weighted imaging (DWI) for the differentiation of biliary atresia (BA) from non-BA in liver MRI.

Methods and Materials: Patients, who underwent liver MRI with suspicion of BA from November 2017 to September 2018, were retrospectively included and divided as BA and non-BA groups. Liver MRI included DWI using 10 b values at 1.5T. Free-hand ROIs were drawn in the two representative axial images. From mono-exponential model, apparent diffusion coefficient1 (ADC1) using 10 b values and ADC2 using two b values (0, 800s/mm²) were obtained. From bi-exponential model, true diffusion coefficient (D), pseudo-diffusion coefficient (D*), and perfusion fraction (f) were obtained. From stretched-exponential model, distributed diffusion coefficient (DDC) and diffusion heterogeneity index (α) were obtained. Parameters were compared between two groups and diagnostic performances were assessed.

Results: Among total 17 patients (BA=12, non-BA=5), ADC1, ADC2, D*, f, and DDC values were significantly lower and α value was significantly higher in BA group. The diagnostic performance of all parameters except for D* and α values was good to excellent and area-under-the-curve (AUC) value of ADC2 was 0.925 (95% confidence interval 0.781-0.987).

Conclusion: Children with BA had significantly lower ADC1, ADC2, D*, f, DDC values and higher α values in the liver than in non-BA group. ADC value obtained with two b-values could sufficiently aid the differentiation of BA and non-BA with excellent diagnostic performance.

B-0335 14:16

Technical failure of echo-planar imaging MR elastography in paediatric liver

J.-K. Kim, M.-J. Kim, H. Yoon, M.-J. Lee, K. Han, H.-J. Shin; *Seoul/KR (kyem88@yuhs.ac)*

Purpose: The purpose of this study was to assess the factors influencing technical failure of echo-planar imaging (EPI) MR elastography (MRE) in the paediatric liver.

Methods and Materials: In this retrospective study, 240 patients (≤ 20 years old) who underwent EPI MRE at 3-T system from April 2015 to November 2017 were included. Failure group was defined as no pixel value on elastogram map with a confidence index higher than 95%. Fat fraction and T2* values obtained from 3D volumetric multi-echo gradient sequence MRI were compared between success and failure groups. Logistic regression test using unbiased odds ratio from Firth's penalized maximum likelihood estimation method and ROC curves were obtained to analyse the potential predictive factors for EPI MRE failure.

Results: Technical failure rate of EPI MRE in paediatric liver was 2.5% (6 of 240). MR fat fraction and T2* value were significantly lower in the failure group ($p < 0.05$). In logistic regression analysis using unbiased odds ratio (OR), decreased T2* value was the only independent factor influencing MRE failure (adjusted OR 0.758, 95% confidence interval 0.650, 0.883). Using ROC curve analysis, T2* value equal to or less than 3.8 msec showed 100% sensitivity and specificity for predicting EPI MRE failure.

Conclusion: Technical failure rate of EPI MRE in paediatric liver was low (2.5%). T2* value (≤ 3.8 msec) was the only independent factor associated with failure of EPI MRE in paediatric liver. Increased body mass index or severe fatty liver was not associated with technical EPI MRE failure.

B-0336 14:24

Diagnostic value of ultrasound in paediatric veno-occlusive disease (VOD) after HSCT using the European Society for Blood and Marrow Transplantation (EBMT) criteria

S. Im, H. Chung, S. Kim, H. Park; *Seoul/KR (fllsm@hanmail.com)*

Purpose: The EBMT has recently announced new diagnostic criteria for paediatric VOD after HSCT. We compared the diagnostic value of US in VOD using Seattle criteria and EBMT criteria.

Methods and Materials: Ninety-six US exams of 61 paediatric patients who had grey-scale and Doppler US within 60 days of HSCT were studied retrospectively. Diagnosis of VOD was done clinically in both Seattle criteria and EBMT criteria. Portal vein velocity (PVV), peak systolic velocity (PSV) of hepatic artery (HA), resistance index (RI) of HA, hepatic vein waveform, gallbladder wall thickening, periportal edema, splenomegaly and ascites were recorded and their relationship with VOD was analysed. A scoring system was developed, appointing two points for PVV < 10 cm/s and one point for each of PSV of HA > 90 cm/s, RI of HA > 0.75 , GB wall thickening > 4 mm, and presence of ascites.

Results: The incidence of VOD was 44.3% (27/61) in Seattle criteria and 59.0% (36/61) in EBMT criteria, with all the 9 additionally diagnosed patients in EBMT grade 3 or 4. Five of them had late-onset VOD. In both criteria, non-VOD and VOD group showed significant difference in PVV, PSV of HA, gallbladder wall thickening and ascites. All patients with PVV less than 10 cm/s were in EBMT grade 3/4. The scoring system showed slightly better performance in EBMT criteria, with slightly better AUC (0.78 vs. 0.74), specificity (74.2% vs. 69.8%) and PPV (85.2% vs. 74.1%).

Conclusion: Grey-scale and Doppler US is useful in diagnosing paediatric VOD in the new EBMT criteria.

B-0337 14:32

Comparison of suprapubic vs. transurethral bladder access in voiding cystourethrography

W. Schlötelburg, M. Kriedemann, C. Wirth, T.A. Bley, S. Veldhoen; *Würzburg/DE (schloetelb_w@ukw.de)*

Purpose: To compare suprapubic access (SPA) versus transurethral catheterization (TUC) in voiding cystourethrography (VCUG) in paediatric male patients.

Methods and Materials: Within a 5-year period 311 VCUG performed in male patients under 12 years of age were retrospectively analysed regarding bladder access method, procedural switch rate, complication rates, radiation parameters and examination quality. TUC was performed in 213 patients (mean age, 1.45 \pm 2.35yrs), 98 received SPA (2.46 \pm 3.12yrs). Complication rates were graded in minor (prevesical contrast leakage, premature termination of the examination) and major complications (fever, UTI). Examination quality was assessed based on satisfactory acquisition of fluoroscopic images using a four-point Likert scale: perfect (AP bladder projections with low and maximum filling, AP abdominal projections before and after micturition, dynamic lateral voiding phase projection) good (single missing AP projection), moderate (two missing AP projections) and inadequate (missing lateral voiding phase).

Results: In 4% of all SPA examinations a method switch to TUC was necessary. Minor complication rate was 1.8% for TUC and 33.7% for SPA ($p < 0.001$). Major complication rate was 0.9% for TUC and 2% for SPA ($p = 0.79$). Mean fluoroscopy time and mean radiation dose were significantly lower in TUC (TUC, 26 ± 19 s / 0.06 ± 0.12 mGy / cm²; SPA, 38 ± 33 s / 0.17 ± 0.29 mGy / cm²; $p = 0.01/0.001$). There was no significant difference regarding the contrast media amount needed (TUC, 62 ± 40 ml; SPA, 66 ± 41 ml; $p = 0.32$). Regarding the examination quality, there was no significant difference in the two groups ($p = 0.95$): Full diagnostic quality was achieved in 88% of TUC and SPA examinations.

Conclusion: TUC allows for significantly lower rates of radiation exposure and periprocedural complications.

B-0338 14:40

Evaluation of the split-bolus single-pass contrast CT protocol in paediatric trauma

T. Melis¹, B. Gottfriedova¹, R. Bruna¹, M.J. Willemink², M. Koci²; ¹Prague/CZ, ²Stanford, CA/US (tomas.melis@fnmotol.cz)

Purpose: The Royal College of Radiologists (RCR) recommends a split-bolus single-pass CT-protocol for evaluation of paediatric trauma. Due to the current lack of data, we assess the feasibility of our adaptation of so-called "Camp bastion" protocol.

Methods and Materials: We retrospectively included 102 paediatric trauma-patients who underwent a split-bolus single-pass trauma-CT between February 2016 and August 2018. Contrast-enhancement was measured in the aorta, portal vein, pulmonary trunk, and spleen. Attenuation, contrast-to-noise ratios (CNR) and subjective evaluation of spleen-enhancement homogeneity were compared among four weight groups with 20 kg increments (W1-W4, respectively).

Results: Median aortic attenuation was significantly higher ($p < 0.05$) in low weight-groups of 0-20kg (441[291-535] Hounsfield units (HU)) and 21-40kg (277[222-313] HU) compared to the high weight-groups of 41-60kg (182[151-247] HU) and 61-80kg (191[153-229] HU). Similar results were found for portal vein (W1-W4: 285[249-361]; 236[208-263]; 203[163-217]; 196[175-230] HU), and pulmonary trunk (W1-W4 388[262-581]; 250[229-330]; 180[158-225]; 173[153-210] HU, respectively. Sufficient aortic enhancement of 185HU was not achieved in 25% of the scans. Despite similar noise-levels ($p = 0.14$), CNR was significantly higher ($p < 0.05$) in low weight-groups (W1 15.0; W2 9.8) compared to high weight-groups (W3 6.7; W4 6.0). Spleen inhomogeneity was observed in 54%; 41%; 8%; 25% (W1-W4) of cases ($p = 0.006$), respectively.

Conclusion: Evaluation of the RCR-adapted paediatric trauma protocol showed relatively poor vascular-enhancement in the highest weight-group and high vascular-enhancement in the lowest weight-group. Spleen-homogeneity and angiographic-enhancement were insufficient in a substantial number of cases. Our study indicates that further refining of the split-bolus single-pass CT protocol for children is essential.

B-0339 14:48

The effect of renal function on the intracranial gadolinium deposition in young rats

J. Kim¹, J. Lee²; ¹Cheon-An/KR, ²Seoul/KR (torannip@gmail.com)

Purpose: To assess the effect of renal function on gadolinium deposition in brain after gadolinium-based contrast agents (GBCAs) injections in young rats.

Methods and Materials: A total of 39 young rats were divided into 6 groups according to the renal function (normal or decreased) and injected GBCAs (linear or macrocyclic GBCA or saline). Ten GBCA injections were performed over 2 weeks at a dose of 0.9mmolGd/kg. T1-weighted magnetic resonance image and T1 mapping were performed on a 7 Tesla scanner. Qualitative and quantitative analyses of T1 signal intensity ratio of deep cerebellar nucleus(DCN) to cerebellar cortex or pons, and quantitative analysis of T1 value of DCN were performed.

Results: Decreased renal function group with linear GBCA injection was the only group showed statistically significant increase of T1 signal intensity ratio of DCN/cerebellum on week 2 ($P = 0.043$), T1 signal intensity ratio of DCN/pons on both weeks 2 and 4 ($P = 0.043$), decrease of T1 value of DCN on weeks 2 and 4 ($P = 0.043$) compared to baseline. In rats with decreased renal function with both linear and macrocyclic injections, T1 value of fourth ventricle was markedly decreased at week 2 and week 4 ($P = 0.043$).

Conclusion: Repeated administration of both linear and macrocyclic GBCAs to young rats with decreased renal function caused delayed excretion of contrast material from ventricles. Rats with decreased renal function with linear GBCA injections, not with macrocyclic GBCA, showed T1 hyperintensity and decreased T1 value in DCN, suggesting deposition of gadolinium.

B-0340 14:56

The difficulties of childhood hepatocellular carcinoma MRI diagnosis

M. Gonzalo Carballés¹, L. Riaza Martín¹, A. Coma², A. Castellote Alonso³, G. Guillén Burriaza¹, L. Riera¹, J. Molino Gaete¹, J. Piqueras Pardellans¹, E. Vázquez¹; ¹Barcelona/ES, ²Lleida/ES (martagonzalo1991@gmail.com)

Purpose: Hepatocellular carcinoma (HCC) is an aggressive hepatic neoplasm that rarely affects pediatric population (<0.5%). The pathophysiology of HCC is not clearly understood; cirrhosis is a predisposing condition. Most pediatric HCC arise de-novo without underlying liver abnormalities, but it is also found, the coexistence of HCC with another hepatic tumors "nodule inside a nodule". This study was performed to illustrate the characteristic MRI findings and patterns of HCC in the pediatric population and discuss the differences from the typical imaging features described in adults.

Methods and Materials: Between December 2001 and September 2018 a total of 10 children had been diagnosed as having HCC in our Hospital. We reviewed our imaging database and selected those patients with HCC pathologically proven that had an abdominal MRI done before treatment. The outcome could be analyzed retrospectively in 5 of those patients.

Results: The median age at diagnosis was 10.4 years and the male/female ratio was 4:1. Two patients had predisposing conditions (40%) one had tyrosinemia type 1 and hepatitis C virus and the other Abernethy type II Syndrome. The typical MRI imaging pattern of HCC (T1WI hypointensity, T2WI hyperintensity, early arterial enhancement and venous phase washout) was only seen in one patient (20%). One patient had a coexistent hepatoblastoma (20%) and two of the patients had a malignant transformation of an adenoma (40%).

Conclusion: This study illustrated that most of pediatric HCC do not show the typical MRI patterns and coexist with other hepatic tumors, conditions that make its diagnosis more difficult.

B-0341 15:04

Role of whole-body magnetic resonance imaging in identifying potential diagnostic clues in children with fever of unknown origin

F. Sertorio, S. Signa, M. De Cesario, M.B. Damasio, G.M. Magnano; Genoa/IT (fiammetta.sertorio@gmail.com)

Purpose: To evaluate the ability of WBMRI to identify significant potential diagnostic clues (PDCs) in paediatric patients presenting with fever of unknown origin (FUO), recurrent fever and a non-specific inflammatory clinical picture (IUO, Inflammation of unknown origin). To define if an evaluation of WBMRI using a predefined checklist increases the power of this diagnostic tool.

Methods and Materials: We retrospectively collected cases of paediatric patients who underwent WBMRI between January 2010 and December 2015 for these indications: i) FUO, ii) recurrent fever, iii) IUO. All studies have been evaluated twice, the second time according to a predefined checklist, considering the involvement of bone, bone marrow, subcutaneous tissue, muscle, tendons, fascia, spine, lung, parenchyma, lymph nodes, paranasal sinuses, nervous system, joint and vessels looking for PDCs.

Results: 102 patients were considered: 24 with FUO, 27 with recurrent fever, 51 with IUO. The mean age of WBMRI execution was 9 years. PDCs were identified at the first evaluation in 76/102 cases and in 29/102 cases the identified PDC was useful for the diagnosis. Blind re-evaluation of WBMRI allowed the identification of additional PDCs in 56 cases (12 of them previously negative). In 10 cases the PDC found contributed to the final diagnosis. After the whole diagnostic work-out a final diagnosis was achieved in 42 patients (41%).

Conclusion: WBMRI is a non-radiating accurate method to detect diseases through the body. It can be a powerful diagnostic tool in patients with FUO, recurrent fever and IUO. A predefined checklist increases its diagnostic power.

B-0342 15:12

MRU for diagnosis of obstructive pathology of the upper urinary tract

L. Delfino, M. Damasio, L.E. Derchi; Genoa/IT (delfino.lorenza@gmail.com)

Purpose: We report ureteral anomalies distal to the uretero-pelvic junction (UPJ) detected via MRU subjected to surgery. MRU sensitivity and specificity in presurgical diagnosis are explored. We also determinate US-MRU agreement.

Methods and Materials: MRU performed between 2007 and 2017 have been retrospectively analysed. Children with megaureter, DDP, retrocaval ureter, mid-ureteral stenosis, ureterocele and ectopic ureter were identified. Patients' demographics, prior US, MRU data and surgical findings have been assessed. Patients with severe systemic malformation syndromes, UPJ obstruction or previous reflux treatments have been excluded.

Results: We analysed US, MRU and surgical findings of 46 patients (22 boys, 24 girls) with a median age at the diagnosis, 1.1 years (6 months - 4.0 years). The gap between US-MRU was 38 days (range 1-83) and between MRU surgery 3.2 months (0.8-5.9). The pathology was bilateral in 9 (19.6%), unilateral in 37 (80.4%): 13 (35.1%) on the right and 22 (64.9%) on the left side. On 63 urinary tracts examined, MRU compared to surgical data (gold

standard) showed a sensitivity of 98.0%, specificity of 78.6%, VPP of 94.1%, VPV of 91.7%, with a diagnostic odds ratio of 176.0 (CI 95%: 16.7-1856.8). On 82 urinary tracts examined, US between MRU showed a sensibility of 61.2%, specificity of 54.5%, VPP of 66.7%, VPV of 48.6% with an unsatisfactory odds ratio of 1.9 (CI 95%: 0.8-4.6).

Conclusion: MR urography is highly accurate in the assessment of the ureteral anomalies distal to the UPJ with a sensibility and specificity higher than US.

B-0343 15:20

Pancreas iron overload and fat infiltration in paediatric beta-thalassemia major patients

J. Huang¹, Q. Yang¹, Z. Cheng¹, X. Chen², T. Yu¹, J. Zhong¹, Y. Su¹, H. Guo³, B. Liang¹; ¹Guangzhou/CN, ²Zhanjiang/CN, ³Beijing/CN (huangjw25@mail2.sysu.edu.cn)

Purpose: To determine the iron and fat content (FC) in the three different pancreas regions (head, body, and tail) in paediatric thalassemia major (TM) patients.

Methods and Materials: In 90 paediatric TM patients (10.7±3.1years), pancreatic iron (T2*) and FC were assessed in pancreas head, body and tail, respectively, and were compared with fasting glucose. Iterative decomposition of water and fat with echo asymmetry and least-squares estimation (IDEAL) imaging was used to quantitatively measure FC.

Results: Positive linear correlations were found in both T2* and FC among pancreas head, body and tail ($r=0.911, 0.932, 0.930$, respectively, for T2*, $r=0.876, 0.810, 0.913$, respectively, for FC, all with $p<0.001$), no significant regional difference was found ($F=0.253, 0.259, p=0.776, 0.772$, respectively). Pancreas FC was negatively correlated with pancreas T2* ($r=-0.895, p<0.01$). The scatter plot showed that 63% patients with pancreas iron overload (PIO) had elevated FC, while all (100%) patients with elevated FC had PIO. Receiver operator characteristic analysis (area: 0.904, 0.897, respectively, both $p<0.05$) identified patients with elevated fasting glucose at a pancreatic R2* cut-off level of 268 1/s (sensitivity at 75%, specificity at 91.2%), at a pancreatic FC cut-off level of 0.18 (sensitivity at 75%, specificity at 88.2%).

Conclusion: In paediatric TM patients, fatty replacement is accompanied with pancreas iron overload, but lags behind the latter. Iron overloading and fat infiltration were homogeneously distributed in pancreas head, body and tail in children. Both pancreas iron overload and fat content were correlated with fasting glucose, and could be a predictor of the latter.

Quantifying the change of total tumour volume in whole-body MRI over time improves risk stratification of smouldering multiple myeloma patients

M. Wennmann¹, L. Kintzelé¹, M. Piraud², J. Hofmanner³, B. Menze², H.-U. Kauczor¹, J. Hillengass⁴, G. Langs³, M.-A. Weber⁵; ¹Heidelberg/DE, ²Munich/DE, ³Vienna/AT, ⁴Buffalo, NY/US, ⁵Rostock/DE (kintz_l@hotmail.com)

Purpose: The purpose of this study was to improve risk stratification of smouldering multiple myeloma patients, introducing new 3D-volumetry-based imaging biomarkers derived from whole-body MRI.

Methods and Materials: Two hundred and twenty whole-body MRIs from 63 patients with smouldering multiple myeloma were retrospectively analysed and all focal lesions >5mm were manually segmented for volume quantification. The imaging biomarkers total tumour volume, speed of growth (development of the total tumour volume over time), number of focal lesions, development of the number of focal lesions over time and the recent imaging biomarker '>1 focal lesion' of the International Myeloma Working Group were compared, taking 2-year progression rate, sensitivity and false-positive rate into account.

Results: Speed of growth, using a cutoff of 114mm³/month, was able to isolate a high-risk group with a 2-year progression rate of 82.5%. Additionally, it showed by far the highest sensitivity in this study and in comparison to other biomarkers in the literature, detecting 63.2% of patients who progress within 2 years. Furthermore, its false-positive rate (8.7%) was much lower compared to the recent imaging biomarker '>1 focal lesion' of the International Myeloma Working Group.

Conclusion: Therefore, speed of growth is the preferable imaging biomarker for risk stratification of smouldering multiple myeloma patients.

Intravoxel incoherent motion imaging (IVIM) assessment of bone marrow infiltration in multiple myeloma

R. Balaji; Chennai/IN (ravikanthbalaji@gmail.com)

Purpose: To study the use of intravoxel incoherent motion (IVIM) diffusion imaging in assessing extent of marrow involvement in multiple myeloma before therapy and correlation with histology.

Methods and Materials: 75 patients with biopsy-proven myeloma were included in the study. All patients underwent whole body diffusion imaging using DWIBS (diffusion-weighted whole-body imaging with background signal suppression) sequence on 1.5 Tesla Philips Achieva scanner. The marrow lesions (> 1cm) in the iliac bones were identified for IVIM study. Images were acquired in an axial plane with 11 b values: 0, 20, 30, 50, 80, 100, 200, 400, 800, 1000 and 1200 s/mm². The IVIM parameters (perfusion fraction [f], molecular diffusion coefficient [D], and perfusion-related D [D*]) and apparent diffusion coefficient (ADC) were obtained for marrow and focal lesions. The molecular diffusion coefficient and ADC values were correlated with degree of plasma cell infiltration.

Results: D and f values positively correlated with degree of bone marrow involvement. Multiple myeloma is classified into 3 stages, I < 20% plasma cells, II 20 to 50% and III more than 50%. D values showed greater correlation with stage of involvement ($p<0.05$) D (x 10⁻³ mm²/s) in stage III 0.5 8 ±0.21, in stage II 0.80±0.27, in stage I 1.1 ±0.22. f values were higher in stage III rather than stage I ($p<0.08$).

Conclusion: IVIM MR diffusion imaging may be used to predict degree of marrow infiltration by plasma cells in multiple myeloma and thereby provide pre-biopsy staging.

B-0346 14:25

Response assessment in multiple myeloma using intra-voxel incoherent motion (IVIM) diffusion MRI: a newer paradigm

R. Balaji; Chennai/IN (ravikanthbalaji@gmail.com)

Purpose: To evaluate the performance of intra-voxel incoherent motion (IVIM) model of diffusion imaging in assessing treatment response in multiple myeloma.

Methods and Materials: Hundred patients with biopsy-proven multiple myeloma on appropriate chemotherapy were imaged before start of treatment and at 2 points during treatment - 1 month and 3 months of therapy. Imaging was performed on Achieva 1.5 Tesla scanner (Philips Healthcare, Best, The Netherlands) using a 16-channel pelvic torso coil. Lesions in iliac bones or sacrum were analyzed. Images were acquired in an axial plane with 11 b values (0 to 1200 s/mm²). IVIM parameters (perfusion fraction [f], molecular diffusion coefficient [D], and perfusion-related D [D*]) and apparent diffusion coefficient (ADC) were obtained.

Results: D values (P 0.004) were the most sensitive indicator for response. D values increased in the first month of therapy and continued to rise at 3 months. f values (P 0.05) decreased after one month showing further decrease at 3 months. ADC values derived from mono-exponential equation also showed elevation after therapy.

Conclusion: IVIM-derived parameters may be useful in evaluating response of patients with multiple myeloma to appropriate therapy thereby obviating need for invasive marrow biopsies.

B-0347 14:33

Full-body 150-kV spectral-shaping low-dose CT in multiple myeloma follow-up: evaluation of image quality and radiation dose

A.M. Bucher¹, A. Brendlin², J.E. Scholtz¹, M. Beeres¹; ¹Frankfurt a. Main/DE, ²Tübingen/DE

Purpose: Spectral-shaping by tin-filtration allows for radiation dose savings in computed tomography. Our aim was to evaluate a low-dose protocol using spectral-shaping for multiple myeloma (MM) follow-up in comparison to a low-dose 120-kV protocol.

Methods and Materials: Forty CTs from twenty patients (64.4±12.5years; female/male: 11/9) with clinically indicated follow-up of MM were included. All patients had a full-body CT using low-dose 120-kV/60-mAs protocol (CT₁₂₀) and on follow-up a tin-filtered low-dose 150-kV/60-mAs protocol (CT₁₅₀) for intra-individual comparison. Dose-length-product (DLP) was recorded. Signal-to-noise ratio was calculated for the gluteus maximus muscle (SNR_{GM}). To assess beam hardening, average muscles density from ROIs of artefact-prone regions (sternocleidomastoid, subscapular and lumbar muscles) were subtracted from reference muscles of the same height (BH_{HU}). Subjective image quality for bone, and soft-tissue, and presence of artefacts were rated (5-point Likert-scale) by two independent investigators. We used paired

student *t*-test, Wilcoxon signed-rank test and Cohens-Kappa-statistic.

Results: On average CT₁₅₀ had 49% less radiation exposure compared to CT₁₂₀ (323.5±79.2 mGycm vs. 661.4±78.2mGycm; *p*=0.001). SNR_M (CT₁₅₀: 0.97±0.68; CT₁₂₀: 0.54±0.31; *p*=0.003) and BH_{HU} (CT₁₅₀: 2.4±2.1; CT₁₂₀: 3.5±1.2; *p*=0.001) were significantly higher with spectral shaping. Subjective image quality was rated higher in CT₁₅₀ compared to CT₁₂₀ (5 [IQR: 4-5] vs. 4 [IQR: 3-4]; *p*=0.016). Inter-observer agreement was excellent (*κ*=0.886). Impairment of diagnostic confidence for bone through artefacts was lower in CT₁₅₀ (*p*=0.014).

Conclusion: Spectral-shaping allows for full-body CT at 49% lower radiation dose compared to a 120kV low-dose protocol, while improving image quality. It may be an alternative for follow-up CT in MM.

B-0348 14:41

Spatial heterogeneity in growth dynamics and local volumetric biomarkers for risk stratification and dissemination behaviour in smouldering multiple myeloma

M. Wennmann¹, L. Kintzele¹, T. Hielscher¹, G. Langs², H.-U. Kauczor¹, M. Merz¹, J. Hillengass³, B. Menze⁴, M.-A. Weber⁵; ¹Heidelberg/DE, ²Vienna/AT, ³Buffalo, NY/US, ⁴Munich/DE, ⁵Rostock/DE (mwennmann@hotmail.de)

Purpose: To assess spatial heterogeneity in growth dynamics between different tumour sites, and to determine site-specific tumour characteristics for risk assessment and prediction of appearance of new focal lesions in smouldering multiple myeloma patients.

Methods and Materials: From a cohort of 63 patients with overall 220 whole-body MRI examinations during follow up, local tumour volumes of 151 focal lesions in 29 patients and local growth dynamics of 146 focal lesions in 27 patients were determined using manual volumetry. Volume and speed of growth of the largest focal lesion and speed of growth of the fastest growing focal lesion were used as biomarkers for risk stratification and dissemination behaviour, and their performance was compared using Cox regression and Harrell's C-Index.

Results: Seventy percent of patients with ≥2 focal lesions show a difference of at least factor 5 in local speed of growth between different tumour sites. All local volumetric biomarkers allow significant risk stratifications (*p*<0.001), with local speed of growth showing the best prognostic discrimination (C-index 0.798). Local speed of growth correlates significantly with future appearance of new focal lesions (HR=1.44; *p*=0.026).

Conclusion: Growth dynamics between tumour sites differ substantially in the majority of patients and indicate differences in local biology. Local volumetric tumour assessment performs excellent regarding prognosis assessment and can be used in upcoming Radiomics approaches or to choose biopsy sites. The correlation between local speed of growth and future appearance of new focal lesions supports the thesis that local growth dynamic correlates with advance of tumour biology.

Rapid study assessment in follow-up whole-body computed tomography in patients with multiple myeloma using a dedicated bone subtraction software

M. Sieren, F. Brenne, A. Hering, M. Schenk, T.H. Oechtering, J. Barkhausen, A. Frydrychowicz; Lübeck/DE (malte.sieren@uksh.de)

Purpose: Reading follow-up whole-body computed tomography (CT) examinations in patients with multiple myeloma is a lengthy and demanding process. In line with smart reporting approaches, the aim of this study was to evaluate the diagnostic accuracy and benefit of a software for motion-corrected assisted bone lesion change detection.

Methods and Materials: 20 patients (12m,65±9y) receiving a total of 40 low-dose whole-body CT examinations for follow-up evaluation of myeloma bone disease were identified from our imaging archive. The local ethics committee waived consent for this analysis. Bone subtraction maps were calculated from 2mm CT images using a novel, non-linear deformation algorithm applying a point-wise spatial alignment between current and prior CT images. Image presentation used colour coding to enhance lesion perceptibility. Reading time, number of correctly assessed lesions, and resulting disease classification were compared to a standard PACS reading software by two readers following a standardized protocol (reader A: 3y of experience, reader B: 1y of experience). De novo clinical reading by a senior body radiologist with 10y of experience served as reference standard.

Results: For both readers, reading time was significantly lower using subtraction maps (reader A: 441±135s, reader B: 1100±397s) compared to standard reading (reader A: 645±162s, reader B: 1652±426s), both *p*<0.001. Lesion detection rate for subtraction mapping/conventional reading was 92%/78% for reader A and 87%/67% for reader B. All patients were correctly classified by both methods (7x progressive disease, 6x stable disease, 7x remission).

Conclusion: Motion-corrected bone subtraction maps significantly speed up reading time and are slightly superior compared to conventional CT reading regarding lesion detection.

B-0350 14:57

Whole-body magnetic resonance imaging (WBMRI) for the assessment of response to treatment in multiple myeloma patients after autologous haematopoietic stem cell transplantation

N. Lutsik, L. Mendeleeva, M. Solovov, G. Yatsyk, S. Kulikov, V. Savchenko; Moscow/RU (natalia.parubenko@gmail.com)

Purpose: To determine the differences in bone marrow lesions and value of apparent diffusion coefficient (ADC) detected by whole-body MRI in patients with multiple myeloma (MM) before and after autologous haematopoietic stem cell transplantation (auto-HSCT).

Methods and Materials: 18 patients with MM (8 male and 10 female) aged 37 to 66 (median 55) were enrolled in a prospective study in the period from February 2017 to May 2018. WBMRI was carried out with a Philips Ingenia 1.5 T before and 100 days after auto-HSCT. DWI with background body signal suppression (DWIBS) sequences (b values: 0, 500, 1000 mm²/sec) were qualitatively analysed, along with T1 spine echo and short tau inversion recovery T2-weighted images, to evaluate bone lesions. The bone marrow infiltration lesions (≥ 5 mm) were counted and ADC values were calculated and compared before and 100 after auto-HSCT. ADC values were detected in 6 patients. Descriptive, regression and variance analyses were conducted with SAS 9.4.

Results: WB-MRI after auto-HSCT demonstrated a significant relative reduction of the number of lesions by an average of 16±0.2% (*p*=0.007), a significant relative reduction of the tumour volumes by an average of 23±0.26% (*p*=0.03) and non-significant mean reduction of ADC values by an average of 11±0.13% (*p*=0.08).

Conclusion: WB-MRI with DWIBS sequences, by evaluating posttreatment changes of numbers, total lesion volume and ADC values, might represent a complementary diagnostic tool in the assessment of response to treatment in MM patients after auto-HSCT. For more reliable decrease of ADC values, more patients are needed.

B-0351 15:05

Comparison of 18F-FDG PET/CT and whole-body MRI in assessing newly diagnosed myeloma

O.A. Westerland, A. Amlani, M. Siddique, M. Streetly, I. El-Najjar, G. Cook, V.J. Goh; London/UK (olwenwesterland@gmail.com)

Purpose: Advanced imaging including whole-body (wb) MRI and 18F-FDG PET/CT are now recommended by the International Myeloma Working Group for assessing myeloma. It remains unclear which modality should be used first-line. We aimed to compare the diagnostic performance of 18F-FDG PET/CT and wbMRI.

Methods and Materials: Following IRB approval, 25 patients (12 male; mean±SD = 61±10 years) with newly diagnosed myeloma underwent 18F-FDG PET/CT and wbMRI. Following a 6hr fast, 400 MBq ¹⁸F-FDG was administered intravenously. At 60 +/-5 mins post injection, imaging was acquired from vertex to feet (GE Discovery PET/CT). wbMR included T2-HASTE, T1-DIXON, DWI (B=50 and 900s/mm²) and post-contrast T1-DIXON sequences from vertex to knees (1.5T Magnetom Aera, Siemens HealthCare, Erlangen, Germany). Images were reviewed by two experienced radiologists and the presence/absence of disease and number of focal lesions recorded. Diagnostic performance was compared to clinical parameters including bone marrow aspirate (reference standard).

Results: The sensitivity of wbMRI for diagnosing myeloma was 88%, compared with 84% for 18F-FDG PET/CT (84% for the CT component alone; 48% for PET component alone for detection of bone lesions). In 20/25 patients (80%) wbMRI detected a greater number of bone lesions compared with the CT component of 18F-FDG PET/CT whilst in 3/25 patients (12%) a greater number of lesions were detected on CT compared with wbMRI. 8% of cases were concordant.

Conclusion: wbMRI and 18F-FDG PET/CT have a comparable sensitivity for detection of myeloma, however wbMRI detects a greater proportion of focal bone lesions compared with 18F-FDG PET/CT.

B-0352 15:13

Distinct bone marrow pattern in MR imaging of advanced systemic mastocytosis is associated with poor prognosis

P. Riffel, M. Jawhar, K. Gawlik, H.J. Michaely, W.-K. Hofmann, S.O. Schönberg, A. Reiter; Mannheim/DE (Philipp.Riffel@medma.uni-heidelberg.de)

Purpose: Systemic mastocytosis (SM) is a rare myeloproliferative neoplasm characterized by accumulation of mast cells (MCs) in various organ systems (e.g. bone marrow, BM). The aim of this study was to compare the BM pattern of indolent SM (ISM, normal life expectancy) and advanced SM (advSM,

median survival 2-4 years) using whole-body magnetic resonance imaging (WB-MRI).

Methods and Materials: 115 patients with SM (ISM: 37, smouldering systemic mastocytosis (SSM): 9, advSM: 69) underwent a wb-MR-exam including sagittal T1 and TIRM sequences of the spine. Image evaluation included pattern and extent of pathologic BM in the spine and the extremities (including osteolysis and vertebral fractures).

Results: 89% of patients with ISM revealed a normal BM. 89% of patients with SSM revealed a pathologic BM signal of the spine. 96% of patients with advSM revealed a pathologic BM signal of the spine (activated BM 62%, diffuse sclerotic BM 25%, small-spotted BM 9%). Osteolysis was not seen in any patient. Vertebral fractures were found in ISM (19%) and advSM (19%). MC burden (MC infiltration in BM, serum tryptase, KIT D816V allele burden) was significantly higher in advSM patients with activated/sclerotic BM compared to normal/small-spotted BM with a significantly lower median overall survival.

Conclusion: Pathologic bone marrow changes of the spine in patients with SM are indicative for diagnosis of SSM or advSM. In patients with advSM, activated or diffuse sclerotic bone marrow pattern is associated with a more aggressive form based on clinical, genetic and outcome parameters.

Lack of clinically meaningful anatomical variations in the bone marrow ADC values in diffuse myeloma allows untargeted sampling to confirm disease burden

A. Keeling¹, D.-M. Koh², S. O'Connor¹, K. Boyd¹, M. Kaiser¹, M. Blackledge², C. Messiou¹; ¹London/UK, ²Sutton/UK (archie.keeling@nhs.net)

Purpose: To compare the regional ADC values of bone marrow in the spine and pelvis of patients with diffuse multiple myeloma and their correlation with indices of disease burden.

Methods and Materials: The whole-body DWI studies of 50 patients with biopsy positive and imaging confirmed diffuse myeloma were retrospectively reviewed. In each patient, three regions of interest (ROIs) were drawn over four anatomical sites (right ilium, left ilium, L3 vertebrae, T6 vertebrae) on the ADC maps and the average value recorded at each site. The ADC values were compared using the Wilcoxon signed-rank test with p-value < 0.0125 (Bonferroni correction) taken as statistically significance. The average ADC values of all sites in each patient was correlated with marrow cellularity and proportion plasma cell at histopathology, as well as the international staging system (ISS) scores.

Results: There was no significant difference in the median ADC value of bone marrow in the left ilium (754), right ilium (733) and T6 (701) but was significantly lower in L3 (636). However, the variance of ADC values across sites were within limits of measurement repeatability (15%). No correlation was found between per-patient average ADC values with marrow cellularity (p=0.7), proportion plasma cells (p=0.2) or ISS scores (p=0.5).

Conclusion: There is no clinically meaningful difference in the marrow ADC values across anatomical sites in diffuse myeloma. Untargeted bone marrow biopsy is likely to be representative in this patient group.

MRI-based texture analysis has the potential to predict response to transarterial radioembolization at baseline

R.P. Reimer¹, P. Reimer², A. Mahnken³; ¹Cologne/DE, ²Karlsruhe/DE, ³Marburg/DE (robert.reimer@uk-koeln.de)

Purpose: The purpose of this study was to investigate, whether magnetic resonance imaging (MRI)-based texture analysis (TA) has the potential to predict response to transarterial radioembolization (TARE) in patients with liver metastases.

Methods and Materials: Forty patients (23/17, male/female; mean age 64.2 years) with liver metastases underwent dynamic contrast-enhanced (DCE)-MRI and hepatocellular phase MRI with gadoxetic acid (Primovist®, Bayer Healthcare) after TARE (mean 2.1 days). Response to TARE was evaluated on follow-up imaging (median follow-up, 224 days) based on Response Evaluation Criteria in Solid Tumors 1.1 using a region of interest (ROIs)-based method. Response evaluation and TA was performed using the software mint Lesion™. Results of TA (mean, standard deviation (sd), skewness, kurtosis, entropy (e), uniformity (u)) of the ROIs at baseline were compared between

responders and non-responders using Mann-Whitney-U test. Receiver operating characteristics including the area under the curve (AUC) were calculated.

Results: 12 patients (30%) were responders and 28 (70%) non-responders. Comparing responders and non-responders, median sd (53.4vs.34.0) and u (0.0071vs.0.0106) at arterial phase, as well as median e (7.35vs.6.85) and u (0.0081vs.0.0106) at hepatocellular phase were significantly different (p<0.05). The AUCs for sd and u at arterial phase were 0.72 (p<0.05) and 0.70 (p>0.05). The AUCs for e and u at hepatocellular phase were 0.74 and 0.72 (p<0.05).

Conclusion: Texture analysis at arterial phase and hepatocellular phase MRI has the potential to predict response to transarterial radioembolization at baseline. The results indicate higher tumor heterogeneity of the liver metastases at baseline in responders.

B-0355 14:04

Apparent diffusion coefficient percentage as an early predictor for evaluation of trans-catheter arterial chemoembolisation efficacy in hepatocellular carcinoma

R.M. Mousa¹, F. Fawzy², H. Tantawy¹, T. Sobhy¹; ¹Zagazig/EG, ²Sharkia/EG (Rolamoussa@zu.edu.eg)

Purpose: To emphasize the role of calculating the percent of change in apparent diffusion coefficient value (%ADC) in evaluating the treatment response of hepatocellular carcinoma (HCC) after transcatheter arterial chemoembolization (TACE) as an early predictor of residual tumour.

Methods and Materials: Thirty six patients with 44 hepatocellular carcinoma (HCC) lesions which were all treated with TACE. All lesions were evaluated by conventional MRI, diffusion weighted imaging (DWI), and ADC value measurement before treatment for baseline characterization, then four weeks after TACE to evaluate its efficacy. Results were compared with triphasic study (CT or MRI) done at the same time as a standard of reference.

Results: Significantly higher ADC values were found in lesions that were completely embolized rather than the incompletely embolized ones with residual tumoural tissue. The mean ± standard deviation (SD) of lesions before treatment was 1.23±0.24×10⁻³mm²/s. One month after TACE, completely embolized HCC lesions had an increase in mean (±SD) ADC to 1.44 ±0.26×10⁻³ mm²/s (P=0.004), while incompletely embolized HCCs increased to 1.33±0.24×10⁻³ mm²/s (P=0.41). Completely embolized lesions also had significantly larger increase in %ADC than incompletely embolized ones (22.8% versus -21.2% respectively, p=0.001). On comparing %ADC before and after treatment with the standard of reference (triphasic CT or MRI), %ADC had 96% sensitivity, 100% specificity, and 94.7% accuracy (%ADC threshold was set at 8.5% based on ROC curve analysis).

Conclusion: Percentage ADC represents a reliable early predictor of successful management of HCC by TACE and allows early detection of residual tumoural tissue.

B-0356 14:08

Can intravoxel incoherent motion diffusion-weighted imaging be use for preoperative assessment of microvascular invasion in hepatocellular carcinoma

Y. Wei, B. Song, H. Jiang, J. Chen; Chengdu/CN (drweiyi057@163.com)

Purpose: To prospectively evaluate the potential role of intravoxel incoherent motion diffusion-weighted imaging and conventional radiologic features for preoperative prediction of MVI of HCC.

Methods and Materials: 115 patients with 135 newly diagnosed were evaluated. For all examinations, studies were carried out by using a 3.0 T MR system. IVIM was performed by using an echo-planner imaging sequence with respiratory gating, twelve b values of 0, 10, 20, 40, 80, 100, 150, 200, 400, 600, 800 and 1000 sec/mm² were obtained. All the IVIM images were analysed by two radiologists independently. Freehand region of interest (ROI) was used to outline the tumour on the original IVIM image (b=400 sec/mm²), and try to avoid the necrosis and haemorrhage. The ADC, ADCslow, ADCfast and f values were automatically calculated. Univariate and multivariate logistic regression analyses were used to screen the independent risk factors of MVI, receiver operating characteristics (ROC) curves were drawn and to determine the optimal cut-off value.

Results: Features significantly related to MVI of HCC at univariate analysis were reduced ADC (odds ratio, 0.341, 95% CI: 0.211-0.552; P<0.001) and ADCslow (odds ratio, 0.141, 95% CI: 0.067-0.299; P<0.001). At multivariate analysis, only ADCslow was the independent risk factor for MVI of HCC. The mean ADCslow value for MVI of HCC showed an area under ROC curves of 0.815 (95% CI: 0.740-0.877) with the optimal cutoff value of 0.868.

Conclusion: The results of the preliminary study have demonstrated that the decreased ADCslow value was independent risk factor for predicting MVI of HCC.

B-0357 14:12

Liver surface nodularity score as a new predictor of overall survival in patients with HCC treated by TACE

A. Abou Elkassem¹, A.M.K. Abdel Aal¹, K. Mahmoud¹, A. Gunn¹, S. Irette², A. Smith¹; ¹Birmingham, AL/US, ²Jackson, MS/US (akamel@uabmc.edu)

Purpose: To assess the accuracy of the CT-based liver surface nodularity (LSN) score for predicting overall survival (OS) in patients with hepatocellular carcinoma (HCC) treated with trans-arterial chemo-embolisation (TACE).

Methods and Materials: For this retrospective study, a search of the electronic medical records was performed to identify adult patients with HCC treated by TACE within 6 months of a contrast-enhanced abdominal CT. The LSN score was measured using custom software while blinded to clinical data. Age, gender, race, bead size, Barcelona Clinic Liver Cancer (BCLC) stage of HCC (which includes tumour burden/extent, Child-Pugh score, and performance status), time to progression (TTP), and OS were extracted from the electronic medical records. Predictors of TTP and OS were evaluated by Cox-proportional hazards ratio.

Results: A total of 165 patients were included with BCLC stage A (N=46), B (N=62), C (N=46), and D (N=11). The mean (standard deviation) of the LSN score was 3.10 (0.71). The median TTP and OS were 10.2 and 21.4 months. None of the variables were predictive of TTP ($p > 0.2$ for each). Predictors of OS included the LSN score (HR: 1.41; 95%CI: 1.06, 1.88; $p = 0.019$) and age (HR: 1.03; 95%CI: 1.00, 1.05; $p = 0.029$), but not the BCLC stage of HCC or any of the other variables ($p > 0.10$). For each unit increase in the LSN score, the risk of death increases by 41%.

Conclusion: The CT-based LSN score was an accurate independent predictor of OS in patients with HCC treated by TACE.

Diffusion-weighted imaging of colorectal liver metastases: prospective evaluation of apparent diffusion coefficient in correlation with histologic findings

M.F.A. Almeida, R. Cruz, M.D.F.S. Begnami, P.N.V.P. Barbosa, A.G.V. Bitencourt, F.J.F. Coimbra, R. Chojniak; Sao Paulo/BR (mf_arruda@yahoo.com.br)

Purpose: To prospectively correlate apparent diffusion coefficient (ADC) values of colorectal liver metastases with the degree of viable tumour, necrosis and fibrosis.

Methods and Materials: Thirty-seven patients with colorectal liver metastases were included. All patients had preoperative MRI scans at Signa HDx 1.5 Tesla GE Healthcare, including DWI sequences with b values of 0-200 and 0-600 sec/mm². All patients underwent surgical resection, with systematic mapping of the surgical specimen for radiopathological correlation. A total of 92 metastases detected in the DWI sequences were found to be adequately correlated with the macroscopic mapping and were submitted to standard histological analysis to evaluate the percentage of viable tumour, necrosis and fibrosis. ADC values were calculated using post-processing workstation. Spearman correlation, chi-square, Kruskal-Wallis and Mann-Whitney tests were performed.

Results: Twenty patients were male (54%) and the mean age was 56.4 years (age range, 32-78). Only 5 patients did not perform preoperative chemotherapy (13.5%). MRI lesions ranged from 0.7 to 9.0 cm (mean, 2.3 cm). Mean ADC values obtained with ROI in the entire lesion and ROI in 50% of the lesion area were respectively: 1.69 and 1.35 ($\times 10^{-3}$ /mm²) in DWI b200; 1.33 and 1.20 ($\times 10^{-3}$ /mm²) in DWI b600. ADC values on DWI b600 showed a significant correlation with percentage of viable neoplasm, use of target therapy and number of QT cycles.

Conclusion: The lesions with the highest percentage of viable tumour had lower ADC values, indicating that DWI sequence can be used to evaluate cellularity and tumour viability of colorectal liver metastases.

B-0359 14:20

Comparison of intravoxel incoherent motion DWI, diffusion kurtosis imaging, and conventional DWI in predicting the chemotherapeutic response of colorectal liver metastases

H. Zhang, W. Li, T. Tong; Shanghai/CN

Purpose: The study aimed to compare the performance of pre-treatment intravoxel incoherent motion DWI (IVIM-DWI), diffusion kurtosis imaging (DKI), and conventional DWI for predicting the chemotherapeutic response in patients with colorectal liver metastases (CRLMs).

Methods and Materials: Forty consecutive patients with unresectable CRLMs who underwent the standard first-line chemotherapy regimen were prospectively collected. All the images were collected on a MAGNETOM Skyra 3T MR scanner. The response was assessed by response evaluation criteria in solid Tumours (RECIST Version 1.1) after receiving two cycles of chemotherapy. The parameters were compared between the responding group

(complete and partial response, n=15) and non-responding group (stable and progressive disease, n=25).

Results: Lower baseline ADC, D_{slow} , D ($P = 0.001$, < 0.001 , and $= 0.003$ respectively) and higher baseline K ($P = 0.002$) were independently associated with a good response to chemotherapy with area under the ROC curves (AUCs) of 0.845, 0.832, 0.819, and 0.787, respectively. The best predictive parameter was ADC (AUC = 0.845, sensitivity = 73.3 %, specificity = 84.0 % and cutoff value $\leq 1106.85 \times 10^{-6}$ mm²/s). The statistically different factors were fitted by the logistic regression and a predictive factor (PRE1) was generated. The AUC of the PRE1 reached 0.867.

Conclusion: Our study showed that pre-treatment IVIM-DWI (D_{slow}), DKI (D and K), and conventional DWI (ADC) all demonstrate good diagnostic performance in predicting the chemotherapeutic response of patients with CRLMs, which indicates that the functional MRI parameters might provide additional information for predicting the response of CRLMs.

B-0360 14:24

Diffusion kurtosis imaging-derived histogram metrics for prediction of KRAS/NRAS/BRAF mutation in rectal adenocarcinoma

Y. Cui¹, Z. Zhuo², X. Yang¹, R. Zhang¹; ¹Taiyuan/CN, ²Beijing/CN (yanfen210@126.com)

Purpose: To evaluate the potential role of DKI-derived parameters by using histogram analysis derived from whole-tumor volumes for prediction of KRAS/NRAS/BRAF mutations status in patients with rectal adenocarcinoma.

Methods and Materials: 152 consecutive patients who underwent MRI examination with rectal adenocarcinoma were retrospectively evaluated. The parameters D, K and conventional ADC were measured using whole-tumor volume histogram analysis. Student's t-test or Mann-Whitney U-test, receiver operating characteristic curves, and Spearman's correlation were used for statistical analysis.

Results: All the percentiles metrics of ADC and D values were significantly lower in the mutated group than those in the wild-type group, except for the minimum value of D, while K-related percentiles metrics appeared higher in the mutated group compared with those in the wild-type group. Regarding the comparison of diagnostic performance of all the histogram metrics, K_{75th} showed the highest AUC value of 0.866, and the corresponding sensitivity, specificity, PPV and NPV were 67.57% and 92.31%, 89.29% and 75.0%, respectively.

Conclusion: DKI metrics with whole-tumor volume histogram analysis, especially the K_{75th} parameters, yield preferable AUC and specificity for predicting KRAS/NRAS/BRAF mutations than ADC and D, and thus may potentially serve as an optimal imaging biomarker for the prediction of KRAS/NRAS/BRAF mutations for guiding targeted therapy.

B-0361 14:28

Prediction of loco-regional treatment failure after chemo-radiotherapy in anal cancer using FDG PET/CT-derived feature analysis

P. Brown¹, J. Zhong¹, G.M. McDermott¹, M. Fronza¹, A. Gilbert¹, A. Appelt¹, D. Sebag-Montefiore¹, S. Currie¹, A. Scarsbrook¹; ¹Leeds/UK, ²York/UK (peter.brown30@nhs.net)

Purpose: Chemoradiotherapy (CRT) is the primary treatment of loco-regional disease in anal squamous cell carcinoma (ASCC). Loco-regional treatment failure (LRF) can occur due to sub-optimal therapy response. Tumour phenotyping using radiomic analysis may help identify tumours less likely to fully respond. The study purpose was to develop and validate a prognostic model in patients with ASCC incorporating pre-treatment FDG PET/CT-derived features.

Methods and Materials: Consecutive patients with ASCC (n = 292) treated with curative-intent CRT at a large tertiary referral centre were studied. After exclusions (small tumour size, incomplete follow-up data, tumour excision pre-PET/CT), 199 patients were analysed; separated into training (n = 145) and validation (n = 44) cohorts. Tumour segmentation and radiomic feature (RF) extraction was performed using specialised software (LIFEX, www.lifexsoft.org) on baseline PET/CT imaging. Cox regression modelling was performed. Primary outcome was LRF, (median follow-up 31.0 months, IQR 16.5-55.5 months).

Results: 37 (25.5%) and 12 (27.3%) patients in the training and validation cohorts had LRF within the treatment field. Univariate analysis demonstrated metabolic tumour volume (MTV), SUVmax, 8 CT-derived and 7 PET-derived RFs (first- and second-order parameters) were statistically significant ($p < 0.05$) for LRF prediction. Conventional discriminators (T, N, M stage, age, sex and histological grade) were not significant in predicting LRF.

Conclusion: PET/CT-derived RFs helped predict ASCC patients at higher risk of LRF and may offer additional benefits over conventional imaging and demographic factors. This shows promise for more effective risk stratification and personalisation of CRT regimens in the future.

B-0362 14:32

Increasing reader confidence in cancer imaging using an advanced DWI modification: a prospective evaluation

C. Dreher¹, T. Kuder¹, S. Windhaber¹, F. König¹, D. Paech¹, R. Gnirs¹, T. Benkert², H.-P. Schlemmer¹, S. Bickelhaupt¹; ¹Heidelberg/DE, ²Erlangen/DE (c.dreher@dkfz-heidelberg.de)

Purpose: Oncological imaging commonly includes Diffusion Weighted Imaging (DWI) sequences to identify and characterize suspicious lesions. However, image quality can be challenged by the limited SNR of DWI, especially in abdominal examinations. This prospective study investigated an optimized DWI in oncological imaging for improved detection of malignant abdominal lesions.

Methods and Materials: This IRB-approved, prospective study included 59 patients (mean age: 57 years, male/female: 22/37). Oncological follow-up MRI-examinations of the abdomen were performed with a 1.5T MRI scanner (AERA, SiemensHealthineers, Germany) with both a standard epi-DWI ("routine-DWI") and an oncologically optimized prototype DWI ("oncoDWI") with $b=0,900s/mm^2$. Diagnostic confidence for characterization/detection of suspicious lesions was evaluated by two independent readers using a 5-point Likert Scale. Statistics included Wilcoxon signed rank tests, interreader agreement was analyzed by kappa-statistic ($p<0.05$).

Results: Sixty-one lesions were detected (20 hepatic, 16 lymphatic, and 25 lesion of other origins). Reader confidence for characterization/detection of malignant lesions was significantly improved using the oncoDWI (4.6 ± 0.5) as compared to the routine-DWI (3.7 ± 0.7) ($p<0.001$). The increased confidence of lesion recognition in the optimized DWI remained significant in all subgroups of hepatic, lymphatic and lesions of other origins ($p<0.002$) with an overall good interreader agreement (kappa = 0.744) ($p<0.001$).

Conclusion: An oncologically optimized DWI sequence increased the reader confidence for lesion characterization/detection in oncological abdominal MRI both with regard to screening and follow-up examinations while preserving a high interreader agreement.

Preoperative prediction of regional lymph node metastasis in thoracic oesophageal carcinoma with 18F-FDG PET/CT and contrast-enhanced CT texture analysis: a nomogram model

Z. Xiaochun, W. Shuxia; Guangzhou/CN (zhangxiaochun579@163.com)

Purpose: To develop and validate a nomogram model for preoperative prediction of regional lymph node metastasis in thoracic oesophageal carcinoma.

Methods and Materials: The nomogram model was developed in a primary cohort which consisted of 391 regional lymph nodes from 95 patients with pathologically confirmed thoracic oesophageal carcinoma from January 2015 to December 2016. All patients underwent preoperative 18F-FDG PET/CT and contrast-enhanced CT scans. SUVmax of regional lymph nodes were collected. The texture features of lymph nodes were extracted from enhanced CT images. Lasso regression was used for data dimension reduction, feature selection, and texture feature model building. Multiple logistic regression analysis was used to develop the predictive model. We integrated the SUVmax information with the texture information to develop a nomogram model. A internal validation cohort consisted of 252 lymph nodes from 60 patients in 2017. The calibration and discrimination of the model were assessed.

Results: SUVmax and 12 texture features were associated with lymph node metastasis ($P < 0.05$ for both primary and validation cohorts). Predictors of the nomogram model was constructed. The model showed good discrimination (area under ROC curve: 0.87) and good calibration (P value of Hosmer-Lemeshow test: 0.48) in primary cohort. Application of the model in validation cohort could also obtain good discrimination (area under ROC curve: 0.91) and good calibration (P value of Hosmer-Lemeshow test: 0.41).

Conclusion: This study combined glucose metabolism information and texture features to develop a nomogram model, which could be used to predict regional lymph node metastasis in patients with thoracic oesophageal cancer.

B-0364 14:40

Prospective evaluation of modified DWI MRI for improved image quality and tissue differentiation in oncological follow-up examinations

C. Dreher¹, T. Kuder¹, S. Windhaber¹, F. König¹, D. Paech¹, R. Gnirs¹, T. Benkert², H.-P. Schlemmer¹, S. Bickelhaupt¹; ¹Heidelberg/DE, ²Erlangen/DE (c.dreher@dkfz-heidelberg.de)

Purpose: Diffusion weighted imaging (DWI) is an important part of oncological magnetic resonance imaging (MRI) examinations. This study aims at prospectively evaluating an oncologically adapted DWI sequence for improved image quality and tissue differentiation in patients with abdominal malignancies.

Methods and Materials: This IRB-approved, prospective in-vivo and ex-vivo study included phantom measurements using a dedicated phantom (PVP-K30) and 52 prospectively acquired oncological abdominal MRI examinations (mean age: 57 years; male/female: 21/31) using a 1.5T MRI scanner (AERA, SiemensHealthineers, Germany) including both a standard epi-DWI ("s-DWI"; b -values $0,900s/mm^2$) and an oncologically adapted, prototype optimized DWI ("opt-DWI"; epi-DWI with advanced processing, $b=0,50,900,1500s/mm^2$). Apparent-signal-to-noise-ratio (SNR) was quantitatively evaluated, image quality and tissue differentiation parameters were rated by two independent, blinded readers using a 5-point Likert-Scale. Statistics included Wilcoxon-signed-rank test and kappa statistic ($p<0.05$).

Results: The DWI-phantom demonstrated a significantly optimized contour sharpness and inlay differentiation for the opt-DWI. Apparent-SNR of b900-DWI MRI of the right/left hemiabdomen was significantly increased in opt-DWI (mean: $227\pm 250/150\pm 192$) vs. s-DWI (mean: $37\pm 17/40\pm 23$) ($p<0.001$). Image quality parameters (contour sharpness right liver, left liver and pancreas) were significantly increased in opt-DWI vs. s-DWI ($p<0.001$). Tissue differentiation for the upper abdominal organs and retroperitoneal structures was significantly increased in opt-DWI vs. s-DWI ($p<0.001$). Interreader reliability test showed good agreement (kappa=0.754) ($p<0.001$).

Conclusion: This prospective study demonstrates the superiority of an oncologically optimized DWI over standard DWI for abdominal oncological imaging. Assessment of anatomical structures including the retroperitoneum and reader confidence was significantly improved using the novel approach in oncological follow-ups.

USPIO contrast agents for detecting cancer: which one works best?

L. Müller, U. Keber, A. Mahnken, R. Mandic, M.-L. Martini, P. Seyfer; Marburg/DE

Purpose: Differences regarding physical and chemical properties of ultrasmall superparamagnetic iron oxide (USPIO)-MRI contrast agents influence their uptake, biodistribution and clearance. These characteristics could affect their ability to distinguish between malignant and benign lesions. The purpose of our study was the comparison of four USPIOs to find a suitable agent for possible future clinical practice.

Methods and Materials: This study was performed on forty athymic nude mice and approved by the local animal care committee. Hela cells and intramuscular inflammation were implanted into the hind thighs. On a 7T-scanner imaging was performed precontrast and serially 2, 4 and 24 hours after injecting USPIOs. Following USPIOs were used: Feraheme (AMAG Pharmaceuticals Inc., Waltham, MA, USA), P 904 (Guerbet Group, Villepinte, France), FeraSpin XS-Type and FeraSpin M-Type (Miltenyi Biotec GmbH, Bergisch Gladbach, Germany). Pre- and postcontrast differences of SI, SNR and CNR in tumour and inflammation were measured and analysed for significance using Wilcoxon-signed-rank tests and receiver-operating characteristic curves with Venkatraman's tests. Correlation between MR images and histologic slices stained with hematoxylin-eosin, Prussian blue and MAC 3-antibodies was performed.

Results: All four contrast agents tested were significantly able to distinguish between cancer and inflammation ($p < .05$). No significant differences were noticed between the different contrast media regarding their ability to do so ($p > .05$).

Conclusion: The four USPIOs tested show no significant difference regarding their ability in distinguishing between malignant lesions and inflammations. Therefore, USPIOs with similar physical and chemical properties could be used for this purpose in future clinical practice.

B-0366 14:48

Beyond lymph nodes: 18F FDG PET CT in detection of usual and unusual sites of extra nodal lymphoma

M. Abdel-Kawi, M. Nasr, A. Ibrahim; Cairo/EG (moustafa.kawi@gmail.com)

Purpose: To compare between PET/CT and contrast-enhanced computer tomography (CE CT) in the detection of extra nodal involvement in lymphoma and to correlate between SUV_{max} of the extra nodal lesion and the hottest LN.

Methods and Materials: 100 patients with pathologically proven lymphoma underwent whole body 18F-FDG PET/CT and CECT scan. Images were compared regarding the ability of detection of extra nodal lymphomatous sites. Kappa agreement was used to find the degree of agreement between both modalities. Pearson's correlation was used for correlating SUVmax of the extra nodal lesions and hottest LN. The degree of FDG uptake was correlated with histopathological type.

Results: There was a poor agreement between PET/CT and CE CT in the detection of extra nodal sites ($k=0.32$). There was a significant positive moderate correlation between SUVmax of the extra nodal lesions and hottest LN ($r=0.45$). PET/CT study resulted in up staging of 10% and down staging of

5% of cases.

Conclusion: FDG PET/CT scan enables better detection of extra nodal lymphomatous sites that show normal morphology at CECT. It may differentiate lymphomatous infiltration from benign causes of increased FDG avidity, which provide proper disease staging.

B-0367 14:52

Evaluation of STIR, T1 DIXON "in and out of phase" and DWI sequences, to propose a standardised protocol of the MRWB in patients affected by myeloma

A. Trisoglio, E. Soligo, S. Berardo, L. Sukhovei, S. Bor, G. Buoni, A. Stecco, A. Carriero; *Novara/IT (berardo.sara@gmail.com)*

Purpose: The International Guidelines include MRWB (MR-Whole Body) in the management of patients with plasma cell disorders, but there is no standardized protocol to follow. The aims of the study are: 1) to evaluate the effectiveness of STIR, T1DIXON and DWI, 2) to understand if there is a different ability to diagnose lesions in the patient before and after therapy, 3) to propose a protocol as short as possible.

Methods and Materials: Two radiologists retrospectively reviewed MRWB belonging to 112 patients with myeloma. Inclusion criteria: qualitative suitability of the sequences and presence of an exam after to be used as "control". Exclusion criterion: widespread infiltration. The statistical analysis (Friedman Test and the Sign test) was carried out by considering all patients and then before and after therapy. The "error" of the sequences and the correlation of the two readers with the ICC (Intraclass Coefficient Correlation) were calculated.

Results: There is no statistically significant difference in finding myelomatous lesions using only DWI (with ADC) compared to the simultaneous use of STIR or DIXON. No statistically significant differences were found even between patients before and after therapy despite the signal "change" of the lesions. The agreement is excellent for all sequences with average ICC of 0.99(0.95-1).

Conclusion: We propose the MRWB protocol: sagittal T1 and STIR on the column + coronal DIXON + DWI (ADC). If the DIXON sequences are not available: sagittal T1 and STIR on the column + coronal STIR + DWI (ADC). Both coronal sequences do not add diagnostic value.

B-0368 14:56

Optimisation of prostate cancer radiotherapy management with MR

F. Currò¹, M.C. Ricciardi², R. Danieli¹, M.F. Cavallaro¹, P. Martingano¹, M. Bertolotto¹, F. Stacul¹, M.A. Cova¹; ¹Trieste/IT, ²Padua/IT (francescacurro86@gmail.com)

Purpose: To evaluate the diagnostic accuracy of MR in local staging of prostate cancer and in risk category assessment; to demonstrate the role of MR in radiation therapy planning regarding target volume evaluation.

Methods and Materials: From January 2015 to June 2018, 109 patients with biopsy-proven prostate cancer addressed to radiotherapy were retrospectively identified; all patients underwent MR for local staging. The correlation between clinical stage and MR stage has been evaluated by Cohen's kappa weighted test; the McNemar test was used to analyze the differences in risk category assessment using T parameter as independent variable. The Wilcoxon test was used to determine the differences of radiation treatment volumes obtained on CT and on CT/MR fusion imaging.

Results: The agreement between MR and clinical staging was fair (0.38, CI 95% 0.20-0.56); the different staging resulted in a statistically significant difference in risk category assessment ($p < 0.003$). Finally, the radiation treatment volumes obtained on CT/MR fusion imaging was significantly smaller than the corresponding value obtained on CT ($p < 0.001$).

Conclusion: MR has been proven accurate in the management of patients with prostate cancer candidate to radiotherapy. The use of CT/MR fusion imaging allowed a better evaluation of radiation treatment volumes improving therapy efficacy.

B-0369 15:00

US and CEUS in ovary assessment of a murine model: preliminary findings on protective role of gonadotropin releasing hormone analogue from chemotherapy-induced ovarian damage

A. Colarieti, M. Venturini, L. Perani, A. Esposito, A. Del Maschio, F. De Cobelli; *Milan/IT (colarieti.anna@hsr.it)*

Purpose: The gonadotoxic effect of chemotherapy (CT) can lead to infertility in female cancer survivors. There is controversial evidence regarding the protective role of gonadotropin-releasing hormone analogue (GnRH-a) on CT-induced ovarian damage. First aim of this experimental study on a murine model was to characterize ovaries in normal conditions; second aim was to obtain preliminary findings on anatomical/vascular ovarian changes induced by GnRH-a.

Methods and Materials: US and CEUS (Vevo-2100-Visualsonics, 40-20-MHz probes) were performed (day 0, 10, 20) comparing two groups of female BALB/c mice (n=10/group) in prone position respectively treated with

subcutaneous injection of GnRH-a, Decapeptyl (DECA-treated-mice) and of PBS (Control-untreated-mice). Main US (ovary-diameter, dominant-follicle-diameter) and CEUS (peak-enhancement, wash-in-area-under-the-curve) parameters were investigated.

Results: Ovaries were ultrasonically identified and CEUS analysis was successfully performed in all cases with 100% of technical success. At day 20, a statistically significant increase of the dominant-follicle-diameter and reduced vascularization in DECA-treated-mice compared to Control-untreated mice was recorded.

Conclusion: Ovaries can be accurately studied in the murine model in prone position with US and CEUS. GnRH-a seems to exert a protective role on ovaries although further studies combining GnRH-a and chemotherapeutic agents will be needed to obtain more translational information useful for clinical practice.

B-0370 15:04

DWI predicts surgical outcome in advanced ovarian cancer

H. An, E. Lee, J.A. Perucho, K.W. Chiu, M. Chu, K.Y. Tse; *Hong Kong/HK (610779446@qq.com)*

Purpose: To evaluate the values of DWI-derived tumour burden of peritoneal carcinomatosis (PC) and its biology in determining the surgical outcome in advanced ovarian cancer (AOC).

Methods and Materials: Thirty-four AOC patients were prospectively recruited with pre-surgical DWI ($b=0, 400, 800 \text{ s/mm}^2$). Tumours with intermediate apparent diffusion coefficient (ADC) segmented by k-means clustering were used for solid tumour volume (STV) calculation discarding fatty, fibrous or cystic tissues. A functional peritoneal cancer index (fPCI) was generated by adding up all STVs from 13 abdominopelvic regions with additional points if porto hepatis, mesentery or bowel serosa were involved. Mean ADC was measured from 3 selected lesions with the largest STVs. At surgery, the surgical PCI (sPCI), surgical duration and surgical outcome (complete cytoreductive surgery or with residual disease) were recorded. Mann-Whitney U test, Pearson correlation (r) and logistic regressions were performed.

Results: Patients who achieved complete cytoreductive surgery had lower fPCI (4.30 vs 10.18) and sPCI (5.70 vs 12.00) but higher ADC (0.97 vs 0.73) than patients with residual disease ($p < 0.005$). fPCI was significantly correlated with sPCI ($r=0.899, p<0.001$) and surgical duration ($r=0.528, p=0.001$). fPCI, sPCI and ADC ($r=0.507, 0.529, -0.562$) were significantly correlated with residual disease ($p<0.005$). Both fPCI and ADC were significant in univariate and multivariate analyses ($p<0.05$; accuracy=82.4%, sensitivity=72.7%, specificity = 87.0%).

Conclusion: Pre-surgical fPCI and ADC were significant predictors for complete cytoreductive surgery in AOC.

B-0371 15:08

Accuracy of MDCT and laparoscopy in the prediction of peritoneal carcinomatosis index score in primary ovarian cancer

S.A. Ahmed, D. Fouad, G.S. Seifeldein, H.A. Taleb, A. Yehia, N.A.A. El Malek, D. Badary; *Assiut/EG (Doaafouad11@gmail.com)*

Purpose: To compare accuracy of MDCT and laparoscopy in preoperative prediction of peritoneal carcinomatosis index score compared with surgery.

Methods and Materials: fifty ovarian cancer patients underwent CT, laparoscopy, and laparotomy, peritoneal deposit site and size were documented in each region using Sugarbaker's method by dividing the abdomen into 13 regions, scores calculated based on lesion size (LS) and summed up (range 0-39), calculation of total PCI (peritoneal cancer index) was done radiographic, laparoscopic and compared to surgery.

Results: Exploratory laparotomy detected peritoneal deposits in 560/650 regions, the remaining 90 regions were free. CT and laparoscopy over all sensitivity 95%,98.4% specificity 88%,81.7%, PPV 98%,97%, NPV 75%,89.3%, and accuracy 94 %,96% respectively. The mean PCI in 0-8 abdominopelvic regions by CT and laparoscopy was (12.11 ± 7.04 (range 0-25) and (11.96 ± 6.46 (range 0-26), respectively. While in 9-12 regions mean PCI was 4.55 ± 1.90 (range 0-6), 3.95 ± 1.09 (range 0-6), respectively. However, CT is more accurate in upper abdomen and laparoscopy is more accurate in pelvic and small intestinal regions, no statistically significant difference regarding total PCI score.

Conclusion: CT and laparoscopy are of comparable accuracy regarding peritoneal deposits detection and final PCI scoring, although CT is less accurate than laparoscopy in regional detection and scoring at the pelvic and small intestinal regions, standardized dedicated MDCT protocol with experienced radiologists in addition to routine use of a standardized PCI form may provide better comprehensive multi-regional analysis for better patient outcome.

Quantitative cardiac magnetic resonance in the detection of early cardiac transplant rejection - MRI compared with endomyocardial biopsy

M.W. Raudner, A. Wielandner, K. Uyanik-Ünal, M.-E. Stelzmüller, A. Zuckermann, C. Loewe, D. Beitzke; Vienna/AT
(marcus.raudner@meduniwien.ac.at)

Purpose: Cardiac transplantation is a lifesaving procedure for patients with end-stage heart failure. As acute rejection is a severe complication patients have to undergo invasive endomyocardial biopsy to rule out rejection episodes. This study is focused at comparing extracellular volume (ECV), T1 and T2 mapping via cardiac magnetic resonance imaging (CMR) with results endomyocardial biopsy at early post-transplant follow-ups to provide reference values for rejecting and non-rejecting patients.

Methods and Materials: Forty-five patients underwent endomyocardial biopsy three months after cardiac transplantation alongside CMR on a 1.5T system for evaluation of graft rejection and function. Left ventricular function (LVEF) was derived from short axis steady-state free precision (SSFP) sequences, myocardial ECV (%) was calculated using T1 pre- and postcontrast maps at three short axis slices using a 16-segment model. T2 maps were acquired from identical planes for oedema assessment. CMR findings were compared with histology based on ISHLT guidelines.

Results: Myocardial biopsy showed no signs of rejection (0A/0R) in thirty-nine patients and mild rejection (1A/1R) in six patients. Mean LVEF was normal in both groups (64.1% vs. 72.7%; p=.082). Mean ECV% (31.8% vs. 31.8%; p=.980), T1 in ms (1063.0 vs. 1079.1; p=.418) and T2 in ms (51.2 vs. 53.0; p=.137) did not differ significantly between patients with no or mild rejection.

Conclusion: ECV is known to be increased in post-transplant patients. In the reported patient cohort, there was no significant difference in the observed quantitative CMR markers in patients with early mild vs. no transplant rejection, showing comparable normal values.

B-0375 14:08

Evaluate diffuse myocardial characteristics in rabbit model based on daunorubicin-induced cardiotoxicity by CMR native T1 mapping imaging

H. Liu, R. Xu, Y. Guo, Z. Yang, L. Chen, C. Fu, X. Li; Chengdu/CN
(liuhuiimage@qq.com)

Purpose: This study aimed to quantitatively evaluate diffuse myocardial characteristics of daunorubicin-induced cardiotoxicity in rabbit model, and further to explore the heart injury of different cumulative dose and time point.

Methods and Materials: Twenty-two adult New Zealand rabbits were injected with daunorubicin weekly for 2-4 weeks (8 subjects with 4mg/kg for 2 weeks, 8 subjects with 4mg/kg for 4 weeks and 6 subjects with 3mg/kg for 4 weeks) and 9 normal rabbit were enrolled. According to the cumulative dose, all modelling rabbits were divided into three groups (mild, 20-29mg; moderate, 30-39mg and high, 40-49mg). Cardiac structure, function, mass, and native T1 values measurement were based on cine imaging and pre-contrast T1 mapping.

Results: There were four rabbits (18.2%) occurred LVEF decreased among all of modelling rabbits. The mean native T1 values on CMR in rabbits with 4mg/kg weekly at 2 and 4 weeks were significantly higher than those measured before modelling (native T1 values: 1243.90±39.90ms, 1271.18±98.09ms vs. 1115.91±54.95ms; all p < 0.017), and T1 values of 4 weeks modelling rabbits higher than that of 2 weeks. All modelling rabbit had higher T1 values than normal subjects, the high dose group have higher T1 values than moderate dose group (native T1 values: 1297.75 ± 83.16ms vs. 1220.17± 77.85ms) but there is no significant difference between mild and moderate group.

Conclusion: Native T1 mapping could early detection diffuse myocardial injury cause by daunorubicin, the higher cumulative dose and longer time may have more severe outcome. And further monitor study is ongoing.

B-0372 15:12

IVIM-DWI MRI in meningiomas: a tool to detect early microstructural changes during and after proton-therapy

M.V. Raciti¹, A. Franconeri¹, G. Buizza², G. Fontana¹, G. Viselner¹, A. Iannalfi¹, E. D'Ippolito¹, L.M. Farina¹, L. Preda¹; ¹Pavia/IT, ²Milan/IT
(mariaivittoria.raciti@libero.it)

Purpose: To investigate the early microstructural changes of meningiomas during and after proton-therapy through quantitative analysis of Intravoxel Incoherent Motion-Diffusion Weighted MRI (IVIM-DWI MRI) parameters.

Methods and Materials: Since January 2017, 20 patients with meningioma were enrolled for proton-therapy. Morphological and DWI-MRI (7b-values: 0,50,100,150,200,400,1000[s/mm²]) for a simplified IVIM were acquired before the 1st(t0), at the 10th (t10), 20th (t20), 30th (t30) treatment fraction, 3 and 6 months after the end of the therapy (1st-2nd follow-up). Tumour contours were drawn on T2W images and registered to DW-MRI. Apparent diffusion coefficient maps (ADC), true diffusion (D), pseudodiffusion (D*) and perfusion fraction (f) coefficients from IVIM were obtained for all time-points. Statistical analysis was performed using pairwise Wilcoxon test (α=0.05).

Results: Statistically significant differences were found for ADC, D and D* median values between every intra-treatment time-point and 1st-2nd follow-up. Both ADC and D tumours median values resulted progressively higher from t0 to 2st follow-up; especially, comparing D intra-treatment median values, significant differences were found between t0 and t20 (p=0.03), and between t0 and t30 (p=0.02). f didn't show significant changes at any time-points, but increased its mean and median values at 2nd follow-up. Tumour volume decreased from t0 to 1st follow-up in 12 patients; three of them showed tumour volume reduction greater than 28% and the highest increment of median D from t0 to t30.

Conclusion: IVIM-DWI in meningiomas detects early microstructural changes during proton-therapy and potentially predicts tumour response in follow-up. A future goal is to represent microstructural tissue heterogeneity through parametric response mapping, conceiving MRI as an "in-line" image-biomarker to guide individualized treatments and early treatment adaptation, accounting for heterogeneity and response variability.

B-0373 15:16

Predictive role of apparent diffusion coefficient values from diffusion weighted sequences in patients with sacral chordoma treated with carbon ions radiotherapy alone

S. Casale¹, M. Fanizza¹, C. Paganelli², G. Viselner¹, E. Turpini¹, M. Fiore¹, I. Fumagalli², F. Valvo¹, L. Preda¹; ¹Pavia/IT, ²Milan/IT
(casale.silvia88@gmail.com)

Purpose: To evaluate if baseline Apparent Diffusion Coefficient values (ADC) from Diffusion Weighted sequences could predict response to treatment in Patients with sacral chordoma not suitable for surgery treated with carbon ions radiotherapy (CIRT) alone compared with volume modifications.

Methods and Materials: Patients included had sacral chordoma histological diagnosis, they had one cycle of CIRT alone and a minimum of 12-months follow-up. All patients underwent MRI before treatment (baseline), every three months in the first two years after treatment and every six months afterwards. For each MRI, lesions volume were obtained and median, kurtosis and skewness ADC values were analyzed within the whole lesion volume. Lesions presenting a volume increase more than 20% from the baseline were considered as progression of disease (PD), lesions presenting a volume reduction of at least 30% were considered as a response disease (RD); lesions between those two limits were considered as stable disease (SD).

Results: 60 lesions in 59 patients with sacral chordoma were studied (range follow-up 12-60 months). 6 lesions were categorized as PD, 40 RD and 14 SD. PD showed significant higher baseline median ADC values (mm²/s) (p=0.015) compared with both RD and SD (1659vs1253vs1266). PD showed more negative skewness values (-0.1vs0.26vs-0.03) compared with both the other groups, not significantly different (p=0.2).

Conclusion: preliminary results suggest that baseline ADC values could predict response to treatment with CIRT, in particular to detect potential non responder patients.

B-0376 14:16

Myocardial characterisation using CT extracellular volume in swine acute myocardial infarction model: comparison with CMR T1 mapping and histology

H. Xu, Y. Guo, L. Xie, R. Xu, M. Yang, H. Li, H. Fu, C. Fu; *Chengdu/CN* (xuhuayan89@sina.com)

Purpose: This study sought to evaluate the myocardial damage in acute myocardial infarction (AMI) of swine model using the revolution computed tomography (CT) extracellular volume (ECV), and further comparing with the cardiac magnetic resonance (CMR)-T1 mapping and histology.

Methods and Materials: 10 AMI swine models were generated by left descending coronary artery occlusion with surgery. Pre-contrast plain and post-contrast-enhanced CT were scanned within 24 hours after surgery. And CMR pre-/post-contrast T1 mapping using MOLLI sequence on 3T MR scanner (Skyra, Healthcare, Erlangen, Germany) were performed after CT examination (GE, Revolutions, 256 rows). CT-ECV (Ziostation, Version 2.9.2.2, Japan), CMR native T1 and ECV (cmr42, version 5.6.4; Canada) were computed and compared.

Results: A total of 160 AHA segments were analysed, in which, 36 segments were found infarcted. CT-ECV as well as native T1, CMR-ECV were all increased in infarct segments comparing with remote non-infarct segment (native T1:1476±50ms vs. 1170±46 ms; CMR-ECV:38.35±4.77% vs. 21.21±3.56%, $p < 0.05$). However, post-T1 were decreased for the contrast short T1 time ($p < 0.05$). CT and CMR-T1 mapping had strong correlation in measuring infarct size ($r=0.78$, $p < 0.001$). Linear correlation showed that CT-ECV correlated well with CMR-ECV. In addition, Bland-Altman reveals good agreement for evaluating both infarct size and ECV value (bias: 1.6±11). Histology verified that the size of infarction well corresponded to CT and CMR.

Conclusion: CT-ECV was well related with and showed good agreement with CMR-ECV and histology. In AMI swine model, CT-ECV were usefully for measuring ECV fraction of myocardial damage in the infarction area.

B-0377 14:24

Feasibility of T1-rho mapping as endogenous contrast agent to detect myocardial fibrosis

C. Celeng, M. Froeling, T. Leiner; *Utrecht/NL* (celengcsilla@gmail.com)

Purpose: The aim of this study was to assess the feasibility of native T1-rho mapping as a possible endogenous contrast agent to detect interstitial myocardial fibrosis.

Methods and Materials: In this prospective study we enrolled 219 patients (87 female, 132 male; mean age 48±2) referred for the evaluation of suspected or known non-ischemic cardiomyopathies. All patients underwent T1-rho mapping on a 1.5T clinical MR system. To evaluate the ability of T1-rho to detect myocardial fibrosis native and post contrast T1 maps were acquired and the extracellular volume (ECV) was calculated. After the acquisition was completed all images were transferred to a dedicated workstation for motion correction and standardized automatic processing. Spearman correlation coefficients were calculated to determine the correlation between ECV and whole heart T1-rho values, native T1-values and post-contrast T1-values.

Results: T1-rho and ECV maps were successfully obtained in 211 patients of which 189 datasets were of sufficient quality for automatic processing. Mean T1-rho relaxation time was 63.9±4.9 ms; mean native T1 was 1093.6±55.7 ms; mean post-contrast T1 was 390.3±57.6 ms; ECV values ranged between 5-47% (25.2±8.0). A strong and significant correlation was found between T1-rho relaxation time and ECV fraction (Spearman coefficient: 0.63, $p < 0.001$). Weak correlations were found between native T1 and ECV (0.31, $p < 0.001$) and post-contrast T1 and ECV (-0.26, $p < 0.01$).

Conclusion: T1-rho correlates well with ECV, which indicates that it has the ability to provide information on diffuse myocardial fibrosis without the need for injection of contrast agents.

B-0378 14:32

Myocardial inflammation in DCM and mapping: an elusive connection

F. Hahn¹, D. Fleischmann¹, M.C. Halfmann¹, H.-P. Schultheiss², K.-F. Kreitner¹, P. Wenzel¹, T. Emrich¹; ¹Mainz/DE, ²Berlin/DE (fhahn@uni-mainz.de)

Purpose: The purpose of this study was to evaluate non-invasive detection of immunohistochemically established myocardial inflammation in non-ischaemic dilated cardiomyopathy (DCM) using T1 and T2 mapping.

Methods and Materials: The study population consisted of 59 retrospectively identified patients with DCM phenotypes who underwent endomyocardial biopsy (EMB) and cardiac magnetic resonance (CMR) imaging. EMB served as the gold standard in all patients. Inflammation in EMB was grouped according to the number of LFA1-positive lymphocytes, CD3-positive lymphocytes, and MAC1-positive macrophages. A control consisted of a matched group of healthy volunteers with CMR imaging (n=58). All imaging was acquired with a 3T Siemens Prisma® Scanner. T1 and T2 maps were created and analysed using dedicated cardiovascular software (Circle CVI®). Global and segmental

mapping values as well as septal measurements and tissue heterogeneity parameters were recorded.

Results: Mean global T1 and T2 mapping values of DCM phenotype patients were significantly higher compared to healthy volunteers (both $p < 0.001$). However, the presence of EMB-proven myocardial inflammation within the DCM group did not correlate with T1 and T2 mapping values when regarding global ($p > 0.4$ and $p > 0.6$ resp.), septal (both $p > 0.8$) or maximum segmental values ($p > 0.1$ and $p > 0.9$ resp.).

Conclusion: T1 and T2 mapping parameters were not able to reliably detect myocardial inflammation in DCM phenotypes. The reasons for this behaviour are currently not fully understood. Possible explanations could be different aetiologies of inflammation, sample errors by EMB within the inflammation free-DCM group as well as high inter-individual differences in mapping values.

B-0379 14:40

T1 and T2 mapping assessment of chronic myocarditis vs dilated cardiomyopathy, hypertensive heart disease and healthy controls

M.T.A. Wetscherek¹, W. Rutschke², C. Frank³, M. Grothoff², P. Lurz², H. Thiele², M. Gutberlet², C. Lücke²; ¹Cambridge/UK, ²Leipzig/DE, ³Halle/DE

Purpose: To evaluate T1 and T2 relaxation times (referred to as T1 and T2) and extracellular volume fraction (ECV) in chronic myocarditis vs dilated cardiomyopathy (DCM), hypertensive heart disease (HHD) and healthy controls.

Methods and Materials: Retrospective analysis of 71 consecutive cases that underwent cardiac magnetic resonance (CMR) as part of a full diagnostic workup for suspected myocarditis. All patients had a presentation at >14 days after initial symptoms. 13 cases were excluded due to previous myocardial infarction or technical aspects. The CMR protocol included native T1 and T2 mapping, and post-contrast T1 mapping. The analysis of all cases was done by two readers.

Results: 27 patients were diagnosed with chronic myocarditis, 21 patients with DCM and/or HHD, and 10 subjects were included in the control group. All mapping parameters (cut-off values: T1 1070ms, T2 54ms, ECV 30%) yield good diagnostic performance in the assessment of chronic myocarditis with the best Sensitivity/Specificity/Accuracy of 93/80/88 for ECV, followed by 70/80/74 for T2, and 52/88/69 for T1. Significant difference was found between patients with DCM/HHD and the control group regarding T2 and ECV, but not for T1. No significant difference was found between the chronic myocarditis group and the DCM/HHD group. All mapping parameters achieved excellent interobserver agreement, with correlation coefficients ICC>0.977, $p < 0.001$, the highest achieved for ECV (ICC=0.994).

Conclusion: Mapping parameters have the potential to aid reaching a definite diagnosis of chronic myocarditis, but clinical-radiological correlation remains critical in its differentiation from other generalized chronic myocardial processes, such as DCM and HHD.

B-0380 14:48

The impact of myocardial thickness in hypertrophic cardiomyopathy using combination of CMR native T1 and T2 mapping

L. Huang, L. Ran, L. Xia, R. Han; *Wuhan/CN*

Purpose: The aim of this study was to investigate the abnormal changes of different hypertrophic myocardial segments in HCM using the combination of native T1 and T2 mapping.

Methods and Materials: Forty-seven patients with HCM and 19 healthy volunteers underwent cardiac magnetic resonance imaging (CMR). Imaging protocols included short-axis cine, native T1 and T2 mapping sequences. Native T1 and T2 values, and left ventricular end-diastolic wall thickness (EDTH) were measured for each myocardial segment. The differences in native T1 and T2 values, and EDTH were compared between normal myocardial segments of the healthy volunteers and hypertrophic myocardial segments of HCM patients. The disparity of hypertrophic segments with different severities was also evaluated.

Results: Native T1 and T2 values were significantly elevated in non-hypertrophic segments and hypertrophic segments of HCM patients (both $P < 0.001$). Compared to mild and moderate hypertrophic segment, native T1 value of severe hypertrophic segments in HCM was significantly elevated ($P < 0.05$, respectively), but the degree of myocardial thickening reduced ($P < 0.05$, respectively). T2 value of mild hypertrophic was significantly lower than moderate and severe hypertrophic segments ($P < 0.05$, respectively).

Conclusion: Native T1 and T2 values were elevated in non-hypertrophic segments of HCM. It is more sensitive for T2 value to detect abnormal changes than native T1 in mild hypertrophic segments in HCM. Native T1 and T2 values had linear correlation with EDTH, and may provide potential incremental value to EDTH for risk stratification and prognosis in HCM.

B-0381 14:56

Assessment of diagnostic performance of cardiac magnetic resonance (CMR) mapping parameters in acute myocarditis (AM) patients
 D. Palumbo¹, A. Palmisano¹, R. Faletti², G. Benedetti¹, M. Gatti², A. Del Maschio¹, F. De Cobelli¹, A. Esposito¹; ¹Milan/IT, ²Turin/IT (palumbo.diego@hsr.it)

Purpose: Our aim was to evaluate diagnostic accuracy of CMR mapping parameters in patients with acute myocarditis (AM).

Methods and Materials: Between October 2016 and June 2018 we enrolled 33 patients (39 ± 12.4yrs; 18M, 15F) with clinical suspicion and bioptical confirmation of AM who underwent CMR within three weeks from symptoms onset and 40 healthy controls (37.6±11.8yrs; 22M, 18F). CMR protocol included evaluation of native T1 mapping, T2 mapping and Extra Cellular Volume (ECV), each one then analysed in order to assess mean global, basal, mid ventricular, apical and segmental (AHA) values.

Results: AM patients demonstrated mean global native T1 mapping, T2 mapping and ECV values significantly higher in comparison with healthy individuals (1103.79ms [1068.6 - 1202.88] vs. 1023.48ms [963.39 - 1108], p<.0001; 53.95ms [51.92 - 58.74] vs. 46.79ms [43.10 - 49.62], p<.0001; 30.28% [27.12 - 32.1] vs. 25.88% [22.63 - 28.78], p=0.05). By means of ROC analysis we then identified as best diagnostic performance threshold for native T1 mapping a value of 1045.45ms (AUC: .949; Se: 90.6%; Sp: 87.5%), for T2 mapping a value of 49.51ms (AUC: .982; Se: 92.9%; Sp: 100%) and for ECV a value of 26.7% (AUC: .894; Se: 80%; Sp: 100%). Thus, above these threshold values, CMR mapping parameters were highly suggestive of active disease.

Conclusion: CMR mapping parameters demonstrate an optimal diagnostic performance, with high sensitivity and specificity, in predicting patients with AM.

B-0382 15:04

Evolution of myocardial oedema of acute and subacute myocardial infarction verified in swine model: assessed by native T1 mapping and T2 mapping
 H. Liu, Y.-K. Guo, H. Xu, Z.-G. Yang; Chengdu/CN (liuhuiimage@qq.com)

Purpose: To dynamically investigate the evolution of myocardial oedema in acute and subacute myocardial infarction (MI) using CMR native T1 mapping and T2 mapping technique.

Methods and Materials: 10 acute MI swine model were generated by left descending coronary artery occlusion with surgery. All swine model were performed CMR scanning (MEGNETOM Skyra, Healthcare, Erlangen, Germany) including native T1 and T2 mapping in 24 hours and 7 days. Native T1 mapping were used Modified Look-Locker inversion recovery (MOLLI) sequences. The infarct sizes, native T1 value and T2 value were measured and compared in acute and subacute period in MI swine. Mann-Whitney U test and Pearson correlation coefficient were used for statistical analysis.

Results: For MI sizes, there is no difference in acute and subacute MI indicated by both native T1 mapping (p=0.421) and T2 mapping images (P=0.69). Although, the native T1 values of infarction area showed no significant (p=0.22) difference, the T2 values in subacute MI increased compared to acute MI (p=0.032). In addition, the native T1 and T2 value of both MI had close correlation (r=0.718, P=0.019).

Conclusion: Compared with the acute phase, the degree of myocardial oedema was determined more serious in subacute stage. CMR T2 mapping technique can determine severity of myocardial oedema caused by acute and subacute myocardial infarction.

Long-axis T1 and T2 mapping in Takotsubo cardiomyopathy: trash or treasure?

T. Emrich, R.M. Brumberg, P. Wenzel, S. Lyschik, F. Jungmann, S. Rueppel, C. Düber, K.-F. Kreitner; Mainz/DE (tilman.emrich@gmail.com)

Purpose: Takotsubo cardiomyopathy (TTCM) is a regional disease affecting either the apex, the mid and/or the base of the heart. Long-axis views allow the illustration of these regions in one view. For scientific purposes, short-axis slices are used typically to measure absolute relaxation times in cardiac diseases. The purpose of this retrospective study was to establish the role of long-axis imaging with T1 and T2 mapping in TTCM.

Methods and Materials: We compared CMR and ventriculography of 41 consecutive patients with TTCM. TTCM-involved segments and regions were defined as segments with wall motion disturbances and absence of ischaemia. With a dedicated cardiovascular software (Circle CVI®, Calgary, Canada), T1 and T2 maps were created, TTCM-involved and not-involved segments

analysed and mean absolute relaxation times recorded.

Results: Mean relaxation times significantly distinguished involved from not-involved segments, e.g. TTCM involved: 1408 ± 151 ms (T1 map, 4-chamber view) versus TTCM not-involved: 1296 ± 105 ms; p < 0.001 for all. These results were also achieved in 2-chamber views. Furthermore, T1 and T2 mapping were equally useful for demonstrating myocardial oedema in long-axis views of TTCM patients.

Conclusion: Myocardial T1 and T2 mapping is a powerful tool for the detection of myocardial oedema. In segmental and/or regional-dominated diseases such as TTCM, long-axis imaging is a valuable tool to demonstrate the extent of involved segments in one view.

Performance of native T1 and T2 mapping cardiovascular magnetic resonance to detect myocardial oedema in patients with end stage renal disease

W. Peng, H. Xu, Z. Li, C. Xia, Y. Guo; Chengdu/CN (yimaerlin@163.com)

Purpose: To evaluate the performance of quantitative native T1 and T2 mapping to identify myocardial oedema (ME) in patients with ESRD.

Methods and Materials: Seventy ESRD patients and 16 age-gender-matched healthy volunteers were prospectively enrolled and underwent CMR. All the parameters from CMR, including native T1,T2,T2 SI ratio and myocardial strain, were measured and compared. ROC analysis was performed to determine whether T2 values could be used in discriminating ME between ESRD patients and normal.

Results: The global T2 values of ESRD patients without diffused LGE and with diffused LGE were higher than normal controls (43.69±3.62, 41.82±3.43, 38.79±3.69ms, respectively, all P<0.05). The global T1 values of ESRD patients with diffused LGE was highest among three groups (1356.79±40.08ms,1321.02±56.65, 1286.12±52.60, respectively, all P<0.05),but no statistical difference were found between normal and patients without LGE. The LVEF, GRS, GCS and GLS of patients with diffused LGE were significantly decreased (all p <0.05). No statistical difference were found T2 SI ratios among three groups (P=0.86). By ROC analysis, T2 values exhibited a higher diagnostic accuracy for detecting ME(AUC= 0.846; 95% CI: 0.715 to 0.932, Criterion>41.9448, SE 73.5%(55.6-87.1%) SP 87.5%(61.7-98.4%))than T1 values or T2 SI ratio(all p<0.05).

Conclusion: ME and MF were existed in ESRD patients and had a negative effect on cardiac function. T2 mapping seems to be superior comparing with native T1 and T2 values for assessing ME in ESRD patients . The threshold values of T2 values may be used as indicators for differentiating ME between ESRD patients and normal.

Balanced steady-state free precession MRCP is a robust alternative to respiration-navigated 3D turbo-spin-echo MRCP

F.C. Hasse, B. Selmi-Özer, C. Rupp, H.-U. Kauczor, T. Weber; Heidelberg/DE (felix.hasse@med.uni-heidelberg.de)

Purpose: Despite synchronization to respiration, respiration-navigated (RN) 3D turbo-spin-echo MRCP is limited by susceptibility to motion artefacts. Aim of this study was to assess quality of pancreaticobiliary duct visualization of a non-RN MRCP alternative based on balanced steady-state free precession imaging (BSSFP) with overlapping slices compared with RN MRCP.

Methods and Materials: Prospective study on 50 consecutive patients receiving MRCP at 1.5T without final diagnosis of pancreaticobiliary duct disease. Intraindividual comparison of coronal RN MRCP (thickness, 1.5 mm; interval, 1.5 mm) with combined coronal (thickness, 4 mm; interval, 1.6 mm) and transverse (thickness, 6 mm, interval, 2.4 mm) BSSFP MRCP. Image quality was scored for 6 pancreaticobiliary duct segments (3 pancreatic, 3 biliary) using a 6-point scale (0, not depicted, 5, entirely depicted with excellent details). A score of 2 or lower was defined to indicate insufficient duct visualization. ANOVA tests were used for statistical group comparison.

Results: Overall duct visualization was scored with 4.0±1.0 for RN MRCP (pancreatic, 3.6±1.3; biliary, 4.5±1.0) and 4.7±0.4 for combined coronal and transverse BSSFP MRCP (pancreatic, 4.5±0.7; biliary, 4.9±0.2), respectively (p<0.001). The number of segments visualized insufficiently was lower for BSSFP MRCP (n=6/300) than for RN MRCP (n=56/300, p<0.001). Segments

visualized insufficiently in RN MRCP had a mean score of 4.0 ± 1.0 in BSSFP MRCP. Mean acquisition time was 49% shorter for combined coronal and transverse BSSFP MRCP (100.2 ± 0.4 s) than for RN MRCP (198.0 ± 98.7 s).
Conclusion: Non-RN BSSFP MRCP with overlapping slices is a fast and robust alternative to RN MRCP for pancreaticobiliary duct visualization.

B-0386 14:08

Can two breath-hold 3D-MRCP replace the conventional 3D-MRCP?

M. He, H. Xue, Z. Jin; Beijing/CN (377174431@qq.com)

Purpose: To prospectively evaluate and compare the image quality and diagnostic performance of three 3D MRCP protocols including Compressed-Sensing (CS), Gradient Spin Echo (GraSE) and navigated-trigger(NT) MRCP.

Methods and Materials: A total of 64 patients suspected with duct-related pathologies were prospectively enrolled and done the three MRCP protocols randomly. The acquisition time was recorded and compared by paired t test. The imaging quality(IQ) was subjectively evaluated by 2 radiologists independently. The Wilcoxon signed rank test was used to compare IQ scores. The diagnosis performance was evaluated by the AUC value and compared by McNemar's test. The inter-observer agreement was evaluated by linearly weighted kappa coefficients.

Results: Compared to NT-3D-MRCP, the acquisition time of CS-BH-3D-MRCP and GraSE-3D-BH-MRCP was significantly decreased (both $P < 0.01$), while the IQ of them was significantly improved (4.53 ± 0.72 and 4.37 ± 1.10 vs. 3.75 ± 1.18 , both $P < 0.05$). There is no significant difference in both scan time and imaging quality ($P > 0.05$) between these two breath-hold (BH) MRCP. The AUC was 0.811 with NT-MRCP, 0.892 with CS-MRCP and 0.845 with GraSE-MRCP (all $P > 0.05$). The diagnosis performance of the combination of CS-MRCP and GraSE-MRCP (AUC=0.935) was significant better than that of the NT-MRCP ($P < 0.05$). The subjective evaluation all reached good to excellent level of agreement ranging from 0.623 to 0.945.

Conclusion: Compared to NT-MRCP, CS-BH-3D-MRCP and GraSE-3D-BH-MRCP can provide better image quality, while decreasing the scan time significantly. When combine these two BH-3D-MRCP, the diagnosis performance was significantly better than that with the NT-MRCP.

Role of dynamic contrast-enhanced MRI in early detection of gallbladder carcinoma

N. Yadu, S. Saxena; Lucknow/IN (n_yadu@yahoo.com)

Purpose: Gall bladder carcinoma is a rare disease with notoriously high mortality rates. Gall bladder wall morphology and enhancement pattern on dynamic contrast enhanced MRI can be useful in differentiating early gall bladder carcinoma (stage T2 or lower) from benign mimics.

Methods and Materials: Dynamic contrast enhanced VIBE sequences of upper abdomen along with MRCP images were obtained from 30 patients. All dynamic contrast enhanced MR images were evaluated for the delineation of gallbladder wall morphology and enhancement pattern. Statistical analysis was done using Statistical Package for Social Sciences version 15.0 or above. Measure of agreement between imaging findings and histopathological/surgical staging was expressed in terms of measures of agreement (κ , kappa statistic).

Results: MRI diagnosis was made in 30 cases. The sensitivity, specificity, positive predictive and negative predictive values were 95.7%, 85.7%, 95.7% and 85.7% respectively. The accuracy of test was 93.3%. Early enhancement persisting into delayed phase was the predominant pattern in malignant pathology (78.3%) while early enhancement with subsequent wash out was more common in histologically benign cases (71.4%). Statistically, the enhancement pattern differed significantly for the two diagnoses ($p=0.023$). On evaluating the measure of agreement between MRI and histopathology it was found to have almost perfect agreement, which was also significant statistically ($\kappa=0.814$; $p<0.001$).

Conclusion: Dynamic contrast enhanced MRI was found to be an accurate and reliable method for diagnosis of early Gall Bladder carcinoma. It helped to justify wall thickening with early enhancement persisting into delayed phase as the diagnostic criteria for malignancy.

B-0389 14:32

Utilisation of virtual non-contrast images derived from dual-energy CT in the evaluation of biliary stone disease: should we obtain true non-contrast images?

J. Bae, D. Lee, I. Joo, S. Jeon, J.K. Han; Seoul/KR (jaeseok.bae@gmail.com)

Purpose: To compare the virtual non-contrast (VNC) images acquired through dual-energy computed tomography (DECT) with the true non-contrast (TNC) images in the detection of biliary stones and assess whether VNC images can replace TNC images.

Methods and Materials: Between March 2017 and April 2018, we retrospectively enrolled 75 patients with suspicious biliary disease who underwent dual-source DECT and surgery and/or endoscopic intervention within 2 months from the CT. The sensitivity and specificity for detecting

gallstone and common bile duct (CBD) stone were compared between the VNC and TNC using McNemar test. In addition, the image quality and acceptability of VNC as replacement for TNC were assessed.

Results: In our study, 37 patients had gallstones, 2 had CBD stones, and 6 had both gallstone and CBD stones. For detection of gallstones, the sensitivity and specificity were 90.7% (39/43) and 87.5% (28/32), respectively, for the TNC images, and 88.4% (38/43) and 90.6% (29/32), respectively, for the VNC images. With respect to CBD stones, the sensitivity and specificity were 87.5% (7/8) and 98.5% (66/67), respectively, for the TNC images, and 75.0% (6/8) and 100% (67/67), respectively, for the VNC images. There was no significant difference in the sensitivity and specificity between each image set ($P > .05$). The VNC images were considered as complete replacements for the TNC images in 72 and 71 patients by the two reviewers.

Conclusion: The VNC images acquired through DECT were comparable to the TNC images for the detection of biliary stones and may replace the TNC images.

B-0390 14:40

Diagnosis of biliary stone disease: compressed-sensing-accelerated 3D-MRCP versus conventional MRCP

X. Zhao¹, M. Huang¹, J. Zhu², J. Cheng¹; ¹Zhengzhou/CN, ²Beijing/CN (weybey@163.com)

Purpose: To evaluate the image quality and diagnostic performance of a prototype 3-dimensional magnetic resonance cholangiopancreatography (3D-MRCP) with compressed sensing (CS) in diagnosing biliary stone disease.

Methods and Materials: This retrospective study recruited 62 patients (M:F=27:35; age, 56.9 ± 16.4 years) who underwent 3D-MRCP on a 3T MAGNETOM Prisma (Siemens Healthcare, Erlangen, Germany). Biliary stone disease was confirmed for all patients by subsequent procedures within two weeks. 3D protocols included conventional MRCP (c-MRCP), navigator-triggered MRCP with CS acceleration (NT-CS-MRCP), and 3D breath-hold CS-MRCP (BH-CS-MRCP). 2 radiologists independently rated image quality and duct visibility. Presence of stones in extrahepatic duct (EHD), gallbladder (GB) and intrahepatic duct (IHD) were evaluated based on coronal source images. Receiver operating characteristic (ROC) analysis was used to calculate the area under the curve (Az value), sensitivity, and specificity of biliary stone disease diagnosis in each biliary duct location.

Results: Mean acquisition times of BH-CS-MRCP (17s) and NT-CS-MRCP (207s) were remarkably shorter than c-MRCP (455s, both $P < 0.001$). Overall image quality and duct visualization were not significantly different among the 3 protocols (all $P > 0.05$), except that NT-CS-MRCP and c-MRCP depicted both pancreatic duct and bilateral second IHD better than BH-CS-MRCP (all $P < 0.05$). The diagnostic performances of all three examinations were high for detecting EHD stones, GB stones, and IHD stones, but did not have significant differences (mean Az value: 0.84-0.99). Inter-observer agreement was fair to perfect.

Conclusion: NT-CS-MRCP and BH-CS-MRCP can provide comparable image quality and diagnostic performance to c-MRCP for biliary stone diseases, with significantly shorter acquisition time.

B-0391 14:48

Differentiating and segmenting isoattenuating gallstones from bile with dual-layer spectral CT: an ex vivo phantom study

T.C. Soesbe, M.A. Lewis, Y. Xi, T. Browning, L. Ananthkrishnan, R.E. Lenkinski, J.R. Leyendecker; Dallas, TX/US (todd.soesbe@utsouthwestern.edu)

Purpose: Develop a dual-energy CT (DECT) method for visually segmenting isoattenuating gallstones from bile and compare it to other DECT methods using an ex vivo phantom reader study.

Methods and Materials: Gallstones from 105 cholecystectomy patients were placed inside 120mL vials containing 5% ox-bile. The vials were scanned in a water-filled phantom with dual-layer DECT. From conventional CT, 30 isoattenuating gallstone vials (gallstone diameters 4.3 to 24.7mm) and 30 bile-only controls were selected. Six readers evaluated DECT images for the presence of isoattenuating gallstones on conventional, virtual non-contrast, monoenergetic 200keV, monoenergetic 40keV, and segmented images. The segmented images were created using a 2D-histogram of Compton and photoelectric attenuations and custom ROI software.

Results: Segmented images gave the highest mean intrareader ($88.1 \pm 7.6\%$) and interreader agreements (first reading 88.2%, second reading 93.6%), as well as the highest AUC (0.99, 95%CI (0.97, 1.00), all adjusted P values < 0.02) for all 30 gallstones. No significant difference was found between the segmented and monoenergetic images for gallstones with mean diameters > 9 mm (both adjusted P values > 0.05). For gallstones with mean diameters < 9 mm, the segmented images had the highest AUC (0.99, 95%CI (0.97, 1.00) all adjusted P values < 0.007). The pathology versus segmented image gallstone size mean difference was -0.6mm (LOA 2.6 to -3.8mm).

Conclusion: Isoattenuating gallstones can be segmented from bile ex vivo with improved detection (especially those <9mm diameter) using dual-layer DECT and 2D-histograms of Compton and photoelectric attenuations. Detecting isoattenuating gallstones in vivo with this method could reduce the need for secondary imaging in symptomatic patients with suspected biliary calculi.

B-0392 14:56

Predicting difficulties on preoperative sonographic evaluation in scheduled laparoscopic cholecystectomy in patients with acute calculous cholecystitis

T.-K. Kim, H. Han, J. Park, H. Kim; *Daejeon/KR (goodseven@naver.com)*

Purpose: The aim of this study was to evaluate the role of preoperative sonography in predicting potential technical difficulties that can be encountered in scheduled laparoscopic cholecystectomy in patients with acute calculous cholecystitis.

Methods and Materials: After reviewing the medical records from January 2014 to December 2016, 759 patients meeting the inclusion criteria were enrolled in the final study. The number of the gallstones, the maximum diameter of the gallstones, presence of the sludge in the GB, the thickness of the GB wall, presence of the fluid at the GB fossa, the maximum diameter of extrahepatic duct (EHD), presence of CBD stone, and presence of GB polyp were estimated in preoperative sonography. The duration of operation, the grade of GB inflammation, the grade of adhesion to peritoneal cavity, and the presence of conversion to open cholecystectomy were estimated. The difficulty score was measured by 4 parameters in surgery.

Results: Presence of the sludge in the GB, the thickness of the GB wall, presence of the fluid at the GB fossa, the maximum diameter of EHD, presence of CBD stone were statistically significant in simple univariate analysis ($p < 0.05$). Only presence of the fluid at the GB fossa and the thickness were statistically significant in multiple regression analysis ($p < 0.01$).

Conclusion: In scheduled laparoscopic cholecystectomy, the difficulty of surgery can be predicted by preoperative US findings. Presence of the fluid at the GB fossa and the thickness of the GB wall are most predictable factors of surgical difficulty.

B-0393 15:04

Portal vein and ligamentum teres variations in diverse gallbladder locations: is the left-sided gallbladder always a high-risk feature for pre-intrahepatic assessment?

H.-Y. Lin, R.-C. Lee, H.-H. Yen, C.-A. Liu, J.-L. Chen; *Taipei/TW (b101096132@tmu.edu.tw)*

Purpose: To emphasize the rare condition of the presence of right-sided ligamentum teres (RSLT) with a normal gallbladder location and to determine if the left-sided gallbladder (LGB) is associated with portal vein variations despite the location of ligamentum teres (LT).

Methods and Materials: We reviewed CT studies between June 2005 and July 2018 and excluded data with cholecystectomy ($n = 10,276$). For prevent missing data of rare conditions, the studies were divided into 2 groups first: gallbladder in typical right side location (RGB; $n = 10,248$) and LGB ($n = 28$); then divided into 2 subgroups: LT in typical left side location and RSLT. Each patient with RGB and RSLT was matched with 5 patients with RGB and LT in typical location by sex and age. Outcome was the portal vein anomalies (PVA).

Results: The prevalence of LGB was 0.27%, consistent with previous studies. There were 20 patients (71.4%) with RSLT and 8 patients (28.6%) with typical LT location. The prevalence of PVA was 75% (15/20) and 25% (2/8), respectively, and was statistically significant (OR 9.00; 95% CI 1.36-59.78, $P = 0.023$). The prevalence of RSLT was 0.06% (6/10,248) among all RGBs. The prevalence of PVA was 83% (5/6) in patients with RGB and RSLT and 17% (5/30) in the sex- and age-matched patients with RGB and typical LT location, respectively. The result of conditional logistic regression was significant (OR 5.00; 95% CI 1.45-17.27, $P = 0.011$).

Conclusion: The LGB is not always accompanied with the high-risk feature of RSLT and vice versa.

B-0394 15:12

Prediction for early recurrence of intrahepatic mass-forming cholangiocarcinoma: qualitative and quantitative MRI combined with prognostic immunohistochemical marker

L. Zhao, X. Zhao, X. Ma; *Beijing/CN (zlyjdzhaoli@163.com)*

Purpose: To investigate the predictive performance of qualitative, quantitative MRI features and prognostic immunohistochemical marker for early recurrence (ER) of intrahepatic mass-forming cholangiocarcinoma (IMCC).

Methods and Materials: Forty-seven patients with pathologically proven IMCC were enrolled in this retrospective study. Preoperative contrast-enhanced MRI and immunohistochemical stainings of EGFR, VEGFR, P53 and Ki67 were performed in each patient, respectively. The clinicoradiologic and pathological risk factors of ER were identified using univariate analysis. Texture analysis

(TA) was performed based on four MR sequences including T2-weighted imaging (T2WI), arterial phase (AP), portal venous phase (PVP), and delayed phase (DP) imaging. A clinicoradiologic-pathological (CRP) model, a TA model, and a combined model were developed, and the receiver operating characteristics (ROC) curve was used to explore their predictive performance to stratify ER.

Results: Enhancement pattern and VEGFR showed significant differences between the ER group and non-ER group ($P = 0.001$ and 0.034 , respectively). And the TA model based on AP, PVP, and DP images presented superior area under curve (AUC) (0.889, 95%CI: 0.783-0.996) among seven TA models, with sensitivity and specificity of 0.938 and 0.839, respectively. And the combined model contained enhancement pattern, VEGFR and texture parameters showed preferable predictive performance of ER compared to TA model or CRP model alone, with an AUC, sensitivity and specificity of 0.949, 0.875 and 0.774, respectively.

Conclusion: Combined model was the superior predictive model of ER compared with TA or CRP model alone. Combining qualitative, quantitative MRI features and VEGFR may be useful for predicting ER and thus helpful to guide personalized treatment in patients with IMCC.

B-0395 15:20

Overrepresentation of uncommon biliary confluence types in hilar cholangiocarcinoma patients

M. Shorikov, O.N. Sergeeva, D. Frantsev, M. Lapteva, E. Virshke, B. Dolgushin; *Moscow/RU (mshorikov@gmail.com)*

Purpose: The purpose of the study is to compare distribution of biliary confluence types in hilar cholangiocarcinoma patients and those with unremarkable bile ducts.

Methods and Materials: Biliary confluence types were retrospectively evaluated in 203 hilar cholangiocarcinoma patients ('study group', male/female=108/95, age range 21-84) and 204 patients with unremarkable bile ducts ('control group', male/female=95/109, age range 17-81) at MRCP (all patients) and direct cholangiography (141 study group patients) by 2 radiologists (Cohen Kappa=0.7, differences were resolved by consensus). Nakamura classification was used for confluence typing: I-right biliary duct is present; II-independent drainage of right sectoral ducts to confluence, III-independent drainage of the right posterior duct into common hepatic duct, IV-drainage of the right posterior duct into left bile duct, V-other, right bile duct is absent. Group differences were evaluated with Chi-square and Pearson exact test criteria.

Results: While control group had confluence type distribution close to one described in literature patients in Klatskin tumour group had a significantly different distribution type ($p < 0.001$). Type I was presented in 75% of the patients in control group and in 30% in Klatskin tumour group, other types respectively: II-9% and 24%, IV-14% and 40%, III-0.5% and 1.7%, V-14% and 40%. Statistical and biophysical models showed: uncommon confluences have a larger area of bile ducts where the tumour may originate (10% of difference) and are under higher pressure that is described in animal models as an oncogenic factor for cholangiocarcinoma.

Conclusion: Uncommon hepatic ducts confluence types are significantly more often present in hilar cholangiocarcinoma patients.

T1 mapping for liver function evaluation in gadoteric acid-enhanced MR imaging: comparison of look-locker inversion recovery and B1 inhomogeneity-corrected variable flip angle method

J.E. Kim¹, H. Kim¹, D. Choi¹, D. Nickel²; *Jinju/KR, ²Erlangen/DE (wildmsrla80@hanmail.net)*

Purpose: To compare look-locker inversion recovery (LLIR) and B1 inhomogeneity-corrected variable flip angle T1 mapping methods for estimation of liver function and prediction of hepatic insufficiency and decompensation on

gadoteric acid-enhanced MR imaging.

Methods and Materials: In this retrospective study, 248 patients with normal liver function, chronic liver disease, or cirrhosis underwent gadoteric acid-enhanced liver MR imaging, including T1 mapping at 10 and 20 min hepatobiliary phase (HBP) by using both methods. T1 relaxation times of liver (T1Liver-pre, T1Liver-post) and spleen (T1Spleen) were correlated between two methods. $\Delta T1\text{Liver}$ [(T1Liver-pre - T1Liver-post)/T1Liver-pre], adjusted T1Liver [(T1 Spleen - T1 Liver-post)/T1 Spleen], and functional liver volume-to-weight ratio (liver volume on volumetric T1 map/[T1Liver-post times patient's weight]) were calculated. The diagnostic performance of T1 parameters and predictive performance of models (serum marker, serum marker plus T1 parameter) were compared.

Results: T1Liver-post showed a strong correlation ($r = 0.93$, $p < 0.001$) between two methods but were significantly different. For depicting cirrhosis, LLIR-adjusted T1Liver at 10 min HBP showed the highest performance ($p < 0.025$). For predicting hepatic insufficiency and decompensation, LLIR-adjusted T1Liver (Akaike information criterion [AIC], 58.37; C-index, 0.867) and LLIR-T1Liver-post (AIC, 48.82; C-index, 0.885) at 10 min HBP showed the best performance, respectively, when added to serum albumin level.

Conclusion: T1Liver-post showed a strong correlation between two methods but with significant differences. T1 mapping using LLIR at 10 min HBP with obtaining of adjusted T1Liver and T1Liver-post may be the best approach for estimation of liver function and prediction of hepatic insufficiency and decompensation.

B-0397 16:17

Dual-arterial phases and split-bolus intravenous contrast injection: reduction of transient respiratory motion artefact on gadoxetate disodium-enhanced MRI of the liver

E.-S. Cho, J.M. Choi, J.H. Kim, J.-S. Yu, J.-J. Chung; *Seoul/KR (jjondol@yuhs.ac)*

Purpose: To determine whether dual arterial phases and split-bolus contrast injection could reduce transient respiratory motion artefact during second arterial phase on gadoxetate disodium-enhanced MRI of the liver.

Methods and Materials: One hundred eighty patients underwent gadoxetate disodium-enhanced MRI of the liver with dual hepatic arterial phases. The first arterial phase was performed after injection of 5mL gadoxetate disodium and the additional second arterial phase was performed after injection of 4 mL gadoxetate disodium after 3 minute-delayed transitional phase. Each arterial phase was acquired using a CAIPIRINHA VIBE sequence. The enhancement of focal hepatic lesion on each arterial phase was assessed using subtraction images. The motion artefact on both arterial phases was assessed by two observers using a five-point scale of 1 (no motion) to 5 (non-diagnostic).

Results: Nineteen out of 180 patients (10.6%) had severe motion artefact (mean score, 4.4) on the first arterial phase. Fifteen of them had no or mild motion artefact (mean score, 1.3) on the second arterial phase. In these 19 patients, respiratory motion artefact on the second arterial phase was significantly lower than that of the first arterial phase ($p < 0.05$). The enhancement of focal hepatic lesions was not significantly different between both arterial phases ($p > 0.05$).

Conclusion: Respiratory motion artefact was significantly reduced on the second arterial phase, compared to the first arterial phase. Dual arterial phases and split-bolus gadoxetate disodium injection technique could help evaluate the arterial enhancement of focal hepatic lesion in patients with transient respiratory motion artefact.

B-0398 16:25

Whole-body R2s mapping to quantify tissue iron storage organs: associations with HFE-genotype

J.-P. Kühn¹, T. Kacprowski², A. Röhnert³, V. Hietschold³, R. Bülow¹, D. Fedders³, R.-T. Hoffmann³, M.-L. Kromrey¹; ¹Greifswald/DE, ²Munich/DE, ³Dresden/DE (kuehn@uni-greifswald.de)

Purpose: To investigate the relation between HFE genotypes and the phenotype of tissue iron overload using measurement of transverse relaxation rate (R2s) in whole body magnetic resonance imaging (MRI).

Methods and Materials: 483 volunteers, 214 women, mean age 59.3±27.7 years underwent MRI including a five-echo gradient-echo sequence for whole body coverage. Whole body R2s maps were calculated and R2s values were determined for liver, spleen, pancreas, heart, and bones. Volunteers were genotyped for HFE mutation. R2s values of iron storage organs were compared between volunteers with at least one and volunteers with none mutation.

Results: In 301 subjects without any mutation in HFE genotypes; R2s [mean s-1±standard deviation] were assessed for liver: 33.4±12.7, spleen: 24.1±13.8, pancreas: 27.2±6.6, heart 34.1±14.2 and bone: 69.3±21.0. 182 participants had at least one mutation in HFE gene. Results with cases of heterozygous/homozygous for the types of mutation were for rs74315324: 0/0, rs74315324: 132/9, rs41303501: 0/0, rs1800562: 33/1 and rs1800730: 11/0; respectively. Participants with at least one mutation in the HFE gene did not

show any significant difference in R2s values for any of the organs after correction of multiple testing: liver 35.6±11.8, $p_{BH}=0.09$; spleen: 23.2±13.8, $p_{BH}=0.36$; pancreas: 25.6±6.1, $p_{BH}=0.08$; heart: 32.7±11.8, $p_{BH}=0.36$ and bone: 69.2±19.9, $p_{BH}=0.98$.

Conclusion: Whole body R2s mapping is an approach to quantify tissue iron in iron storage organs of the whole body. Unspecific mutation of HFE genotype (i.e. at least one mutation in rs74315324, rs1800562, rs1800730) seems not to affect the phenotype of tissue iron overload.

B-0399 16:33

Optimised imaging of the lower abdomen and pelvic region in hepatocyte-specific MRI: evaluation of a whole-abdomen first-pass shuttle protocol

U. Fehrenbach¹, U.L. Fahlenkamp¹, J. Kahn¹, A. Baur¹, M. Pavel², D. Geisel¹, T. Denecke¹; ¹Berlin/DE, ²Erlangen/DE (uli.fehrenbach@charite.de)

Purpose: Gadoteric acid (Gd-EOB) has shown its advantages in hepatic tumour evaluation besides its disadvantages in extrahepatic staging due to its short haemodynamic interval. This results in the dilemma of which contrast agent to choose for whole abdominal MRI. The aim was to evaluate the achievable contrast of a shuttle protocol for Gd-EOB MRI with accelerated 3D-T1w-sequences enabling complete dynamic liver imaging plus first-pass pelvic imaging.

Methods and Materials: 74 patients with abdominal neuroendocrine neoplasms were scanned with a protocol including a first-pass pelvic (pelvic_{FP}) sequence in Gd-EOB MRI. Acquisition of this pelvic_{FP} sequence was between portal venous and venous liver phase. Pelvic vessel and tissue enhancement were compared to a commonly acquired late/transitional phase sequence. In the same patients, liver enhancement was compared to a standard Gd-EOB protocol (n=55) as well as to vessel contrast in previously acquired MRI with extracellular contrast medium (ECCM) (n=14).

Results: Pelvic vessel and lymph node enhancement showed significantly higher signal intensities (SI) in pelvic_{FP} than in late phase sequences with Gd-EOB ($p < 0.001$). Liver enhancement showed no significant differences compared to the standard protocol. Vessel enhancement in Gd-EOB pelvic_{FP} showed significantly higher SI than an equilibrium phase sequence with ECCM ($p = 0.003$ to 0.04).

Conclusion: Including a pelvic_{FP} sequence between portal venous and venous liver phases is technically feasible and achieves improved contrast in the pelvis in Gd-EOB MRI. There was no quality loss in liver enhancement compared to a regular Gd-EOB liver examination. Gd-EOB pelvic_{FP} vessel enhancement was not inferior to an equilibrium phase with ECCM.

Should multiparametric MRI with semi-quantitative perfusion replace triphasic CT in follow-up post TACE

N. Taha, D. Zidan, E. Geneidi; *Cairo/EG (nohataharadio@gmail.com)*

Purpose: To evaluate the role of multiparametric MRI and compare it with triphasic CT in follow up post TACE

Methods and Materials: Fifty-four patients were included in this study, all the patients were known to have hepatocellular carcinoma for which they underwent transarterial chemoembolization. Follow up was done clinically by measuring alpha-fetoprotein level and radiologically by triphasic CT and multiparametric MRI. Mp-MRI sequences included were T2 and STIR WIs, T1 inphase and outphase WIs, DWI (b value 0, 200, 800), dynamic T1 thrive including early arterial, late arterial, portovenous, venous and delayed phases. Semi-quantitative perfusion images and curves were done. Confirmation of MRI findings was referred to the typical features of residual lesions by MRI criteria, correlation with alpha-fetoprotein level and follow-up.

Results: Thirty-two patients showed well-embolized lesion in CT with residual lesion on MRI. Six patients showed well-embolized lesion in CT and MRI, eight patients showed well-embolized lesion in CT and MRI with another HCC, which was not appreciable by CT, six patients showed residual lesion by both CT and MRI studies and two patients showed residual lesion by CT with negative mp-MRI study. Mp-MRI showed 97.96 % sensitivity, 85.71 % specificity, 98% positive predictive value, 84.5 % negative predictive value and 96.4% accuracy compared to 32% sensitivity, 75% specificity, 61% positive predictive value, 11.1 % negative predictive value and 26.4 % accuracy in detecting residual/recurrent and denovo lesions post TACE.

Conclusion: Multiparametric MRI should replace triphasic CT in the assessment of post -TACE patients.

B-0401 16:49

Assessment of whole-body fat in magnetic resonance imaging as a new approach in imaging of metabolic disorders

J.-P. Kühn¹, R. Bülow¹, D. Fedders², D. Seppelt², R.-T. Hoffmann², M.-L. Kromrey¹; ¹Greifswald/DE, ²Dresden/DE (kuehn@uni-greifswald.de)

Purpose: To determine whole-body fat volume using confounder corrected chemical shift encoded magnetic resonance imaging (CSI-MRI).

Methods and Materials: Four hundred sixty-seven volunteers aged 36 to 87 years (260 women) underwent a whole-body MRI including five-echo chemical shift encoded sequences acquired in 5 steps. After confounder correction, whole-body proton-density fat fraction was acquired. Based on tissue fat content, we developed a post-processing algorithm for segmentation of fat compartments. Using this algorithm, total body fat volume (TAT), subcutaneous fat volume (SAT) and visceral fat volume (VAT) were assessed. Robustness of the algorithm was tested by evaluation of inter- and intra-observer reliability (n=73 participants) by two observers using a Bland-Altman analysis. Further, TAT, SAT, and VAT were correlated with BMI, gender, and age.

Results: Intra-observer reliability (mean bias (%) \pm standard deviation; TAT/SAT/FAT: $-0.1\pm 0.3 / 0.4\pm 1.0 / 0.2\pm 0.4$) and inter-observer reliability (TAT/SAT/FAT: $0.0\pm 0.3 / 0.9\pm 1.4 / 0.4\pm 0.8$) was small. TAT, VAT and SAT increased significantly with rising body BMI, $p\leq 0.001$. Although SAT and VAT demonstrated significant gender-related differences ($p=0.001$), no significant differences were seen for TAT ($p=0.21$).

Conclusion: CSI-MRI is an approach to assess whole-body fat volume and fat compartments. TAT, SAT, VAT are associated in changes in BMI. The technique may offer the possibility of advanced imaging in metabolic disorders.

B-0402 16:57

The feasibility of diffusion-weighted magnetic resonance imaging of the liver using multiplexed sensitivity encoding

Y. Kim, M.-J. Kim, N. Seo; *Seoul/KR (cookieks35@gmail.com)*

Purpose: To assess the feasibility of multiplexed sensitivity-encoding (MUSE) technique for high-resolution diffusion-weighted magnetic resonance imaging (DWI) of the liver.

Methods and Materials: Thirty-eight patients with 31 lesions who underwent liver MRI with conventional DWI and respiratory-triggered MUSE-DWI at a 3.0-T system for the investigation of suspected hepatic pathology or oncological follow-up were included. Qualitative parameters were independently evaluated by two radiologists blinded to the protocol, and quantitative parameters were calculated based on region of interest measurements. Per-patient parameters were compared between the two sequences using Wilcoxon signed-rank test and paired t test, and per-lesion parameters were compared by linear mixed model.

Results: Both reviewers found better overall image quality, sharper liver contour, reduced cardiac motion and susceptibility artefacts, and improved lesion conspicuity in MUSE-DWI (reader average $P < 0.05$). However, ghosting by gallbladder, artefact by pericardial fat, and chemical shift artefact reduced the image quality (reader average $P < 0.01$) in MUSE-DWI. Lesion characterization results were comparable in both sequences. Signal-to-noise ratio (SNR) of the liver was significantly higher (mean, 9.62 vs. 7.37; $P < 0.001$), while lesion to non-lesion contrast-to-noise ratio (CNR) was lower (least square means, 21.68 vs. 28.79; $P = 0.023$) in MUSE-DWI.

Conclusion: MUSE-DWI can provide better image quality in terms of distortions, comparable image quality for lesion characterization, and improved SNR of the liver. However, some artefacts can interfere with image interpretation in MUSE-DWI, and CNR was lower than conventional DWI.

B-0403 17:05

Evaluation of liver MRI examinations with two dosages of gadobenate dimeglumine: a retrospective blinded intra-individual study

M. Kamali, S.E. Clarke, A.F. Costa; *Halifax, NS/CA (mh870250@dal.ca)*

Purpose: There is discrepancy in the literature regarding the optimal dose of gadobenate dimeglumine for liver MRI. This study evaluated the quality of liver MRIs performed in the same individual using two dosages.

Methods and Materials: This retrospective intra-individual study was performed with ethics approval. Patients who underwent liver MRIs between Sept 2015-May 2017 (0.06 mmol/kg) and May 2017-September 2018 (0.10 mmol/kg) were included. Regions of interest were drawn over the aorta, portal veins and liver on unenhanced, arterial, portal venous and delayed phases; relative enhancement values were compared (paired t-tests). Two blinded radiologists graded the arterial and portal venous sequences of each MRI from 1-4 (1=suboptimal, 2=adequate, 3=good, 4=excellent); grades were compared (Wilcoxon's signed rank test). Blinded radiologists also graded each MRI pair from 1-5 (1=substantially inferior, 2=slightly inferior, 3=equivalent, 4=slightly improved, 5=substantially improved). Inter-reader agreement was assessed (kappa statistic).

Results: 60 patients were included. Relative enhancement increased significantly with the higher dose for all structures on all phases ($p<0.05$). Grades 1-4 were assigned to 18,72,65 and 81 low-dose sequences, and 17,57,68 and 94 high-dose sequences, respectively; for both radiologists and both post-contrast phases, grading was better for the high-dose MRIs ($p<0.05$). Inter-observer agreement was fair (K range, 0.22-0.37). Compared to the low-dose MRIs, the number of high-dose MRIs graded 1-5 were 9,31,97,90 and 11; inter-observer agreement was moderate-fair (K=0.48 and 0.36 for arterial and portal venous phases, respectively).

Conclusion: A higher dose of gadobenate dimeglumine results in increased relative enhancement and improved qualitative assessment of imaging quality for liver MRI.

Author Disclosures:

S.E. Clarke: Research/Grant Support; Dr. Sharon Clarke has a research agreement with GE Healthcare, however this did not impact our study in any way.

B-0404 17:13

Clinical evaluation of 3D magnetic resonance cholangiopancreatography using three different methods: feasibility of compressed sensing and/or parallel imaging

M.-L. Kromrey¹, S. Funayama², D. Tamada², S. Ichikawa², H. Onishi², U. Motosugi^{2,1}, Greifswald/DE, ²Chuo/JP (*marie-luise.kromrey@uni-greifswald.de*)

Purpose: To evaluate the diagnostic quality of 3D MRCP acquired with respiratory triggering compared to breath-hold techniques using compressed sensing (CS) and parallel imaging (PI) in a clinical setting.

Methods and Materials: In 93 patients (45 men, mean age 69.7 ± 9.3 years) 3 types of 3D MRCP were performed: breath-hold MRCP with CS and PI reconstruction (BH-CS-MRCP) and PI reconstruction only (BH-PI-MRCP) additionally to respiratory triggered MRCP with navigator echoes (Nav-MRCP) on a 3T scanner. Visualization of common bile duct (CBD), common hepatic duct (CHD), central right and left hepatic duct (cRHD, cLHD), peripheral right and left hepatic duct (pRHD, pLHD), cystic and pancreatic duct and overall image quality was rated on a four-point scale. For quantitative analysis, relative duct-to-periductal contrast (RC) of three main biliary segments was calculated.

Results: Acquisition time was accelerated in breath-hold MRCP (23s each vs 1min 29s in Nav-MRCP). Mean grading (Nav/CS/PI) for CBD (2.74/2.87/2.94), CHD (2.82/2.92/3.00), cRHD (2.75/2.85/2.98), cLHD (2.75/2.85/2.92) and cystic duct (2.22/2.34/2.42) was higher in BH-CS- as well as BH-PI-MRCP, whereas Nav-MRCP showed higher grading in the peripheral segments (pRHD: 2.24/2.01/2.12; pLHD: 2.23/2.02/2.13). Overall image quality of Nav-MRCP (2.91 \pm 0.7) was not different from BH-PI-MRCP (2.92 \pm 0.6) ($p=0.163$), but higher than that of BH-CS-MRCP (2.80 \pm 0.7) ($p=0.031$). RC for CS-MRCP and PI-MRCP were lower than for Nav-MRCP.

Conclusion: Breath-hold 3D MRCP was feasible using PI and CS showing comparable overall image quality and visualization of the greater duct system to Nav-MRCP. The methods are suitable for revised MRI protocols notably in patients with irregular respiratory cycle.

B-0405 17:21

Histogram analysis of stretched-exponential model diffusion-weighted imaging for staging of liver fibrosis: a feasibility study

F. Hu, B. Song, R. Yang, M. Wang; *Chengdu/CN (yingxianghu_cmc@163.com)*

Purpose: To determine the feasibility of stretched-exponential model diffusion-weighted imaging based on histogram analysis for staging of liver fibrosis in patients with chronic liver diseases, with histopathologic findings as the reference standard.

Methods and Materials: 56 consecutive patients with chronic liver diseases underwent liver DWI using nine b values at 3.0T. Histogram metrics including mean, standard deviation, skewness, kurtosis, minimum, maximum, range, interquartile (IQ), and percentiles (10, 25, 50, 75, 90th) were extracted from apparent diffusion coefficient (ADC), distributed diffusion coefficient (DDC) and intravoxel heterogeneity index (α) maps. Liver fibrosis and inflammation were evaluated using the METAVIR scoring system. The relationship between histogram metrics and histopathological features was evaluated by Spearman correlation and multiple regression analysis. Receiver operating characteristic curve analyses were further performed for staging liver fibrosis.

Results: At multiple regression analysis, liver fibrosis independently influenced with histogram metrics of DDC (mean, 50th and 75th percentiles; all <0.001) and α (50th percentile and skewness). Inflammation was not associated with histogram metrics. The mean, 50th and 75th percentiles of DDC and 50th percentile, skewness of α provided good to excellent diagnostic performance for identifying significant fibrosis (F2 or higher) and for diagnosing cirrhosis (F4), with AUCs ranging from 0.752 to 0.936 (all $P < 0.001$). For identifying significant fibrosis, the highest AUC was 0.885 for skewness of α ; for diagnosing cirrhosis, the highest AUC was 0.936 for 75th percentiles of DDC.

Conclusion: Stretched-exponential model DWI based on histogram analysis can be used to stage liver fibrosis and provides more quantitative imaging biomarkers.

Quantitative tissue-tracking and T1 mapping cardiac magnetic resonance (CMR) in active acromegaly

P. Liu, Y. Wang, J. Cao, L. Lin; Beijing/CN (liupeijun_yu@163.com)

Purpose: To evaluate myocardial strain and extracellular volume of left ventricular (LV) in patients with active acromegaly by 3T Cardiac Magnetic Resonance.

Methods and Materials: 23 patients (mean age 44±16 years, 9 males) with active acromegaly and 15 healthy controls (mean age 44±13 years, 7 males) were included. All participants underwent a 3.0T (MAGNETOM Skyra, Erlangen, Germany) CMR examination including native and 15-20min post-contrast T1 mapping imaging in identical short axis 2-chamber slices of basal, middle and apical LV level. Feature-tracking analysis included assessment of peak strain of the short-axis slice in longitudinal, circumferential and radial direction of left ventricle (LV). Native T1 value, ECV and strain in of basal, mid and apex slice, left ventricular mass index (LVMI) and left ventricular ejection fraction (LVEF) were measured via CVI42 software (Circle Cardiovascular Imaging, Canada).

Results: In acromegaly group, LVMI (60 ± 26.1 vs. 47.5 ± 6.9 g/m², $P < 0.05$) and ECV in basal slice (30.3 ± 7.2 vs. 24.7 ± 6.9 , $P < 0.05$) increased significantly, while longitudinal strain of apex slice (-19.17 ± 5.01 vs. -22.20 ± 2.37 , $P < 0.05$) decreased compared to control group. Average per-slice Native T1 and ECV in mid and apex slice, circumferential and radial strain in basal, mid and apex slice showed no significant differences between acromegaly and healthy controls.

Conclusion: Compared to healthy controls, acromegaly patients had increased LVMI, increased ECV in basal slice and decreased longitudinal strain of apex slice by CMR, which might indicate heart abnormality in early periods with normal LV systolic function.

The assessment of carotid plaque morphology using magnetic resonance imaging and computed tomography as biomarkers of carotid plaque vulnerability

N. Giannotti, P. Kelly, S. Foley, G. Horgan, E. Kavanagh, M.J. O'Connell, J. McNulty; Dublin/IE (nicola.giannotti@ucd.ie)

Purpose: Looking beyond the degree of carotid stenosis and exploring plaque morphology based on the lipid-rich necrotic core (LRNC), fibrous tissue, and calcification, is an emerging approach for the assessment of plaque vulnerability/risk of future ischaemic cerebrovascular events. Validation studies are necessary to establish the utility of different imaging techniques to support clinical decision making. This study explored the correlation between plaque morphology assessment from computed tomography angiography (CTA) and magnetic resonance imaging (MRI) datasets.

Methods and Materials: A sub-group of patients (n=22) from a larger cohort study were included. Inclusion criteria were speech/motor transient ischaemic attack or stroke (Rankin≤3) <72hours; ipsilateral carotid stenosis ≥50%; age≥50 years; carotid MRI and CTA performed. Semi-automated measurements of plaque morphological features were performed using TeraRecon iNtuition™ and MRI-Plaque View2.1. The Wilcoxon signed-rank, Spearman's correlation, and Bland-Altman plots were used to test for statistical differences between CT and MRI, the level of agreement, and for proportional bias, respectively.

Results: Results showed a significant agreement in LRNC measurements between CT and MRI ($p < 0.001$). Spearman's test confirmed excellent agreement for calcified area between the two imaging modalities ($p < 0.001$). The absence of proportional bias was confirmed with Bland-Altman plot for lipids and calcium, $p=0.54$ and $p=0.33$ respectively. No significant differences were found between CTA and HRMRI measurements of other morphological plaque features.

Conclusion: Results of this study found that CT and MRI plaque measurements demonstrate significant agreement for LRNC and calcification. Therefore, if confirmed in larger studies, either modality may be recommended for such analysis.

Clinical impact of combined compressed sensing and sensitivity encoding on three-dimensional magnetic resonance cholangiopancreatography at 1.5 T

D. Morimoto, T. Hyodo, M. Itou, H. Fukushima, K. Kamata, M. Takenaka, M. Kudo, K. Miyagoshi, K. Ishii; Osakasayama/JP (morimoto-d@med.kindai.ac.jp)

Purpose: To assess the utility of combined compressed sensing and sensitivity encoding (CS-SENSE) applied to three-dimensional (3D) magnetic resonance cholangiopancreatography (MRCP) at 1.5 T.

Methods and Materials: This prospective study was approved by our institutional review board, and all patients provided written informed consent. Fifty-one patients (23 men and 28 women; mean [±SD] age, 68±13 years) underwent 3D navigator triggered MRCP with SENSE alone (MRCP_{SENSE}) and CS-SENSE (MRCP_{CSNT}), and 3D breath-hold MRCP with CS-SENSE (MRCP_{CSBH}) at 1.5 T. The acquisition time and relative duct-to-periductal contrast ratios (RCs) of the right and left hepatic ducts, and common bile duct, respectively, were quantitatively obtained for each of the three MRCP methods. The visualisation of bile and pancreatic duct; background suppression; artifacts; and overall image quality were evaluated on 5-point scale. The Friedman test was used to compare the results of MRCP_{SENSE}, MRCP_{CSNT}, and MRCP_{CSBH}. A p -value < .05 was considered statistically significant.

Results: Mean acquisition time of MRCP_{SENSE}, MRCP_{CSNT}, and MRCP_{CSBH} was 348, 143, and 18 seconds, respectively ($p < .001$ in all comparisons). The RCs of MRCP_{CSNT} and MRCP_{CSBH} were lower than MRCP_{SENSE} ($p < .001$ for both). All qualitative scores were not significantly different between MRCP_{SENSE} and MRCP_{CSNT}. The visualisation scores of bile ducts in MRCP_{CSBH} were inferior compared with those of MRCP_{SENSE} and MRCP_{CSNT} ($p < .05$), while those of pancreatic duct were not significantly different compared with MRCP_{CSNT}.

Conclusion: MRCP_{CSNT} provides comparable image quality to MRCP_{SENSE} in about half the acquisition time. MRCP_{CSBH} could be a supplemental technique for pancreatic duct.

B-0409 16:24

Quantitative diffusion-weighted knee MR imaging and ADC mapping in healthy volunteers

A. Alqattan, A. McGee, E. Delahunt, S. Eustace, J. McNulty, A. Craddock; Dublin/IE (abrar.alqattan@ucdconnect.ie)

Purpose: This healthy volunteer study forms part of a larger clinical study exploring knee bone bruising at sites associated with anterior cruciate ligament (ACL) injury using diffusion-weighted imaging (DWI). The aim was to analyse diffusion characteristics of normal cancellous bone in the mid-lateral femoral condyle and posterolateral tibial plateau.

Methods and Materials: Fourteen healthy subjects (18-35 years) without knee pain or trauma were scanned using the routine knee MRI protocol and an optimised axial-DWI sequence with multiple b-values. Thirty circular, 50mm², regions-of-interest (ROIs) were positioned for each case and included locations associated with ACL-related bone bruising (anterior, medial, and lateral ROIs in the medial and lateral femoral condyles (MFC, LFC), medial and lateral tibial condyles (MTC; LTC). ADC values were calculated for each ROI using b-values of 50 and 800s/mm².

Results: Mean ADC values for the ROIs in the femoral condyles ranged from 0.318×10^{-3} mm²/sec (SD=0.117x10⁻³) to 0.375×10^{-3} mm²/sec (SD=0.135x10⁻³) (posterior and medial ROIs in LFC respectively). For ROIs in the tibial condyles, the range was 0.233×10^{-3} mm²/sec (SD=0.072x10⁻³) to 0.434×10^{-3} mm²/sec (SD=0.147x10⁻³) (anterior and posterior ROIs in LTC respectively). Overall, ADC values for the distal femur were 0.311×10^{-3} mm²/sec (SD=0.109x10⁻³) and 0.288×10^{-3} mm²/sec (SD=0.129x10⁻³) for the proximal tibia.

Conclusion: Measurement of ADC values, in association with DWI sequences, can be used to identify ADC ranges associated with normal/healthy cancellous bone. These ADC values may then be compared to ADC values in subjects with ACL-related bone bruising in the distal femur and proximal tibia, which may provide additional insights into understanding injury severity and patient recovery.

B-0410 16:32

Evaluation of hippocampus volume in the elderly people by magnetic resonance imaging: comparison of two segmentation methods

P.A.T. Gamboa¹, M.C. Ribeiro², A.P.L. Macedo²; ¹Vila Franca de Xira/PT, ²Lisbon/PT (patricia24.gamboa@hotmail.com)

Purpose: The total volume of the hippocampus has been linked to cognitive function and to the risk of dementia. However, being a complex structure, the role of sub-regions of cognition and the risk of dementia remain unexplored. With the age increasing there is a significant loss of neurons in the encephalic mass, in general, and particularly in the hippocampus. The segmentation of images is one of the most important tasks in the evaluation of this change.

Methods and Materials: The aim of this study was to measure and compare the volume of hippocampus Left (HL) and Right (HR) in 100 elderly subjects (≥ 65 years old). The images obtained retrospectively by MRI T1W, were followed by post-processing through FreeSurfer® (non-operator dependent) and through OsiriX® (operator dependent).

Results: The values obtained by FreeSurfer® are higher than OsiriX® (LH=3995,850 mm³ and RH=3501.850mm³) respectively. The lowest value obtained in this study is assessed through OsiriX® in the RH corresponding to a 3481,200mm³. The difference between the LH and RH is higher with any software, corresponding to 470,350mm³ and 308,100mm³ respectively, however, through Wilcoxon test these differences aren't significant ($p > 0,05$). In both systems, between genders, the males obtained a highest values (average=4000mm³) than the females(3500mm³).

Conclusion: The obtained values with manual procedures are in agreement to the other identical studies concerning anatomy, measures and software used. The results show that the software used can produce different results. Even having higher time consuming, the manual methods are yet considered the more reliable and preferred by the physicians.

B-0411 16:40

Prediction of type 2 diabetes mellitus using noninvasive MRI quantitation of visceral abdominal adiposity tissue volume

M. Wang, S.-T. Feng, Z.P. Li; Guangzhou/CN (king_6509@sina.com)

Purpose: To investigate the quantitation of visceral adipose tissue volume (VATV) in patients with type 2 diabetes mellitus (T2DM), impaired glucose tolerance (IGT) and normal glucose tolerance (NGT) using MRI to assess the role of non-invasive imaging in predicting the presence of T2DM.

Methods and Materials: Forty-eight patients were included and scanned with iterative decomposition of water and fat with echo asymmetry and least square estimation-image quantification (IDEAL-IQ) sequence. VATV was obtained at the level of second and third lumbar vertebra (VATV L2, VATV L3) and the sum (total VATV) was computed. Proton-density fat fraction (PDFF) of pancreas and liver was measured. ROC curve and binary logistic regression model analysis were employed to evaluate their ability in predicting the presence of T2DM.

Results: The values of VATV L2, VATV L3 and total VATV of the T2DM were higher than those of the IGT and NGT. There was no difference in the values of VATV L2, VATV L3, and total VATV between IGT and NGT. The ROC curve analysis showed the areas under curve for VATV L2, VATV L3 and total VATV were 0.76, 0.80 and 0.80 in predicting the presence of T2DM, failed to predict the presence of IGT and NGT. Binary logistic regression model analysis revealed that only VATV L3 was independently associated with incident of T2DM and the sensitivity, specificity and accuracy were 80.00%, 88.20%, and 84.40%, respectively.

Conclusion: Compared to hepatic PDFF, pancreatic PDFF, VATV L2 and total VATV, VATV L3 was a better predictor for T2DM.

B-0412 16:48

Comparison of MRI acoustic noise levels in different types of sequences

V.M.F. Silva, I. Ramos, J. Moreira, M. Marques; Porto/PT (vitorssoft@gmail.com)

Purpose: This study aimed to evaluate acoustic noise levels (equivalent continuous sound level - dB(A) and peak sound pressure level - dB(C)) of different sequences used in a 1.5T and a 3T scanner.

Methods and Materials: This study was performed in MRI Department of Centro Hospitalar São João, Oporto, Portugal. A Bruel & Kjaer sound level meter, model 2250, was used. The sequences used on this study were: spin-echo (SE), gradient-echo (GE), inversion-recovery (IR) and echo planar (EPI). 2D and 3D sequences were used also. These sequences were performed in brain, spine, abdominal and knee MRI.

Results: In 1.5T scanner, values of all types of sequences reached to higher values when compared to 3T scanner. It was found statistically significant differences ($p < 0,05$) in: a) the peak sound pressure level between SE and EPI sequences; b) the two acoustic noise parameters evaluated between IR and EPI sequences. Statistically significant differences were found also when comparing 2D and 3D sequences for both parameters evaluated.

Conclusion: This study showed that patients and sometimes workers are exposed to relatively high acoustic noise levels of acoustic during MRI procedures. However, those levels do not exceed exposure the limit values, but several of them are near the limits imposed in Portuguese legislation. Radiographers have to take into account safety decisions related to MRI acoustic noise, when it concerns to optimization of sequences' acquisition time (acoustic noise exposure), specially those that almost reach the values imposed in legislation, such as EPI and 3D sequences.

B-0413 16:56

Investigating the impact of fragrance on patient anxiety during MRI scans

A. Formosa, C. Portanier Mifsud, J.L. Portelli, P. Demicoli; Msida/MT (altheaformosa3@gmail.com)

Purpose: Despite its benefits, magnetic resonance imaging (MRI) may induce anxiety in some patients. This study aimed to investigate whether patient anxiety can be reduced using lavender fragrance during brain/IAMs MRI scans.

Methods and Materials: This experimental study adopted a randomised control-group pretest-posttest design. Patients referred for a brain/IAMs MRI were randomly appointed into one of six scanning sessions forming part of this study. These sessions, consisting of 10 patients each, were then randomly assigned as being control or experimental. Convenience sampling was used to recruit the first 20 willing participants for each group of the study. All patients were scanned in accordance with routine MRI protocols; however, a lavender fragrance was additionally released during the 'experimental' sessions. Each participant was asked to complete the State-Trait Anxiety Inventory (STAI) before and after their MRI scan.

Results: The paired samples T test showed a statistically significant decrease between mean pre-test and post-test state anxiety scores in patients of both groups. The mean state anxiety score for control-group patients decreased from 49.9 to 45.1 ($p=0,044$), whereas that for experimental-group patients decreased from 38.4 to 31.4 ($p=0,018$). While sample size may have influenced findings, the greater reduction in mean anxiety score (7.0) observed for experimental-group patients was not found to be statistically significant when using the independent samples T test ($p=0,534$).

Conclusion: While fragrance-infused MRI sessions may help decrease anxiety levels in patients, the small sample size of this study necessitates further investigation into how fragrance-infused sessions may impact patients' experience.

B-0414 17:04

Accessibility for patients with cardiac device implantable electronic to magnetic resonance exams: a national survey

D.M.L. Miranda¹, B. Mateus², C.A. da Silva³, R.P. Almeida⁴, A.P. Ribeiro⁵, C.T. Brites⁶, A.F. Abrantes⁴, L. Ribeiro², ¹Jeddah/SA, ²Amadora/PT, ³Evora/PT, ⁴Faro/PT, ⁵Miraflores/PT, ⁶Carcavelos/PT (duchamiranda@gmail.com)

Purpose: Portuguese population with cardiovascular implantable electronic devices (CIEDs) increased in the last years. According to with Portuguese national registry on cardiac electrophysiology, in 2014, were implanted 1256 (one hundred and ten per million) cardioverter-defibrillator in registered centers. The accessibility, for this patient's, to any type of magnetic resonance (MR) study is an issue for MR major centres. This survey allows us to understand the difficulties from MR centres to satisfy this patient's needs.

Methods and Materials: An online survey was sent to radiology or/and cardiology departments from national centres with MR, to determine the accessibility for patients with CIEDs (pacemakers and ICD). A twenty questions survey of closed response questions plus some limited free text answers was used.

Results: Departments are aware of MR conditional devices, but only a small percentage offers MR scans to patients with CIEDs. The major issue for all centres is the lack of support from cardiology/electrophysiology and safety evidence. The exams average in this centres is 1 to 10 scans with CIEDs per year and (90%) of them are performed in 1.5T equipment.

Conclusion: With the increase of CIEDs, the accessibility to a MR decrease drastically for this patient group. This survey shows that in some Portugal regions it is impossible to perform a MR. The patient needs to drive more than 200km to do it. However, the majority of MR centres mentioned that training with applied practice, guidelines and closer collaboration with local cardiologist might increase the confidence of the professionals to perform those exams.

OLEA/NOVA+ SyntenticMRI application on workflow in pelvis MRI studies

A. Attanasio, G. Corrias, L. Saba; Cagliari/IT (tonyattan@gmail.com)

Purpose: The MRI acquisition protocol in standard practice for rectal cancer has an approximate duration of 30 minutes. The purpose of this study is to define a radiographer workflow in order to substitute standard protocol with syntetic MRI (sMRI) and to see if there are any differences in terms of time savings.

Methods and Materials: We examined 20 patients with double bolus of Hyoscine-butylbromide injection using an MRI scan with a field of 3 Tesla. The sequences used for our purpose are [T2]-multi-TE-FSE2D and [T1]-MP2RAGE-(3D), the images obtained have been reconstructed on the dedicated workstation with post processing commercial software (Olea Sphere 3.0, Olea Medical, Paris) in order to obtain T1, T2 and fat saturated images.

Results: Adding synthetic MRI sequences, would increase the duration of the protocol of 6:53 minutes. The post processing phase showed that 36 seconds are needed to view T1 & T2 maps and 60 seconds are needed to generate T1W, T2W, STIR images. All the images generated would be ready on PACS after 1:58 minutes. However, substituting standard T1, T2, STIR sequences with a synthetic MRI protocol would allow for a shortening of the total acquisition time down to 24 minutes of acquisition time.

Conclusion: sMRI reduces the acquisition time of pelvic region MRI of 6 minutes. Another study is currently in progress to understand if these sequences are clinically equivalent to their standard counterparts.

MRI principles and technical issues: where do European radiographers study from?

M. Zanardo¹, F.M. Doniselli¹, C.B. Monti¹, S. Durante², L.M. Sconfienza¹, F. Sardanelli¹; ¹Milan/IT, ²Bologna/IT (moreno.zanardo@unimi.it)

Purpose: To analyse where and how MRI principles and technical issues are investigated by radiographers and radiographers in training (RGt).

Methods and Materials: We proposed an online survey with 8 multiple-choice questions. We investigated how often radiographers have doubts about MRI principles or technical issues, where and what kind of information they search for, in which language and on which websites. χ^2 test was used.

Results: We obtained 300 answers (228 radiographers, 72 RGt, from 9 European countries). Radiographers and RGt mostly search for information both in English and in their native language (66% vs 72%, respectively), with no statistically significant difference ($p=0.590$). No differences were also found in frequency of consultation: radiographers and RGt frequently or often (64% vs 48%, $p=0.485$) have doubts about MRI principles. Post-processing details are equally searched for by radiographers and RGt (23% vs 13%, $p=0.249$) as well as advanced/new techniques (54% vs 50%, $p=0.713$). Clinical protocol settings are borderline significantly more searched by RGt than radiographers (64% vs 44%, $p=0.054$) as well as basic sequences details (36% vs 22%, $p=0.088$). Regarding source of information, radiographers and RGt mostly use internet (74% vs 81%, $p=0.404$) and books (46% vs 56%, $p=0.343$). Radiographers and RGt equally refer to mriquestions.com (43% vs 53%, $p=0.303$) for both technical and clinical issues, radiopaedia.org, (36% vs 47%, $p=0.227$), and mrimaster.com (25% and 14% $p=0.149$).

Conclusion: Radiographers and RGt frequently search for information about MRI principles and technical issues with slight differences regarding web sources, clinical protocol settings and MRI sequences.

Comparison of therapeutic outcome prediction among dynamic perfusion area-detector CT, dynamic perfusion MRI and FDG-PET/CT in small cell lung cancer patients with limited disease

Y. Ohno¹, Y. Fujisawa², M. Yui², Y. Kishida¹, S. Seki¹, T. Yoshikawa¹, T. Murakami¹; ¹Kobe/JP, ²Otawara/JP (yosirad@kobe-u.ac.jp)

Purpose: To directly compare the capability for therapeutic outcome prediction among dynamic contrast-enhanced (CE)-perfusion area-detector CT (ADCT) and CE-perfusion MR imaging (MRI) and FDG-PET/CT in small cell lung cancer (SCLC) patients evaluated as limited disease (LD).

Methods and Materials: Forty-three consecutive pathologically diagnosed SCLC patients assessed as LD underwent PET/CT, dynamic CE-perfusion ADCT and MRI, chemoradiotherapy, and follow-up examination. In each patient, therapeutic outcomes were assessed as therapeutic effect, disease-free interval and overall survival. Then all patients were divided into two groups as follows: 1) responder (CR+PR: n=33) and 2) non-responder (SD+PD: n=10) groups. In each patient, total perfusion (TP) and tumour perfusions from pulmonary (TPp) and systemic (TPs) circulations calculated by dual-input maximum slope method from dynamic ADCT and MRI data and SUV_{max} on PET/CT were assessed at targeted lesions. Then final values were determined as average values from all targeted lesion. To compare the capability for distinguishing two groups, all indexes as having significant difference were assessed by ROC analysis. Finally, disease-free and overall survivals between responders and non-responders assessed by each index were compared by Kaplan-Meier method followed by log-rank test.

Results: Area under the curves (Azs) of TPs (ADCT: Az=0.92, MRI: Az=0.92) were significantly larger than that of SUV_{max} (Az=0.73, $p<0.05$). Disease-free survivals of responder were significantly longer than that of non-responder by TPs on ADCT ($p<0.05$) and MRI ($p<0.05$).

Conclusion: Dynamic CE-perfusion ADCT and MRI have better potential for predicting therapeutic outcome than PET/CT in SCLC patients with limited disease.

Correlation between pulmonary function tests, histogram-based analysis indexes and visual HRCT scores in a population of IPF patients

F. Tiralongo¹, M. Palermo¹, D. Falsaperla¹, A. Stefano², S.E. Torrissi¹, P. Foti¹, A. Basile¹, C. Vancheri¹, S. Palmucci¹, ¹Catania/IT, ²Segrate/IT (tiralongofrancesco91@hotmail.it)

Purpose: To investigate relationship between visual HRCT score and Pulmonary Function Tests (PFTs), and between histogram-based HRCT analysis and PFTs.

Methods and Materials: 33 IPF patients having two HRCT (baseline and follow-up) and two PFTs - collected within three months from HRCT - were retrospectively investigated. A HRCT visual score was calculated quantifying the overall extent (percentage) of normal attenuation, reticulations, honeycombing and traction bronchiectasis measured at three HRCT levels. Histogram-based analysis was performed providing HRCT indexes - represented by kurtosis, skewness, High Attenuation Areas (HAA) and Fibrotic Areas (FA). Strength of association between HRCT visual scores and PFTs values, and between HRCT indexes and PFTs values was investigated using Pearson correlation; multiple linear regression model was performed to investigate variance between HRCT indexes and PFTs values, and between the latter and HRCT visual scores.

Results: Fair correlation between HRCT fibrosis score and FVC was found ($r=-0.2212$); moderate negative correlation was observed between average HRCT fibrosis score and DLCO ($r=-0.58$). Correlation between HRCT indexes and PFTs was stronger than visual assessment: coefficient r were 0.5762 between kurtosis and FVC, 0.5268 between kurtosis and DLCO, -0.5477 between HAA and FVC, -0.4186 between HAA and DLCO, -0.5035 between FVC and FA, and -0.3836 between DLCO and FA. Multiple regression analysis for FVC, DLCO and HRCT fibrosis score revealed a coefficient of determination R^2 equal to 0.3456; R^2 -adjusted reported a value of 0.30.

Conclusion: Histogram-based indexes provided mild-to-moderate correlation with PFTs - whereas visual HRCT assessment reported lower and controversial relationships.

B-0419 16:08

Radiomics machine learning classifiers for predicting Ki-67 proliferation index in non-small cell lung cancer

P. Rong, Q. Gu, Z. Feng; [Changsha/CN \(729570216@qq.com\)](mailto:Changsha/CN (729570216@qq.com))

Purpose: To develop radiomics classifiers for predicting the expression level of Ki-67 in non-small cell lung cancer (NSCLC) noninvasively and to evaluate the increment compared with the subjective imaging feature classifiers.

Methods and Materials: Non-enhanced CT images and tumour Ki-67 expression levels were acquired from 245 patients. A lesion volume of interest (VOI) was manually delineated and radiomics features were extracted by MaZda software from original CT images. A random forest feature selection algorithm (RFFS) was used to reduce features. Six kinds of machine learning methods were used to establish predictive classifiers including radiomics classifiers, subjective imaging feature classifiers and the combined classifiers. The performance of these classifiers was evaluated by the average area under the curve (AUC), and the performance between different classifiers was compared with the Delong test.

Results: Among the 245 patients, 117 had high Ki-67 expression, and 128 had low Ki-67 expression, respectively. The differences in gender, age and pathological type between the two groups were statistically significant (all $P < 0.05$). The radiomics random forest classifier achieved the best performance in predicting the Ki-67 expression level (AUC=0.776, SEN=0.726, SPE=0.661); this classifier performed better than the subjective imaging feature classifiers (AUC=0.625, SEN=0.780, SPE=0.417; $P<0.05$). The combined classifiers did not improve the predictive performance (AUC=0.780, SEN=0.752, SPE=0.633; $P>0.05$).

Conclusion: The radiomics machine learning classifier based on CT radiomics features is helpful to predict the expression level of Ki-67 in patients with NSCLC and can provide a non-invasive technique for assessing the proliferation of NSCLC.

B-0420 16:12

Quantitative perfusion MRI of the lung in COPD: the problem of short-term repeatability

A. Ter-Karapetyan¹, M.O. Wielpütz², H.-U. Kauczor², S. Triphan²; ¹Yerevan/AM, ²Heidelberg/DE (alvardterkarapetyan@gmail.com)

Purpose: 4D perfusion magnetic resonance imaging (MRI) with intravenous injection of contrast material allows for a radiation-free assessment of regional lung function. It is, therefore, a valuable method to monitor response to treatment in patients with chronic obstructive pulmonary disease (COPD). This study was designed to evaluate its potential for monitoring short-term response to hyperoxia in COPD patients.

Methods and Materials: 19 prospectively enrolled COPD patients (median age 66 years) underwent paired dynamic contrast-enhanced 4D perfusion MRI within 35min, first breathing 100% oxygen (O₂) and then room air (RA), which was repeated on two consecutive days. Post-processing software was employed to calculate mean transit time (MTT), pulmonary blood volume (PBV) and pulmonary blood flow (PBF), based on the indicator dilution theory, for the automatically segmented whole lung and 12 regions of equal volume.

Results: Comparing O₂ with RA conditions, PBF and PBV were found to be significantly lower at O₂, consistently on both days ($p < 10^{-8}$). Comparing day 2 to day 1, MTT was shorter by (0.59±0.63)s ($p < 10^{-8}$), PBF was higher by (22±80)ml/min/100ml ($p < 3 \cdot 10^{-4}$), and PBV tended to be lower by (0.2±7.2)ml/100ml ($p = 0.159$) at both, RA and O₂, conditions.

Conclusion: The measurement setup did not reproduce the established hypothesis that hyperoxia increases lung perfusion, instead showing an opposite effect. This shows that the quantification of 4D perfusion MRI based on current mathematical approaches is limited by residual circulating contrast material in the short term and, for COPD patients, even the next day due to limited clearance.

B-0421 16:16

The role of 4D flow MRI in evaluating the outcome of balloon pulmonary angioplasty

W. Sun, H. Ota, S. Chibana, H. Sato, K. Sugimura, K. Takase; Sendai/JP (sunwenyu910920@gmail.com)

Purpose: To access the value of haemodynamic features of patients with chronic thromboembolic pulmonary hypertension (CTEPH) before and after balloon pulmonary angioplasty (BPA) using 4D flow MRI.

Methods and Materials: Thirty consecutive patients (mean age, 68.4 ± 7.9-year-old, female, 25) with inoperable CTEPH underwent serial MR scans before and after BPA. Haemodynamic features extracted from 4D flow MRI include maximum energy loss (max EL), maximum wall shear stress (max WSS) map and maximum backward flow ratio (BFR) in the systolic phase in the pulmonary trunk. The ratio of the pulmonary trunk to the ascending aorta (PA/AA ratio) and right ventricular (RV) volumetry were evaluated using cardiac cine MRI. Mean pulmonary arterial pressure (mPAP) was obtained by right heart catheterization. Pearson's correlation coefficients were evaluated between mPAP and MRI-derived parameters before BPA and between their differences (Δ mPAP and Δ MRI-derived parameters) before and after BPA. Statistical significance was assumed for $P < 0.05$.

Results: The mean of mPAP was significantly decreased after BPA (39.0 ± 9.3 mmHg vs 25.0 ± 6.8 mmHg, $p < 0.01$). Significant correlations with pre-BPA mPAP were observed in BFR ($r = 0.42$, $p = 0.02$) and max-WSS ($r = -0.37$, $p < 0.05$). Significant correlations with Δ mPAP were observed in Δ PA/AA ratio ($r = 0.402$, $p = 0.03$), Δ BFR ($r = 0.57$, $p < 0.01$), Δ max EL ($r = 0.38$, $p = 0.04$), Δ max WSS ($r = -0.47$, $p < 0.01$). Δ RV end-systolic volume index was marginally correlated with Δ mPAP ($r = 0.36$, $p = 0.052$).

Conclusion: Haemodynamic parameters evaluated using 4D flow MRI can reflect the improvement of mPAP after effective BPA and can be used for the management of patients with CTEPH treated by BPA.

B-0422 16:20

Inspiratory/expiratory 3D pulmonary MRI with UTE: capability for clinical stage classification in smokers as compared with thin-section CT

Y. Ohno¹, M. Yui², Y. Kishida¹, S. Seki¹, T. Yoshikawa¹, T. Murakami¹; ¹Kobe/JP, ²Otawara/JP (yosirad@kobe-u.ac.jp)

Purpose: To prospectively and directly compare the capability for pulmonary functional loss assessment and clinical stage classification between inspiratory and expiratory 3D MR imaging with ultra-short TE (IS/ES UTE-MRI) and thin-section CT in smokers.

Methods and Materials: Eighteen consecutive smokers underwent IS/ES UTE-MRI, thin-section CT and %FEV₁. All smokers were classified into three stages ('Without COPD', 'Mild COPD', 'Moderate COPD') according to the GOLD guideline. From IS/ES UTE-MRI data in each smoker, signal intensity (SI) change ratio within the lung was computationally generated by pixel by pixel analyses. Then ROIs were placed over the lung on all slices, and averaged to determine mean SI change ratio in each subject. On quantitative CT in each subject, percentage of low attenuation area within entire lung

(LAA%) was also measured. Then SI change ratio was correlated with LAA%. To compare the capability for pulmonary functional loss assessment, both indexes were correlated with each pulmonary function parameter. Furthermore, both indexes were compared four clinical stages by Tukey's HSD test.

Results: SI change ratio had significant and good correlation with LAA% ($r = -0.86$, $p = 0.003$). SI change ratio and LAA% were correlated with %FEV₁ (SI change ratio: $r = 0.91$, $p = 0.0006$; LAA%: $r = -0.91$, $p = 0.0006$). SI change ratio had significant difference between 'Without COPD' group and others ($p < 0.05$), although LAA% had significant difference between 'Moderate COPD' group and others ($p < 0.05$).

Conclusion: Inspiratory/expiratory 3D MR imaging with UTE has a potential for pulmonary functional loss assessment and clinical stage classification in smokers as well as thin-section CT.

Diagnostic value of quantitative dual-source CT dual-energy iodine maps combined with morphological CT features in assessing histological subtypes of lung cancer

X. Xu, X. Sui, W. Song, L. Song, Y. Huang, Z. Jin; Beijing/CN (xxlpositive@163.com)

Purpose: To investigate the clinical usefulness of quantitative dual-energy CT (DECT) iodine metrics combined with morphological CT features in distinguishing lung cancer subtypes.

Methods and Materials: Consecutive patients suspected with lung cancer were prospectively enrolled and underwent DECT prior to biopsy or surgery. Tumour histological subtypes were determined in 110 patients. Two radiologists interpreted CT morphologic features and measured DECT parameters in a consensual manner. Multinomial logistic regression models were applied to evaluate the accuracy of DECT parameters and CT features in discriminating lung cancer subtypes.

Results: Histology revealed adenocarcinoma in 48, squamous cell carcinoma (SCC) in 36 and small cell lung cancer (SCLC) in 26 patients. In analysis of CT features, tumour diameter, distribution, spiculation, pleural retraction, vascular involvement, confluent mediastinal lymphadenopathy, encasement of mediastinal structures and enhancement heterogeneity showed statistical difference (all $P_s < 0.05$). Iodine density and iodine ratio were different among three lung cancer subtypes ($H = 16.817$, $P < 0.001$; $H = 20.338$, $P < 0.001$). Iodine density of adenocarcinoma and SCC was (1.50±0.80) mg/ml and (1.40±0.40) mg/ml, respectively, higher than the (1.20±0.40) mg/ml for SCLC ($P_s < 0.01$). Iodine ratio of adenocarcinoma and SCC was (16.10±7.02)% and (15.05±4.62)%, higher than the (11.55±3.15) mg/ml for SCLC ($P_s < 0.01$). No significant difference of DECT parameters was observed between adenocarcinoma and SCC. Accuracy of the model based on CT features was 69.1% and accuracy of the model based on CT features combined with DECT parameters was 80.9%.

Conclusion: Quantitative DECT metrics were different among adenocarcinoma, SCC and SCLC; when combined with morphological CT features, higher diagnostic performance can be achieved.

B-0424 16:28

Ultra-high-resolution CT vs state-of-the-art area-detector CT: can higher spatial resolution improve nodule detection capability at same radiation dose in chest nodule phantom study?

D. Takenaka¹, K. Fujii², N. Sugihara², S. Seki³, T. Yoshikawa³, Y. Ohno³; ¹Akashi/JP, ²Otawara/JP, ³Kobe/JP (yosirad@kobe-u.ac.jp)

Purpose: To determine the influence of higher spatial resolution for nodule detection capability on newly installed ultra-high-resolution CT (UHR-CT) as compared with state-of-the-art area-detector CT (ADCT) in chest nodule phantom study.

Methods and Materials: A commercially available chest phantom with simulated subsolid and solid nodules, whose diameters were 4, 6, 8, 10, 12 and 14mm at upper, middle and lower lung field levels, were scanned by standard-dose UHR-CT (Aquilion Precision, Canon Medical Systems) and ADCT (Aquilion ONE, Canon) three times. In this study, UHR-CT applied 0.25mm×160 detector collimation, and ADCT applied 0.5mm×80 detector collimation, and CTDIvols of UHR-CT and ADCT were 9.3mGy and 9.0mGy. Then UHR-CT data were reconstructed as 0.25mm, 0.5mm and 1mm thicknesses. On the other hand, ADCT data were reconstructed as 0.5mm and 1 mm thicknesses. To assess image quality and probability of nodule presence, two chest radiologists were visually assessed, and each final score was determined by the consensus of two readers. To evaluate image quality difference and nodule detection capability among all protocols, Wilcoxon's signed rank tests and ROC analyses were performed. Finally, detection performance was compared among all protocols by McNemar's test.

Results: There were no significant differences of image quality and area under the curve among all protocols ($p > 0.05$). Sensitivity of UHR-CT reconstructed as 0.25mm was significantly higher than that of ADCT reconstructed as 0.5mm thickness with 512 matrix ($p = 0.03$).

Conclusion: Higher spatial resolution on UHR-CT has a potential to improve nodule detection capability as compared with ADCT in chest phantom study.

B-0425 16:32

The utility of the ultra-high-resolution CT to evaluate the detailed bronchial tree for COPD

D. Takenaka, A. Higashida, Y. Kono, T. Hashimoto, H. Maeda, S. Sakamoto; Akashi/JP (daisuket@hp.pref.hyogo.jp)

Purpose: The purpose of this study was to compare the availabilities to image peripheral bronchus as a tool of COPD evaluation on CT between conventional high-resolution CT (HRCT) and the ultra-high-resolution CT (UHRCT).

Methods and Materials: Twenty-five consecutive patients who underwent CT examination were enrolled retrospectively. All CT studies were performed by using ultra-high-resolution CT machine (Aquilion Precision; Canon Medical Systems, Otawara, Japan). All CT examinations were performed with 160-detector row CT scanner; 120kVp, auto-mAs, 1792 channels, collimation 0.25 mm x 160 rows, 1024 matrix. HRCT images were reconstructed with 1mm slice, 1mm interval, 512 x 512 matrix. UHRCT images were reconstructed with 0.25 mm slice, 0.25 mm interval, 1024 x 1024 matrix. Each bronchial tree was defined by Synapse Vincent (Fujifilm Medical; Tokyo, Japan) and evaluated the percent of wall area (WA%), and luminal area (LA) through 3rd to 9th generation. The WA% and LAs of the proximal bronchus (3rd and 4th Generation) and the peripheral bronchus (5th and more) were statistically compared by using Wilcoxon rank sum test. P value less than 0.05 was considered to be significant in all statistical analyses.

Results: The p-values of WA% of proximal and peripheral bronchus were 0.08 and 0.03, respectively. The p-values of LA were 0.10 and 0.00, respectively. Thus, the UHRCT images revealed more detailed visualization of peripheral bronchus to evaluate WA% and LA for evaluation of regional COPD change.

Conclusion: The UHRCT image has improved the detailed measurement of peripheral bronchial tree compared to conventional HRCT image.

B-0426 16:36

Late phase lung perfusion by dual energy CT: image quality and clinical findings compared to arterial perfusion

M.S. May, I. Prael, R. HeiB, M. Kopp, M. Uder, W. Wuest; Erlangen/DE (matthias.may@uk-erlangen.de)

Purpose: Arterial Dual-Energy-CT (aDE) is an established technique for evaluation of pulmonary perfusion. The aim of this study was to assess the image quality and clinical findings in the portal-venous-phase (vDE).

Methods and Materials: vDE-CT was performed in 94 patients using a dual source scanner (70/Sn150kV, 560/140ref.mAs). Pulmonary triggered aDE-CT from the chest served as reference (n=95). Iodine maps were calculated and attenuation was measured in the pulmonary trunk and the aorta. Subjective overall diagnostic image quality was assessed on a five point Likert scale. Image artefacts were classified into five groups and evaluated on a dichotomous scale. Pathological findings were correlated with the anatomical image datasets.

Results: No significant difference was found for iodine uptake of the lung parenchyma in both groups (vDE: 23±13HU and aDE: 22±14HU), but iodine attenuation in the aorta and the pulmonary trunk was lower in vDE. Overall perfusion image quality was comparable ($p = 0.394$). Rotation and streak artefacts were found in most of the patients in at least one location. Dual source artefacts were found in only few patients in both groups (vDE 5%, aDE 7%). Recess artefacts were higher (vDE 61%, aDE 23%) and subpleural artefacts were only observed in vDE (17%). Pathological findings were found in 20% of all vDE patients and in 35% of all aDE patients including areas of hyper- (35/30%) and hypoattenuation (65/70%).

Conclusion: vDE provides robust image quality of lung perfusion. Relative iodine uptake is increased, suggesting a pooling effect. Different appearance of artefacts should be known for interpretation.

Computed tomography pulmonary angiography for acute pulmonary embolism: prediction of adverse outcome and 90-day mortality in a single test

N. Akhounji, T. Faghihi Langroudi; Tehran/IR (neda.akhounji@sbm.ac.ir)

Purpose: Pulmonary embolism (PE) is a potentially fatal cardiopulmonary disease; therefore, rapid risk stratification is necessary to make decisions of appropriate management strategies. The aim of this study was to assess various CT findings to find new predictors of adverse outcome and mortality.

Methods and Materials: The study retrospectively enrolled 104 patients with acute PE. Patients were categorised into 4 groups: group 1: patients who experienced adverse outcome, group 2: patients who died within 30 days, group 3: patients who died between 30 and 90 days, group 4: patients who survived without experiencing adverse outcome. Comorbidities such as ischaemic heart disease (IHD) were obtained from their medical records. Patients' CT angiography were reviewed for recording variables such as main pulmonary artery diameter (MPA), RV/LV ratio. Patients death till three months of diagnosis of PE had been registered. Logistic regression analysis was done to find predictors.

Results: 16 patients experienced adverse outcome, 10 deaths occurred within 30 days and 5 deaths were between 30 and 90 days. Based on multiple logistic regression, RV/LV ratio (OR 11.54; 95% CI 1.16 to 114.35; $p = 0.037$), LV diameter (OR 0.813; 95% CI 0.681 to 0.969; $p = 0.021$), right-sided pulmonary infarction (OR 0.111; 95%CI 0.017 to 0.730; $p = 0.022$) are predictors of mortality in 30 days. RV/LV ratio of 1.19 could successfully discriminate patients who died within 30 days and who did not.

Conclusion: RV/LV ratio, LV diameter, right-sided pulmonary infarction, assessed with helical CT, can help predict mortality in 30 days.

B-0429 16:44

Reduced- and no-dose thin-section radiologic examinations: comparison of capability for nodule detection in patients having pulmonary nodules

Q. Peng, W. Tang, N. Wu, Y. Huang, H. Ouyang, B. Wu; Beijing/CN (meetsumay@hotmail.com)

Purpose: To evaluate the capability of pulmonary MR imaging with zero echo time (ZTE) in pulmonary nodules assessments, using low-dose computed tomography (LDCT) as the reference standard.

Methods and Materials: Institutional review board approval and informed consent were obtained. Eight-nine consecutive patients (51 males: mean age, 69 years and 38 females: mean age, 71 years) with various pulmonary nodules were examined with chest LDCT and pulmonary MR imaging with ZTE. The interval between two examinations was within two weeks for each patient. Lung images were visually scored by two experienced radiologists who assessed the probability of nodule presence in comparison with LDCT. To compare nodule detection capability of the two methods, consensus for performances was evaluated by means of kappa statistics and χ^2 test, and receiver operating characteristic analyses were used to compare diagnostic performance of both methods.

Results: There was no significant difference ($F = 0.75$, $P = 0.56$) in figure of merit between methods (LDCT, 0.84 Vs. MR imaging with ZTE, 0.86). Inter-method agreements between ZTE MR imaging and LDCT were significant ($0.70 \leq \kappa \leq 0.98$; $P < 0.001$). Areas under the curve for pulmonary nodules on LDCT were significantly larger than those on MR imaging with ZTE ($P = 0.02$).

Conclusion: Pulmonary thin-section MR imaging with ZTE was useful in nodule detection, and it is considered at least as effective as low-dose thin-section CT.

B-0430 16:48

Assessment of EGFR mutation status in patients with non-small-cell lung cancer using different iodine quantification methods in dual-energy CT: areal vs volumetric analyses

X. Xu, X. Sui, L. Song, Y. Huang, Z. Jin, W. Song; Beijing/CN (xxlpositive@163.com)

Purpose: To investigate the feasibility of areal and volumetric iodine quantification metrics with dual-energy CT in predicting EGFR mutation status of non-small cell lung cancer (NSCLC) and the correlation between the two methods.

Methods and Materials: 58 untreated NSCLC patients who underwent DECT in an arterial phase before biopsy or surgery were prospectively enrolled. For each lesion, areal iodine content (IC) and normalized iodine content (NIC) with maximum area among slices and volumetric IC and NIC of the whole tumour were evaluated by two radiologists. In the volumetric analysis, tumour was further sectioned, volumetric parameters of every segment and peel were noted. The diagnostic performances of areal and volumetric iodine metrics in characterizing EGFR mutations were compared and the two iodine quantification methods were correlated with each other.

Results: EGFR mutations were found in 28 of 58 patients. NIC_{areal} of EGFR mutant group was higher than that of wild-type group ($t=2.869$, $P=0.006$). $NIC_{volumetric}$ of the inner segment and peel in EGFR mutant group was higher than that in wild-type group ($t=2.415-2.699$, $P=0.009-0.019$). However, volumetric parameters of the total lesion and marginal part showed no significant difference between the two groups. ROC curve analysis revealed that diagnostic performance of NIC_{areal} ($AUC=0.693$) was similar to that of $NIC_{volumetric}$ of inner segments and peels ($AUC=0.655-0.677$). NIC_{areal} was strongly correlated with inner segmental $NIC_{volumetric}$ ($r=0.818-0.821$).

Conclusion: Areal and volumetric iodine metrics were applicable in predicting EGFR mutation status, the maximum area iodine quantification was suggested in clinical use due to its convenient access.

B-0431 16:52

Systematic review and meta-analysis of randomized trials on the impact of lung cancer screening by low-dose computed tomography in populations highly exposed to tobacco

A. Sadate, B. Océan, A. Larbi, P. Fabbro-Peray, J. Beregi; *Nîmes/FR* (alexandre.sadate@gmail.com)

Purpose: Lung cancer (LC) has the highest cancer mortality worldwide with poor prognosis. Screening with low-dose computed tomography (LDCT) in populations highly exposed to tobacco has been proposed to improve LC prognosis. Our objective is to perform a systematic review and meta-analysis to evaluate the efficacy of screening by low-dose computed tomography (LDCT) compared to any other intervention in populations who reported tobacco consumption for more than 15 years on LC and overall mortality.

Methods and Materials: We searched randomized controlled trials (RCTs) studying screening by LDCT compared with any other intervention with data on LC-specific and all-cause mortality from inception until the 19th of February 2018 using Medline and Cochrane Library databases. Publication selection and data extraction were made independently by two double-blind radiology residents. Two groups of meta-analysis were created with either long or short follow-up.

Results: Six RCTs were included in the meta-analysis. In the short-follow-up group, a non-significant excess of overall mortality was observed in the screening group ($RR=1.26$, 95% CI: 0.78-2.04). In the long-follow-up group, a significant relative reduction of overall mortality of 6% ($RR=0.94$, 95% CI: 0.89-0.99) and a significant relative reduction of LC-specific mortality of 14% was observed in the screening group ($RR=0.86$, 95% CI: 0.77-0.96) compared with the control group. The limitations were the heterogeneity of interventions and the over-representation of one study in the long-follow-up group.

Conclusion: In populations highly exposed to tobacco, screening by LDCT reduces LC and overall mortality over the long term.

B-0432 16:56

Application of LDCT and Lung-RADS classification in lung cancer screening of the urban population in China

Q. Meng; *Zhengzhou/CN* (mengke436@163.com)

Purpose: To evaluate the application of LDCT and Lung-RADS classification in lung cancer screening in healthy people.

Methods and Materials: 8850 volunteers were selected and screened by LDCT from November 2013 to December 2017. All volunteers were divided into high-risk group ($n=1339$), medium-risk group ($n=6344$) and low-risk group ($n=1167$); male group ($n=4900$) and female group ($n=3950$); less than 40-year-old group ($n=110$), 40-45-year-old group ($n=794$), 45-50-year-old group ($n=1633$), 50-55-year-old group ($n=2565$) and over 55-year-old group ($n=3858$). Grade 3 +4 in the Lung-RADS classification was positive. The Lung-RADS classification of nodules and lung cancer incidence between different groups was compared.

Results: According to the classification of Lung-RADS, 590 cases of positive nodules were screened at baseline, and the detection rate was 6.67%, in which the difference between male and female was statistically significant (7.5% vs. 5.6%, $p=0.00$). The positive rate of pulmonary nodules gradually increased with age in each group, and the difference of nodules classification in each group was statistically significant, $p<0.05$, the incidence of lung cancer in 40-45-year-old group was significantly higher than that in other groups, and the difference was statistically significant. The difference in nodule classification between the three groups was statistically significant, $p<0.05$. The incidence rate of lung cancer in high-risk group was significantly more than 3 times higher than that of medium-risk group and low-risk group ($2=7.337$, $p=0.026$).

Conclusion: LDCT combined with Lung-RADS classification is suitable for lung cancer screening in healthy people, especially in the high-risk group of over 40 years old.

B-0434 17:04

Single- and dual-energy CT pulmonary angiography using second- and third-generation dual-source CT systems: comparison of radiation dose and image quality

L. Lengua¹, C. Booz¹, J.L. Wichmann¹, J.-E. Scholtz¹, S.S. Martin², T.J. Vogl¹, M.H. Albrecht¹, I. Yel¹; ¹Frankfurt/DE, ²Charleston, SC/US (lukas.lengua@gmail.com)

Purpose: To evaluate radiation exposure and image quality in matched patient cohorts for CT pulmonary angiography (CTPA) acquired in single- and dual-energy mode using second- and third-generation dual-source CT (DSCT) systems.

Methods and Materials: Two-hundred patients (100 men and 100 women) with suspected pulmonary embolism who had undergone clinically indicated CTPA in pulmonary arterial contrast phase were retrospectively enrolled. Patients were equally assigned to one of the four study groups (each with $n=50$), and matched by gender and body-mass-index. CTPA was performed with vendor-preset second-generation DSCT (group A, 100-kV-SECT; group B, 80/Sn140-kV-DECT) or third-generation DSCT (group C, 100-kV-SECT; group D, 90/Sn150-kV-DECT) scanners. Radiation metrics were recorded using a normalized scan range of 27.5 cm. For objective image quality assessment dose-independent figure-of-merit (FOM) contrast-to-noise ratios (CNR) were calculated. Three blinded radiologists evaluated overall image quality, reader confidence and image artefacts subjectively using five-point Likert-scales.

Results: Effective radiation dose calculations revealed no significant differences between SECT and DECT acquisition for each scanner generation ($P\geq0.353$). The mean effective radiation dose was lower for third-generation groups C (1.5 ± 0.8 mSv) and D (1.5 ± 0.7 mSv) compared to second-generation groups A (2.5 ± 0.9 mSv) and B (2.3 ± 0.6 mSv) (all with $P\leq0.012$). Highest FOM-CNR measurements were observed for third-generation DECT ($P\leq0.032$). Ratings for subjective image quality, reader confidence and image artefacts showed no significant differences among the four groups ($P\geq0.158$).

Conclusion: Dual-energy CTPA can be performed with both second- and third-generation DSCT systems without detrimental effects on image quality or radiation dose in comparison with SECT.

Percutaneous needle biopsy for lung lesions focused on needle angle and lesion depth: 14-year results

J. Lee, I. Lee, J. Kim; *Anyang/KR* (jeehyeon@hallym.or.kr)

Purpose: To evaluate the effects of needle angle and lesion depth on complications and technical success of percutaneous needle biopsy (PCNB) for intrapulmonary lesions.

Methods and Materials: From 2004 to 2017, total of 689 cases of PCNB were retrospectively reviewed. The angle and the depth were intensively calculated for each case. The angle was subdivided into three categories on the basis of 30 degrees (0-30, 31-60, 61-90). The depth was documented as a continuous variable. The pathologic results and complications were evaluated to assess relationship with the angle and the depth of PCNB by using univariate analysis. Complications were divided into minor and major complications according to severity and necessity for additional procedure.

Results: The overall success rate was 93.1% (642/689). Technical success showed no significant correlation with both needle angle ($P=0.568$) and lesion depth ($P=0.144$). The overall complications rate was 17.9% (123/689) with 15.7% for minor complications and 2.2% for major complications. No significant correlation was found between complications and the angle ($P=0.101$). However, complications was influenced by the depth ($P<0.01$; mean lesion depth \pm SD for no complications, minor complications and major complications are 1.49 ± 1.65 , 3.39 ± 1.71 , and 4.72 ± 1.54 , respectively).

Conclusion: Needle angle showed no significant relation with technical success and complications. Lesion depth also had no effect on technical success. However, the depth was strongly correlated with the severity of complications after PCNB.

B-0436 17:12

Mare Nostrum and tuberculosis: the role of chest x-ray and clinical-laboratory data among Mediterranean migrants on landing

G. Scavone¹, M.V. Raciti², M.C. Calcagno¹, D.C. Caltabiano¹, G. Galvano¹, A. Scavone¹; ¹Catania/IT, ²Pavia/IT (mariavittoria.raciti@libero.it)

Purpose: To report the experience of the Italian centre most involved in clandestine landings, end point of arrival for Mediterranean migrants and bridge to Europe. To determine the still relevant importance of chest x-ray in diagnostic setting of migrants suspected for tuberculosis (TB) infection, comparing radiological findings with clinical-laboratory data.

Methods and Materials: From 2010 to 2016, 15115 migrants, mainly from sub-Saharan Africa, have landed at the Catania port. They underwent an initial clinical evaluation on the dock looking for two conditions: fever >37°C and cough with or without sputum. 510 migrants had fever, of these 191 with cough were considered suspect for TB and were carried into the high bio-containmentment unit: 149 (cough without sputum) were studied with chest x-ray, 42 (cough with sputum) were subjected to GeneXpert (GX), a rapid laboratory test for TB.

Results: 25TB pulmonary infections were diagnosed (13.1% of TB suspected, 4.9% of febrile patients, 0.16% of migrants), 19 (76%) of these diagnosed by chest x-ray (16 miliary, 2 with consolidations, 1 with cavitations) and 6 (24%) by GX. 14 suspected patients presented non-TB-related pathology diagnosed by x-ray, 13 lobar and atypical pneumonia, and 1 pleurisy.

Conclusion: Mediterranean migratory flows have re-introduced TB and timely diagnosis on landing is mandatory. In symptomatic migrants, chest radiography is the first line technique that allows a timely diagnosis of active or latent tuberculosis and a prompt treatment, preventing the infection spread in the country of landing and in Europe. GX can detect the TB infection but chest x-ray is still necessary to detect GX-negative pulmonary infections.

Prostate imaging self-assessment and mentoring (PRISM): a prototype self-assessment scheme for radiologists

Y. Chen¹, E. Michalopoulos¹, A.G. Gale¹, T. Barrett², P. Haslam³, A. Patel⁴, H. Ahmed⁵, ¹Loughborough/UK, ²Cambridge/UK, ³Newcastle Upon Tyne/UK, ⁴Stevenage/UK, ⁵London/UK (Y.Chen@lboro.ac.uk)

Purpose: The PRISM scheme is a web-based self-assessment and continuous learning platform designed for radiologists across the UK to develop their expertise in interpreting prostate mpMRI images before biopsy, so that they build the confidence to recommend for some men to avoid an immediate biopsy.

Methods and Materials: The PRISM Expert Reference Group (ERG) facilitated by Prostate Cancer UK and consisting of expert radiologists, computer scientists and several members of a wider mpMRI clinical expert group was established. Qualitative data regarding software structure and application design were collected, while a focus group moderator generated interviews to capture deeper information on image examination and reporting processes. A collection of validated mpMRI cases acquired from the PROMIS Trial team was used to evaluate participants' image interpretation performance. Different potential variations of an initial conceptual model of the envisioned application were developed and circulated around the ERG. Further face-to-face meetings and interviews were conducted with consultant radiologists to gain their feedback and finalise the application. The final design was then generated and coded.

Results: To date, the system has been developed and tested. It is now being piloted in specific sites across the UK and the data resulting from these pilots will be analysed and presented at the conference. We understand at this time no meaningful data can be usefully presented in this abstract of work in progress.

Conclusion: This work is at the stage of data collection and will complete at the end of 2018. All data will be presented at ECR 2019.

B-0438 16:08

Use of kZ space for sub-mm through-plane resolution in T2-weighted 2D spin-echo prostate MRI

S. Kargar¹, S. Riederer¹, E. Borisch¹, A. Froemming¹, R. Grimm¹, A. Kawashima², B. King¹, E. Stinson¹; ¹Rochester, MN/US, ²Scottsdale, AZ/US (riederer@mayo.edu)

Purpose: To describe how sub-mm through-plane resolution can be obtained with multi-slice kZ-processed data for improved sharpness in prostate T2SE MRI.

Methods and Materials: Through-plane resolution of multi-slice MR images is typically no finer than several mm, as limited by the slice profile. Here we describe a method for obtaining sub-mm resolution by compensation for slice profile, done in combination with fine slice-to-slice spacing. The multiple slices are transformed to kZ space for reconstruction. The time for acquiring more slices is accounted for in part by reduced signal averaging. The method was evaluated in 16 subjects for whom prostate MRI was indicated. A reference

(TR/TE 3000/100, 28 3.0-mm-thick slices, 4:14 scan time, 0.75 x 0.75 x 3.00 mm³ resolution) and the proposed (TR/TE 3000/100, 78 overlapped 3.0-mm-thick slices, 6:38 scan time, 0.75 x 0.75 x 1.00 mm³ final resolution) axial scans were performed. Images from the two were compared blindly by three experienced urologists using five evaluation criteria of sharpness (prostate capsule, zonal differentiation, structures within the peripheral and transition zones, seminal vesicles) and artefact. Individual acquisitions were also assessed for overall image quality.

Results: The proposed method was superior for all five sharpness-related criteria (p<0.04, Wilcoxon signed rank test) but inferior for artefact (p<0.02). Both T2SE scans were rated highly for overall image quality.

Conclusion: Multi-slice axial T2SE images can be acquired with modest overlap and reconstructed to provide 1-mm slice resolution for prostate MRI. The resultant images provide improved sharpness of clinically relevant structures.

B-0440 16:16

MRI of the prostate at 3.0T with and without endorectal-coil: two-centre comparison in kiwi-fruit and patients

U. Mueller-Lisse, S. Murer, J. Scheidler, M. Kuhn, A. Meister, M.K. Scherr, U.L. Mueller-Lisse; Munich/DE (ullrich.mueller-lisse@med.uni-muenchen.de)

Purpose: To test by means of the kiwi-fruit phantom and validation in patients with benign prostate hyperplasia (BPH) if bi-parametric 3.0T-MRI provides equivalent signal-to-noise-ratio (SNR) and contrast-homogeneity without and with ERC, including both full-field-DWI and reduced-field-DWI.

Methods and Materials: ERC/noERC axial T2-weighted (T2WI, TR/TE 7,500/98-101 ms) and diffusion-weighted (full-field-DWI 380x297 mm2, reduced-field-DWI 149-179x71-73 mm2, TR/TE 4,500-5,500/61-74 ms) MR-images were compared for SNR and anterior-posterior contrast in green "Hayward" kiwi-fruit (Actinidia deliciosa, 105-115 g). Ethics-committee-approved retrospective validation in benign-prostate-hyperplasia-patients (negative prostate-biopsy, PIRADSV2 ≤2, age+/-standard-deviation, 62+/-8 years, PSA, 6.3+/-2.4 ng/ml, prostate-volume, 91+/-51 cm3, noERC, n=10, centre 1, ERC, n=11, centre 2) involved identical prostate-MRI-protocols. Two-tailed Wilcoxon-matched-pairs-signed-rank-tests were significant for p<0.05.

Results: SNR(noERC) in peripheral kiwi-fruit tissue was higher posteriorly (median/minimum,maximum, 41/22,91) than anteriorly (40/21,87) in T2WI (0.010<p<0.025), but not in full-field-DWI, reduced-field-DWI, and mono-exponential ADC-maps (10/4,17-80/13,126 versus 11/6,20-83/8,137, 0.05<p<1.0). SNR(ERC) was higher posteriorly in T2WI, full-field-DWI and reduced-field-DWI (17/7,74-39/8,80 versus 6/2,72-25/14,64, p<0.001-0.05), but not in ADC-maps (26/17,47-61/8,104 versus 22/15,45-56/7,121, 0.05<p<1.0). Anterior-posterior contrast in kiwi-fruit was higher for ERC than noERC in DWI-sequences (p<0.001-0.05). SNR was higher in reduced-field-DWI than in full-field-DWI for both noERC (median, 15-85 versus 10-37) and ERC (9-61 versus 6-39) in kiwi-fruit and patients.

Conclusion: Study results in both kiwi-fruit and patients imply that SNR is similar in noERC and ERC in a bi-parametric prostate-MRI-protocol, image-homogeneity is higher for noERC, and SNR is higher in reduced-field-DWI than in full-field-DWI.

B-0441 16:24

T2-mapping with simulated T2-echo - a diagnostic alternative for 3-Tesla prostate MRI?

J. Pfeil¹, C. Lee², M. Haas¹, M. Taupitz¹, B. Hamm¹, P. Asbach¹; ¹Berlin/DE, ²Singapore/SG (julian.pfeil@charite.de)

Purpose: T2-mapping sequences provide quantitative information and also allow the reconstruction of a simulated T2-weighted image which could be used instead of the standard T2-weighted fast spin-echo sequence to save scan time. The aim of this study was to evaluate the image quality and diagnostic utility for PI-RADS scoring of a T2-mapping sequence with simulated T2-echo in comparison to a standard T2-weighted fast spin-echo sequence for prostate MRI.

Methods and Materials: In this IRB approved prospective study on 40 patients a multi-echo T2-mapping sequence was added to the routine 3-Tesla prostate MRI protocol. Three readers separately reviewed sets of images blinded to the sequence technique. Reader preference for either the standard T2-sequence or the simulated T2-sequence was compared using the Z-test and the intra-observer agreement for assigning PI-RADS scores was calculated for each reader using the Cohen kappa (κ).

Results: All 3 readers preferred the standard T2-sequence over the simulated T2-sequence (p<0.05). All 3 readers showed moderate intra-observer agreement between the standard T2- and simulated T2-sequence regarding the assigned PI-RADS scores (R1 κ = 0.58, R2 κ = 0.44, R3 κ = 0.43).

Conclusion: T2-mapping with reconstruction of a simulated T2-sequence shows potential for including quantitative sequences into routine prostate MR protocols but image quality is not equivalent to standard T2 fast spin-echo imaging.

Assessment of diagnostic yields of significant prostate cancer by altering the prostate-specific antigen density thresholds for biopsy according to MRI findings

L. Boesen¹, V. Logager³, N. Nørgaard¹, R. Bisbjerg¹, I. Balslev¹, K.-C.D. Thestrup¹, H. Jakobsen¹, H.S. Thomsen¹, A.R. Padhani²; ¹Herlev/DK, ²Northwood, Middlesex/UK, ³Copenhagen (lars.boesen@dadlnet.dk)

Purpose: To assess the influence of prostate-specific antigen density (PSAd) on the diagnostic yields of a negative-, equivocal- and positive biparametric (bp) MRI, to detect and rule out significant prostate cancer (sPCa).

Methods and Materials: Prostate bpMRI (T2W and DWI) was performed in 808 biopsy-naive men with clinical suspicion of PCa (PSA<20 ng/ml, cTstage<T3). BpMRI findings were stratified into negative/equivocal/positive for sPCa suspicion using modified PI-RADS. All men underwent standard- and targeted biopsies of bpMRI equivocal/positive lesions. PSAd thresholds were assessed according to bpMRI findings using sPCa detection rates (Gleason grade group≥2) from combined biopsies as reference. Net benefits and decision curve analyses were compared to determine the optimal biopsy strategy.

Results: Overall, any and sPCa was detected in 460/808 (57%) and 283/808 (35%) men with median age and PSA [inter-quartile range] of 65 years [60-70] and 6.9 ng/ml [5.4-9.5], respectively. PSAd significantly influenced the diagnostic yield of sPCa stratified by bpMRI suspicion. For biopsy risk-thresholds ranging from 10-30%, the best strategy was restricting biopsies to men with positive bpMRIs or PSAd ≥0.15 ng/ml/cc for equivocal and ≥0.20 ng/ml/cc for negative bpMRIs. This reduced the number of men requiring biopsies by 45% (363/808), over-diagnosis rate of insignificant cancers by 51% (90/177), while missing only 7% (20/283) of men with sPCas.

Conclusion: Altering the PSAd threshold according to bpMRI suspicion and restricting biopsies to men with positive bpMRIs or PSAd ≥0.15 for equivocal- and ≥0.20 for negative bpMRIs was the best biopsy strategy in biopsy-naive men, effectively balancing risks and benefits.

B-0443 16:40

Natural history of prostate cancer on active surveillance: stratification by MRI using the PRECISE recommendations in a UK cohort over 11 years

F. Giganti¹, A. Stabile², V. Stavrinides¹, C. Orczyk¹, S. Punwani¹, C. Allen¹, A. Kirkham¹, M. Emberton¹, C.M. Moore¹; ¹London/UK, ²Milan/IT (f.giganti@ucl.ac.uk)

Purpose: To compare the PRECISE score (a 1-5 Likert scale for the likelihood of radiological change of prostate cancer over time; 1: regression, 3: stability and 5: definite stage progression) with clinical progression in men on an MRI-led active surveillance (AS) protocol.

Methods and Materials: Men on AS for low or intermediate risk prostate cancer who had had two or more MRI scans between April 2006 and September 2017 were included. A total of 150 men (535 scans) were re-reported by a dedicated radiologist to give a PI-RADS v2 score for each scan, measurement of all lesions and a PRECISE score. Clinical progression was defined by histological progression to ≥ Gleason Grade Group 3 and/or initiation of active treatment. Tumour growth rate between serial scans was calculated.

Results: Freedom from clinical progression at 12, 24 and 60 months for PRECISE 1-2 was 100% at all time points; for PRECISE 3 it was 98.4%, 96.7%, 96.7% and for PRECISE 4-5 it was 98.5%, 92.4%, 67.1%, respectively. There was a significant difference between PRECISE 1-2 vs 4-5 and PRECISE 3 vs 4-5 (p<0.001). Fifty-six men (37%) had a visible lesion on all scans, and their tumour growth rate (%) by planimetry was higher with higher PRECISE scores (all p<0.05). Limitations include the fact that serial biopsies were not routinely performed and that the biopsy approach varied (standard vs targeted).

Conclusion: Radiological stability (PRECISE 1-3) in men on AS is associated with a high rate of freedom from clinical progression.

B-0444 16:48

Orthopaedic metallic artefact reduction is indispensable for CT evaluation of the urinary tract after hip replacement

P.N. Kaposi, T. Youn, P. Borsos, P. Magyar, V. Bérczi; Budapest/HU (kaposipal@gmail.com)

Purpose: The metallic hip prosthesis (TEP) causes extensive artefacts on CT scans. Orthopaedic metallic artefact reduction (O-MAR) may augment evaluation of the bladder and ureter after TEP.

Methods and Materials: 30 patients with 41 TEPs were retrospectively enrolled in the study. CT examinations were performed on an Ingenuity Core 64 scanner (Philips Healthcare, the Netherlands) with diagnostic protocols. Series were reconstructed both with a body kernel (NOM) and O-MAR from the same acquisitions. CT densities were measured in freehand regions of interest (ROIs) drawn around the ureters and in ROIs inside the bladder at both sides. Four visibility levels were used for semi-quantitative assessment of image quality.

Results: The average (μ) density of 41 prosthesis side ureters was significantly lower on NOM ($\mu=94.76$ HU \pm SD 150.48HU) than on O-MAR images ($\mu=13.40$ HU \pm SD 36.37HU; p<0.0004). The TEP side of the bladder ($\mu=-138.62$ HU \pm SD 182.64 HU vs. $\mu=-35.55$ HU \pm SD 40.21 HU; p<0.0003) was also darker on NOM images. 53.7% of the TEP side ureters was obscured on NOM series compared to 4.9% on O-MAR. A linear-by-linear test found significantly improved conspicuity of the ureters with O-MAR across all levels (p<0.001). The diagnosis was altered in four cases (13%). In two cases ureter stones, in one case a bladder stone and a bladder tumour were discovered with O-MAR.

Conclusion: O-MAR significantly improves the conspicuity of the bladder and ureters after TEP, and it can be indispensable for the detection of otherwise invisible lesions adjacent to metallic implants.

B-0445 16:56

Wide-detector axial scan on revolution CT for combining application of ASIR-V and ASIR on unenhanced abdominal CT in vivo: the image quality and radiation dose evaluation

Z. Zhu, X.-M. Zhao, C. Zhou; Beijing/CN

Purpose: To investigate the performance of combining adaptive statistical iterative reconstruction v technique (ASIR-V) and ASIR on non-contrast abdominal computed tomography (CT).

Methods and Materials: 141 patients (21-78 years; 78 male, 63 female) were enrolled. The scan protocol from group A to E were 0%, 20%, 40%, 60%, 80% ASIR-V respectively in 256 row wide-detector Revolution CT and F with no ASIR-V in 64-detector Discovery 750 HD CT. Each group was divided into 5 subgroups with 0%, 20%, 40%, 60%, 80% ASIR, respectively. Image noise was measured in spleen, aorta and muscle. The CT attenuation and image noise were analysed using the student t-test.

Results: With increased ASIR-V (from group A to E), the image noise decrease except group B in aorta and muscle (Noise_B>Noise_A, P_{muscle A&B}=0.233, P_{aorta A&B}=0.796). With fixed ASIR-V (same group) in three organs, the image noise decrease when ASIR increasing (subgroups 20% to 80%). With fixed ASIR (same subgroup) in three organs, the image noise increase when ASIR-V increasing except subgroup ASIR 20%-80% in group D and E in aorta, subgroup ASIR 40% in group B and C in muscle. The CTDIvol and DLP from group A to E decreased with significant difference when ASIR-V increased. The CTDIvol and DLP in group F are higher than group A with significant difference.

Conclusion: Simply applying either ASIR-V or ASIR is good for the image quality of non-contrast abdominal CT scan. While applying both, the image quality deserved no further improvement but with some certain compromise.

B-0446 17:04

Evaluation of a compressed-sensing accelerated high-resolution VIBE sequence for an improved morphologic and functional assessment ("one-stop shop") of the uterus: initial analysis

D. Hausmann¹, S. Ignjatovic¹, D. Kreul¹, M. Klarhöfer², M. Nickel³, B. Kiefer³, R.A. Kubik-Huch¹; ¹Baden/CH, ²Zurich/CH, ³Erlangen/DE (danielhausmann@hotmail.com)

Purpose: To compare a prototype compressed-sensing-accelerated VIBE (csVIBE) with variable temporal resolution (range: 4-12 seconds) with a conventional VIBE (convVIBE) and to explore the benefits of additional quantitative perfusion analysis.

Methods and Materials: So far, 30 datasets (15 csVIBE/15 convVIBE) were independently assessed by two experienced readers in this IRB-approved study. All patients were examined on state-of-the-art 1.5T clinical MRI scanners (MAGNETOM Avanto Fit/Aera, Siemens Healthcare, Erlangen, Germany). Mann-Whitney U tests were performed to compare image quality (IQ), delineation of structures (DoS), artefacts (A) and diagnostic confidence (DC), which were rated on Likert-type scales (IQ/DoS/DC: 1 (non-diagnostic)-5 (perfect); A: 1 (no artefacts)-5 (severe artefacts)). For perfusion analysis a

Tofts model was used. Ktrans was measured in cervix (Cx), junctional zone (Jz) and myometrium (Mm). These values were compared between first (fp)/second phase (sp) of the menstrual cycle and between pre- and postmenopausal (post) women using t tests. Interobserver agreement was assessed.

Results: Ratings for IQ/DoS/DC of csVIBE ($4.3\pm 0.7/4.7\pm 0.5/4.6\pm 0.8$; $\kappa: 0.8/0.2/0.7$) and convVIBE ($4.1\pm 0.6/4.3\pm 0.7/4\pm 0.7$; $\kappa: 0.5/0.7/0.9$) were generally high, while A was rated low (cs/convVIBE: $2\pm 0.8/2.2\pm 0.6$; $\kappa: 0.6/0.3$) ($p\geq 0.05$). Ktrans in Jz was (not significantly) higher in fp than in sp and post (0.43 versus $0.19/0.24$; ($p=0.32$)). Values were similar independent of cycle phase and menopausal status in Cx/Mm ((Cx (fp/sp/pm): $0.16/0.12/0.11$; Mm (fp/sp/pm) $0.26/0.24/0.15$); $p\geq 0.05$).

Conclusion: csVIBE is useful to morphologically and functionally assess the uterus in a single acquisition at a similar IQ compared to convVIBE. Perfusion analysis and multiple-phase imaging may have the potential to differentiate between various uterine pathologies.

Dual-energy CT dose reduction for GU CT while preserving diagnostic performance

I. Duba¹, A. Khandelwal², J. Weaver², S. Leng², A. Ferrero², M. Wells², J.G. Fletcher², C. McCollough², A.F. Halaweish²; ¹Malvern, PA/US, ²Rochester, MN/US (Khandelwal.ashish@mayo.edu)

Purpose: To investigate the diagnostic accuracy of low dose radiation protocols for urological dual-energy (DE) CT applications.

Methods and Materials: All data were acquired using a 3rd generation dual-source CT. Accuracy of reduced dose DECT renal stone classification was evaluated, as a function of phantom size and dose, by scanning 88 stones of known composition at 100%, 75%, 50% and 33% of routine dose. Findings were confirmed by measuring stone identification accuracy in reduced dose (via noise insertion) patient DECT's. Dose reduced CT urograms (CTU) were evaluated in 5 CTU cases at similar dose levels. Mixed kV, virtual non-contrast, iodine map and 50 keV monoenergetic images were generated for the full and dose reduced CTUs. Mixed image & 50 keV CNR values were compared across doses and diagnostic quality assessed by a urologist.

Results: Phantom validation demonstrated up to 70% & 50% dose reduction for lateral widths <41cm and ≤ 45 cm respectively, while maintaining 100% and 98% stone characterization accuracy respectively. Using this validation, clinical protocols were adjusted accordingly to account for new dose reductions. Iodine CNRs in 50keV low dose CTU images were an average of 82%, 101% and 126% of the full dose values for 33%, 50% and 75% of full dose, respectively. Radiologist review of CTU images found that all 75% dose exams and 2/5 of 50% dose exams were diagnostically acceptable.

Conclusion: Optimization of routine DECT acquisitions is achievable at lower dose levels. Continued optimization of CTU exams are ongoing using increased IR strengths and more reader validation.

Value of static first-pass dual-energy CT perfusion analysis in patients with acute pancreatitis

I. Yel¹, L. Lenga¹, J.L. Wichmann¹, M.H. Albrecht¹, T.J. Vogl¹, S.S. Martin²,
¹Frankfurt a. Main/DE, ²Charleston, SC/US (Dr.IbrahimYel@gmail.com)

Purpose: The aim of this study was to investigate the correlation and discriminative diagnostic accuracy of dual-energy CT (DECT)-derived iodine uptake and fat fraction analysis in patients with acute pancreatitis of varying severity.

Methods and Materials: In this retrospective study, 53 patients with acute pancreatitis were included, who had undergone portal-venous-phase DECT examinations of the abdomen. Three blinded readers independently evaluated all cases using the modified CT severity index (CTSI) taking pancreatic inflammation, necrosis, and extrapancreatic complications into account. In addition, readers performed region-of-interest (ROI) measurements on DECT iodine perfusion images in the inflammatory pancreatic parenchyma. The correlation between disease severity and iodine uptake, as well as fat fraction values was investigated. The optimal discriminative cut-off iodine uptake value to diagnose severe acute pancreatitis was determined using receiver operator curve (ROC) statistics.

Results: Mean CTSI was 5.6 ± 3.2 . A significant correlation was found between CTSI scores and mean iodine uptake (Pearson's correlation coefficient $r = 0.657$; $p < 0.01$). An iodine uptake threshold of ≤ 1.7 mg/ml was found to indicate a severe acute pancreatitis with a sensitivity of 86.7% and specificity of 87.5%. Fat fraction analysis revealed no significant correlation in patients with CTSI scores ≤ 2 ($p = 0.278$). In patients showing CTSI scores > 4 , however, a moderate correlation was found between mean fat fraction values and disease severity ($r = 0.482$; $p < 0.05$).

Conclusion: First-pass perfusion analysis in contrast-enhanced DECT shows high diagnostic accuracy to diagnose severe acute pancreatitis. Furthermore, iodine uptake directly correlates with CTSI scores.

Diagnostic efficacy of acute necrotizing pancreatitis on early CT scan and correlation with laboratory exams

Y. Song, H. Park, M. Yu, Y. Kim, S. Jung, H. Jeon; Seoul/KR
(thdgustjs88@gmail.com)

Purpose: To investigate the diagnostic efficacy of early and short-term follow up (< 2 weeks) CT scan in necrotizing pancreatitis based on revised Atlanta classifications and to correlate it with laboratory exams.

Methods and Materials: From Sep 2007 to Aug 2018, a total of 210 patients (147 men and 63 women, mean age 54.9 years) with acute pancreatitis who underwent initial contrast enhanced CT at admission and a short term (within 2 weeks) follow up CT were included. Two abdominal radiologists performed a consensus review of two sets of CT in each patient, and determined the type of acute pancreatitis as interstitial oedematous pancreatitis (IEP) or necrotizing pancreatitis (NP) according to the revised Atlanta classifications. Values of laboratory exams including pancreatic enzymes and C-reactive protein were recorded and compared between the IEP and NP groups at each time point using t-test.

Results: The time interval between symptom onset and initial CT scan was 0-3 days (mean 1 day). The type of acute pancreatitis at admission was IEP ($n = 166$) or NP ($n = 45$). In IEP group, 53 (31.9%) patients were diagnosed as NP at short term follow up CT (mean 6.6 days, range 1-13 days) (IEP-NP), while stationary or improved IEP was in remaining 113 (68.1%) patients (IEP-IEP). At the time of initial CT, serum C-reactive protein was significantly higher in IEP-NP group (5.46 ± 9.14 mg/dl) than in IEP-IEP group (4.01 ± 7.22 mg/dl) ($P = .042$).

Conclusion: The diagnosis of necrotizing pancreatitis can be overlooked on early CT scan (within 3 days after symptom onset). Serum C-reactive protein may be helpful in predicting the progression of IEP into NP in the early phase.

B-0450 08:46

Relapse of type 1 autoimmune pancreatitis after steroid therapy: imaging findings and risk factors

L. Zhu¹, T. Denecke², P. Asbach², B. Hamm², H.-D. Xue¹, Z.-Y. Jin¹;
¹Beijing/CN, ²Berlin/DE (zhuliang_pumc@163.com)

Purpose: To evaluate the imaging pattern of relapsed autoimmune pancreatitis (AIP) after corticosteroid therapy (CST), and to identify clinicoradiological risk factors for relapse.

Methods and Materials: Radiological and clinical database (2012-2018) of AIP patients treated and followed up for more than 18 months at our institution was retrospectively reviewed. Pattern of pancreaticobiliary manifestations and other organ involvement (OOI) were recorded. Univariate and multivariate analyses were conducted to identify risk factors predicting relapse.

Results: Among 103 AIP patients, 44 (42.7%) experienced relapse. The median time interval between initial attack and relapse was 17 months (range 4-61 months). Pancreas involvement was less frequent at relapse compared to initial attack (81.8% vs 100%, $p = 0.003$) and pancreas size was smaller (mean size of pancreatic head, body and tail was 27.6, 17.3 and 20.2 mm at relapse, in contrast to 34.5, 25.0 and 27.3 mm at initial attack, all ($p < 0.01$)). Patients who experienced relapse had higher frequency of extra-pancreatic bile duct (ExPBD) involvement at initial diagnosis compared to non-relapsed patients (52.3% vs. 25.4%, $p = 0.023$). During relapse, extra-pancreatic bile duct involvement became even more frequent (59.1%) and more extensive. Univariate analysis identified male gender, initial serum IgG4 level, OOI, ExPBD involvement and kidney involvement as risk factors for relapse. Multivariate analysis revealed ExPBD involvement as a significant independent predictor of relapse (hazard ratio 1.976, 95% confidence interval 1.149-3.570, $p = 0.023$).

Conclusion: During AIP relapse pancreas was less involved and smaller, whereas bile duct and kidney were more involved. ExPBD involvement at initial diagnosis was a significant risk factor for relapse.

B-0451 08:54

Early prediction of the severity of acute pancreatitis using radiologic and clinical scoring systems with classification tree analysis

A. Ko, H. Park, E. Lee, H. Choi, J. Do, S. Park, B. Choi; Seoul/KR

Purpose: This study was to develop a decision tree model for the early prediction of the severity of acute pancreatitis (AP) using clinical and radiologic scoring systems.

Methods and Materials: For this retrospective study, 192 patients with AP who underwent CT less than 72 hours after symptom onset were divided into two cohorts: a training cohort ($n = 115$) and a validation cohort ($n = 77$). Univariate analysis was performed to identify significant parameters. For early prediction of disease severity, a classification tree analysis model was constructed using significant scoring systems shown by univariate analysis. To assess the diagnostic performance of the model, we compared the area under the ROC curve (AUC) with each selected single parameter and their diagnostic performance in the validation set.

Results: The Acute Physiology and Chronic Health Evaluation (APACHE)-II score, bedside index for severity in acute pancreatitis (BISAP) score, extrapancreatic inflammation on CT (EPIC) score, and Balthazar grade were included in the CTA model. In the training set, our CTA model showed a higher AUC (0.853) than that of each single parameter (all, $p > 0.0125$) while achieving specificity (100%) higher than and accuracy (94.8%) comparable to each single parameter (both, $p < 0.0125$). The CTA model also achieved similar diagnostic performance to the training set with an AUC of 0.833.

Conclusion: Our CTA model consisted of clinical and radiologic scoring systems and may be useful for the early prediction of the severity of AP and identification of high-risk patients who require close surveillance.

B-0452 09:02

Preoperative prediction of pancreatic neuroendocrine tumours' grade: the added value of contrast-enhanced ultrasound with quantitative analysis

Y. Dong, X. Han, D. Yang, W. Lou, Q. Zhang, W.-P. Wang; Shanghai/CN
(dr_mimi@163.com)

Purpose: To evaluate whether the contrast-enhanced ultrasound (CEUS) with quantitative analysis could effectively predict tumour grade of pancreatic neuroendocrine tumours (pNETs) before operation.

Methods and Materials: From January 2016 to October 2018, twenty cases of pathologically confirmed pNETs were included. All the patients were confirmed by histopathology after surgery ($n = 18$) or endoscopic -guided fine-needle biopsy ($n = 2$). CEUS were performed before operation or biopsy. An ACUSON S2000 OXANA US system (Siemens Medical Solutions, Mountain View, CA, USA), equipped with a C6-1 transducer was used. Time intensity curves were created and quantitative indexes of CEUS were analysed. CEUS quantitative

indexes were compared to histopathological features using the Mann-Whitney U test. Diagnostic accuracy was assessed by ROC-AUC analysis, sensitivity and specificity were assessed for each quantitative index.

Results: After injection of ultrasound contrast agents, most pNET lesions displayed focal hyperenhancement (85%) in the arterial phase. During the late phase, most pNET lesions were hyper- (80%) or iso-enhancing (20%). Liver metastases were detected in 3 patients during the late phase scan of the whole liver. Among all CEUS quantitative indexes, area under curve (AUC) was significantly higher in G2 and G3 pNETs tumours with ROC-AUC 0.723, sensitivity 80.7% (95% CI: 61.3-90.5) and specificity 64.1% (95% CI: 40.9-81.7).

Conclusion: Preoperative CEUS with perfusion analysis might be helpful in predicting tumour grade and liver metastases of pNETs. AUC might be the potential accurate parameter for identification of pNETs with malignant behaviour.

B-0453 09:10

Diagnostic performance of computerised 3D CT texture analysis of pancreas for the assessment of patients with diabetes

S. Jang¹, J. Kim¹, S.-Y. Choi², S. Park¹, J. Han¹; ¹Seoul/KR, ²Gyeonggi-do/KR (junemiru@gmail.com)

Purpose: To evaluate the diagnostic performance of computerised 3D CT texture analysis of the pancreas for assessing diabetes.

Methods and Materials: Among 2,493 patients with diabetes, 39 patients with type 2 diabetes (T2D) and 12 patients with type 1 diabetes (T1D) who underwent CT using two, selected CT scanners, were enrolled in our study. We compared these patients with age, body mass index (BMI), and CT scanner-matched normal subjects. Computerised texture analysis for the entire pancreas was performed by extracting 17 variable features. A multivariate logistic regression analysis was performed to identify the predictive factors for diabetes and its subtypes. A receiver operator characteristic (ROC) curve was constructed to determine the optimal cut-off values for significant variables.

Results: In diabetes, the mean attenuation, standard deviation, variance, entropy, homogeneity, surface area, sphericity, discrete compactness, grey-level co-occurrence matrix (GLCM) contrast, and GLCM entropy showed significant differences ($P < .05$). Multivariate analysis revealed that a higher variance (adjusted OR, 1.002), sphericity (adjusted OR, 1.649×10^4), GLCM entropy (adjusted OR, 1.057×10^6), and lower GLCM contrast (adjusted OR, 0.997) were statistically significant differentiators of diabetes ($P < .05$). The mean AUCs for each feature were 0.654, 0.689, 0.620, and 0.613, respectively ($P < .05$). In the subgroup analysis, a larger surface area (adjusted OR, 1.000; $P = .025$) was a significant predictor for T2D.

Conclusion: Computerised 3D CT texture analysis of the pancreas could be helpful for predicting diabetes. A higher variance, sphericity, GLCM entropy, and a lower GLCM contrast were the significant predictors of diabetes.

B-0455 09:18

DWI and dynamic MRI in the study of intraductal papillary mucinous neoplasms (IPMNs): pathological comparison with tumour grade correlation

G. Giannotti, G. Tedesco, A. Beleù, G. Rizzo, N. Cardobi, R. De Robertis Lombardi, M. D'Onofrio; Verona/IT (gabriele200590@gmail.com)

Purpose: Evaluation of mural nodules (MNs) and septa of IPMNs through diffusion-weighted imaging (DWI) and contrast-enhanced magnetic resonance (CE-MR) for the characterization of tumour grade.

Methods and Materials: 96 patients with pancreatic IPMNs were included in the study. All patients had histological diagnosis after surgical resection (between 2012 and 2017) and a pre-operative MR exam. Histological grade of dysplasia for each lesion was available in all cases. There were 37 mild, 10 moderate, 24 high-grade dysplastic lesions and 25 ductal adenocarcinomas. MR exams were retrospectively and separately reviewed by two radiologists, blinded to surgical and pathological results. A third experienced radiologist played the role of judge in case of doubtful findings or conflicting analyses. The enhancement after i.v. injection of Gd and DWI signal intensity of mural nodules and cystic septa of IPMNs were judged.

Results: The degree of dysplasia was divided into two groups: mild-moderate and high-ductal adenocarcinoma. The Pearson's chi-squared test was used to verify the statistical correlation between imaging findings and IPMN histology. There was a statistically significant difference ($p < 0.05$) between mural nodule enhancement and degree of dysplasia and DWI signal intensity of mural nodules and degree of dysplasia. Instead, there was no statistical significant difference ($p > 0.05$) between septal enhancement and degree of dysplasia and DWI signal intensity of septa and degree of dysplasia.

Conclusion: Enhancement and DWI signal intensity of MNs can be used as parameters to predict the degree of dysplasia of IPMNs.

B-0456 09:26

Solid pseudopapillary tumour of the pancreas: correlation of MR imaging appearance with biological behaviour

W. Mingliang, M. Zeng; Shanghai/CN (wang.mingliang@zs-hospital.sh.cn)

Purpose: To describe MR imaging features of pancreatic solid pseudopapillary tumours (SPTs) and to identify MR imaging features in predicting biological behaviour.

Methods and Materials: Clinical, pathological and MR imaging data of 47 patients (8 men and 39 women; age range 13-58 years) with pathologically proven SPTs were retrospectively reviewed. Image analysis included tumour location, diameter, shape, margin, signal intensity on precontrast images, enhancement pattern, pancreatic duct dilatation, secondary pancreas atrophy and extrapancreatic spread. According to pathological biological behaviour of the tumour, all cases were divided into two groups (invasiveness group and non-invasiveness group). For data analysis, the comparison between subgroups was performed with Student's *t* test. Categorical variables were tested using χ^2 test or Fisher's exact test.

Results: 47 lesions were found by surgical specimen analysis in all patients. All lesions were correctly identified and located with MRI. The tumours originated from pancreatic head and neck (n=17), body and tail (n=28), and extrapancreatic area (n=2). 22 lesions were found in invasiveness group and 25 lesions in non-invasiveness group. The median maximum diameter of SPTs in invasiveness group was 5.99 ± 3.08 cm, and 4.8 ± 2.28 cm in non-invasiveness group. Significant differences in age, tumour shape and tumour margin were found between two groups ($P < 0.05$). There were no significant difference found in gender, tumour location, cystic changes, intratumoural haemorrhage, enhancement pattern, pancreatic duct dilatation, secondary pancreas atrophy and extrapancreatic spread.

Conclusion: MR imaging features such as tumour shape and tumour margin may preoperatively suggest the biological behaviour of SPTs, assisting decisions about treatment.

B-0457 09:34

Solid pseudopapillary neoplasms of the pancreas: clinicopathological and radiological features according to size - 20-year experience from a high-volume centre

R. De Robertis Lombardi¹, A. Grecchi², M. Catania², A. Beleù², G. Rizzo², M.C. Ambrosetti², M. D'Onofrio²; ¹Peschiera del Garda/IT, ²Verona/IT (annamaria.grecchi88@gmail.com)

Purpose: To analyse and correlate clinicopathological and radiological features of resected solid pseudopapillary neoplasms of the pancreas according to their size.

Methods and Materials: Clinicopathological and radiological features of resected solid pseudopapillary neoplasms (SPN) of the pancreas over a 20-year period were retrospectively analysed. For the purpose of statistical analysis, tumours were divided into three groups according to their size (≤ 30 mm, 31-50 mm, and > 50 mm). Clinicopathological and radiological features were compared among groups using Kruskal-Wallis and Fisher's exact tests.

Results: Between January 1997 and December 2017, the study population consisted of 106 patients, with a median age at diagnosis of 31 years (range 7-68). Patients with small tumours (≤ 30 mm) had a significantly higher age at diagnosis compared with the other groups of patients ($p = .038$). Large tumours (31-50 mm and > 51 mm) were more frequently located in the pancreatic body/tail compared with tumours ≤ 30 mm ($p = .008$). No other significant differences were found between the clinicopathological features of the three groups of patients (all $p > .05$). Most tumours presented a mixed solid and cystic appearance (54.7%), with well-defined margins (87.7%). Tumours ≤ 30 mm were significantly more frequently entirely solid (53.8%) compared with larger tumours ($p = .028$). The rate of incorrect preoperative diagnosis was higher in tumours ≤ 30 mm compared with larger tumours, albeit without significant differences between groups ($p = .561$).

Conclusion: Malignancy in solid pseudopapillary neoplasms is not correlated with tumour size; tumours ≤ 30 mm may present atypical imaging features, which may overlap with those of other solid tumours of the pancreas.

B-0458 09:42

Risk assessment for pancreatic fistula after pancreaticoduodenectomy with preoperative computed tomography

R. Menghini, G. Zamboni, A. Cybulski, R. Valletta, G. Marchegiani, G. Mansueto; Verona/IT (rossella.menghini@gmail.com)

Purpose: to evaluate the predictive value of preoperative CT features for the risk of postoperative pancreatic fistula.

Methods and Materials: we included 58 Patients who underwent preoperative MDCT and pancreaticoduodenectomy in our institution. The Patients were divided in 2 groups in according to clinical data: 29 patients with postoperative pancreatic fistula (POPF) (group A), and 29 patients without POPF (group B). One reader reviewed the CTs and measured at the planned resection plane the main pancreatic duct (MPD) diameter, the density of the parenchyma in the

different enhancement phases and the parenchymal thickness. The difference in attenuation between the venous and arterial phase was calculated as a surrogate for parenchymal fibrosis. Body composition was analysed by calculating visceral adipose tissue area (VAT), subcutaneous adipose tissue area (SAT), and skeletal muscle area at the L2-level using ImageJ software. Retrorenal fat thickness and psoas density were also measured. Fisher's exact test was used for categorical variables and Student's t-test for continuous variables.

Results: MPD diameter was 3.2 ± 3.1 mm in group A and 6.9 ± 3.3 mm in group B ($p < 0.0001$). The mean attenuation difference between venous and arterial phase was -15.86 HU in group B and 0.89 HU in group A ($p = 0.0034$). No significant difference was observed between groups for all the other parameters.

Conclusion: fibrosis, expressed by increasing enhancement of the normal pancreatic parenchyma at the planned resection plane, and MPD diameter may predict the occurrence of pancreatic fistula after pancreaticoduodenectomy.

B-0454 09:50

Comparison of reduced field-of-view (rFOV) and full FOV (fFOV) diffusion-weighted imaging (DWI) in the assessment of insuloma: image quality and WHO grading

M. He, H. Xue, Z. Jin; Beijing/CN (377174431@qq.com)

Purpose: To prospectively compare the imaging quality (IQ) of reduced field-of-view (rFOV) and full FOV (fFOV) DWI in detecting the insuloma and correlate the ADC value with WHO classification.

Methods and Materials: 48 patients suspected insulomas underwent pancreas MRI with two DWI sequences. Two radiologists independently assessed the IQ with 4-point scale. The SNR and CNR were evaluated. The Wilcoxon signed rank test was used to compare IQ scores, CNR and SNR. The ADC value of the tumour and the parenchyma were compared by paired-t test between the two sequences. The association between ADC value and WHO classification was assessed by the Spearman correlation analysis. The inter-observer agreement was evaluated by linearly weighted kappa coefficients for IQ and ICC for ADC values.

Results: Thirty-six patients with 36 tumours and 21 histological results (G1: $n=11$, G2: $n=10$) were enrolled. The IQ score (3.64 ± 0.487 vs. 3.310 ± 0.577), SNR (22.520 ± 8.690 vs. 10.284 ± 3.321) and CNR (3.454 ± 2.642 vs. 1.327 ± 2.801) were significantly higher in rFOV DWI than in fFOV DWI (all $P < 0.05$). There is no significant difference in the ADC values with rFOV and fFOV DWI of the tumour (1.106 ± 0.181 vs. $1.100 \pm 0.171 \times 10^{-3}$ mm²/s) and the parenchyma (1.320 ± 0.205 vs. $1.371 \pm 0.223 \times 10^{-3}$ mm²/s). There is no correlation between the WHO grading and the ADC values of rFOV ($r = 0.024$) or fFOV ($r = 0.142$). Inter-observer agreement was good to excellent for IQ (rFOV: 0.733-0.882, fFOV: 0.611-0.889) and ADC values (rFOV: 0.757-0.915, fFOV: 0.709-0.790).

Conclusion: Compared with fFOV DWI, rFOV DWI provides significant better IQ in detecting insuloma. No correlation between ADC value and WHO grading was found in this study.

How preoperative sentinel lymph node contrast-enhanced ultrasound helps intraoperative sentinel lymph node biopsy in breast cancer: initial experience

M. Lu; Chengdu/CN (graceof@163.com)

Purpose: To evaluate the value of sentinel lymph node contrast-enhanced ultrasound (SLN-CEUS) and surface tracing for the biopsy of intraoperative sentinel lymph nodes (SLN).

Methods and Materials: Between June 2015 and December 2017, 473 patients with early invasive breast cancer were recruited. Patients received an intradermal injection of microbubble contrast agent around areola the day before surgery. The locations and sizes of lymphatic channels (LCs) and SLNs were marked on the body surface using gentian violet. Then injection of double blue dye was performed half an hour before the operation. We compared the pathway of LCs and the location of SLNs obtained from SLN-CEUS and blue dye during an operation.

Results: Among the 473 patients, the mean number of LCs and SLNs detected by SLN-CEUS was 1.42 and 1.72, respectively, and the coincidence rate was 98.1% compared to blue dye during operation. The medium distance of SLN to skin measured by preoperative CEUS and blue dye was 1.95 ± 0.69 cm and 2.03 ± 0.87 cm, $P = 0.35$. There were three enhancement patterns of SLN, including homogeneous enhancement, inhomogeneous enhancement, and no enhancement in our research, with the sensitivity, specificity, negative predictive value, and positive predictive value of SLN-CEUS for the diagnosis of SLN being 96.75%, 91.80%, 88.17% and 97.82%, respectively.

Conclusion: SLN-CEUS with skin marking can identify the pathway of LCs and the location of SLN, measure the distance of SLN to skin, and determine if SLN is metastatic. SLN-CEUS can be used as an effective complement of the blue dye method.

B-0460 08:34

Contrast-enhanced spectral mammography: is it useful in predicting invasiveness in suspicious breast micro-calcifications?

M. Gomaa, A.F.I. Moustafa; Cairo/EG (mohammedgomaa555@yahoo.com)

Purpose: To assess the ability of contrast-enhanced spectral mammography for the prediction of invasiveness of suspicious malignant micro-calcifications.

Methods and Materials: 150 cases were enrolled for analysis including suspicious malignant microcalcifications on mammogram with no related mass and with pathological proof. The microcalcification morphology and associated enhancement were reviewed according to BIRADS lexicon with results of pathology reviewed and classified into benign, atypical and malignant with evaluation of invasive components.

Results: Of the 250 with microcalcifications 130/250 cases with associated mass were excluded. 30/120 cases were benign and 90/120 cases malignant. 17/90 cases were diagnosed as invasive carcinomas and 63/90 DCIS. Out of the 63 patients with DCIS 15/63 cases were low grade, 7/63 cases intermediate grade and 51 cases were high grade (29 with micro-invasion). Pathological enhancement was associated with all 17 cases with invasive cancers, 50/51 cases of the high-grade DCIS and 4/7 of the intermediate invasive cases. No pathological enhancement was elicited with benign masses, all low-grade DCIS cases and 3/7 of the intermediate DCIS. Diagnostic performances of CEMM in prediction of high grade DCIS or invasive cancer were sensitivity 98.5%, specificity 81.8% and accuracy 87.5%. The diagnostic performances of CEMM in prediction of high grade in DCIS patients were sensitivity 98%, specificity 81.8% and accuracy 93.1%.

Conclusion: CEMM has a pivotal role in assessment of suspicious micro-calcifications as the presence of associated non-mass enhancement is an indicator of invasive malignancy or high-grade DCIS. Lack of enhancement is favourable to diagnose non-malignant lesion or non-invasive DCIS.

B-0461 08:38

Residual fibroglandular tissue (RGT) following unilateral and bilateral prophylactic mastectomies in BRCA 1/2 germline-mutation carriers

B. Krug, O. Grinstein, W. Malter, B. Hanstein, F. Siedek, R. Schmutzler, D. Maintz, K. Rhiem, M. Hellmich; Cologne/DE (Barbara.krug@uk-koeln.de)

Purpose: The oncologic risk resulting from residual fibroglandular tissue (RGT) has not been sufficiently investigated in women carrying pathogen BRCA 1/2-germline mutations. Therefore, the presence of RGT was retrospectively evaluated in a unicentre approach.

Methods and Materials: All women with PM between 2006 and 2016 and at least one postoperative breast MRI were extracted from the centre's register. 2 radiologists evaluated the index breast MRIs independently using a structured questionnaire. Different assessments were assessed in consensus. The volume of RGT was quantified electronically.

Results: 169 women (338 breasts) were eligible. 67 patients had bilateral PM (41.2%) and 102 had unilateral PM and contralateral curative mastectomy (58.2%). RGT was found in 128 mastectomies (37.9%). 68 of the 128 breasts with RGT (53.1%) were related to bilateral PM, 37 (28.9%) to unilateral PM and 23 (18.0%) to curative mastectomy ($p < 0.0001$). RGT was predominantly unifocal and retromamillary. The RGT volume was 6.7 ± 11.9 ml in bilateral PM, 2.5 ± 1.6 ml in unilateral PM and 3.2 ± 1.9 ml in curative mastectomies. There was a positive correlation between preoperative breast volume and RGT in 75 cases with preoperative MRI ($p < 0.001$) and a tendency towards a higher number of RGT in surgery units with < 20 PM compared to those with > 40 PM ($p = 0.033$). The thickness of residual subcutaneous fat tissue correlated with RGT in non-retroareolar areas. 2 patients developed breast cancer 2 and 5 years after PM.

Conclusion: The radicalness of mastectomy may be influenced by the surgeon's and the patient's expectations regarding the aesthetic appearance of the breasts after PM.

B-0462 08:42

Factors that influence performance of the contrast-enhanced ultrasound prediction model in 1023 breast lesions: a multi-center study
L. Tang¹, Y. Chen¹, Z. Du¹, Z. Zhong¹, Q. Chen², J. Luo², L. Yang³;
¹Fuzhou/CN, ²Sichuan/CN, ³Kunming/CN (cxxxmx@fjzlhospital.com)

Purpose: To investigate the influence of patient and lesion characteristics on the diagnostic performance of contrast-enhanced ultrasound (CEUS) model in breast lesions.

Methods and Materials: We conducted a multicenter study with eight participating medical centers in China, which compared 1,023 breast lesions that were categorized as breast imaging reporting and data system (BI-RADS) 4 or 5, to evaluate a newly established CEUS-based diagnostic model, and to compare its results with patients' pathological outcomes. Univariate and multivariate logistic regression analyses were conducted to determine the influence of clinicopathological characteristics on the performance of CEUS model.

Results: Overall diagnostic results for CEUS model in diagnosis of breast lesions were sensitivity: 89.4%, specificity: 65.3%, positive predictive power: 66.4%, and negative predictive power: 88.9%. Logistic regression analysis showed that patients' age (odds ratio [OR]: 0.673; $P=0.033$), lesion maximum diameter (LMD; OR: 0.983; $P=0.038$), and distance from the lesion's deep edge to the pectoralis muscle (DtPM; OR: 1.093; $P<0.001$) were independent influencing factors. The model's diagnostic accuracy was greater for patients older than 35 years than younger patients ($P=0.005$), for LMD > 20 mm than LMD < 10 mm (OR: 1.61), and for DtPM < 3.05 mm than DtPM > 3.05 mm (OR: 1.81).

Conclusion: The application of CEUS model for breast lesions is promising. However, its diagnostic performance is influenced by patients' age; LMD and DtPM. Consideration of influencing factors is required to optimize clinical use of the CEUS model.

B-0463 08:46

Effect of breast-conserving surgery with radiotherapy on the apparent diffusion coefficient of fibroglandular tissue at MRI
N. Radovic, G. Ivanac, I. Biondic Spoljar, E. Divjak, I. Dumic Cule, B. Brkljacic;
Zagreb/HR (niko.radovic@gmail.com)

Purpose: To determine whether breast-conserving surgery (BCS) with radiotherapy (RT) is associated with different apparent diffusion coefficient (ADC) values of fibroglandular tissue (FGT) when comparing the treated breast to the contralateral side on MRI.

Methods and Materials: This retrospective study included 108 women who underwent clinical MRI exams following unilateral BCS with RT. Diffusion-weighted imaging was performed at 1.5T using $b = 0, 400, \text{ and } 800 \text{ s/mm}^2$. ADC of FGT was calculated separately for each breast using manually drawn regions of interest which excluded areas containing any lesions. Fat-suppressed T2-weighted images were evaluated in order to investigate the presence of diffuse treatment-related breast oedema. Association of previous treatment with FGT ADC and association of treated-to-untreated ADC ratio with treatment-related oedema were assessed using two-tailed t-tests. Relationship between treated-to-untreated ADC ratio and time elapsed since completion of RT was assessed by calculating Pearson's correlation coefficient.

Results: Mean ADC value of FGT was higher on the treated side ($1.995 \pm 0.351 \text{ mm}^2/\text{s}$) compared to the contralateral breast ($1.709 \pm 0.309 \text{ mm}^2/\text{s}$) ($p < 0.001$). Treated-to-untreated ADC ratio was higher in patients showing diffuse post-treatment oedema (1.311 ± 0.213) than in cases where it was absent (1.117 ± 0.184) ($p < 0.001$). There was a moderately negative correlation between treated-to-untreated ADC ratio and time passed since completion of RT ($R = -0.442, p < 0.001$).

Conclusion: Follow-up of BCS with RT is associated with increased ADC values of FGT, which could result in a greater contrast between normal breast parenchyma and recurrent cancer on quantitative diffusion-weighted MRI.

B-0464 08:50

Relevance of arbitration in the management of discrepant screening mammography: Trieste's Breast Unit experience in 2013-2014 biennium
C. Sachs, F. Giudici, M. Bortul, F. Zanconati, C. Gasparini, M. Assante, M. Tonutti, M.A. Cova; Trieste/IT (cami_sachs@hotmail.it)

Purpose: The introduction of digital mammography caused an increased rate of second level recalls. Even with the use of digital mammography (since November 2012) Trieste Breast Unit Recall Rate (RR) is one of the lowest in Italy. For this reason the role of the third reader in reducing recalls has been analyzed.

Methods and Materials: Mammography of all women adhering to screening between 2013 and 2014 biennium was included. Definition of discrepant and concordant reading number and arbitration outcome were obtained by using MR_mammo_report software. The discrepant cases were read by an "expert" third reader. Arbitrate impact, particularly recalls rate reduction and detection rate (DR) modification, was valuated.

Results: 95% of 21006 double readings were concordant (310 positive - 19740 negative). 956 readings (5%) were discordant. Arbitrate evaluation of discordant cases classified 536 negative mammograms (55%) and 420 positive (45%). Decreased recall rate was proved using a third reader (6.03% without arbitrate to 3.49% with arbitrate, $p<0.001$). Diagnosed carcinomas were 148 (DR =7%), of these 106 (72%) from concordant readings, 40 (27%) for positive arbitrate and 2 (1%) after negative arbitrate (interval cancers). Discordant readings showed a lower positive predictive value (PPV) compared to concordant ones (4.4% vs 34.2%, $p<0.001$).

Conclusion: Contribution by an "expert" third reader to keep RR into the European standards has been fundamental in our experience. Future purpose: to evaluate arbitrate cost savings, including women's behaviour for a spared useless recall.

B-0465 08:54

Technique and diagnostic performance of contrast-enhanced spectral mammography: a systematic review
A. Cozzi¹, M. Zanardo¹, C.B. Monti¹, L.A. Carbonaro², R.M. Trimboli², F. Sardaneli¹; ¹Milan/IT, ²San Donato Milanese/IT (andrea.cozzi@gmail.com)

Purpose: To perform a systematic review on technique and diagnostic performance of contrast-enhanced spectral mammography (CESM).

Methods and Materials: A literature search was performed using MEDLINE/EMBASE for studies investigating CESM. For each included article, we extracted: study design; contrast agent (CA) type, concentration, dose and flow rate; use and dose of a saline flush; total examination time (TET), first acquisition delay (FAD); order of views; sensitivity and specificity.

Results: Of 184 initially retrieved articles, 60 were included, totaling 8,225 examinations. Design was prospective in 31/60 studies (52%). Fifty-two studies reported CA type and concentration, iohexol 350 mg/mL being the most used (16/52 studies, 31%). CA dose and flow rate were reported in 53/60 (88%) studies, with 1.5 ml/kg at a 3 ml/s flow rate in 38/53 studies (72%). Saline flush was used in 20/60 (33%); only 11/20 (55%) reported the dose (10-30 mL). A TET <10 minutes was reported in 39/40 studies (98%), 120 seconds FAD in 44/54 (81%). Order of views was reported in 29/60 (48%) studies; mediolateral-oblique view of the affected breast was firstly acquired in 9/29 (43%). Sensitivity was $\geq 90\%$ in 31/38 (82%) studies while a specificity $\geq 70\%$ was provided in 19/31 (61%).

Conclusion: As it was for breast MRI, CESM has high sensitivity and acceptable (but more variable) specificity. An agreement was found for some technical parameters but no dose finding study has been performed. Protocol standardization should be pursued to build a more robust evidence for this new contrast-enhanced breast imaging modality.

Development and validation of nomograms predictive of axillary nodal status to guide surgical decision-making in early-stage breast cancer
J. Li, W. Ma, Y. Wu, L. Li; Guangzhou/CN (lijiao@susucc.org.cn)

Purpose: To develop and validate nomogram models using preoperative noninvasive imaging parameters with clinical-related variables to predict the extent of axillary nodal involvement for stratifying treatment options.

Methods and Materials: From May 2007 to December 2017, 397 patients who underwent preoperative routine and dynamic contrast-enhanced MRI for clinical T1-2/N0 breast cancer with clinically negative axilla were enrolled. Patients with data on AUS were included in the study. MR imaging descriptors were retrospectively collected according to BI-RADS (5th edition). Based on logistic regression analyses, nomograms summarizing the strength of the associations between the predictors and each nodal status endpoint were developed. Predictive performance was assessed using the area under the receiver operating characteristic curve (AUC). Bootstrap resampling was performed for internal validation.

Results: Age, MRI descriptors (mass margin, lymph node margin, hilum and symmetry), AUS descriptors (cortical thickening and hilum), vascular invasion and HER2 were identified as predictors of any nodal disease. Nomograms that included age and imaging parameters showed good calibration and discrimination; AUC of was 0.809 (0.756, 0.863) for negative axilla (N0) versus any lymph node metastasis, 0.749 (0.675, 0.823) for one or two positive nodes versus N0, and 0.874 (0.819, 0.929) for at least three positive nodes versus two or fewer metastatic nodes. Additionally, the predictive ability of the three nomograms which added vascular invasion and HER2 was significantly elevated.

Conclusion: The preoperative nomograms facilitate patients to choose no axillary staging, sentinel lymph node biopsy or completion axillary lymph node dissection according to the burden of axillary nodal metastasis.

B-0467 09:02

Ultrasound-guided vacuum-assisted resection: could it be enough for the diagnosis and treatment of intraductal papilloma?

Z. Wang; Beijing/CN (wzllg@sina.com)

Purpose: To evaluate whether ultrasound-guided vacuum-assisted excisional biopsy (VAB) could be enough for the diagnosis and treatment of intraductal papilloma, and to evaluate the lesion characteristics and histologic features affecting the complete resection rate.

Methods and Materials: Between March 2008 and October 2016, 2816 patients underwent US-guided VAB. 101 (3.6%) were diagnosed with intraductal papilloma pathologically. The accurate rate and the complete resection rate of intraductal papilloma were evaluated by surgical biopsy or follow-up US. The follow-up period ranged between 14 months and 72 months; meanwhile, lesion characteristics were analysed.

Results: 83 (82.2%) were benign papilloma and the recurrence was observed in 8 cases. 2 were intraductal papilloma accompanied by invasive carcinoma. 16 (15.8%) were with signs of atypical hyperplasia by VAB. In them, one intraductal papilloma accompanied by severe atypical hyperplasia underwent surgery, and was diagnosed as invasive carcinoma. 4 cases accompanied by atypical hyperplasia demonstrated atypical intraductal hyperplasia by surgery. 3 cases demonstrated no atypical lesions by surgical pathology. The accurate rate of VAB was 99.0% (100/101). The complete excision rate of intraductal papillomas by VAB was 87.1% (88/101). Intraductal papilloma with largest diameter < 1 cm, with clear margin, without branch involvement or calcification had a significantly higher complete excision rate.

Conclusion: VAB is an effective method for the diagnosis of intraductal papilloma. If benign character was demonstrated pathologically, surgery may be avoided but regular follow-up is recommended. If histopathological examination confirms a papilloma with moderate to severe atypical hyperplasia, it was strongly recommended for surgical excision.

B-0468 09:06

Diffusion kurtosis imaging (DKI) in breast cancer: diagnostic accuracy of DKI-derived values in characterization of breast lesions and correlation with prognostic factors

H. Ahmad Aiuuddin, S.K. Kirat Singh, K. Rahmat, M. Ramli Hamid, F. Fadzli, H. Ahmad Aiuuddin; Kuala Lumpur/MY

Purpose: To evaluate the diagnostic performance of diffusion kurtosis imaging (DKI) in the characterization of breast lesions and study the correlation with cancer histological grade.

Methods and Materials: A total of 28 women with histologically proven 21 malignant and 28 benign lesions had undergone MRI with DKI/ DWI between September 2017 and October 2018. The imaging findings, DKI (at b : 0-2800) and quantitative DWI/ADC (b: 800)-derived parameters were analysed using Pearson and ANOVA tests.

Results: The mean kurtosis (MK) demonstrated significantly higher values in malignancy (0.86 ± 0.18) compared to benign lesions (0.63 ± 0.22) ($p < 0.001$). The ADC and mean diffusivity (MD) values were significantly lower for malignancy (ADC: $0.73(10^{-3} \text{ mm}^2/\text{s}) \pm 0.26$ and MD: $1.21(10^{-3} \text{ mm}^2/\text{s}) \pm 0.40$) compared to benign lesions (ADC: $1.43(10^{-3} \text{ mm}^2/\text{s}) \pm 0.31$ and MD: $1.70(10^{-3} \text{ mm}^2/\text{s}) \pm 0.39$) ($p < 0.001$). A cut-off MK/MD value of $0.74/1.39(10^{-3} \text{ mm}^2/\text{s})$ provided sensitivity of 81%/93% and specificity of 75%/81% with area under curve (AUC) of 0.82/0.83, respectively. ADC showed highest sensitivity/specificity (82%/100%) using a cut-off value of $1.12(10^{-3} \text{ mm}^2/\text{s})$ with AUC of 0.96. In lower tumour grades, MK (1.00 ± 0.22 , grade 1) was significantly higher and ADC ($0.46(10^{-3} \text{ mm}^2/\text{s}) \pm 0.29$) was significantly lower compared to higher grade (MK: 0.70 ± 0.14 , ADC: $0.88(10^{-3} \text{ mm}^2/\text{s}) \pm 0.26$, grade 3) ($p < 0.05$).

Conclusion: DKI provides additional functional information and is useful in the characterisation of breast lesions. The higher MK, lower diffusivity and lower ADC values showed strong correlation with malignancy.

B-0469 09:10

Can 18 F-FDG PET/CT predict invasive components in DCIS of breast diagnosed by needle biopsy? Comparison with variable imaging modalities including mammography, USG and MRI

N. Choi¹, Y. Kim¹, N. Jung¹, B. Kang², J. Lee²; ¹Bucheon/KR, ²Seoul/KR (yossi6876@gmail.com)

Purpose: The purpose of this study was to determine whether the 18F-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) predicts the underestimation of invasive cancer in patients with biopsy-proven DCIS.

Methods and Materials: This study retrospectively reviewed 167 cases in 162 patients with biopsy-proven DCIS who underwent preoperative 18F-FDG-PET/CT between April 2008 and September 2015. The clinicopathological and imaging findings were compared between subgroups divided by the presence of invasion and maximum standardized uptake value (SUVmax), respectively. The correlation of tumour characteristics with underestimation of invasive

component was performed. The receiver operating characteristics (ROC) analyses were performed for each imaging modality to predict the invasion.

Results: Final pathology was confirmed as pure DCIS in 120 and DCIS with invasion in 47 cases. The age, SUVmax, semiquantitative and visual analyses at 18F-FDG-PET/CT and pathologic tumour size were significantly different between DCIS with invasion group and pure DCIS group. High SUVmax was significantly associated with age, the primary tumour size on MRI, visual detection of primary tumour and axillary lymph node on 18F-FDG-PET/CT, the presence of invasion and pathologic tumour size. The underestimation of invasive cancer was significantly correlated with age ($p = 0.0138$), semiquantitative and visual analyses on 18F-FDG-PET/CT ($p = 0.0001$ and $p = 0.0028$) and tumour size ($p = 0.0026$). The area under the curve (AUC) on ROC analysis was 0.541 for mammography, 0.550 for US, 0.500 for MRI, 0.670 for semiquantitative analysis and 0.620 for visual analysis on 18F-FDG-PET/CT.

Conclusion: The 18F-FDG-PET/CT can be a useful imaging tool to predict the upgrade of DCIS to invasive cancer.

B-0470 09:14

Reliability of contrast-enhanced spectral mammography (CESM) in the pre-surgical evaluation of breast cancer: CESM vs histological maximum diameter

P. Tonelli, C. Boeri, D. Cirone, S. Bianchi, V. Miele, J. Nori Cucchiari; Florence/IT (paolina.tonelli@gmail.com)

Purpose: The first aim is to assess the reliability of CESM in pre-surgical measurement of breast cancer (BC), compared to the histological size on the surgical piece. The secondary aim was to analyse what factors influence the gap, between CESM and histological measurements.

Methods and Materials: We retrospectively evaluated 167 women with histologically proven (in situ or invasive) BC who underwent pre-operative CESM, from from 1.1.2016 to 31.1.2017. Pearson's correlation coefficient was calculated between CESM size and histological size. Further analyses to evaluate factors influencing the discrepancy between the CESM measurement and histological measurement were conducted.

Results: CESM measurements showed a strong, consistent correlation with the histological findings (correlation coefficient = 0.852). A slight CESM size overestimation was detected. A gap of 10 mm between CESM diameter and histological diameter was assumed as a critical cut-off. A prevalence of invasive ductal carcinoma associated with an in situ ductal carcinoma was found in cases with difference between CESM size and histological size out of the cut-off. This type of cancer has a mass+non-mass enhancement.

Conclusion: These results encourage the use of CESM in pre-surgical staging of BC. The ability to measure non-mass enhancement extension affects the greater discrepancy between the two measurements.

B-0471 09:18

Impact of 18F-FDG-PET/CT using time-of-flight in evaluating axillary lymph node metastases of breast cancer

M. Mori, T. Fujioka, J. Tsuchiya, K. Kubota, U. Tateishi; Bunkyo-City Tokyo/JP (m_mori_116@yahoo.co.jp)

Purpose: To evaluate the performance of preoperative N-staging assessment in breast cancer by 18F-FDG-PET/CT using three-dimensional time-of-flight (3D-TOF).

Methods and Materials: Sixty-three women with breast cancer (mean age 60 years; range 30-84 years) underwent PET/CT scan with 3D-TOF reconstruction system (Celesteion, Canon Medical Systems). For axillary lymph nodes, visual assessment, short axis diameter, and the maximum standardized uptake value (SUVmax) were compared with pathological diagnosis.

Results: There were 61 patients with invasive breast carcinoma (mean invasive diameter 18.9 mm; range 2-90 mm) and 2 patients with non-invasive carcinoma. Axillary lymph node metastases were histologically confirmed in 10 of 63 patients (16%). By visual assessment, there were 8 true positives, 10 false positives, 43 true negatives, and 2 false negatives, respectively. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy were 80%, 77%, 40%, 95%, and 78%, respectively. Histological lymph node metastases were significantly associated with short axis diameter of the lymph node (7.2 vs. 6.1 mm, $p = 0.03$) and SUVmax of the lymph node (1.60 vs. 0.64, $p = 0.02$). The area under ROC curve of SUVmax was larger than that of the short axis diameter, but there was no significant difference (0.885 vs. 0.742, $p = 0.0829$).

Conclusion: Both visual assessment and SUVmax measurement showed good results in axillary lymph node evaluation. 18F-FDG-PET/CT using 3D-TOF achieved high accuracy in N-staging of breast cancer.

B-0472 09:22

The development of a novel manganese dioxide-based nanoparticles and real-time monitoring of its anticancer effect by MRI

X. Zhou, B. Xiao, H. Hu, J. Tang; Zhejiang/CN (misaki20@163.com)

Purpose: Facile synthesis a manganese dioxide (MnO₂)-based MRI contrast agent and in vivo evaluation of its photothermal breast cancer therapy.

Methods and Materials: Bovine serum albumin (BSA)-MnO₂-melanin-like-polymer nanoparticle (BMD NP) was obtained via KMnO₄-initiated in situ dopamine-polymerization-induced self-assembly in the presence of BSA, and its size and r₁ relaxivity were carefully measured. Mice were injected with 4T1 breast cancer cells for MR imaging. Images were acquired before injection and at 30, 60, 90, and 120 min post-injection and then signal-to-noise ratio (SNR_{post}/SNR_{pre}) at the tumour ring was quantitatively calculated. Mice bearing same tumours were randomized into the following four groups: BMD NP with/without photothermal therapy; PBS with/without photothermal therapy as control groups. The tumour sizes were measured and calculated every other day.

Results: BMD NP had a diameter of 60 nm and a high r₁ relaxivity of 38.14 mM⁻¹ s⁻¹, which was incredibly 9 times higher than those of clinically used contrast agent (Gd-DTPA). In vivo, an obvious SNR_{post}/SNR_{pre} at the tumour margin showed 1.54 times that of contralateral tissue at 30 min post-injection, which provided detailed imaging features for precise diagnosis differentiation. The group treated with both nanoparticle and irradiation showed complete ablation without recurrence in 20 days, and the tumour-free period up to 60 days, exhibiting excellent therapeutic efficacy in comparison with the other three groups.

Conclusion: The BMD NP having excellent MRI contrasting capability and PTT efficacy plus its facile synthesis was a very promising theranostic agent for MRI-mediated photothermal anti-cancer therapy.

B-0473 09:26

Survey: imaging surveillance among Belgian breast clinics for primary locoregional breast cancer in non-high-risk women

J. Swinnen, M. Keupers, R.M. Prevos, S. Postema, M. Lavens, T. Thywissen, P. De Beul, J. Soens, C. Van Ongeval; Leuven/BE (jeroen.swinnen@gmail.com)

Purpose: To assess imaging surveillance among Belgian breast cancer (BC) centres for primary locoregional breast cancer in non-high-risk women, compared to the international practice guidelines.

Methods and Materials: An anonymous e-mail checkbox survey was sent to the coordinating radiologists and clinicians of all Belgian BC centres, 01/2017-06/2017. All departments received telephone follow-up. For different treatment subgroups, respondents were asked their preferred imaging modalities, onset, frequency, intermediate frequency alteration and termination of imaging surveillance.

Results: Survey was completed by 55/98 (56%) radiologists and clinicians from 37/49 centres (76%). After radiation therapy, 17 (31%) respondents commenced imaging follow-up after a 6-month and 18 (33%) after a 12-month imaging delay. If no adjuvant radiation therapy, 48 (87%) respondents started imaging follow-up 12 months after diagnosis. After sentinel breast-conserving surgery, 55 (100%) and 51 (93%) respondents performed annual radiographic and ultrasound screening, respectively, with 21 (38%) routinely implementing tomosynthesis. Imaging of the reconstructed ipsilateral mastectomy site was performed by 12 (22%) respondents. Annual MRI surveillance was not recommended by 52 (95%) respondents. For BIRADS density C/D breasts, 15 (27%) respondents performed annual MRI. Intermediate alteration of annual imaging frequency was recommended by 17 (31%), with 13 (76%) respondents recommending consecutive biannual imaging. Imaging was not adjusted according to tumour subtype by 47 (85%) respondents.

Conclusion: Most Belgian BC centres perform routine ultrasound screening, although controversial among international guidelines. Use of MRI is limited to specific indications, according to the guidelines. Breast tomosynthesis is emerging as a routine surveillance tool despite performance remaining unclear.

B-0474 09:30

Combining ultrafast TWIST VIBE Dixon sequences with diffusion-weighted imaging: a clinically applicable evaluation tool with high accuracy for suspicious masses in breast MRI

S. Ellmann, E. Wenkel, S. Peter, M. Dietzel, E. Weiland, R. Janka, T. Bäuerle, M. Uder; Erlangen/DE (stephan.ellmann@uk-erlangen.de)

Purpose: To develop an evaluation tool for classification of suspicious masses in breast MRI when using TWIST VIBE Dixon (TVD) dynamic sequences combined with diffusion-weighted imaging (DWI), and compare it to a tool based on conventional dynamic contrast enhancement (DCE) and DWI. As ultrafast TVD sequences offer the potential to shorten breast MRI protocols, diagnostic accuracy might be hampered. A special focus was thus to maintain high diagnostic accuracy in lesion classification.

Methods and Materials: 65 patients received breast MRI between 02/2014 and 04/2015, with 83 reported lesions (60 malignant, 23 benign). Inclusion criteria were suspicion of breast cancer or pre-therapeutic staging. Patients with non-mass-enhancements only were excluded. The protocol consisted of our institute's standard protocol complemented by ultrafast prototype TVD sequences. The apparent diffusion coefficient (ADC) and the peak enhancement of the TVD sequences were used to calculate a generalised linear model (GLM) for malignancy prediction. A second model was calculated using ADC and DCE curve types. Generalisability was ensured by applying leave-one-out cross validations. For easy application of the GLMs, nomograms were created.

Results: The GLM based on ultrafast TVD sequences and ADC performed comparably accurate to the model based on conventional DCE and ADC (sensitivity 93.3% vs. 93.3%, specificity 91.3% vs. 87.0%, PPV 96.6% vs. 94.9%, NPV 84.0% vs. 83.3%; no significant differences).

Conclusion: This study presents a method to reduce breast MRI examination time while maintaining diagnostic accuracy with ultrafast TVD sequences. The presented GLMs can easily be applied in clinical routine using the supplied nomograms.

Accuracy comparison of breast cancer detection based on microcalcifications between full-field digital mammograms and synthetic 2D mammograms using a deep convolution neural network

M. Gurumoorthy¹, S. Kaur¹, N. Kwan Hoong², S. Soo¹, K. Rahmat¹, C. Hongmin³; ¹Kuala Lumpur/MY, ²Petaling Jaya/MY, ³Guangzhou/CN (mahen123owen@hotmail.com)

Purpose: To retrospectively compare the accuracy of breast cancer detection based on the analysis of microcalcifications between full-field digital mammograms (FFDM) and synthetic 2D mammograms (C-View) using a deep convolution neural network (DCNN) computer model.

Methods and Materials: With institutional ethics committee approval, we retrospectively collected FFDM and digital breast tomosynthesis (DBT) cases using Hologic DBT system. The results of 67 consecutive breast biopsies performed for suspicious microcalcifications via stereotactic-guided core biopsy or surgical excision in 2016 were analysed (22 malignant, 45 benign). Image datasets which consisted of craniocaudal and mediolateral (MLO) views (FFDM and C-view) were analysed in a blinded manner using DCNN and provided a probability of malignancy. The DCNN uses probabilistic relationships between breast disease and mammography findings to predict malignancy. The accuracy of DCNN in FFDM images and DCNN in C-view images are compared.

Results: DCNN use in FFDM achieved an accuracy of 56.9%, which was very similar to the accuracy of DCNN in C-view which was 56.34%, in predicting breast cancer malignancy.

Conclusion: The analysis indicated that the detection accuracy based on microcalcifications between FFDM and synthetic 2D mammogram was comparable. The utilisation of C-view in this clinical setting hence can be considered.

B-0477 09:42

Initial experience of an online mammographic screening test

M. Iodice¹, B. Brancato², L.A. Carbonaro¹, A. Bert³, C. Perassi³, C. Zuiani⁴, F. Sardanelli¹; ¹Milan/IT, ²Florence/IT, ³Turin/IT, ⁴Udine/IT (maidice@gmail.com)

Purpose: To evaluate the performance of breast radiologists in an online mammographic screening test and their acceptance of it.

Methods and Materials: A mammographic test was composed by 132 screening mammograms with about 1/3 positive cases. Thresholds were set at 62% of sensitivity and 86% of specificity, resulting from 3/4 of 17 expert radiologists exceeding. Test was passed when both thresholds were achieved. The test was free and disposable online for all radiologists members of Italian College of Breast Radiologists (ICBR) by SIRM; no dedicated workstations but average personal computers were required.

Results: Five months after the test was published, 488 radiologists signed up for it (27% of ICBR members), 194 (41%) completed it and 88 (45%) passed. Overall 44/194 radiologists (23%) passed the test at the first time: 67/194 radiologists (35%) repeated the test at least once, and 44/67 (66%) of them passed it. Median sensibility resulted 62% and median specificity 86%. Radiologists who passed the tests read a higher number of mammograms per year (median mammograms per year 2528 vs 1090, P<0.001), and more likely work in organised screening programs (40.3% vs 21.0% radiologists who do not work in organised screening programs, P<0.001).

Conclusion: With the exception of few local courses with an included final test, no mammographic screening test has been available for Italian radiologists to challenge themselves so far. The SIRM mammographic online test was well accepted by radiologists and the initial results showed a balanced rate of tests passed.

Imaging characterisation of breast desmoid tumours

M. Le Boulch¹, A. Lusque¹, C.S. Balleyguier², C. Dratwa³, P. Chereh⁴, M. Kind⁵, C. Vaysse¹, S. Le Guellec¹, B. Boulet¹; ¹Toulouse/FR, ²Villejuif/FR, ³Paris/FR, ⁴Saint Cloud/FR, ⁵Bordeaux/FR (morwenn.le.boulch@gmail.com)

Purpose: Breast desmoid tumours (BDT) are very rare myofibroblastic tumours, locally aggressive without metastatic potential, with high rate of recurrence. The diagnosis, based on core needle biopsy (CNB), could be very difficult, especially for sporadic tumours without CTNNB1 mutation. Their radiologic patterns have not been studied much and are closed from breast cancer radiologic patterns even though treatments differed. For BDT, watch and wait is the front line approach.

Methods and Materials: 34 patients with 36 pathologically confirmed BDT were included in this national French multicentric retrospective study. Radiological examinations were reviewed by an expert.

Results: Median presentation age was 46 years, mostly women (91.2%), and 25.7% had prior history of breast surgery or biopsy. Mammography visualised the tumour in 14/14, tomosynthesis 1/1, ultrasound in 26/27, magnetic resonance imaging (MRI) in 26/26 BDT in whom it has been performed. In mammography, BDT were spiculated masses or architectural distortions. Ultrasonography interest was to permit CNB needed. MRI helped for diagnosis and preoperative staging. In MRI, BDT were masses, spiculated (92.3%), with spicules touching skin and/or major pectoralis muscle (87.5%), with a fascial tail sign (26.9%). They had early enhancement, persistent on later slides. Sporadic BDT without CTNNB1 mutation had demographic, mammographic and MRI-specific patterns.

Conclusion: It is the biggest BDT study ever published. Spiculated breast mass could be BDT, moreover, if some spicules touch skin and/or major pectoralis muscle, or if it owns a fascia tail sign. Persistent enhancement on MRI later slides permit to distinguish BDT from breast cancer.

Application of low-radiation and low-contrast dose protocol combined with high-strength ASIR-V algorithm in 'one-stop' coronary and carotid and cerebrovascular CT angiography

W. Li, Y. Zhigang, P. Han, Z. Li; Chengdu/CN (452766554@QQ.com)

Purpose: To investigate the value of low-radiation dose and low-contrast agent dose (double-low) protocol combined with high-strength adaptive statistical iterative reconstruction (ASIR-V) algorithm in the 'one-stop' coronary and carotid and cerebrovascular CT angiography.

Methods and Materials: 80 patients with suspected cardiovascular and cerebrovascular disease were randomly divided into two groups. In both groups, coronary CT angiography (CCTA) scan was immediately followed by carotid and cerebrovascular CT angiography (CCCTA). Group A (n=42) used double-low protocol: CCTA: 80 kV, 550 mA, 80% ASIR-V; CCCTA: 80 kV, 500 mA, 70% ASIR-V, with a 0.6 ml/kg contrast dose. Group B (n=38) used routine-dose protocol: CCTA: 100kV, 500 mA, 50% ASIR-V; CCCTA: 100 kV, 450 mA, 50% ASIR-V, with a 0.8 ml/kg contrast dose. The subjective image quality was assessed using a 4-point system (4=best). Contrast-noise-ratio (CNR) for vessels was calculated to evaluate the objective image quality of CTA. The dose length product of both groups was recorded and the effective dose was calculated.

Results: There was no significant difference in the objective and subjective (A vs. B: 3.50±0.68 vs. 3.60±0.73, P=0.54) image quality for these images between the two groups. The group A had 25% less contrast dose (42±6.69 ml vs. 56±7.56 ml) and 70% less overall radiation dose (1.03±0.28 mSv vs 3.38±0.80 mSv) than group B (both P < 0.001).

Conclusion: The 'one-stop' cardiovascular and cerebrovascular CTA using double-low technique combined with higher strength ASIR-V algorithm can effectively reduce the radiation and contrast dose without loss of image quality compared with the routine-dose CTA protocol.

B-0480 10:38

Assessment of coronary in-stent stenosis using high-resolution scan mode and dual-energy CT: a phantom study

M. Svanteson, A. Afadzi, A.C. Martinsen, N.E. Kløw, E.K. Lysvik, K. Bjørklund, T.R. Ender; Oslo/NO (monasvanteson@gmail.com)

Purpose: To assess image quality of an in-stent stenosis model comparing single energy with and without novel high-resolution (HiRes) scan mode and dual energy.

Methods and Materials: An in-stent stenosis model with a straw containing a 3.5-mm expanded coronary stent was placed within an anthropomorphic chest phantom. The stenosis was created with lip-balm (-120HU) imitating a soft plaque. The lumen was filled with contrast (300HU). Five scans were performed; 100 and 120 kV +/- HiRes, and dual energy reconstructed to monochromatic images at 50, 68, 74, 90, 100, and 130 keV. Reconstructions with standard and detail filters were performed for all scans plus high-definition (HD) filters for HiRes scans. Two radiologists blinded to scan parameters evaluated the reconstructions in a random order. Stent diameter, stenosis grading, and image quality on a 5-point scale (stent and plaque visualization) were assessed. Noise texture deviation (NTD) and noise power spectrum (NPS) were assessed using 5 images for all reconstructions.

Results: The mean overall image quality (stent+plaque score) for 100kV, 100 kV+HiRes, 120 kV, 120 kV+HiRes, and dual-energy scans were 5.50±0.7, 6.75±0.4, 6.25±1.1, 7.0±0.0 and 4.2±1.1, respectively. The mean underestimation of stent diameter with various filters was 27.6±0.1% for standard, 23.9±0.1% for detail, 17.5±0.0% for HD-standard, and 16.5±0.0% for HD detail. There was no difference in NTD between reconstructions (p=0.22). The HD detail filter had the highest NPS peak frequency, indicating finer image texture.

Conclusion: This phantom study indicated that high-resolution CT with HD-detail resulted in the best image quality for assessment of in-stent stenosis.

B-0481 10:46

Patient habitus and renal volume have no effect on a reduced patient-specific contrast media administration during renal CTA: impact on contrast media, radiation dose and image quality

C. Saade; Beirut/LB (charbel.saade@aub.edu.lb)

Purpose: To investigate the effect of patient kidney volume, patient habitus and contrast media volume (CMV) on renal artery and parenchymal opacification using a patient-specific contrast formula during renal CTA (rCTA).

Methods and Materials: IRB approval for this retrospective study was obtained. RCTA was performed on 101 patients with suspected renal disease. Patients were assigned to a patient-specific contrast formula protocol that is based on patient cardiovascular dynamics. Mean renal volume was quantified using computer-aided software. Multivariate analysis compared renal and contrast media volumes, and effective radiation dose. For each patient, the arteriovenous contrast ratio (AVCR), corticomedullary contrast ratio (CMCR) and contrast-to-noise ratio (CNR) were calculated employing a Student's t test. Regression analyses were performed between each of the CMV groups: 1: <37mL, 2: >37-<50mL and 3: >50mL. Receiver operating (ROC) and visual grading characteristics (VGC) measured the confidence intervals and image quality, respectively.

Results: There was no significant difference in patient demographics and radiation dose between each CMV group (p>0.05). Increased mean opacification of the renal arterial vasculature (≥232.34±56.19), parenchyma; anterior cortex (≥101.57±33.62) and medulla (≥49.60±19.30), and posterior cortex (≥98.67±33.98) and medulla (≥47.59±21.01) were above these thresholds (p>0.05). Mean AVCR and CMCR had no statistical significance (p>0.05) between each kidney with a strong correlation of opacification difference between the renal cortex and medulla in each kidney (r=0.993) and renal artery and vein (r=0.946). Both VGC and ROC demonstrated increased confidence in image quality (p<0.03) and pathology (p<0.0001) detection, respectively.

Conclusion: Patient habitus and kidney volume have no statistical significance in CMV reduction when employing a patient-specific contrast media formula during rCTA.

B-0482 10:54

The study of usefulness of blending injection method in dynamic liver CT scanning with reduced contrast medium

J. Kawashima, F. Washizuka, H. Nakano, Y. Shimada; Tokyo/JP (junji.kawashima@med.toho-u.ac.jp)

Purpose: Currently, there are concerns about contrast CT examinations leading to CIN in patients with CKD (chronic kidney disease). Patient with CKD are required to reduce the contrast medium. However, the injection time is fixed in dynamic CT scan. Therefore, reducing the amount of contrast medium causes a reduction in the injection pressure, which disrupts the bolus injection. In this study, we investigated effect of blending injection guaranteeing normal injection pressure.

Methods and Materials: The subject is a patient who did dynamic liver CT scan. The normal case is 600 [mgI/kg] but patient with CKD case is 480[mgI/kg]. Patients with CKD were randomly assigned to the following 2 groups: 1. single injection (injection of contrast medium only); 2. blending injection (blend of contrast medium and saline). From the obtained image, comparison was made with normal cases, single injection, blending injection. For the study items, the CT numbers of each scan phase were compared.

Results: The variability of the CT number decreased in each scan phase. The medium value of the liver in the portal phase was 103.0HU for single injection and 117.5HU for blending injection. Addition of the saline solution significantly increased the CT number. Blending injection resulted in an increase in volume, so injection pressure could be maintained and significantly increased CT number.

Conclusion: Blending injection significantly improved the contrast effect in dynamic liver CT scan.

B-0483 11:02

Post-mortem computed tomography angiography (PMCTA): optimising a targeted PMCTA protocol

C. [Robinson](#), A. Deshpande, G. Rutty, B. Morgan; *Leicester/UK*
(claire.robison@uhl-tr.nhs.uk)

Purpose: Post-mortem computed tomography angiography (PMCTA) is essential to diagnose coronary artery disease as a cause of death. A technique was developed using negative contrast (air) and positive contrast (PC) (clinical contrast) to delineate soft plaques and calcified stenosis. The behaviour of the contrasts, together with factors that may influence the efficacy of PMCTA, has been explored and an optimized protocol has been developed.

Methods and Materials: 200 cases were selected from our database of PMCT cases that had successful PMCTA. Each scan was evaluated to determine the order in which the contrast was administered, the degree of vessel filling (classified as 0%, 1-25%, 25-50%, 50-75% and 75-100%) and factors that may have affected the PMCTA.

Results: 8 cases with pathologically occluded vessels were excluded. 192 cases were included in the analysis (111 male, mean age 71.1 years (range 18-99)), 102 had the negative contrast first protocol. Using PC first achieves filling of the left anterior descending and circumflex arteries in all cases and only 2% of right coronary arteries failed to fill; a greater percentage of cases achieve more than 50% filling and more clots are removed from the aorta. Multiple injections of contrast achieve better filling of all vessels and increases confidence in diagnosing pathologies. Rolling the deceased into the right decubitus position prior to the third run removes all but 0.5% of persistent clots.

Conclusion: A targeted PMCTA protocol of PC first with rolling prior to the third injection achieves the optimal imaging and highest diagnostic potential of PMCTA.

B-0484 11:10

Effect of the scan mode and focal spot size on airway measurement for ultra-high-resolution computed tomography

R. [Mikayama](#), T. Shirasaka, H. Yabuuchi, Y. Sakai, T. Kojima, M. Kondo, H. Yoshikawa, T. Kato; *Fukuoka/JP* (mt_mika_jan_5@yahoo.co.jp)

Purpose: The large inaccuracies were confirmed for small airway measurements in conventional computed tomography (CT). Ultra-high-resolution CT (UHRCT) might improve airway measurements accuracy using precise scan modes with minimal focal spot. The purpose of our study was to assess the effects of the scan mode and focal spot size on airway measurements for UHRCT.

Methods and Materials: The COPDGene phantom II containing a plastic tube simulating airway inner diameter of 3 mm and wall thickness of 0.6 mm with rotation at 30 degrees was scanned with super-high-resolution (SHR, beam collimation of 0.25 mm x 160 rows) and high-resolution (HR, beam collimation of 0.5 mm x 80 rows) modes for UHRCT. Each examination was performed with small (0.4 x 0.5 mm) and large (0.6 x 1.3 mm) focal spots five times. The wall area percentage (WA%) was calculated as the percentage of total airway area occupied by airway wall. Statistical analysis was performed to compare the measurement errors for WA% among each scan mode and focal spot size using Tukey-Kramer method (p < .05).

Results: The measurement errors of WA% at SHR mode were 9.8 ± 1.5% with small focal spot and 18.8 ± 0.4% with large focal spot. The measurement errors of WA% at HR mode were 13.3 ± 0.6% with small focal spot and 21.4 ± 0.8% with large focal spot. There were significant differences in all pairings of the scan mode and focal spot size (p < .05).

Conclusion: SHR mode with small focal spot could improve airway measurement accuracy at UHRCT.

B-0485 11:18

Organ-based tube current modulation in chest CT: effect on radiation dose and noise

B.R. [Mussmann](#)¹, S. [Deppe](#)², P. [Marschall Skov](#)¹, S. [Foley](#)³, H. [Precht](#)⁴;
¹*Odense/DK*, ²*Kolding/DK*, ³*Dublin/IE*, ⁴*Middelfart/DK*
(peter.skov.madsen@gmail.com)

Purpose: Organ-based tube current modulation (OBTCTM) is designed for anterior dose reduction in CT. This study assessed the dose reduction capability of using organ dose modulation from two vendors at a range of kVp settings in chest CT. The secondary purpose was to assess noise between dose-modulation systems.

Methods and Materials: A Lungman phantom with thermo-luminescent dosimeters circumferentially attached around the phantom surface was scanned with and without OBTCTM at 80-135/140 kVp using a Toshiba Aquilion Prime and a GE Revolution CT scanner. Equivalent dose was measured. Noise was measured in ROIs in the vertebral body, pulmonary trunk and in free air anterior to the phantom at the level of the carina. Comparisons were performed using Wilcoxon's signed-rank test.

Results: Using GE, dose reductions between 1.1 mSv (12%) and 1.56 mSv (24%) (p<0.01) were found in the anterior segment and no differences were found posteriorly and laterally. Total dose reductions between 0.64 (8%) and 0.98 mSv (13%) were found across kVp levels (p<0.01). With Toshiba anterior dose reductions of 6 to 7% and total dose reduction of 0.34 to 0.76 mSv across kVp levels (p<0.02) were found. A dose difference of 60% between right and left lateral positions was found with and without OBTCTM (p<0.0001). Between OBTCTM and non-OBTCTM mean noise change across scanners and ROI positions was not clinically relevant, i.e. ranging from -0.6 to 1.5 HU.

Conclusion: Both OBTCTM systems are capable of anterior and total dose reduction with slightly altered noise at all kVp levels.

Computed tomography (CT) imaging in weight-bearing positions: the positives and challenges in an institutional trial

G. [Bengo](#); *Singapore/SG* (galileojbengo@yahoo.com)

Purpose: In orthopaedic practice, conventional (CT) studies are routinely performed for evaluation of lower limb injuries, bony deformity & evaluation of bony alignment for pre-operative planning. Cone-beam CT has allowed studies to be performed while patients weight-bear. The benefits and challenges of CBCT compared to conventional CT were reviewed in this study.

Methods and Materials: Weight-bearing lower extremity was performed with a CareStream OnSight 3D Extremity System in 6 months. The mean CTDIvol and mean DLP from every study was recorded for comparisons to similar studies performed at conventional CT for age and gender-matched patients. A post-procedure patient satisfaction survey and technologist was administered to evaluate patients' qualitative and quantitative experiences in CBCT unit. Feedback on image quality and diagnostic value was obtained.

Results: A total of 20 patients were scanned in a weight-bearing position in the CBCT unit. Compared to conventional CT, there was reduction of mean CTDIvol (P<0.05) and mean DLP (P<0.05). The patient survey showed positive overall experience of scan performed and levels of comfort. There was no compromise in image quality in all studies despite of significant reduced doses. Ability to perform weight-bearing studies allows accurate detection of injuries, with surgeons citing Lisfranc fracture-dislocation injuries.

Conclusion: The ability to perform weight-bearing studies at reduced doses without compromising image quality was the main advantage of CBCT. Other benefits includes patient comfort, a positive patient experience and enhanced workflow among technologist. Overall, there is potential for CBCT to serve as a lower dose and lower cost alternative to conventional CT in imaging.

B-0488 11:42

Evaluation of usefulness of virtual calcium scoring in dual-energy cardiac CT

H. [Han](#); *Seoul/KR* (gum790311@hanmail.net)

Purpose: This paper evaluates the reliability of virtual noncontrast (VNC) images and virtual mono-chromatic (VMC) images derived from dual-energy CT for coronary artery calcium scoring, in order to decrease patient exposure radiation dose and increase the efficiency of the procedure.

Methods and Materials: 60 patients, They were divided into two groups depending on whether calcium in the coronary artery visible in images viewed with the naked eye. Calcium scoring of Lesions, Voxel, Volume and Agatston Score was done on TNC, VNC and VMC images. An independent t-test of a parametric test was used for statistical analysis with SPSS.

Results: In the group showing no visible calcium in the coronary artery, there were significant differences between TNC and VNC images (p<0.001). On the other hand, there were no significant differences between TNC and VMC

images in Lesions ($p>0.605$), Voxel ($p>0.406$), Volume ($p>0.521$), and Agatston Score ($p>0.072$). In the group showing visible calcium in the coronary artery, there were no significant differences in Volume ($p>0.136$) and Agatston Score ($p>0.716$), but there were significant differences in Lesions ($p<0.001$) and Voxel (0.046). Significant differences between VNC and VMC images were found in all aspects.

Conclusion: The results of this study to evaluate TNC, VNC, and VMC in dual-energy CT for coronary artery calcium scoring were unexpected. However, if software that can distinguish calcium is developed in the future, it is expected that it will contribute to increase the efficiency of the procedure and reducing the exposure dose of the patient.

B-0489 11:50

Patient perceptions of radiographer communication skills in CT examinations

L. Ribeiro¹, A.F. Abrantes¹, K.B. Azevedo¹, O. Lesyuk², S.I. Rodrigues¹, R.P. Almeida¹, A.C. Viriato³, M.V. Reis¹; ¹Faro/PT, ²São Brás de Alportel/PT, ³Lagos/PT (oksanalesyuk@gmail.com)

Purpose: The improvement of results in healthcare through the transmission of information to the patient within a relation of empathy and trust is already a verified hypothesis. Healthcare professionals should base themselves on interpersonal competence throughout their daily work routine, to promote quality in medical imaging, patient safety and technical excellence. The aim of this study was the exploration of patient's perceptions regarding the performance of radiographer in terms of interpersonal communication skills during CT procedures.

Methods and Materials: The instrument used was the questionnaire "Communication Assessment Tool" (Makoul et al. 2007) adapted to the professional reality of the radiographers. A total of 98 valid questionnaires (including 15 questions with a five-point Likert scale) from patients aged between 18 to 85 years old. The paper-based instrument was delivered and filled by the patients after the performance of CT procedures in two public hospitals.

Results: The internal consistency of the questionnaire was excellent (Cronbach's alpha = 0.949). Highest ratings were for radiographer behavior items, such as "greet the patients" (4.48), "respect for the patients" (4.63) and "time available to patient-centered care" (4.41). Lowest ratings were "encouraged to make questions" (3.77), "involved patients in decision-making process" (4.03) and "talk with patients about the next following steps" (3.70).

Conclusion: Radiographers communication skills were evaluated with good levels of patient confidence with the radiological examinations. Despite the overall positive results, this area of health service delivery must be accorded the attention it deserves to continually improve on patient satisfaction through improved communication.

Using the lean body weight (LBW) instead of total body weight (TBW) to dose the iodinated contrast medium (ICM) for abdominal CT: a randomised controlled trial (RCT)

M. Zanardo, F.M. Doniselli, G. Di Leo, A. Esseridou, S. Tritella, C. Mattiuz, L. Menicagli, F. Sardanelli; Milan/IT (moreno.zanardo@unimi.it)

Purpose: Due to low diffusion in fat and high in muscles, ICM could be more appropriately dosed on LBW instead of TBW, a hypothesis to be verified on liver contrast enhancement (LCE) in the portal venous phase.

Methods and Materials: Ethics Committee-approved RCT involved patients scheduled for contrast-enhanced abdominal CT. Patient LBW was estimated using a balance with bioelectrical impedance analysis. Patients were randomly assigned to the LBW-group, administered 0.65 g/kg of LBW, or to the TBW-group, administered 0.40 g/kg of TBW, as controls. Enrolled patients with liver disease or deemed to receive a too low or high ICM dose were excluded. Levene's test for variances and χ^2 test were used.

Results: We enrolled 315 patients. After 57 exclusions for protocol violation, 258 were assigned to LBW-group (n=119) or TBW-group (n=139). Age was 65±12 years in LBW-group and 67±12 years in TBW-group ($p=0.068$), TBW 70±13 kg for both ($p=0.635$), LBW 51±11 kg and 51±10 kg ($p=0.562$), body

mass index 25±4 kg/m² for both ($p=0.866$); injected ICM (ml) 85±18 and 83±16, respectively ($p=0.437$). LCE (HU) was 41±9 in LBW-group and 40±7 in TBW-group, with means not significantly different ($p=0.659$), but with different variances ($p=0.004$). Suboptimal LCE (<40HU) was found in 76 (55%) patients in the TBW-group and in 64 (54%) in LBW-group ($p=0.886$), but no repeat examination was needed.

Conclusion: ICM doses of 0.65 g/kg of LBW or 0.40 g/kg of TBW lead to a comparable diagnostic LCE with a slightly larger variation for the latter, thus negating the study hypothesis.

B-0491 10:38

High-pitch, low-kVp computed tomography for ruling out pulmonary embolism with 17-mL contrast media

H. Al-Ubeidy, M. Alshamari, J. Widell, T. Eriksson, M. Lidén; Örebro/SE (matsliden@yahoo.com)

Purpose: The purpose of this phase 4 clinical trial (EudraCT 2015-004657-40) was to perform CT pulmonary angiography (CTPA) for ruling out pulmonary embolism (PE) using a minimal amount of iodinated contrast media.

Methods and Materials: 47 patients (25 women) referred for contrast-enhanced chest CT were included in the study. All participants underwent the same study-specific CTPA in addition to the chest CT. The participants received 80 mg I/kg body weight iohexol contrast media using a preparatory saline bolus, a dual-flow iohexol/saline bolus and a saline flush, and a scanner protocol with 80kVp dual-source high-pitch mode. Three readers independently assessed the diagnostic quality for ruling out PE on the three-point scale non-diagnostic, adequate or good-excellent image quality. Additionally, the pulmonary arterial opacification was measured.

Results: On average, the patients received 16.8 mL (range 12-20 mL) iohexol 350 mg I/mL. Mean patient weight was 71 kg, range 50-85 kg. Identically for all readers, PE was detected in 1/47 participants. The median number of examinations visually scored concerning PE as good-excellent was 47/47 (range 44-47); adequate 0/47 (0-3) and non-diagnostic 0/47 (range 0-0). The proportion of adequate or better examinations for all readers was 47/47, 100% (95% C.I. 92-100%). The mean attenuation±standard deviation in the pulmonary trunk was 327±71 HU, range 174-515 HU.

Conclusion: Diagnostic CTPA with 17-mL contrast media is possible using low-kVp, high-pitch and carefully designed contrast media administration, which can be useful to reduce the risk of nephrotoxic complications.

B-0492 10:46

Determining optimal scan delay in indirect CT venography: time to peak attenuation correlates with cardiac output and heart rate

T.T. Tran¹, C.H. Kristiansen¹, F. Haidl¹, S. Roy¹, J.C. Lindstrom¹, H. Ashraf², P. Lauritzen³; ¹Lorenskog/NO, ²Rasta/NO, ³Oslo/NO

Purpose: Determine whether scan delay 120s is optimal for indirect-CT venography (CTV).

Methods and Materials: Twenty-four patients with clinical suspicion of deep-vein thrombosis were prospectively included. CTV was performed with fixed scan delay 120s after injection. Single scans of popliteal vein were obtained at 30s intervals from 30s to 210s to determine time-to-peak-attenuation (TPA). Cardiac output (CO) and heart rate (HR) were recorded continuously/non-invasively using a photoplethysmography-device (NexfinHD, BMEYE, Amsterdam). Attenuation measured at specified sites in inferior vena cava, and each external iliac/common femoral/popliteal veins. Associations between CO and TPA and HR and TPA were estimated by Spearman's rank correlation and linear regression.

Results: Median CO=7.8L/min (range: 4.1-11.5), median HR=72.4bpm (range: 58.4-102). Mean TPA=159s (95%CI: 141,176). TPA varied inversely with both CO and HR. Correlation-coefficients between TPA and CO, and between TPA and HR were 0.52 ($p=0.009$) and 0.41 ($p=0.047$), respectively. Regression-coefficients were 10.4 for CO and 2.1 for HR. This indicates 74s variation in optimal scan delay from highest to lowest CO. In 63% TPA exceeded scan delay of 120s. At 120s mean attenuation was appreciably higher than essential for diagnostic purposes in larger central veins: 140HU (95%CI, 128, 153) in inferior vena cava, 129HU (95%CI, 118, 139) in external iliac veins, 127HU (95%CI, 115, 139) in common femoral veins and 117HU (95%CI, 105, 129) in popliteal veins.

Conclusion: At 120s majority of patients had not reached peripheral venous peak attenuation, although attenuation was higher in larger central veins. Lengthening and individually tailoring scan delay to CO may be helpful.

Real-time patient-specific scan initiation for CT of the abdominal aorta: impact on image quality

F.R. Schwartz¹, J. Ramirez Giraldo¹, R. Gutjahr², D. Boll³, D. Marin¹, L. Hurwitz¹; ¹Durham, NC/US, ²Nürnberg/DE, ³Basle/CH
(fidesreginadorotheaann.schwartz@duke.edu)

Purpose: To assess the impact of real-time modulation of scan initiation based on patient-specific haemodynamics on contrast enhancement of the abdominal aorta on MDCT.

Methods and Materials: This is a HIPAA-compliant, IRB-approved QI project. Exams were performed on a DS-MDCT scanner (120 kVp, 65-75 mL of contrast, 4 ml/sec). Contrast administration was monitored in the descending aorta for the abdominal aortic (AA) and the thoracoabdominal (TAA) protocols. The delay prior to initiation of the diagnostic scan was modulated by a real-time patient-specific (RTPSM) software, incorporating time to threshold and the slope of the enhancement curve. 100 patients (cohort 1) were scanned using RTPSM triggering of scan delay for abdominal aortic protocols. A reference cohort of 30 patients (cohort 2) was identified with exams on the same scanner (preceding 12 months), using a fixed diagnostic delay (FD). Patient demographics, average aortic HU values and coefficients of variance (COV) at 1-mm increments from the diaphragm through the right common femoral artery were collected. Descriptive statistics and Student's t tests were applied.

Results: Cohort 1 and 2 had 73% TAA and 27% AA exams. The average scan delay was significantly longer for TAA (12.3 vs 11 sec; $p < 0.01$) and AAA protocols (11.5 vs 8 sec; $p < 0.01$) using RTPSM compared to FD. Average HU values were significantly higher in the RTPSM cohort (406.6 ± 37.9 vs 371.9 ± 38.4 HU; $p < 0.01$) and COV was significantly reduced using RTPSM (9.5 vs 11.6% ; $p < 0.01$).

Conclusion: RTPSM results in higher HU values and better contrast homogeneity throughout the abdominal aorta.

Patient-specific scan delay for optimised venous triggering in CT abdomen

W. Coudyzer¹, L. Cockmartin¹, D. Konings¹, T. Busselot², D. Bielen¹, D. Vanbeckevoort¹, H. Bosmans¹; ¹Leuven/BE, ²Brussels/BE
(Walter.Coudyzer@uzleuven.be)

Purpose: While the start of arterial phase contrast-enhanced CT scans is personalized to the patient's contrast bolus passage using automated triggering, this procedure is not available for venous phase scans. Fixed scan delays are used. To optimize the contrast injection scheme for venous phase abdominal CT scans, the parameters of impact on venous signal enhancement have been investigated using manually triggered acquisitions.

Methods and Materials: Venous phase CT abdomen scans of 100 patients (61 male/39 female) were acquired on a Siemens Definition Flash CT using a Nemoto injector with iCalc option. The venous signal enhancement was monitored from a region of interest in the hepatic parenchyma. Scans were started manually, immediately after peak enhancement. Registered patient parameters included gender, weight, age, blood pressure and heart rate. Linear regression analysis and Pearson correlations were performed to study their impact on peak enhancement time.

Results: Observed peak enhancement times in males and females were significantly different (mean difference 9.1 ± 2.7). Neither heart rate nor blood pressure correlated with observed peak enhancement times. Age had a limited impact depending on the gender (male: $r = 0.32$, $p = 0.012$; female: $p = 0.86$) while body weight (male: $r = 0.45$, $p < 0.0001$; female: $r = 0.76$, $p < 0.0001$) was significant. From this analysis, a reference scan delay of 95s for a 65kg female and 104s for a 75kg male could be increased with 7s/10kg and 3s/10kg extra body weight respectively.

Conclusion: The fixed scan delay for venous phase CT could be improved by including gender and weight parameters. A candidate time scheme can now be tested in practice.

To determine the image quality of non-linear blending (NLB) technique in aortic angiography acquired by novel injection protocol compared with linear blending (LB) technique

L. Xing; Zhengzhou/CN (278459366@qq.com)

Purpose: To determine the image quality of non-linear-blending (NLB) technique in aortic angiography acquired by novel injection protocol compared with linear-blending (LB) technique.

Methods and Materials: 30 patients were prospectively enrolled in the study. Third-generation dual-source scanner (SOMATOM Force) were utilised with tube voltage 70/sn150 kVp. The dose of contrast medium was tailored to the patients' body weight as 0.5 ml/kg with the injection duration defined as examining time (scanning time + time delay after achieving the trigger threshold value). LB image series with weighting factor of 0.5 were compared with non-linear blended image series. The difference in the vessel enhancement, signal-to-noise-ratio (SNR) and contrast-to-noise-ratio (CNR) were evaluated using paired t-test and Mann-Whitney U test. Overall image quality was also rated for both groups. And the consistency of the scores was analysed by Kappa test.

Results: The average effective radiation dose was 4.83 mSv. Mean contrast volume was 34.12 ml(350mg/ml). The average injection rate was 3.24 ml/s. The degree of the enhancement, SNR and CNR of the vessel in NLB group were significantly higher than LB group ($p < 0.05$), while the enhancement of soft tissue was of no difference in both groups ($p > 0.05$). The rated scores for the image quality of two groups achieved good consistency ($\text{kappa} = 0.708$, $p > 0.05$). And the scores of NLB group increased 0.55.

Conclusion: Low ionised-radiation dose dual-energy CT aortic angiography with novel injection protocol of low-contrast medium and low-flow rate might be feasible when using NLB technique, as it improve the image quality compared to LB technique.

B-0496 11:18

Systematic accuracy assessment of a real-time automated patient specific bolus tracking delay calculation algorithm

R. Gutjahr¹, G. Jost², H. Pietsch², B. Schmidt³, T. Flohr³; ¹Nürnberg/DE, ²Berlin/DE, ³Forchheim/DE

Purpose: To evaluate a fully scanner-integrated automated patient specific bolus tracking delay calculation algorithm utilizing real time monitoring measurements on a realistic circulation phantom.

Methods and Materials: Dynamics of contrast media (CM) were mimicked using a circulation phantom with a heart rate of 80bpm and blood pressure of 120/80mmHg. Iodinated CM was injected with flow rates (FR) of 2, 4, 6mL/s while the amount of CM (40mL) was maintained. Measurements were acquired using a perfusion scan protocol (100kVp, 50mAs, 0.1s/image). The mean enhancement was subsampled in three cycle times (CyT, 1, 1.5, 2s) until a threshold CT-values were exceeded (100 or 150HU). The time to peak enhancement was predicted and retrospectively compared for different FR and CyT.

Results: At a AT CT-value of 100HU the calculated delay in the ascending aorta (AA), descending aorta (DA), suprarenal aorta (SRA) and external iliac artery (EIA) showed a deviation to the time to peak of 0.18 ± 0.7 s at a CyT of 1s, 0.92 ± 0.5 s at a CyT of 1.5s, and 0.53 ± 0.5 s at a CyT of 2s. Comparing the time to peak enhancement at the AA using low/mid/high flow rates the deviations were 0.51 ± 0.44 s at a CyT of 1s, 0.53 ± 0.66 s at a CyT of 1.5s, and 0.71 ± 1.13 s at a CyT of 2s. The suggested delay times ranged from 3.5 to 14.9s. An overall average deviation of 1.2 ± 1.0 s was observed.

Conclusion: The calculated bolus delay times achieved very good accuracy in predicting the time of peak enhancement. This facilitates optimal usage of CM injections and eventual CM or radiation dose reduction.

B-0497 11:26

3D quantitative analysis of the aorta and pulmonary artery on non-contrast CT

Z. Sedghi Gamechi¹, A.M. Arias-Lorza¹, J. Holst Pedersen², K.F. Kofoed², D. Bos¹, M. De Bruijne¹; ¹Rotterdam/NL, ²Copenhagen/DK
(z.sedhigamechi@erasmusmc.nl)

Purpose: Accurate measurements of the size and shape of the aorta and pulmonary arteries are important as risk factors for cardiovascular diseases and Chronic Obstructive Pulmonary Disease (COPD). A fully automatic method is proposed to extract volumes and assess diameters.

Methods and Materials: Non-ECG gated, non-contrast chest CT scans were used from 365 participants (mean age 57.4, 49.9% female) of the Danish Lung Cancer Screening Trial. The aorta and pulmonary arteries were manually

segmented on 25 scans and the diameters of the ascending aorta (AA) and pulmonary artery (PA) at the pulmonary bifurcation level were measured in axial slices on 200 scans. Our automatic algorithm extracted the seed points and a landmark at the pulmonary bifurcation level by multi atlas registration and then traced the centerlines with a minimum cost path. Subsequently, an optimal surface was extracted around the centerline. Diameters were measured in axial slices to compare with manual measurements. Repeatability of diameter measurements was evaluated on 140 baseline- one-year follow-up scan pairs.

Results: Segmentation overlap between manual and automated segmentation was 0.95 ± 0.01 for aorta and 0.92 ± 0.02 for pulmonary arteries. The intra-class correlation between manual and automatic AA, PA, and PA:AA ratio were 94%, 87%, and 86% and repeatability was 96%, 92%, and 89%, respectively.

Conclusion: Our full automatic method can assess the diameters of the aorta and pulmonary arteries reliably in non-ECG gated, non-contrast CT. This method may replace time-consuming manual segmentations in large-scale studies and, eventually, in clinical practice.

Magnetic particle imaging: artefact-free imaging of the in-stent lumen of coronary stents

F. Wegner, T. Friedrich, A. von Gladiss, T.M. Buzug, J. Barkhausen, J. Haegele; Lübeck/DE (franz.wegner@uksh.de)

Purpose: Cardiovascular magnetic particle imaging (MPI) is a tracer-based method that visualizes the spatial distribution of superparamagnetic iron oxide nanoparticles with magnetic fields. In MRI and CT artefact-induced artificial lumen narrowing limits the assessment of the in-stent lumen. This study aims to investigate the potential of MPI for imaging of the in-stent lumen.

Methods and Materials: We evaluated eight commercially available coronary stents of different dimensions (diameter: 3 - 4 mm) and materials (stainless steel, platinum-chromium) implanted in silicone vessel phantoms. Prior to imaging, signal-to-noise ratio (SNR) of the stents and the tracer (Resovist diluted 1:100) were calculated separately from the MPI signal. Imaging of eight stented phantoms and a non-stented reference phantom for each diameter (all filled with tracer-solution) was performed in a preclinical MPI-Scanner (Bruker-Biospin, Ettlingen, Germany). For comparison, the stents were also visualized by MRI (Ingenia 3 T, Philips, Hamburg, Germany) and CT (Somatom Definition AS, Siemens, Erlangen, Germany).

Results: SNR values of the stents were in the range of background noise. SNR of the tracer-solution was 436 and thus suitable for image reconstruction. It was possible to visualize all of the stented vessel phantoms with MPI. The reconstructed MPI images did not show any stent artefacts, whereas MRI and CT images revealed multiform artefacts and significant artificial lumen narrowing in all devices.

Conclusion: MPI is able to visualize the in-stent lumen of coronary stents without any artefacts. Thus, MPI may overcome the disadvantages of MRI and CT concerning the visualization of the in-stent lumen.

B-0499 11:42

Magnetic particle imaging for pulmonary circulation time measurements

M.G. Kaul, J. Salamon, C.S. Jung, H. Ittrich, M. Graeser, G. Adam, K. Peldschus; Hamburg/DE (mkaul@uke.uni-hamburg.de)

Purpose: Magnetic particle imaging (MPI) is a new imaging modality providing a high temporal resolution scanning magnetic particle distributions in 3D. The purpose of our study was to determine the time of the passage of a bolus of superparamagnetic nanoparticles through the lungs of mice.

Methods and Materials: Nine mice were imaged by 7T MRI (ClinScan, Bruker) to localize heart and lungs. Mice were transferred on a MR/MPI-compatible couch to a MPI scanner (Philips/Bruker). An own-developed receiver coil for mice was used. During the measurement sequence, a bolus of 1 μ L of a high concentration SPIO (Perimag, Micromod) was injected into the tail vein. The temporal resolution for a 3D dataset was 21 ms. MRI and MPI images were co-registered to identify the left and right ventricles. A model function was fitted to each pixel time series extracting the time of arrival. Next, regions of interest were drawn in the left and right ventricles and the time difference of the arrival times of left and right ventricle was determined.

Results: In all ten mice, the injection was successful generating short bolus profiles. The difference of the bolus arrival times were 0.9 ± 0.1 s.

Conclusion: Due to its high temporal resolution, MPI is able to image the passage of a bolus from the right ventricle through the lungs to the left ventricle. The technique might be used to depict pathologic changes. In combination with the estimation of the cardiac output the blood volume of the lungs can be measured.

B-0500 11:50

Pre-TAVR scanning by a comprehensive contrast-free cardiovascular magnetic resonance imaging protocol: comparison with contrast-enhanced computed tomography

M.J. Pamminger, G. Klug, S.J. Reinstadler, M. Reindl, C. Kremser, C. Kranewitter, B. Metzler, W.R. Jäschke, A. Mayr; Innsbruck/AT (Mathias.Pamminger@tirol-kliniken.at)

Purpose: To compare an entirely non-enhanced cardiovascular magnetic resonance imaging (MRI) protocol with contrast-enhanced computed tomography angiography (CTA) for prosthesis sizing and access guidance in transcatheter aortic valve replacement (TAVR) evaluation.

Methods and Materials: 25 patients (mean age 82.6 ± 4.6 years, 14 female [56%]) with severe aortic stenosis referred for TAVR evaluation underwent non-contrast three-dimensional (3D) 'whole heart' MRI for aortic root measurements as well as non-enhanced quiescent-interval single-shot (QISS) MR angiography for evaluation of aortoiliac access routes. CTA was performed in 20 (80%) patients.

Results: Aortic root geometry assessed by 3D 'whole heart' MRI showed strong to very strong correlations ($r = 0.606$ to 0.874 , all $p < 0.005$) compared to CTA. QISS and CTA based measurements of aortoiliac vessel diameters correlated moderately to very strong ($r = 0.555$ to 0.816 , all $p < 0.011$) with good to excellent inter-observer reliability (ICC = 0.81 to 0.999 , all $p < 0.0001$) regarding MRI measurements. Mean diameters of infrarenal aorta, common iliac arteries and common femoral arteries differed significantly (bias -0.44 to -0.96 mm, $p = 0.026$ to < 0.0001) between the two modalities. However, inter-method agreement for the decision of transfemoral accessibility was strong ($k = 0.828$, $p = 0.004$).

Conclusion: MRI 3D 'whole heart' and QISS angiography provide contrast-free evaluation of aortic root and access routes in TAVR patients with moderate to strong correlations compared to CTA measurements. Moreover, decision for transfemoral access strategy showed strong agreement between both modalities, highlighting this MRI protocol to might obviate the need for contrast administration in pre-TAVR scanning.

Is ADC a predictor of hypoxia in ER+ breast cancer? A study using ¹⁸F-FMISO PET-MRI

J.C. Carmona-Bozo, R. Woitek, A.J. Patterson, G. Baxter, C. Caraco, E. Provenzano, T.D. Fryer, M.J. Graves, F. Gilbert; Cambridge/UK (jcc83@cam.ac.uk)

Purpose: To investigate the relationship between ADC and hypoxia in ER+ breast cancers using combined ¹⁸F-FMISO-PET and DWI-MRI.

Methods and Materials: Imaging was performed on patients with biopsy-confirmed ER+ breast cancer prior to treatment. Following injection of 300 MBq ¹⁸F-FMISO and a 2-hour uptake period, a 60-min PET/MR scan was performed on a GE SIGNA PET/MR scanner. PET data was analysed by K_i from Patlak analysis with a scaled population-based arterial input function. Tumour hypoxic fractions were calculated as the percentage of voxels with K_i values $> 2SD$ of the mean of normoxic muscle. Mean ADC values were calculated from DWI using b-values 0 and 900 s/mm^2 . The group median ADC value was used to partition tumours into high and low diffusion groups.

Results: 15 patients/16 lesions were assessed (ductal: $n=10$; lobular: $n=2$; other: $n=3$; HER2+: $n=4$ HER2-: $n=11$). Hypoxia was identified in 50% of the lesions, with hypoxic fractions ranging between 1-58%. Higher mean hypoxic fractions were observed in grade 3 (10.5%) vs grade 2 (5.8%) cancers ($p=0.620$) and lower median ADC values were found in grade 3 vs low-grade (0.83 vs 1.10 respectively; $p=0.160$). In addition, lesions in the low diffusion group ($ADC \leq 1.05 mm^2/s$) demonstrated a higher median hypoxic fraction (4.4%) than tumours in the high diffusion group (0.3%), although this difference was not statistically significant ($p=0.957$). There was an inverse heterogeneous relationship between mean tumour K_i and ADC ($\rho = -0.262$; $p=0.327$).

Conclusion: Low ADC may be associated with a higher degree of hypoxia in ER+ breast cancer.

B-0502 10:38

Proton MR spectroscopy: a non-invasive tool for the detection of ovarian cancer

P.N.S. Fahmy, A. Elkalawy, M. Gomaa, S.A. Mansour; *Cairo/EG*
(nashaat.peter.med@gmail.com)

Purpose: To assess the role of MR spectroscopy (MRS) - as it is a non-contrast-based MR sequence - in the screening of malignancy in ovarian masses.

Methods and Materials: This prospective work included 230 females who had 245 adnexal/ovarian masses. Tumours were spotted by preliminary pelvic ultrasound. Masses were assessed by MRI, multi- or single-voxel spectroscopy. Patients' spectra were assessed for peaks of lactate (Lac, 1.31 ppm), lipid (Lip, 1.33 ppm), N-acetyl aspartate (NAA, 2.0 ppm), acetone (A, 2.05 ppm), choline (Cho, 3.23 ppm) and creatine (Cr, 3.4 ppm). The mean values of (Cho/Cr) ratios were performed by a semi-quantitative approach. The operative pathology served as the standard of reference.

Results: Cho peak twofold higher than the average noise level was detected in 72% of the malignant and only 5.4% of the benign masses with an accuracy of 83%. Adding lactate to the choline enhanced the accuracy to 93%. The mean Cho/Cr ratios of the malignant ovarian masses (2.8) were significantly higher than that of the benign ones (1.2). We used a ROC curve to determine the best cut-off value (1.7) for the mean Cho/Cr ratio to discriminate malignancy with sensitivity: 81.2%, specificity: 93.3%, PPV: 92.9%, NPV: 82.4% and accuracy: 87.1%.

Conclusion: The simultaneous presence of choline and lactate peaks in MR spectroscopy examination of the ovarian masses minimizes the overlap between benign and malignant categories. N-acetyl aspartate and acetone are the specific metabolites in diagnosing complex cystic masses.

B-0503 10:46

MR monitoring of cytolysis and inflammatory tumour microenvironment after oncolytic adenovirus injection in a novel transgenic pancreatic adenocarcinoma mouse model

F.M. Kubicka¹, B. Fleischmann-Mundt², P.M. Kazmierczak¹, M.J. Schneider¹, J. Brooks², M. Meier², J. Ricke¹, F. Kühnel², C.C. Cyran¹; ¹Munich/DE, ²Hannover/DE (felix.kubicka@gmx.de)

Purpose: To investigate if a novel pancreatic cancer model (EP-PDAC) is suitable for preclinical monitoring of virotherapy using MRI.

Methods and Materials: 3 weeks after pancreatic electroporation (EP) with oncogenes (KRasG12V, Akt2, Cre-p53fl/fl) in mice (n=116), tumour growth was assessed by inspection and histology. Tumour-related complications (ileus, peritonitis, bleeding, invasive growth) were investigated in relation to tumour size. Tumour growth and complications were additionally examined (n=30) by T2-weighted MSME sequence (TR/TE=1238/11, FOV=25.6x25.5 mm) on a 7T small animal MRI. Of these, mice (n=5) were treated at day 22 post-EP by 100 µl intratumoural hTert-adenovirus injection (1x10E9 ifu), or NaCl (n=5, control group) and reexamined by MRI (day 25 post-EP). The extent of the oncolytic-necrotic area was measured by manual MRI-3D-rendering. Results were validated with histological investigations of inflammation (CD45-immunohistochemistry), virus-induced lysis (HE), and fibrosis (Sirius-red).

Results: 116 mice reliably developed solitary tumours until day 21 (diameter=1.3-10 mm), which were histologically and MRI-morphologically (n=30) authentic to human PDAC. In contrast to controls, lower T2-signals were detected after virotherapy, histopathologically (HE and CD45) corresponding to oncolytic-necrotic tissue reaching a maximum-ratio of 1-3 regarding intact EP-PDAC using MRI-3D-rendering. Rim-fibrosis was only detectable by Sirius-red staining in all virus-treated, but not in saline-treated mice. MRI and histopathology represented PDAC-characteristic complications (ileus, peritonitis and bleeding) with high, significant correlations to tumour size (p=0.03, p=+0.85) with the exception of invasive growth (p=0.09, p=+0.52).

Conclusion: The EP-PDAC is well suited for preclinical evaluation of oncolytic virotherapy by MRI and allows monitoring of microenvironmental changes as validated by immunohistochemistry.

B-0504 10:54

Assessment of tumour hypoxia response to sorafenib in rabbit VX₂ liver tumour xenografts by tissue-oxygen-level-dependent MR imaging

S. Qin, X. Li, Z. Qi, Y. Mei, X. Quan; *Guangzhou/CN*
(qinshuping1226@163.com)

Purpose: To investigate the alteration in tumour oxygen inhalation and hypoxia levels of rabbit liver VX₂ tumour before and after the application of sorafenib, using tissue-oxygen-level-dependent (TOLD) MR.

Methods and Materials: 26 VX₂ tumours were implanted in the livers of 13 New Zealand white rabbits, which were incubated for control and treated group (5 rabbits) were given a week of sorafenib (20mg/kg/d) at 3weeks after

implantation. TOLD was performed on a 3.0T MR scanner before and after 30min of oxygen inhalation, using an animal coil. The longitudinal relaxation rate ($R_1=1/T_1$) was calculated. R1 difference ($\Delta R_1=R_1(O_2)-R_1(\text{air})$) was measured for whole lesion ($\Delta R_1^{\text{whole}}$) and non-necrotic area ($\Delta R_1^{\text{non-necrotic}}$), and the corresponding relative change $\Delta R_1\%^{\text{whole}}$ and $\Delta R_1\%^{\text{non-necrotic}}$. Immunohistochemical analysis of hypoxia-inducible factor-1 α expression of VX₂ liver tumour was graded from H0 to H4.

Results: No significant differences were found between control and treated group at week 3 in different ΔR_1 . Significant differences ($P < 0.01$) were found in ΔR_1 between treated group and control group at week 4. Significant differences were also detected in treated group before and after application of sorafenib. There was no significant difference in the pathological grade of HIF-1 α between the treated and the control group after a week of sorafenib ($P > 0.5$), but the HIF-1 α -positive cell expression rate of treated group was significantly ($P < 0.05$) higher than control group (week 4).

Conclusion: Our results show the potential of TOLD as a non-invasive technique to detect early tumour hypoxia response in rabbit VX₂ liver tumour receiving sorafenib.

B-0505 11:02

Amide proton transfer (APT) MRI is a predictor of survival and progression in high-grade glioma patients

D. Paech, C. Dreher, S. Regnery, S. Goerke, A. Unterberg, W. Wick, M. Bendszus, M. Ladd, H.-P. Schlemmer; *Heidelberg/DE* (d.paech@dkfz.de)

Purpose: The purpose of this study was to investigate the predictability of patient overall survival (OS) and progression-free survival (PFS) in newly diagnosed high-grade glioma (HGG) patients using relaxation-compensated chemical exchange saturation transfer (CEST) MRI at 7 Tesla (7T).

Methods and Materials: Twenty-six patients with newly diagnosed high-grade glioma (WHO grade III-IV) were included in this prospective ethical committee-approved study. CEST MRI was performed at a 7T whole-body scanner. Predictability of patient OS and PFS were assessed employing relaxation-compensated CEST MRI contrasts by means of amide proton transfer (APT, downfield rNOE-suppressed APT = dns-APT) and relayed nuclear Overhauser effect (rNOE/NOE) imaging. Furthermore, OS and PFS predictability were assessed for clinical parameters (age, treatment, and O6-methylguanine-DNA methyltransferase (MGMT) promoter methylation status) and diffusion-weighted imaging (apparent diffusion coefficient). OS and PFS analyses were performed according to the Kaplan-Meier method with two-sided log-rank statistics.

Results: Relaxation-compensated APT imaging was a significant predictor for patient OS ($p=0.009$) and PFS ($p=0.012$). Median OS/PFS of patients with low tumour signal intensities $\leq 4.23\%$ (signal median) was 411/293 days compared to 292/112 days for patients with increased APT values. Strongest association with PFS was found for the dns-APT metric ($p=0.009$). Among the tested clinical parameters, patient age (older/younger 57 years=median, $p=0.005$) and treatment (surgery vs. no surgery, $p=0.018$) were significant for OS.

Conclusion: Relaxation-compensated APT MRI serves as a predictor of overall survival and progression-free survival in newly diagnosed, previously untreated glioma patients and may, therefore, help to customize glioma patient treatment and response monitoring in the future.

B-0506 11:10

Early response assessment of glioma patients to definitive chemoradiotherapy using chemical exchange saturation transfer imaging at 7 Tesla

J.-E. Meissner, A. Korzowski, S. Regnery, S. Goerke, J. Debus, M. Ladd, H.-P. Schlemmer, S. Adebeg, D. Paech; *Heidelberg/DE* (d.paech@dkfz.de)

Purpose: Patients with newly diagnosed inoperable glioma receive chemoradiotherapy (CRT). Standard response assessment in neuro-oncology (RANO) takes a minimum of 4 weeks after the end of treatment. In this longitudinal study, we assessed whether chemical exchange saturation transfer (CEST) MRI enables earlier assessment of response to CRT in glioma patients.

Methods and Materials: Twelve glioma patients that underwent definitive CRT were included in this study. Three longitudinal CEST MRI measurements were performed for each patient at 7T - the first before, the second immediately after completion of CRT and the third as a 6 week follow-up. The relaxation-compensated relayed nuclear-overhauser-effect CEST signal (rNOE) and the downfield-rNOE-suppressed amide proton transfer (dns-APT) CEST signal were investigated. Additionally, choline-to-N-acetyl-aspartate ratios (Cho/NAA) were evaluated using single-voxel ¹H-MRS in six of these patients. Performance of obtained contrasts was analysed in assessing treatment response as classified according to the updated RANO criteria.

Results: The rNOE signal significantly separated stable and progressive disease directly after therapy (post-treatment normalized to pre-treatment mean \pm SD: rNOE_{responder}=1.09 \pm 0.11, rNOE_{non-responder}=0.87 \pm 0.09, $p=0.015$). In contrast, no significant difference could be observed between both groups when assessing the normalized dns-APT (dns-APT_{responder}=0.95 \pm 0.38, dns-

APT_{non-responder}=0.97±0.48, p=0.95). In the smaller MRS sub-cohort, normalized Cho/NAA decreased in therapy responders (Cho/NAA_{responder}=0.632±0.007, Cho/NAA_{non-responder}=0.946±0.124, p=0.070).

Conclusion: rNOE mediated CEST imaging at 7T allowed for discrimination of responders and non-responders immediately after end of CRT, additionally supported by ¹H-MRS data. This is at least 4 weeks earlier than the standard clinical evaluation according to RANO. Therefore, CEST MRI may enable early response assessment in glioma patients.

B-0507 11:18

A GPC3-specific aptamer-mediated MR probe for hepatocellular carcinoma

M. Zhao; Shanghai/CN

Purpose: To construct and test a HCC-targeted MR probe based on a GPC3-specific aptamer (AP613-1) with ultrasmall superparamagnetic iron oxide (USPIO).

Methods and Materials: Oleic acid-coated USPIO nanoparticles were modified with amino polyethylene glycol on the surface. Amino groups of the USPIO nanoparticles were reacted with carboxyl group of 5' carboxyl modified AP613-1, forming an aptamer-mediated USPIO (Apt-USPIO) probe. The material characterizations of this probe including TEM, zeta potential, dynamic laser scattering and magnetic behavior were measured. The targeting efficiency and MR imaging performance of Apt-USPIO were evaluated both in vitro and in vivo with USPIO alone as a control. The cytotoxicity and biocompatibility of Apt-USPIO and USPIO were analysed by cell counting kit-8 tests in vitro and animal experiments in vivo.

Results: TEM imaging revealed the Apt-USPIO nanoparticles were spherical and well dispersed. Specific uptake of Apt-USPIO in Huh-7 cells could be observed by Prussian blue staining test, but no uptake of USPIO could be found. In vitro phantom T2-weighted MR imaging showed a significant decrease of the signal intensity in Apt-USPIO-incubated Huh-7 cells compared to USPIO-incubated Huh-7 cells. In vivo T2-weighted MR imaging showed significantly negative enhancement in the Huh-7 tumours enhanced with Apt-USPIO whereas no enhancement was found with USPIO alone. Excellent biocompatibility of Apt-USPIO and USPIO was also demonstrated.

Conclusion: In this study, a molecular MR imaging probe which was highly specific to GPC3 on HCC is successfully prepared. Our results validated the targeted imaging effect of this Apt-USPIO probe in vivo for GPC3-expressing HCCs in xenograft mice.

Evidence from in vivo MRI: ferritin heavy chain and interferon-β gene-modified mesenchymal stem cells transplanted peritumorally inhibit malignant gliomas

J. Mao, J. Shen; Guangzhou/CN (707982289@qq.com)

Purpose: In our previous study, we demonstrated that ferritin heavy chain (FTH) gene-based MRI could be used to track the tumour tropism of MSCs to orthotopic gliomas in vivo. However, the tumour tropism of MSCs showed no impact on the progression of gliomas. The purpose of this study was to determine the therapeutic effect of up-regulation IFNβ secretion of MSCs on gliomas, to monitor the biological behaviors of transplanted MSCs, and to determine the best transplantation method.

Methods and Materials: Rat MSCs were transduced with a lentiviral vector overexpressing FTH-IFNβ gene. The feasibility, efficacy and biological safety of this genetic modification were investigated in vitro. Intra-arterial, intertumoural and peritumoural injections of FTH-IFNβ transgenic MSCs (FTH-IFNβ-MSCs) were performed in rats bearing intracranial orthotopic C6 gliomas. The progression of gliomas, as well as the location, migration and survival of transplanted FTH-IFNβ-MSCs were tracked using in vivo MRI and confirmed by histology.

Results: The transduction efficiency achieved 73.59 ± 0.28%. FTH-IFNβ-MSCs can overexpress FTH and IFNβ effectively and safely. The FTH-IFNβ-MSCs were detected as hypointense signals on T2- and T2*-weighted images on a 3.0 T clinical MRI. FTH-IFNβ-MSCs could be monitored by MRI until 7 days after intra-arterial and intratumoural injection, and 11 days after peritumoural injection. The tumour growth rate of peritumoural injection group was significantly lower than other groups (P<0.05).

Conclusion: FTH-IFNβ-MSCs transplanted peritumorally can effectively inhibit intracranial orthotopic C6 gliomas in rats, providing a new idea for stem cell-based therapy for malignant gliomas.

B-0510 11:42

Detection of gut inflammation with MR and PET imaging in the insect *Manduca sexta*: A new screening system for effectors and inhibitors of gut inflammation

A.G. Müller¹, F.H. Müller², M. Hentschel³, C.-R. von Bredow¹, Y. von Bredow¹, T. Trenczek¹; ¹Giessen/DE, ²Neustadt/DE, ³Berne/CH (anton.g.mueller@allzool.bio.uni-giessen.de)

Purpose: This study aims to propose and validate MR and PET imaging features of gut-inflammation in the insect *Manduca sexta*. The epithelial structure and intestinal innate immune response in *M.sexta* are functionally and mechanistically comparable to humans, making *M.sexta* a valuable model to study the innate part of gut inflammation. This, together with the cost-effective rearing and the large, cylindrical gut of *M.sexta* larvae will provide a quick and easy system to screen for new effectors and inhibitors of gut-inflammation for pharmaceutical and agricultural purposes.

Methods and Materials: We established Gd-BOPTA-MR and ¹⁸F-FDG-PET, as well as fusion MRI-PET imaging, methods firstly applied to insects, to detect gut-inflammation. *Bacillus thuringiensis*-infected (n=20) animals were used as a positive control and compared to healthy animals (n=20). We tested contrast-enhanced, T1-weighted (CHESS/Fat-Sat) gut wall thickness and area, gut wall signal-enhancement, as well as the contrast-enhanced gut diameter and SUVMax as MR and PET diagnostic features.

Results: Bt-fed animals showed a significantly lower survival (Log-rank/Gehan-Breslow-Wilcoxon test, p≤0.0001) compared to control animals. Control and Bt-infected animals differed significantly (p≤0.0001) in each diagnostic finding. All diagnostic features were excellent or good with ROC-areas of 0.96-0.8 and strongly correlated to each other (r=0.5-0.75). We propose contrast-enhanced gut wall thickness with a threshold of 2.05mm and a sensitivity and specificity of 90% as a key diagnostic finding of gut-inflammation in *M.sexta*. Finally, we compared and validated the empirical MRI resolution using gut phantoms (SD=0.078mm).

Conclusion: The *M.sexta* screening system is a quick and easy tool that allows screening for new effectors and inhibitors of gut-inflammation.

B-0511 11:50

The experimental study of prostate cancer imaging using PSMA targeting ultrasound/MRI dual modality nanobubbles

Y. Zhu, Y. Chen, W. Guan; Shanghai/CN (tttmax2004@126.com)

Purpose: The prostate specific membrane antigen (PSMA) is broadly overexpressed on prostate cancer (PCa) cell surfaces. The aim of this study is to develop dual modality contrast agents for PSMA targeted ultrasound/magnetic resonance imaging (US/MRI) dual modality imaging.

Methods and Materials: The nanobubbles, characterised by strong penetrating power and stable performance, were served as the US imaging components of the dual modality contrast agents. SPIONs were encapsulated in the polymer shell of the nanobubbles to produce T2-negative contrast enhancement. The polypeptide CQKHHNYLC was conjugated to the nanobubbles for targeting PSMA. The SPIONs loaded nanobubbles (SPIONs/Polypeptide-PLGA NBs) were prepared by a modified double emulsion method. Series of in vitro and in vivo experiments were employed to evaluate the characterisation, targeted dual modality imaging ability, biodistribution and toxicity of SPIONs/Polypeptide-PLGA NBs.

Results: The average size of SPIONs/Polypeptide-PLGA NBs was 415nm, spherical shaped, uniformly distributed with superparamagnetic characteristic. SPIONs/Polypeptide-PLGA NBs provided positive contrast enhancement on ultrasound images and negative contrast enhancement on T2 MRI images. In in vivo dual modality imaging, the SPIONs/Polypeptide-PLGA NBs provided specific dual modality contrast on both US and MRI images by targeting PSMA. The NBs was breakdown and metabolised mainly in the reticuloendothelial system and showed no obvious toxicity in vivo.

Conclusion: SPIONs/Polypeptide-PLGA NBs could specifically enhance both ultrasound and MRI images via binding with PSMA expressed on prostate cancer cells. Our work provides new strategy for PCa detection, and further broadens the application of nanobubble in cancer imaging.

Muscle involvement in juvenile localised scleroderma: do we need a volumetric approach?

S.K.J. Flores Quispe¹, A. Cavaliere¹, F. Zulian¹, M. Weber², M. Zuliani¹, R. Stramare¹, E. Quaia¹, C. Giraud¹; ¹Padua/IT, ²Vienna/AT (flo_silvia@hotmail.it)

Purpose: To perform a qualitative and quantitative MR-based muscle assessment in juvenile localised scleroderma patients (JLSp) including volumetric analyses.

Methods and Materials: JLSp referring to our pediatric unit who underwent to at least one MR scan at diagnosis including axial T2w fat-sat and axial T1w of both extremities were examined. The last available follow-up MR, satisfying the above-mentioned criteria, was also included. Fatty atrophy (Mercury Scale) and oedema (5 points scale) were assessed. Muscle area (MA) performing a ROI at the most affected level, and muscle volume (MV) were measured on the injured (i) and healthy contralateral (hc) extremity (Student's T-test, p<0.05). To assess the repeatability two radiologists performed all measurements independently (intra-class correlation coefficient, ICC).

Results: Fourteen JLSp (9 females; mean age 7.1±3.6yrs) met the inclusion criteria and 23 MR examinations (nine at follow-up) were evaluated. Muscle oedema was detected in 12 JLSp (mean 1.4±1.3) whereas fatty replacement was identified in one case (stage 2). At diagnosis MA and MV were significantly lower on the injured side (MAi 31.5±17.9 vs MAhc 38.6±22.7, p<0.009; MVi 553±330 vs MVhc 652±432, p<0.033). At follow-up, muscle oedema decreased in 6 JLSp (mean 1.2±1.4), and no significant difference between the two extremities occurred for MA or MV (p>0.05, each). All measurements showed high ICC (>.750, each).

Conclusion: In JLSp oedema and significant hypoplasia, rather than atrophic changes, occur at diagnosis and decrease after treatment. This evidence demonstrates the importance of muscle assessment in JLSp but without the necessity of a complex volumetric approach.

B-0513 10:38

MRI evaluation of ankle joint in juvenile idiopathic arthritis

P. Rampal¹, N. Sachdev¹, A. Taneja²; ¹Delhi/IN, ²New Dehli/IN (parikha2993@gmail.com)

Purpose: To evaluate changes in ankle joint in patients of Juvenile Idiopathic Arthritis by MRI and to correlate these changes with the clinical scores which indicate disease severity.

Methods and Materials: Study design - Prospective observational study. Inclusion Criteria - 30 patients less than 16 years of age with a clinical diagnosis of Juvenile Idiopathic Arthritis as per the International League of Rheumatology definition with clinically involved ankle joint (pain/ swelling) shall be included in the study. Exclusion criteria - Any Patient with contraindication to MRI. They are subjected to contrast enhanced MRI to look for bone marrow edema, erosions, synovial thickening and enhancement and cartilage destruction and these findings are graded according to the Juvenile Arthritis MRI Score (JAMRIS). This score is compared with the Juvenile Arthritis Disease Activity Score (JADAS - 27) which is calculated using various clinical and biochemical parameters.

Results: The sensitivity of clinical diagnosis of ankle joint arthritis is 80% and specificity is 92% when compared with the MRI findings. Patients with higher JADAS tend to have more severe MRI findings in terms of synovial thickness, cartilage surface area involvement thereby making a higher JAMRIS. Bone marrow edema did not show a significant correlation with the disease severity of the patient. Patients on treatment may show clinical improvement early but their MRI findings take weeks to show any significant change.

Conclusion: Juvenile Arthritis MRI Score (JAMRIS) could be used to indicate the level of disease activity and thereby indicate prognosis in JIA patients.

B-0514 10:46

Ultra-low-dose CT detects synovitis in patients with suspected rheumatoid arthritis

T. Diekhoff, S.-T. Ulas, D. Poddubnyy, U. Schneider, S. Hermann, R. Biesen, G.R. Burmester, B. Hamm, K.-G.A. Hermann; Berlin/DE (torsten.diekhoff@gmail.com)

Purpose: To prove feasibility and diagnostic accuracy of contrast-enhanced ultra-low-dose CT (ULD-CT) for inflammatory soft tissue changes (synovitis, tenosynovitis and peritendonitis) in patients with arthritis of the hand.

Methods and Materials: In this institutional review board-approved study, 36 consecutive patients over the age of 50 with suspected rheumatoid arthritis underwent ULD-CT (estimated radiation exposure <0.01 mSv) and MRI of the hand with weight-adapted intravenous contrast administration. ULD-CT subtraction and MR images were assessed for synovitis, tenosynovitis and peritendonitis by three readers using a modified rheumatoid arthritis MRI score (RAMRIS). Patients were asked which modality they would prefer for future examinations. Sensitivity and specificity of ULD-CT for detection of inflammatory changes were calculated using MRI as standard of reference. The sum scores were correlated using Pearson's r.

Results: All 36 patients showed synovitis in MRI. ULD-CT had 69% sensitivity on the patient level and 65% on the joint level with 87% specificity. Sensitivity was higher in patients with more severe inflammation (80% for MRI RAMRIS >1). There was almost perfect correlation between the modified RAMRIS sum scores of ULD-CT and MRI (Pearson's r=0.94). Regarding preferences for future examinations, 85% preferred ULD-CT over MRI. ULD-CT detected more differential diagnoses than MRI (8 vs. 2/12).

Conclusion: Contrast-enhanced ULD-CT of the hand allows for depiction of soft tissue inflammation at the hand and can be achieved using very low radiation exposure (<0.01 mSv). ULD-CT may evolve to a fast and comfortable alternative to MRI, although it is not as sensitive as MRI for detecting mild disease.

B-0515 10:54

Prevention of the progressive biochemical cartilage destruction under methotrexate therapy in early rheumatoid arthritis

M. Frenken, D. Abrar, A. Ljimini, P. Sewerin, M. Klingebiel, G. Antoch, C. Schleich; Düsseldorf/DE (miriam.frenken@med.uni-duesseldorf.de)

Purpose: Objective of the study was to investigate biochemical cartilage composition under methotrexate (MTX) therapy and to intra-individually assess the impact of inflammation severity on cartilage composition using dGEMRIC MRI in patients with early rheumatoid arthritis (eRA).

Methods and Materials: dGEMRIC of MCP joints of the index and middle finger of 28 patients from the AthroMark cohort were examined prior to MTX-therapy as well as after 3 and 6 months. OMERACT RA MRI score and clinical parameters (CRP and DAS28) were registered at any time point. Each patient's second and third MCP joints were dichotomized into the joint with more severe synovitis versus the joint with less severe synovitis according to the RAMRIS synovitis subscore.

Results: MCP joints with more severe synovitis ('bad joints') demonstrated significantly lower dGEMRIC values compared to MCP joints with less severe synovitis ('good joints') at time-points 0 and 3 months (p = 0.002; p = 0.019, respectively). After 6 months of MTX therapy no significant difference of dGEMRIC index was found between good and bad joint (p = 0.086).

Conclusion: Under MTX therapy, biochemical cartilage integrity remains stable; no further cartilage destruction occurred if patients are treated early in the course of the disease. This might be explainable through reduced inflammation on joint level. In addition, six months of MTX therapy triggered an alignment of dGEMRIC index of MCP joints with initially severe synovitis and less severe synovitis in an intra-individual assessment.

B-0516 11:02

Rheumatoid arthritis magnetic resonance imaging score predicts therapy response

D.B. Abrar, M. Frenken, Y. Klosterkemper, G. Antoch, C. Schleich; Düsseldorf/DE (danielbenjamin.abrar@med.uni-duesseldorf.de)

Purpose: The aim of the study was to assess the performance of the RA magnetic resonance imaging (MRI) scoring system (RAMRIS) in combination with serum biomarkers to predict response to methotrexate (MTX) treatment in therapy-naive patients with early RA using high-field MRI.

Methods and Materials: 28 patients with RA were prospectively assessed with baseline 3-T MRI of the clinical dominant hand, 3 and 6 months after MTX. The patients met the 2010 American College of Rheumatology/European League Against Rheumatism (EULAR) criteria. RAMRIS and serum biomarkers consisting of various proteins including receptor activator of nuclear factor-κB ligand (RANKL) were obtained. Remission or treatment response was defined according to EULAR. To adjust for intrapersonal correlation, generalised linear mixed models were used.

Results: Treatment response at 3 months was associated to low RAMRIS erosion subscores and low total RAMRIS scores ($p = 0.019$ and 0.03 , respectively). Remission at 6 months was associated to low RANKL levels ($p = 0.033$). Response at 3 and 6 months was predicted more accurately with the inclusion of total RAMRIS score, RAMRIS synovitis subscore at the second metacarpophalangeal (MCP) joint, or a combination of the two (p value likelihood ratio test = 0.035 , 0.035 , and 0.041 , respectively). Remission was more accurately predicted with inclusion of RANKL, with no significant predictive effect of MRI.

Conclusion: Baseline total RAMRIS can predict EULAR response. RAMRIS synovitis subscore at the second MCP joint and RANKL are associated with response and remission, respectively.

B-0517 11:10

The value of the simplified RAMRIS-5 in early-RA patients under methotrexate therapy using high-field MRI

M. Frenken, D. Abrar, A. Ljmani, P. Sewerin, G. Antoch, C. Schleich; Düsseldorf/DE (miriam.frenken@med.uni-duesseldorf.de)

Purpose: The aim of the study was to evaluate a simplified version of the Rheumatoid Arthritis Magnetic Resonance Imaging Score (RAMRIS) to five joints of the hand (RAMRIS-5) in patients with early rheumatoid arthritis (RA) before and after the initiation of a methotrexate (MTX) therapy using high-resolution, 3 Tesla (T), magnetic resonance imaging (MRI).

Methods and Materials: 28 RA patients according to 2010 ACR/EULAR criteria (\bar{O} 56.8 years (range 39 - 74)), seropositive, disease duration < 6 months (range 2 - 23 weeks) were prospectively assessed with baseline investigation including clinical assessment (DAS-28 and CRP) and 3T MRI of the clinical dominant hand, as well as 3 and 6 months after starting MTX therapy. MRI scans were analysed according to RAMRIS and the simplified RAMRIS-5.

Results: DAS-28, CRP, RAMRIS and RAMRIS-5 decreased significantly after initiation of a MTX therapy. There was a strong correlation between RAMRIS-5 and RAMRIS at baseline ($r=0.838$; $p<0.001$) and follow-up (3 months: $r=0.876$; $p<0.001$; 6 months: $r=0.897$; $p<0.001$).

Conclusion: 3T MRI-based RAMRIS-5, the simplified version of the well-established RAMRIS is a resource-saving, appropriate alternative not only for patients with established but also with early RA. Regarding its shorter expenditure of time, there may be a high potential for using RAMRIS-5 in daily clinical practice to detect and monitor RA.

B-0518 11:18

Silent progression in patients with rheumatoid arthritis: is DAS28 remission an insufficient goal in RA?

D.B. Abrar, M. Frenken, Y. Klosterkemper, G. Antoch, C. Schleich; Düsseldorf/DE (danielbenjamin.abrar@med.uni-duesseldorf.de)

Purpose: Remission is arguably the ultimate therapeutic goal in rheumatoid arthritis (RA). Applying modern strategies, clinical remission can be achieved in a substantial number of patients with early RA (ERA). We, therefore, investigated the value of MRI for the detection of radiological progression in patients with DAS28 improvement and/or clinical remission.

Methods and Materials: Data sets of 80 RA patients (according to 2010 ACR/EULAR criteria), who fulfilled the following criteria, were retrospectively analysed: availability of two consecutive MRI scans (low-field MRI, follow-up interval 1 year) of the clinically dominant hand and wrist, and the presence of DAS28 (CRP) scores at both time points, which was used to assess disease activity.

Results: 71 of the 80 investigated patients presented a numerical improvement of DAS28 (CRP) after 12 months (DAS28 (CRP) T0 average (\bar{O}) 4.96, SD 1.2; DAS28 T4 (12 months) \bar{O} 2.6, SD 1.0), 73% of them also improved in the RAMRIS-Score, while 24% demonstrated an increase despite DAS28 improvement and 3% showed equal values. 48% of patients who improved in the DAS28 reached remission. 41% of these patients had an increase in the RAMRIS Erosion-subscore after 12 months. When considering EULAR response criteria (non-response ($n=7$), moderate response ($n=19$), good response ($n=45$)), an increase of erosions was found in 71.4% of non-responders, 52.6% of moderate responders, and 31.1% of good responders after 12 months, all compared to baseline.

Conclusion: Up to 40% of patients in this study demonstrated a progressive erosive disease detected by MRI despite DAS28 improvement or EULAR remission.

B-0519 11:26

Is an abbreviated version of psoriatic arthritis magnetic resonance imaging score (PsAMRIS), PsAMRIS-6, applicable for detection and monitoring of disease-related joint changes?

D.B. Abrar, M. Frenken, P. Sewerin, G. Antoch, C. Schleich; Düsseldorf/DE (dba0501@gmail.com)

Purpose: Aim of this study was to evaluate a simplified version of the OMERACT psoriasis arthritis magnetic resonance imaging score (PsAMRIS) reduced to six joints of the clinically dominant hand in patients with psoriatic arthritis (PsA) before and after treatment escalation to a TNF- α inhibitor using high-resolution, 3-Tesla (T) MRI.

Methods and Materials: 17 patients with PsA according to the CASPAR classification criteria (mean age 53.2, \pm 11.6, minimum/maximum 26/72 years) who qualified for TNF- α inhibitor due to inadequate csDMARD treatment response were prospectively assessed by both baseline investigation and 6 months after escalation using 3T MRI of the clinically dominant hand. Scans were analysed using the OMERACT PsAMRIS and the simplified PsAMRIS-6 (DIP 2-5 + PIP 2 + MCP 2).

Results: We found a strong correlation between OMERACT PsAMRIS and the simplified PsAMRIS-6 at baseline ($r = 0.871$; $p < 0.0001$) and after six months ($r = 0.894$; $p < 0.00001$). Evaluation time was significantly ($p < 0.001$) reduced from 306.2 to 112.4 seconds at baseline and from 321.25 to 120.5 seconds at follow-up.

Conclusion: The simplified PsAMRIS-6 is a time- and resource-saving modification of the OMERACT PsAMRIS. The PsAMRIS-6 is a reliable diagnostic tool for detecting morphological changes and therapy monitoring in PsA.

B-0520 11:34

Diffusion-weighted magnetic resonance imaging in axial spondyloarthritis patients and healthy subjects: inter-MRI reliability and relation to gender, age and inflammation

J.M. Møller¹, M. Østergaard¹, H.S. Thomsen¹, I.J. Sørensen², O.R. Madsen³, S.J. Pedersen², ¹Herlev/DK, ²Glostrup/DK, ³Gentofte/DK (jakob.moeller@regionh.dk)

Purpose: To examine test-retest reliability, age and gender influence on spinal DWI and correlation with presence/absence of bone marrow oedema (BME) in SpA patients and healthy subjects.

Methods and Materials: In a test-retest setup 25 SpA patients (12 males) and 24 healthy subjects (11 males) were MRI examined at 1.5T twice with a mean interval of 6.8 days (SD 0.9). A sagittal STIR and a single-shot echo-planar-imaging DWI sequence were performed on Th8-L5. On the midsagittal STIR-image, the disco-vertebral unit (DVU) was divided into 4 quadrants by a vertical line through the midpoint of the vertebral bodies. BME was scored present/absent per quadrant (total score range 0-4). On ADC maps six 40mm² circular ROIs were measured in each DVU (anteriorly, centrally and posteriorly in each vertebral endplate) and mean ADC ($\mu\text{mm}^2/\text{s}$) was calculated. All measurements were performed on the central sagittal slice. The inter-MRI agreement was measured by intra-class correlation coefficient (ICC). Variation was also tested by unpaired t tests and ANOVA.

Results: Inter-MRI ICCs ranged from 0.66 at T9/T10 to 0.94 at L2/L3. Mean ADC (SD) in females and males was 378(156) and 242(100), $p<0.01$. Mean ADC (SD) in females <50y was 412(149) and >50y 258(114), $p<0.01$. For BME scores 0, 1, and 4 in the midsagittal slice, mean ADC (SD) was 298(136), 296(138), and 828(406), respectively.

Conclusion: The inter-MRI agreement of ADC measurements by DWI sequences in the lower thoracic/lumbar spine was high. ADC depends on age and gender and the degree of inflammation.

B-0521 11:42

Axial spondyloarthritis: dual-energy virtual noncalcium CT for detection of bone marrow oedema in the sacroiliac joints

H. Wu, G. Zhang; Guangzhou/CN (15876530875@163.com)

Purpose: To determine the diagnostic performance of dual-energy CT for the detection of bone marrow (BM) oedema in patients with sacroiliitis of axial spondyloarthritis (axSpA) using a virtual noncalcium (VNCa) technique.

Methods and Materials: Forty-seven consecutive patients with 55 sacroiliitis were studied between April 2016 and December 2017. All patients underwent dual-energy CT and 3-T MRI. Two independent readers visually evaluated all sacroiliac joints for the presence of abnormal BM attenuation on VNCa images using a four-point classification system (0 = no oedema, 3 = severe oedema). MR images served as the reference standard. CT numbers on VNCa images were performed a quantitative analysis.

Results: In the visual analysis of dual-energy VNCa images, the respective sensitivity, specificity, accuracy, positive predictive value, and negative predictive value for detecting BM oedema for reader 1 and reader 2 were 87.3% and 92.7%, 94.1% and 91.2%, 89.9% and 92.1%, 96.0% and 94.4%, 82.1% and 88.6%, respectively. The interobserver agreement was excellent

($\kappa = 0.81$). CT numbers obtained from VNCa images gradually increased from no oedema to severe oedema ($P < 0.001$). ROC analysis of CT numbers revealed an area under the curve of 0.930 and 0.908 for reader 1 and reader 2. A cutoff value of -33.4 HU provided overall sensitivity, specificity and accuracy of 89.9%, 82.9%, and 86.5% for the detection of oedematous sacroiliac joints. **Conclusion:** Visual and ROI-based analyses of dual-energy VNCa images had excellent diagnostic performance for detecting different extents of BM oedema in sacroiliac joints in patients with axSpA.

B-0522 11:50

Muscle and pulmonary involvement in patients with antisynthetase syndrome: two aspects of the same disease or two different conditions? Preliminary results of an MR and HRCT study

A. Fraia¹, E. Zanatta¹, M. Weber², E. Balestro¹, R. Stramare¹, A. Doria¹, C. Giraud¹, E. Quaia¹; ¹Padua/IT, ²Vienna/AT (annasara.fraia@gmail.com)

Purpose: To assess the relationship between muscle and pulmonary involvement in patients with antisynthetase syndrome (ASS) at diagnosis.

Methods and Materials: Treatment-naïve patients with ASS who underwent MR of the upper and lower limb and HRCT (6 months maximal interval) were retrospectively investigated. Fat muscle infiltration (FMI) and muscle oedema (ME) were assessed using the Goutallier classification (grade 0-4) and a four grades score (0=no edema; 1=slight-interfascicular; 2=slight-intrafascicular; 3=moderate-intrafascicular), respectively. In each pulmonary lobe, the extension of ground-glass opacities (GGO) and interstitial thickening (IT) was assessed by the Kazerooni score (0-100%), whereas a modified-Bhalla score was applied for consolidations (Co) (0=absent;1=subsegmental;2=segmental-lobar) and bronchiectasis (Br) (0-3, considering the ratio with vessels). The relationship between muscle involvement and the most frequent pulmonary findings, considering the maximum values (max), was assessed (Spearman coefficient).

Results: Eight patients (56±16 yrs, 7 female) matched the inclusion criteria. All patients showed FMI (mean±SD 1.26±0.82, max=3), and ME (mean±SD 0.79±0.74, max=3). GGO (mean±SD 9.12%±8.28%, max=40%) and IT (mean±SD 6.72%±7.4%, max=30%) were the most severe pulmonary findings affecting all patients. Co (mean±SD 0.02±0.16, max=1) and Br (mean±SD 0.3±0.46, max=1) occurred in one and five patients, respectively. No significant correlations emerged ($r_{FMIvsGGO}=0.301, p=0.469$ and $r_{FMIvsIT}=0.477, p=0.232$), even if a reciprocal trend occurred for ME ($r_{MEvsGGO}=-0.273, p=0.513$ and $r_{MEvsIT}=-0.326, p=0.431$).

Conclusion: It is well-known that lung interstitial disease may precede, concur or follow the onset of myositis and our findings further suggest that pulmonary and muscle involvement are fully independent. Future studies on a larger population are expected to better characterize this evidence and its clinical implications.

Towards a new model for therapy monitoring of PRRT ¹⁷⁷Lu-DOTATATE treatment of liver metastases in PNET patients

O.J. Pettersson, K. Fröss-Baron, J. Crona, A. Sundin; Uppsala/SE (olofjp@gmail.com)

Purpose: Monitoring of cancer treatment by contrast-enhanced CT (CECT), applying RECIST 1.1 criteria, is less suitable for neuroendocrine tumours (NETs) which, when responding, tend to show stable disease and not response. Consequently, new methods are needed to classify those that show stable disease on RECIST. Changes in arterial tumour attenuation and contrast enhancement may earlier reflect therapy effect than decreased tumour diameter.

Methods and Materials: 47 patients with metastatic pancreatic NETs (PNETs) undergoing peptide receptor radiotherapy (PRRT) with ¹⁷⁷Lu-DOTATATE underwent CECT at baseline, mid-treatment (cycles 3-5) and at follow-up, 3 months after the last PRRT cycle. In each patient, the liver metastasis at baseline-CT with the highest arterial attenuation was identified and the fold changes in arterial tumour attenuation, contrast-enhancement and transversal tumour area between CT at baseline, mid-treatment and follow-up were calculated. Data were correlated to best response, time to best response and progression-free survival.

Results: As an internal control, it was first tested and established that the tumour attenuation was not related to the attenuation of the abdominal aorta. The mean arterial attenuation decreased 19 HU from baseline to follow-up ($p < 0.05$) and between mid-treatment and follow-up ($p < 0.05$) as did the transversal tumour area between baseline and follow-up ($p < 0.05$). A 17 HU increase ($p > 0.05$) of the contrast enhancement from baseline to mid-treatment correlated with time to best response ($R^2=0.36, p=0.0003$) and to progression-free survival ($R^2=0.27, p=0.0008$).

Conclusion: Changes in arterial tumour attenuation and contrast enhancement, in addition to lesion size (RECIST 1.1), may add information on therapy response to PRRT.

B-0524 10:38

Early prediction of response of CT textural analysis in unresectable liver metastases of colorectal cancer treated with Cetuximab chemotherapy

E. Raimondi¹, S. Picchia¹, K. Kouvelakis¹, K. Khan¹, D. Cunningham¹, D.-M. Koh², M. Bali¹; ¹London/UK, ²Sutton/UK (dr.edoardo.raimondi@gmail.com)

Purpose: To explore changes of CT texture analysis (CTTA) metrics in unresectable liver metastases (LM) in CRC patients treated with Cetuximab.

Methods and Materials: After IRB approval, baseline and first-assessment (FA) contrast enhanced CT images of 30 CRC-LM patients treated with Cetuximab monotherapy were retrospectively reviewed. Regions of interests were drawn around up to two target hepatic metastases to record volume and area-derived first-order LM CTTA-metrics, and their percentage change from baseline to FA. Results were compared between responders (Complete Response + Partial Response) and non-responders (Stable disease + Progressive disease) defined at best-response according to RECIST 1.1 throughout treatment.

Results: Of the 30 patients, 16 were responders (R) and 14 non-responders (NR). At baseline no differences were observed between R and NR. At FA, in R compared to NR, average area-CTTA metrics showed lower entropy (6.06 vs 6.36; $p=0.006$) and higher uniformity (0.02 vs 0.014; $p=0.002$). R showed percentage change in area-entropy of -2.08% and volume-entropy of -1.89% significantly different ($p < 0.05$) from NR who showed +1.09% area-entropy and +0.91% change in volume-entropy. The percentage changes in area-uniformity and volume-uniformity in R was +8.10% and +8.09% compared with -4.51% and -3.92% in NR ($p > 0.05$).

Conclusion: Differences were observed for area and volume-entropy and uniformity between R and NR. These metrics could be used as predictive imaging biomarker of response. Further studies should confirm these data and identify a threshold for early prediction of response.

B-0525 10:46

CT-texture analysis of liver metastases in PNETs vs NPNETs: correlation with histopathological findings

I. Martini¹, M. Polici¹, M. Zerunian¹, F. Landolfi¹, F. Panzuto¹, M. Rinzi¹, B. Annibale¹, A. Laghi², E. Iannicelli¹; ¹Rome/IT, ²Latina/IT (isabella.martini88@gmail.com)

Purpose: To compare CT-texture analysis and CT features of liver metastases in pancreatic neuroendocrine tumours (PNETs) and in non pancreatic neuroendocrine tumours (NPNETs) according to tumour grading.

Methods and Materials: Contrast-enhanced CT images of liver metastases in 23 patients with PNETs and in 25 patients with NPNETs were analysed with 3D CT texture analysis (parameters evaluated: mean attenuation, standard deviation, skewness, kurtosis, entropy, mean of positive pixels and Tx_sigma) at baseline, arterial and portal phase; delta enhancement of the lesions was also calculated. The CT exams were performed before the beginning of any medical treatment. All patients presented a well differentiated tumour according to WHO classification (G1 and G2). Data were analysed with Kaplan Meyer's test.

Results: Among CT texture analysis, in a comprehensive comparison between PNETs and NPNETs the parameter "Skewness" was significantly higher in NPNETs (p -value<0.05). This data was confirmed in subgroup comparisons evaluated in portal phase (NPNETs G1 vs PNETs G1, NPNETs G2 vs PNETs G2, and NPNETs G1+G2 vs PNETs G1+ G2). The parameter "Mean" was significantly higher in PNETs in comparison to NPNETs (p -value=0,0066). Among CT features the "delta enhancement" was significantly higher (p -value<0.05) in PNETs in two comparisons: PNETs G1 Vs NPNETs G1 and PNET Vs NPNETs.

Conclusion: These results demonstrate significant differences between CT texture parameters of liver metastases in PNETs and NPNETs, and highlight the diversity of the two groups of NETs. These findings, in future, could be used as an "imaging biomarker" to predict therapy response.

B-0526 10:54

Preoperative staging of colorectal liver metastases: is MRI of the liver needed for the surgical planning?

P. Boraschi, F. Donati, F. Pacciardi, R. Cervelli, G. Tarantini, L. Urbani, M. Castagna, D. Caramella, F. Falaschi; *Pisa/IT (p.boraschi@gmail.com)*

Purpose: To evaluate the efficacy of multiparametric 3T MR imaging in the preoperative staging of colorectal liver metastases in patients previously undergone to neoadjuvant chemotherapy (nCT).

Methods and Materials: Fifty-eight patients affected by colorectal cancer and focal liver lesions who received preoperative nCT and underwent parenchymal-sparing liver surgery were retrospectively included. All the patients performed multiphase contrast-enhanced CT (CE-CT) and multiparametric 3T MRI within one month before surgery. At MRI unenhanced (T1- and T2-weighted), DWI with multiple b-values (150, 500, 1000, 1500 sec/mm²) and Gd-EOB-DTPA-enhanced T1-weighted LAVA-flex sequences (including both dynamic and hepato-biliary phase) were obtained. All CT and MR examinations were reviewed by two observers in conference in order to identify and characterize focal liver lesions. CT and MRI findings were related with histopathology, which was our gold standard. Only benign lesions at intraoperative ultrasound remained un-resected and underwent imaging follow-up.

Results: A total of 370 hepatic lesions were detected: 292 metastases (79%) and 78 benign lesions. At MRI 359/370 (97.0%) lesions were detected, whereas at CT 245/370 (66.2%) were identified. The sensitivity, specificity, PPV, NPV of MRI and CT metastases characterization were 98.9%, 97.3%, 99.3%, 96.0%, and 87.6%, 41.3%, 82.7%, 51.0%, respectively. The higher yield of MRI could improve the surgical planning in 37 out of 58 patients (63.8%) compared to CE-CT.

Conclusion: Multiparametric 3T MRI may provide better diagnostic performance than CE-CT for the identification and characterization of colorectal liver metastases before surgery. It can also potentially improve the surgical planning in over 60% of patients.

B-0527 11:02

CT texture analysis to predict response to target therapy of hepatic metastases from colorectal cancer

C. Maglia¹, L. Pusceddu¹, V. Vani², G. Giannetto¹, V. Romano¹, A. Defeudis¹, V. Giannini¹, S. Mazzetti¹, D. Regge¹; *Candiolo/IT, ²Turin/IT (claudiomaglia@hotmail.it)*

Purpose: In colorectal cancer 50% of patients develop liver metastases (mCRC). Chemotherapy and surgery in oligo-metastatic cases are the therapeutic standard, but this strategy is not resolutive in most cases. Differentiating non- and short-term responders from potentially "cured" patients will spare needless toxicity. In this study we aimed to use CT texture analysis (CTTA) to identify specific imaging biomarkers for mCRC, able to predict patient's response to therapy and overall survival (OS).

Methods and Materials: 23 patients with amplified HER2 mCRC received anti-HER2 treatment and underwent CT examination every 8 weeks, until disease progression. CT scans were segmented to extract all liver metastases. CTTA was performed on each segmented area, evaluating 34 parameters. Both mono- and multi-parametric analysis were assessed to identify features most correlated to therapy response. We also performed OS analysis, considering good survivor those with OS>9 months.

Results: In 23 patients we found 124 metastases, 55 of which were classified as responder and 69 as non-responder. Nine parameters reached statistical significance in the mono-parametric analysis (best AUC=0.67, p=0.001), while "cluster prominence" and "sum entropy" predicted OS with AUC equal to 0.78 and 0.83, respectively. In the multivariate regression to predict therapy response, ten parameters were considered (AUC=0.82, sensitivity=82%, specificity=72%). The regression model for OS analysis included two variables ("cluster prominence" and "dissimilarity"), reaching sensitivity and specificity of 83% and 82%, respectively.

Conclusion: CTTA is a potential biomarker to predict treatment response, possibly saving non-responder patients from toxicity. CTTA could give indications on patients OS, without additional tests.

B-0528 11:10

Histopathological growth patterns of colorectal cancer liver metastases: predictive value of MRI morphological features

P.A. Bonaffini¹, A. Salman¹, A. Lazaris¹, G. Zu-Hua¹, P. Metrakos¹, H. Vargas², C. Hoeffel³, B. Gallix¹, C. Reinhold¹; *Montreal, QC/CA, ²New York, NY/US, ³Reims/FR (pa.bonaffini@gmail.com)*

Purpose: To retrospectively assess the ability of MRI morphological features to predict histopathological growth patterns (HGP) of colon cancer liver metastases (CRCLM).

Methods and Materials: Forty-tree patients with 69 CRCLM were evaluated, with the following criteria: MRI <3 months prior to surgery, CRCLM HGP subtype on pathology (desmoplastic/non-desmoplastic); correlation between MRI w.r.t. location/size and final pathology. Desmoplastic HGP has a better

prognosis, potentially benefiting from anti-VEGF-A treatment. Four independent readers, blinded to HGP, evaluated five features per lesion: (1) border regularity (BORDER); (2) peripheral rim presence-thickness (RIM); (3) septa presence-thickness (SEPTA); (4) peri-tumoural liver enhancement (PL); (5) kinetic rim enhancement pattern (KIN RIM ENHANC). A binary score (1 desmoplastic, 0 non-desmoplastic) was given for each parameter and final impression. Descriptive statistics on rater agreement was presented. Univariate logistic regression was used to evaluate the desmoplastic predictability classification.

Results: A total of 44/69 (64%) lesions had a confirmed desmoplastic pattern, 25 non-desmoplastic. The MR morphological classification predicted the desmoplastic pathology outcome for all reviewers with a 70-90% accuracy. All reviewers consistently flagged two features as more important predictors of desmoplastic HGP: PL and KIN RIM ENHANC, with an odds ratio (OR) range of 3-9 each. Two reviewers achieved an OR of 5 using RIM. However, the prediction inference was highly consistent when all five features classified a desmoplastic HGP (OR=8.93;95%CI=1.80-44.3).

Conclusion: Peritumoural liver signal intensity and kinetic rim enhancement pattern, followed by peripheral rim morphology, are the main MRI morphological features that might non-invasively predict CRCLM desmoplastic HGP, improving treatment stratification.

B-0529 11:18

Volumetric vs bidimensional CT assessment of sarcopenia in patients candidate for liver transplantation

P. Barbieri, A. Cina, E. Amodeo, R. Manfredi, G. Marrone; *Rome/IT (pierluigi.barb@gmail.com)*

Purpose: Sarcopenia is a crucial issue in clinical management. Our aim was to evaluate the prognostic value of a CT bidimensional measure (muscular area at inferior border of L3) and a new proposed volumetric evaluation to identify sarcopenia before transplant, their correlation with post LT mortality and to identify optimal threshold for the tridimensional analysis.

Methods and Materials: We evaluated 50 pre-transplant CT scans (venous phase) of adult patients with cirrhosis who underwent LT between 2016 and 2018. We performed both standard bidimensional and volumetric analysis. Images were analyzed with Volume Viewer software (GE Medical Systems). We included a volume from iliac crests to the base of the heart, excluding the visceral content by segmentation. Tridimensional analysis was performed indexing total volume by height squared (cm³/m²).

Results: A Cox proportional regression-model was employed for post-LT survival analysis. A significant difference (p<0.05) was found in population survivability by adopting the lower quartile as cut-off for L3-SMI values, showing thresholds of ≤ 37.9 cm²/m² for women and ≤ 39.4 cm²/m² for men (IHR] 4.3 [95% CI 1.4-13.2], p = 0.01). Furthermore, also tridimensional values reflected a difference in survivability above and below 25th percentile, thus identifying new potential thresholds of ≤583.7 cm³/m² for women and ≤629.9 cm³/m² for men (IHR] 7 [95% CI 2.3-21.6], p = 0.001).

Conclusion: Volumetric measurements appeared to be a reliable predictor in identifying subjects with high post-LT mortality, and thus should be further investigated to evaluate a potential superior prognostic value compared to standard bidimensional analysis.

B-0530 11:26

Prevalence and prognosis of intrahepatic cholangiocarcinoma (ICC) with radiological enhancement patterns that mimic hepatocellular carcinoma (HCC)

R. Muglia, L. Viganò, N. Gennaro, L. Samà, F. Colapietro, G. Torzilli, L. Di Tommaso, M. Colombo, L. Solbiati; *Milan/IT (riccardo.muglia@humanitas.it)*

Purpose: To analyse the radiological enhancement patterns of ICC and their association with prognosis, with particular interest to lesions mimicking HCC.

Methods and Materials: We retrospectively evaluated all consecutive patients affected by ICC undergoing surgery between 2007 and 2017, whereas those with mixed HCC-ICC were excluded. Two expert radiologists reviewed the arterial and portal/late phases of preoperative CT or MRI. Full-nodule hyper-enhancement in arterial phase and hypo-enhancement in portal/late phase was classified as "HCC-like pattern". Imaging of ICCs with HCC-like pattern was reviewed by an additional radiologist blinded to clinical data.

Results: We reviewed imaging of 92 patients (mean age 68 yrs; males 49%, cirrhosis 20%), including multiphase CT in all and MRI in 87 (95%). Sixty-six (71%) tumours showed arterial hyper-enhancement, categorized as full-nodule (12/66, 18%), >25% of nodule (20/66, 30%) and peripheral (34/66, 52%). The remaining ICCs were either iso-enhancing (5%) or hypo-enhancing (24%). Among 12 ICCs with full-nodule arterial enhancement, 4 were hypo-enhancing in portal/late phase (HCC-like pattern), including 1 cirrhotic patient. Overall, 4/94 (4%) ICCs (1/18 cirrhosis, 6%) showed a HCC-like pattern, accounting for misclassification as HCC on imaging review. After a median follow-up of 29 months, 3-year survival was 62%. All patients with HCC-like pattern ICC are alive and disease free (median 64 months). Peripheral rim enhancement was

associated with a worse prognosis (48% versus 70%; $p=0.150$).

Conclusion: ICC can be misdiagnosed as typical HCC in 4% of cases, showing a favourable survival. ICCs with peripheral rim enhancement are associated with the worst prognosis.

B-0531 11:34

The role of dynamic contrast-enhanced MRI analysis of perfusion changes in hepatocellular carcinogenesis

A.M. Elzeneini¹, M.I. Yousef², M.M. Refaat²; ¹Cairo/EG, ²Benha/EG
(dr.elzeneini@gmail.com)

Purpose: To evaluate the functional role of DCE-MRI analysis of perfusion changes in multi-step hepatocarcinogenesis.

Methods and Materials: 53 patients with liver cirrhosis having 87 hepatic lesions (14 DN, 52 de novo HCCs, 16 recurrent HCCs, 2 malignant PV thrombi, 3 periablation hyperemic rims) and 42 patients without cirrhosis (30 positive for viral hepatitis, 12 negative) all underwent 3T multiphase DCE-MRI assessment. Maximum relative enhancement (MRE), area under curve (AUC), relative area under curve (r AUC), wash-in ratio (WIR), wash-out ratio (WOR), time-to-arrival (T₀), and time-to-peak (TTP) semi-quantitative measurements were analysed across groups. Multiphase mean time-%relative enhancement curves were also portrayed.

Results: Comparing perfusion metrics across different pathologies of liver cirrhosis revealed the correlation of haemodynamics with multi-step hepatocarcinogenesis and grades of cirrhosis. Significant performances were highest between DN and HCCs (MRE 0.88, WIR 0.84, WOR 0.78, TTP 0.74, AUC 0.73, T₀ 0.70) compared to those between cirrhotic liver and DN (MRE 0.74, T₀ 0.62). Least performances were between de novo and recurrent HCCs (TTP 0.66, r AUC 0.66, MRE 0.63). Performances between non-cirrhotic and cirrhotic livers (WOR 0.81, TTP 0.80, r AUC 0.63) surpassed those among different grades of cirrhosis (highest was between non-tumoural and tumoural cirrhosis: TTP 0.74, MRE 0.68, WIR 0.65, WOR 0.65).

Conclusion: DCE-MRI haemodynamic metrics promise potential usefulness as non-invasive biomarkers in the assessment of liver cirrhosis, characterization of cirrhotic nodules, and evaluation of multi-step hepatocarcinogenesis.

B-0532 11:42

Is CT-texture analysis an useful instrument to predict aggressive behaviour of intrahepatic cholangiocarcinoma?

A. Fighera, G. Cardano, A. Mazzaro, G. Zamboni, A. Ruzzenente, G. Mansueto; Verona/IT (alessandrofighera@gmail.com)

Purpose: To assess the value of CT-texture analysis in predicting disease aggressiveness of resected intrahepatic cholangiocarcinoma.

Methods and Materials: we analyzed the texture of the main lesion in the preoperative multiphase CT of 28 patients with histologically confirmed intrahepatic cholangiocarcinoma. Texture analysis was performed using LIFEx software on the largest slice of the lesion in each contrast-enhanced phase (baseline, arterial, portal and 8-minute delayed phase). First order texture histogram parameters (skewness, kurtosis, entropy) were related with tumour size, presence of macroscopic vascular invasion, satellite lesions, histologically confirmed metastatic lymphnodes, tumour recurrence and overall survival. Comparison was made with an unpaired t-test. For categorical variables, the median value was used to divide the patients into two groups (long axis: 56,5 mm; overall survival: 10,5 months).

Results: entropy values in the delayed phase were significantly different in lesions <56,5 mm or ≥56,5 mm (3,15±0,08 vs 3,44±0,1; $p=0,037$), and in single or multiple lesions (3,18±0,07 vs 3,50±0,12; $p=0,042$). Although differences for all the other indexes were not statistically significant, we noticed a trend to less uniformity in the portal and delayed phase for lesions with metastatic lymphnodes or overall survival <10,5 months after surgery.

Conclusion: delayed phase entropy is significantly higher in larger lesions and in tumours with satellite lesions. Additionally, lesions with higher entropy show a trend to earlier recurrence/mortality. These could depend on the presence of higher cellularity and necrotic areas in more aggressive tumours, causing inhomogeneous enhancement.

B-0533 11:50

Imaging response assessment and outcomes in hepatocellular carcinoma after stereotactic body radiotherapy: iRECIST as a potential substitute for traditional criteria

F. Vernuccio¹, D. Godfrey², M. Meyer³, H.V. Williamson², D. Niedzwiecki², J. Ronald², M. Palta², D. Marin²; ¹Palermo/IT, ²Durham, NC/US, ³Mannheim, NC/US (federicavernuccio@gmail.com)

Purpose: To investigate whether, compared to traditional criteria, modified RECIST 1.1 for immune-based therapeutics (iRECIST) improves prediction of local tumour control and survival in patients with hepatocellular carcinoma (HCC) treated with stereotactic body radiotherapy (SBRT).

Methods and Materials: 56 HCC lesions (mean size 3.1 cm) treated with SBRT in 45 patients (mean age 67 years) were retrospectively included. Each patient underwent CT/MR exam prior to SBRT and at least once after SBRT. Best overall response was categorized using RECIST 1.1, iRECIST, WHO, mRECIST and EASL criteria. Lesions were then classified as local tumour control (i.e., stable disease, partial or complete response) or local treatment failure (i.e., progressive disease) by each tumour response criteria. Proportions of local tumour control were compared using McNemar's exact test. The 1-year overall survival by each tumour response criteria was estimated using the Kaplan-Meier method.

Results: The local tumour control rate was 85.7% by iRECIST, 80.4% by RECIST 1.1, 67.9% by WHO, 76.8% by mRECIST and 71.4% by EASL. The local tumour control rate by iRECIST was significantly higher compared to WHO, mRECIST, and EASL (p values: 0.0010, 0.0391, 0.0074, respectively). The 1-year survival rate for patients with local tumour control was higher (though not statistically significant) for the iRECIST (86.4% [90% CI, 73.7-93.3]) compared to the other tumour response criteria.

Conclusion: iRECIST may provide more robust interpretation of HCC response after SBRT, yielding improved prediction of local tumour control and 1-year survival rates compared to traditional criteria.

Cranial nerve enhancement in multiple sclerosis (MS) is associated with younger age at onset and more severe disease

L. Haider¹, E.C. Wei-Shin¹, E. Olbert², S. Mangesius³, A. Dal-Bianco¹, F. Leutmezer¹, D. Prayer¹, M. Thurnher¹; ¹Vienna/AT, ²Tulln/AT, ³Innsbruck/AT (l.haider@live.at)

Purpose: The overall frequency of cranial nerve (CN) pathology and its relation to brainstem lesion formation on magnetic resonance imaging (MRI) in multiple sclerosis (MS) is uncertain. Our purpose was to determine the frequency of cranial nerve enhancement (CNE) on MRI scans and its association with structural imaging findings and clinical outcome measurements.

Methods and Materials: We retrospectively analysed 651 MRI scans from 183 randomly selected MS patients. Visually screened and signal intensity measurement-confirmed frequencies of CNE (CN III-XII) on post-contrast T1-weighted MRI images were compared to lesion counts and the MS severity score (MSSS).

Results: CNE was present in 8.2% of the analysed MS patients (oculomotor nerve: 1.1%, trigeminal nerve: 2.7%, abducens nerve: 2.2%, facial and vestibulocochlear nerve: 1.6%, vagal nerve: 0.5%). From these, 13% suffered from repeated episodes of CNE and 27% exhibited a CNE duration of >12 months. Median age at MS onset was lower in patients with CNE, 23 vs. 28, $p=0.049$. MSSS, 5.15 vs. 0.88 ($p=0.019$), median T2 brainstem, 1 vs. 0 ($p=0.041$) and total intracranial contrast enhancing lesion counts, 2 vs. 0 ($p=0.000$), were higher in patients with CNE, compared to age-, disease duration and gender-matched MS patients without CNE.

Conclusion: CNE, present in 8.2%, associates with younger age at MS onset, brainstem lesions and more severe disease course.

B-0535 10:38

Multiple sclerosis: evolution of magnetic resonance imaging diagnostic criteria from McDonald 2001 to McDonald 2017, including MAGNIMS 2016

J.J. Jover Sánchez, J. Díaz Díaz, C. Ferreira Argüelles, P. Núñez Valentín, E. Rodríguez García; Madrid/ES (jjjover90@gmail.com)

Purpose: To compare the efficiency of the diverse McDonald criteria and MAGNIMS criteria after a clinically isolated syndrome (CIS) in patients diagnosed with multiple sclerosis (MS).

Methods and Materials: This is a retrospective, from 2009 to 2018, evaluation of clinical notes and 1.5 T MRI scans of 73 patients diagnosed with relapsing-remitting MS.

Results: Percentage of patients that did not fulfill the different McDonald criteria: 2001 and 2005 criteria-20%, 2010 criteria-11% and only 1% did not fulfill 2017 criteria (1 patient); 11%-MAGNIMS 2016. Diagnosis performing only one MRI study in 3% using McDonald 2001 or 2005 criteria, 32% using 2010 criteria, 47% using MAGNIMS 2016 and 90% using 2017 criteria (47% had dissemination in space demonstrated by MRI and cerebrospinal fluid

oligoclonal bands but not dissemination in time). Time between CIS and diagnosis of MS was also longer using McDonald 2001-2010 and MAGNIMS criteria than 2017 criteria. Percentage of diagnosis within the first 6 months after CIS: 2001 criteria-18%, 2005 criteria-21%, 2010 criteria-37%, MAGNIMS 2016 criteria-48% and 83% applying 2017 criteria. Spine MRI was performed in 47% of CIS showing abnormalities in 85%.

Conclusion: McDonald 2010 criteria improves the diagnosis of MS compare to McDonald 2001-2005 criteria. Inclusion of symptomatic lesions in the DIT criteria, in MAGNIMS 2016, increased the proportion of patients satisfying the MRI diagnostic criteria for MS in the first MRI. 2017 Revised McDonald Criteria seems to allow an earlier diagnosis. Using these new criteria, most patients presenting with a CIS would need only 1 MRI to fulfill the criteria.

B-0536 10:46

Evaluation of signal intensity in dentate nucleus and globus pallidus after repeated administrations of gadolinium in multiple sclerosis patients

I. Zorzenon, M. Ukmar, A. Gennari, A. Zdjelar, L. Bottaro, A. Sartori, A. Dinoto, M.A. Cova; Trieste/IT (irene.zorzenon@gmail.com)

Purpose: The recently described association between repeated administration of gadolinium based contrast agents (GBCAs) and increased signal intensity (SI) in the basal ganglia on T1-weighted unenhanced MR images is subject of debate. Aims of the study were to evaluate in multiple sclerosis (MS) patients SI ratio changes in the dentate nucleus (DN) and globus pallidus (GP) on T1-weighted unenhanced MRI after repeated administrations of GBCAs. We compared patients who received gadobutrol-only with patients who received gadobutrol plus other macrocyclic GBCAs.

Methods and Materials: We retrospectively identified 52 MS patients (37 F, 15 M; age 46.2±11 years) who received repeated administrations of GBCAs (median 5, range 3-12) during follow-up MR scans. Baseline and follow-up T1-weighted image series obtained on the same 1.5T scanner were analysed by two readers; ROI measurements of mean SI were performed and SI ratios (DN-to-pons and GP-to-thalamus) differences were calculated for both groups. Paired samples T-test was used for the statistical analysis (p<0.05).

Results: 27 MS patients received gadobutrol only, 25 patients gadobutrol + other macrocyclic GBCAs (gadoteridol and/or gadoterate meglumine). No changes in DN-to-pons and GP-to-thalamus SI ratios have been observed in both groups (p=0.79, p=0.26). Differences between baseline and follow-up SI ratios did not differ between groups (p=0.08, p=0.37).

Conclusion: Repeated administrations of macrocyclic GBCAs were not associated to SI changes of DN and GP in MS patients, both in gadobutrol only and gadobutrol plus other macrocyclic GBCAs group. Furthermore, SI ratio difference between last and first examinations did not differ between the two groups.

Brain imaging in 43 serologically positive cases of Chikungunya virus infection with neurological complications at our institute during epidemic outbreak

A. Aryan, K. Sethi; New Delhi/IN (abhaykaryan@gmail.com)

Purpose: Brain imaging in 43 serologically positive cases of Chikungunya virus infection with neurological complications at our institute during epidemic outbreak.

Methods and Materials: Retrospective study of 43 seropositive (PCR positive) cases of Chikungunya virus infection who underwent magnetic resonance imaging (MRI) for neurological complications such as altered sensorium, seizure or stroke-like symptoms from July to November, 2016. The two neonates who were included in the study were maternal seropositive cases. MRI brain findings such as T2W-FLAIR signal and diffusion and gradient images were analysed for pattern of involvement.

Results: Patients aged between 5 days to 83 years were included in the study. There were 43 patients, 35 males and 8 females. MRI brain was normal in 13 patients (30%). There were predominantly discrete and confluent supratentorial T2W and FLAIR hyperintense white matter foci in 22 patients (51%) and restricted diffusion was seen in 14 patients (32%). Four patients had infratentorial cerebellar white matter or middle cerebellar peduncle lesions with restricted diffusion. In three paediatric patients including two neonates, pattern of involvement was diffuse white matter changes with restricted diffusion. Haemorrhage in supratentorial white matter was seen in one patient only.

Conclusion: Confluent white matter T2 and FLAIR hyperintensity with restricted diffusion were observed in all the paediatric patients of Chikungunya virus fever with neurological complications. Focal and confluent supratentorial white matter T2 and FLAIR hyperintense foci were seen in adult age group with some showing restricted diffusion.

B-0538 11:02

Regional grey matter atrophy by MR volumetry in early relapsing-remitting multiple sclerosis (RRMS) as a predictor of clinical and motor outcome

E. Kurys-Denis, U. Skrobas, Z. Brudkowska, H. Karakula-Juchnowicz, W. Krupski, R. Maciejewski; Lublin/PL (ekurys@gmail.com)

Purpose: Recent MR studies have shown that in MS not only global and white matter (WM) atrophy, but also selective regional grey matter (GM) atrophy appear. We aimed to identify any specific areas of GM volume changes and investigate their importance in correlation to disease length, number of relapses and clinical motor scores in little known early stage of the disease.

Methods and Materials: We prospectively recruited 60 patients (46 F, 14 M, aged 34.58 +/- 8.03, median age 35) with RRMS at an early clinical stage (median EDSS score of 1.75). All participants were analysed with EDSS score, 9-peg hole test and 25-feet walk test. The length of the disease and the number of relapses were noted. Brain structures volumetry was done using automatic segmentation technique (Volbrain) with 1.5T MR system acquisition.

Results: Decreases of total brain, cerebrum, cerebellum normalised volumes and total WM and both total cerebral and cerebellar WM volumes correlated significantly with the disease length and number of relapses. Only specific sub-cortical GM areas (brainstem, putamen, thalamus, accumbens nucleus) showed significant volume reductions associated with the disease length and the number of relapses. EDSS and clinical motor scores showed significant correlations with the total WM and cerebral WM normalised volumes, as well as with thalamus and amygdala volume decreases.

Conclusion: Only sub-cortical part of the GM decreases in the early stage of RRMS. Thalamus volume decrease, followed by amygdala volume decrease seem to be strongly associated with the outcome of EDSS and clinical motor scores.

B-0539 11:10

Automated volumetric assessment of multiple sclerosis disease burden and activity with artificial neural networks

G. Brugnara, F. Isensee, W. Wick, M. Bendszus, K.H. Maier-Hein, P. Kickingereder; Heidelberg/DE (gianluca.brugnara@med.uni-heidelberg.de)

Purpose: To evaluate the potential of artificial neural networks (ANN) for automated volumetric assessment of multiple sclerosis (MS) disease burden and activity.

Methods and Materials: We used a single-institutional dataset from 334 patients with MS at any disease stage to develop an ANN for automated segmentation of FLAIR and contrast-enhancing (CE) lesions on MRI. Independent testing of the ANN was performed in a single-institutional longitudinal dataset with 82 patients (median number of exams: 3). The performance of the ANN was evaluated by calculating f1 score, positive predictive value (PPV) and sensitivity for the detection of both FLAIR and CE lesions. The f1 score was optimised in the training set and yielded an optimal working point of 14mm3 for CE, and 7mm3 for FLAIR.

Results: The total f1 score for the segmentation of FLAIR lesions was 87% (training set) and 88% (test set). The f1 score for the segmentation of CE lesions was 78% (training set) and 80% (test set). The ANN yielded a sensitivity of 76% (160 TP / 52 FN) and a PPV of 85% (160 TP / 29 FP) for detection of CE lesions in the longitudinal test set, and 82% (4873 TP / 1053 FN) and 95% (4873 TP / 235 FP) for detection of FLAIR lesions in the same cohort.

Conclusion: Our results highlight the capability of ANN for quantitative state-of-the-art assessment of lesion load on MRI and potentially enable a more accurate assessment of disease burden in patients with MS.

Increased ADC values within normal appearing white matter as a predictor of a poor response to interferon beta therapy in patients with multiple sclerosis in the 4-year follow-up

J. Bladowska, A. Zacharzewska-Gondek, A. Koltowska, A. Pokryszko-Dragan, S. Budrewicz, M. Sasiadek; Wroclaw/PL (asia.bladowska@gmail.com)

Purpose: The purpose was to assess the usefulness of apparent diffusion coefficient (ADC) measurements within normal appearing white (NAWM) and grey matters (NAGM) in the prediction of interferon beta (IFN-Beta) treatment response in patients with multiple sclerosis (MS) during 4-year follow-up.

Methods and Materials: Ninety-five patients: 29 with MS, who presented relapse during 4 years of treatment (MS1), 35 MS patients without relapse (MS0) and 31 age and sex matched control subjects (CG) underwent plain MR followed by diffusion weighted imaging (DWI) on a 1.5T MR unit. MR examinations were performed before the treatment with IFN-Beta or during the first year of treatment. In DWI the ADC values were measured in 13 regions of interest within NAWM and NAGM.

Results: MS1 patients showed significantly higher ADC values in frontal and fronto-parietal WM regions (p<0.01) compared to MS0 and CG and additionally in right temporal WM compared to CG. ADC values in both caudate nuclei

were significantly lower in MS0 subjects compared to CG. No other statistically significant differences in ADC values between groups were found.

Conclusion: Measurements of ADC values within NAWM performed in baseline MRI before or during the first year of treatment may be useful in the prediction of treatment response in MS. Increased ADC values in the frontal and fronto-parietal WM regions can predict a poor response to INF-Beta therapy during the 4-year follow-up. Normal ADC values in these regions and decreased ADC values in both caudate nuclei may predict a good response to treatment.

B-0541 11:26

Quantitative brain lesion distributions in MOG-Ab-positive and AQP4-Ab-positive patients: overlaps and differences

L. Yang, H. Li, C. Quan, L. Zhou, D. Geng, Y. Li; *Shanghai/CN*
(mozi001_ren@sina.com)

Purpose: The aim of this study is to quantitatively delineate and compare the brain lesions and their distributions in two subsets of patients with NMOSD phenotype and related disorder: myelin oligodendrocyte glycoprotein antibody positive (MOG-Ab-positive) and aquaporin-4 antibody positive (AQP4-Ab-positive).

Methods and Materials: Fifty-seven and thirty-three clinical MR examinations were performed on fifty-two AQP4-Ab-positive and twenty-eight MOG-Ab-positive patients, respectively. Hyper-intense T2 lesions were segmented manually on each axial FLAIR image and the lesion sizes were calculated. Probabilistic lesion distribution maps were created for each group by averaging the lesion images after normalization to standard space. Lobe-wise and voxel-wise quantitative comparisons of the two distributions were performed.

Results: We found infratentorial and supratentorial brain lesions in both AQP4-Ab-positive and MOG-Ab-positive patients, with high occurrence frequency and large inter-group overlap mainly in deep white matter (WM). In comparison with AQP4 group, the brain lesions of the MOG-Ab-positive patients had larger size, dispersed distribution, and significantly higher probabilities in grey matter (GM) and juxtacortical WM regions prominently in temporal, limbic and parietal lobes.

Conclusion: MOG-Ab-positive and AQP4-Ab-positive group showed similar but quantitatively different brain lesion distribution. These results provide valuable information for imaging-based initial diagnosis and understanding of pathogenesis in the two subsets of patients.

B-0542 11:34

Magnetic resonance imaging findings at optic neuritis of recurrent optic-spinal phenotype, multiple sclerosis in a cohort of Brazilian patients from Rio de Janeiro

A.C. Brandão Nascimento, A.R. Araujo e Araujo, N.S. Meneguette, M. Papais Alvarenga, C.C.F. Vasconcelos, C.A.M. Bento, P.P. Rafful, L.A. Brandao, R.M. Papais Alvarenga; *Rio de Janeiro/BR*
(annachrisbrandao@outlook.com)

Purpose: Optic neuritis may evolve into multiple sclerosis and MRI demonstrates lesions in optic nerves. Objective: to study MRI of optic nerves.

Methods and Materials: Patients with recurrent optic neuritis (ON) with a good recovery and transverse myelitis (TM) were followed from 2000 to 2015, 10 years of disease and EDSS<3, were classified as "benign" with a recurrent optic spinal phenotype multiple sclerosis (OSMS). A prospective population study was performed on 16 patients OSMS. All patients were negative (AQP4)-IgG and negative (MOG)-IgG. Most patients showed brain and spine lesions met MAGNIMS criteria (2016). For lesions on MRI in sequence, STIR with the optic nerves were divided into three segments: intra-orbital (IO) (25 mm: the longest segment and communication between subarachnoid space around the optic nerve that in suprasellar cistern, canalicular (CAN) (9 mm: as through optic canal and prechiasmatic and chiasmatic (CHI) (16 mm: intracranial segment in suprasellar cistern).

Results: 2 (12.5%) patients showed normal optic nerves. Lesions on MRI the optic nerves in 9 (56.25%) patients with lesion unilateral, 5 (31.2%) patients with lesions bilateral, 14 (87.5%) patients with lesion intra-orbital (IO), 7 (43.7%) showed lesion CAN, 14 (87.5%) IO and 1(6.2%) patient showed lesion prechiasmatic. No patient showed contrast enhancement.

Conclusion: Patients with recurrent ON and TM, at least 10 years of disease and low EDSS indicate that optic spinal recurrent phenotype of MS and not a NMO spectrum syndrome. Most patients did not have extensive lesions in optic nerves and visual event good recovery could be classified as a subgroup of MS with a benign course.

B-0543 11:42

Voxel-based analysis of relaxation rates in multiple sclerosis: correlates of cognitive impairment and physical disability

M. Quarantelli, R. Lanzillo, M. Comerci, M. Cassiano, T. Costabile, A. Prinster, R. Megna, V. Brescia Morra, A. Brunetti; *Naples/IT* (quarante@unina.it)

Purpose: Brain tissue relaxation rates have shown significant correlations with clinical data in multiple sclerosis (MS). Aim of this retrospective study was to assess voxelwise the correlation between cortical relaxation rates, obtained by relaxometric segmentation of clinical MRI studies, and both physical and cognitive impairment in MS.

Methods and Materials: R1 and R2 relaxation rate maps and GM maps were calculated using a multiparametric relaxometric segmentation procedure, analysing clinical MRI studies in 241 patients with relapsing-remitting MS. Correlation with EDSS and with the percentage of failed tests at a cognitive test battery (Rao's Brief Repeatable Battery and Stroop test, available in 186 patients) were assessed voxelwise, including age, sex, disease duration and voxel GM content as covariates, using the SPM-based "Biological Parameter Mapping" software package.

Results: Extensive clusters ($p < 0.05$, corrected for familywise error at cluster level) of inverse correlation between both EDSS and cognitive scores and cortical R1, and to a lesser extent R2, values were present, mostly in the perirolandic cortices for EDSS ($p < 0.001$), and in the hippocampi ($p = 0.001$), precuneus ($p < 0.001$), dorsolateral prefrontal cortices ($p < 0.001$) and cingulate ($p = 0.003$) for cognitive scores.

Conclusion: Cortical R1 and R2 values significantly correlate with both physical and cognitive impairment in MS, independent of atrophy, with distinct regional patterns.

B-0544 11:50

Deep grey matter and multiple sclerosis: is there a correlation between MR imaging and disability?

S. Torlone¹, A. Corridore¹, M. Martino², M. Micelli¹, L. Panebianco¹, R. Totaro¹, A. Splendiani¹, C. Masciocchi¹; ¹L'Aquila/IT, ²Rome/IT
(torlone.silvia@gmail.com)

Purpose: To investigate the association between deep grey matter (DGM) lesions and clinical features in relapsing remitting multiple sclerosis (RR-MS) patients in a long-term follow-up.

Methods and Materials: We considered 228 patients with RR-MS, chosen among 460 MS patients of the MS Centre of L'Aquila, with clinical evaluation by EDSS at the onset and during clinical/MRI follow-up. In 45 patients DGM lesions appeared during MRI follow-up. 45 patients without DGM lesions were selected among the 228 RR-SM patients as a control group, according to sex, age, disease duration and EDSS at the onset. In both groups the first and the last MR examination were compared to assess the differences in White Matter (WM) lesion load, cortical lesions frequency and EDSS.

Results: WM lesion load and cortical lesions frequency were significantly higher in the group with DGM lesions compared to control group ($p = 0.005$). Although EDSS scores at the onset were similar for both groups, it was increased in patients with DGM lesions ($p = 0.01$). 7 Patients (15.5%) with DGM lesions developed Secondary Progressive MS (SP-MS) with statistically significant frequency compared to control group ($p = 0.01$).

Conclusion: A strong correlation between the presence of DGM lesions and EDSS, WM lesion load, cortical lesions frequency and development of SP-MS was observed. EDSS increase was noted at the time of DGM lesions appearance and showed a persistent growth in the follow-up. Future research is needed to improve DGM lesions detection in order to confirm their prognostic value and to help the specialist in therapeutic choices.

Dependence of MRI-based size estimates of small invasive breast cancers on patient and tumour characteristics

W. [Sanderink](#), L.J. Strobbe, P. Bult, I. Sechopoulos, N. Karssemeijer, R.M. Mann; *Nijmegen/NL (wendelien.sanderink@radboudumc.nl)*

Purpose: To determine the reliability of MRI tumour size measurements with respect to patient and tumour characteristics in small breast cancers that can be selected for minimal invasive therapy.

Methods and Materials: All consecutive cases of cT1 invasive breast carcinomas that underwent pre-operative MRI, treated in two hospitals between 2005 and 2016, were identified retrospectively from the Dutch cancer registry and cross-correlated with local imaging and pathology databases. Concordance between MRI-based measurements and final pathological size was analysed. In addition, the influence of patient (age, WHO performance status) and tumour (location, histological type, grade, molecular subtype) characteristics on the accuracy of the measurement was analysed using the Student's t test, chi-square and multilinear regression analyses.

Results: Analysis included 354 cT1 invasive carcinomas in 348 patients (age: 55.1±11 years), including 255 ductal carcinomas, 64 lobular carcinomas and 35 other types. MRI and pathology measurements were available for 318 lesions (36 missing). Mean MRI size was 13.1±4.6 mm and pathology size 12.8±7.5 mm (p=0.573). Pathology tumour size was equal or smaller in 208 lesions (65.4%), and larger in 110 lesions (34.6%). Median MRI underestimation was 4 mm, with 35 lesions (10%) underestimated by more than 5 mm. Neither patient characteristics (p≥0.343) nor tumour characteristics (p≥0.208) were predictive of underestimation of tumour size on MRI.

Conclusion: Size measurements of small breast cancers on breast MRI are within 5 mm of pathological size in 90% of patients. However, neither patient nor tumour characteristics predict underestimation, which may hinder patient selection for minimal invasive therapy.

B-0546 10:38

Diagnostic accuracy of magnetic resonance (MRI) to predict axillary lymph node metastases in patients with breast cancer: does neo-adjuvant chemotherapy impact accuracy?

G. [Bansal](#), A. Jaipal; *Cardiff/UK (gjbansal@gmail.com)*

Purpose: The aim of this study was to evaluate the diagnostic accuracy of preoperative breast MRI for axillary lymph node (LN) metastases in two groups of patients with breast cancer. Those who received neo-adjuvant chemotherapy (NAC) prior to surgery were compared to patients, which proceeded straight to surgery (non-NAC).

Methods and Materials: Between 2011 and 2017, 198 patients with primary breast cancer were divided into two groups (NAC and non-NAC). The preoperative MRI results of axilla were compared to postoperative results in both groups. The axillary LN status (number of abnormal LNs, long axis-short axis ratio, loss of fatty hila and cortical thickness) on MRI was recorded. SPSS (ver 21) was used for data analysis and two-sided p less than 0.05 was taken as statistically significant.

Results: There were 112 patients in the non-NAC group and 86 patients in NAC group. Diagnostic accuracy and diagnostic odds ratio (OR) in non-NAC group were 86.3 and 25.9 (95% CI 7.8-86.05) versus 73.8 and 7.2 (95%CI 2.4-16.13) in the NAC group. There was greater correlation between the number of abnormal nodes on MRI and postoperative results in the non-NAC group (p less than 0.001). Long-to-short axis ratio of axillary nodes was not significantly different between metastatic and non-metastatic nodes in the NAC group.

Conclusion: MRI should be used with caution for the assessment of axillary LNs in patients who received NAC prior to surgery. These results underscore the importance of post-NAC biopsy of clipped nodes and limited sentinel node biopsy.

B-0547 10:46

Association between background parenchymal enhancement and tumour response in breast cancer patients receiving neoadjuvant chemotherapy

F. [Petta](#), R. Rella, A.R. Scrofani, E. Bui, M. Rosignuolo, M. Romani, P. Belli, R. Manfredi; *Rome/IT (federicapetta@gmail.com)*

Purpose: To investigate the association between background parenchymal enhancement (BPE) of the contralateral breast on pre-operative breast magnetic resonance imaging (MRI) and response to neoadjuvant chemotherapy (NAC) in breast cancer patients.

Methods and Materials: Two hundreds and twenty-six patients with unilateral invasive breast cancer who underwent breast MRI before and after NAC between 2006 and 2012 were retrospectively analyzed. All images were reviewed by two blinded readers who classified BPE into four categories (1=minimal, 2=mild, 3=moderate, 4=marked) before and after NAC. Cohen's kappa coefficient was calculated to measure the agreement between the two readers. We determined the correlation between BPE and other clinicopathological variables (age, adjuvant therapy, menopausal status, histologic grade, T stage, N stage, histological subtype, molecular subtype, surgical margin status, and mammographic density). Histopathological tumour responses (pathologic complete response, pCR versus non-pCR) were analyzed and a correlation analysis between BPE and tumour response was performed (chi-square test).

Results: Cohen's kappa showed substantial agreement (k=0.64) between readers. BPE was significantly higher in premenopausal patients (P=0.004 for reader 1; P=0.011 for reader 2) and in patients with high mammographic density (P=0.04 and P=0.03 reader 1 and reader 2, respectively). Triple negative tumours were more likely to show low BPE (78%, P<0.0001). The pre-treatment BPE was significantly higher in the pCR group than in the non-pCR group (P=0.0377) while there was no significant difference in BPE changes after NAC between the two groups (P>0.05).

Conclusion: A higher pre-treatment BPE was related to pCR suggesting a possible role in prediction of response.

B-0548 10:54

Association between background parenchymal enhancement in breast MR imaging and outcome of breast cancer patients treated with neoadjuvant chemotherapy

R. Rella, A.R. [Scrofani](#), F. Petta, E. Bui, M. Conti, M. Giuliani, P. Belli, R. Manfredi; *Rome/IT (annarita.scrofani90@gmail.com)*

Purpose: To retrospectively investigate the association between background parenchymal enhancement (BPE) of the contralateral breast in magnetic resonance imaging (MRI) and long-term outcome in breast cancer patients treated with neoadjuvant chemotherapy (NAC).

Methods and Materials: Two hundreds and twenty-two women with invasive breast cancer who underwent breast MRI before and after NAC between 2006 and 2012 were retrospectively analysed. All images were reviewed by two blinded readers, who classified BPE into four categories (1=minimal, 2=mild, 3=moderate, 4=marked) before and after NAC. Patients were grouped according to BPE category (high [moderate or marked] or low [minimal or mild]). Cox regression was used to test associations between BPE, patient and tumour characteristics, recurrence-free survival (RFS) and overall survival (OS).

Results: Median follow-up was 59 months. An event occurred in 83 of 222 patients (37%) for RFS and in 27 of 222 patients (12%) for OS. On multivariate analysis, high BPE on pre-NAC MRI (hazard ratio [HR]=0.0737, P=0.0034) and adjuvant chemotherapy (HR=0.5313, P=0.0484) were associated with better RFS. A greater reduction of BPE on post-NAC MRI (HR=26.6275, P=0.0003), menopausal status (HR=2.8290, P=0.0006) and higher nuclear grade (HR=1.6470, P=0.0262) were independent factors associated with worse RFS. BPE on pre-NAC MRI (P=0.022) and reduction of BPE on post-NAC MRI (P=0.009) were the only significant covariates for overall survival.

Conclusion: Results suggest that BPE in the contralateral breast is significantly associated with long-term outcome in breast cancer patients treated with NAC.

B-0549 11:02

Breast MRI: potential use of unenhanced morpho-functional diagnostic protocols

M. [Nadrjanski](#), Z. Milosevic; *Belgrade/RS (dr.m.nadrjanski@gmail.com)*

Purpose: To test different unenhanced (UE) breast MRI protocols in lesion detection with different b-gradients on diffusion-weighted imaging (DWI) added to unenhanced T2W and T1W series.

Methods and Materials: Sixty patients (N=60) were included in the retrospective analysis (1.5T) with histologically proven lesions: malignant (n1=40) and benign (n2=20) and the detection was evaluated with 4 different UE protocols (P1 - 4) with the blinded data: P1 (T2W-STIR, T2W-TSE, T1W-TSE), P2 (P1 + b50, 850), P3 (P2 + b1000), P4 (P3 + b1200). Upon the completion of the study, the full diagnostic protocol (FDP) was unblinded and

the histologic diagnosis revealed. Performance assessment was performed for all protocols.

Results: The average patient age and tumour size in n1 and n2 were similar (64.3+/-4.4 vs. 64.2+/-4.6; 1.39+/-0.46 cm vs. 1.49+/-0.56, p=0.57). In malignant lesion detection (n1), the following sensitivity (Se) was obtained [%]: P1 67.5, P2 80, P3 92.5, and P4 95. In benign lesions (n2), the following Se was obtained [%]: P1 70, P2 80, P3 90, and P4 95. Se of the FDP was 100% in n1 and n2.

Conclusion: UE protocols with added DWI with high b values (b 1200, b 1000) contributed to high rate of either benign or malignant lesion detection (Se>=90%). All missed lesions on UE were smaller than 1cm. The difference in Se per protocol between benign and malignant lesion detection was not considered significant (p>0.05). Potential use of UE protocols with high b values may contribute to lesion detection.

B-0550 11:10

Non-enhanced breast MRI (DWIBS mammography) for screening women with dense breasts: a feasibility study

T. Uematsu; Shizuoka/JP (t.uematsu@schr.jp)

Purpose: To evaluate clinical feasibility of diffusion-weighted whole-body imaging with background body signal suppression (DWIBS) mammography for detecting mammographically occult breast cancer in women with dense breasts and develop assessment criteria.

Methods and Materials: 330 patients with 360 lesions including 34 mammographically occult breast cancers were examined with DWIBS and short T1 inversion recovery (STIR) with 3 T MRI at b values of 0 and 1,000 s/mm². The scanning time was 8 minutes and 20 seconds. Mammographically occult breast cancers were evaluated for visibility on DWIBS mammography. Each reading time including all 360 lesions was measured, then the signal and morphology on STIR were compared with breast cancers and benign lesions to make the diagnostic criteria. DWIBS mammography was displayed as an inverted grey-scale maximum intensity projection. A lesion detected on DWIBS mammography was considered positive if it showed low signal intensity relative to the background breast parenchyma.

Results: DWIBS mammography sensitivity for mammographically occult breast cancer was 91% and the average reading time was 11 seconds. Low/iso-intensity on STIR (p<0.0001), non-mass lesion type (p<0.026), and ill-defined margin (p<0.0001) were significantly associated with breast cancer.

Conclusion: Unenhanced DWIBS mammography with STIR has high sensitivity for mammographically occult breast cancer with the shorter scanning and faster reading time; this technique might be useful as a supplemental screening modality for women with dense breasts. A unique area of low signal intensity on DWIBS mammography with low/iso-intensity on STIR should be recalled, especially with ill-defined margin.

B-0551 11:18

Rethinking abbreviated breast MRI: potential to skip DCE scans by integrated semi-quantitative T2 and ADC analyses

M. Dietzel, R. Schulz-Wendtland, E. Wenkel, C. Bielowski, T. Bäuerle, M. Uder, S. Ellmann; Erlangen/DE

Purpose: To evaluate, whether T2 signal-intensity mapping (T2-SIM) and apparent-diffusion-coefficient (ADC) analysis could allow skipping dynamic-contrast-enhanced scans (DCE) from an abbreviated breast MRI.

Methods and Materials: 173 consecutive patients with equivocal breast lesions (BI-RADS IV/V) upon mammography and/or ultrasound received histopathological verification and standardized breast MRI. Protocols included DCE, T2-STIR and SPAIR-DWI sequences according to international standards (B values 50, 400, 800s/mm²). Lesions were defined by regions-of-interest (ROI) by two blinded observers independently (R1/R2: intermediate/no experience in breast MRI). ROIs were automatically copied between the different scans (DCE, T2, DWI). The following parameters were used for lesion characterization: DCE: enhancement characteristics normalized to baseline during the early and delayed phases, T2: signal intensity normalized to noise and background (pectoral muscle), and DWI: mean ADC. Univariate analysis (area under the ROC curve: AUC) was followed by multivariate regression analysis. This allowed to compare integrated assessment of ADC+DCE, ADC+T2 and ADC+DCE+T2 (AUC comparison; alpha<5%). Intraclass-correlation-coefficients/ICC were calculated to assess observer-related bias.

Results: There were 176 lesions (malignant: 107/60.8%). Inter-observer variability was "excellent" (ICC: 0.81-0.98). DCE and T2 performed similarly (AUC=0.657/0.669; P=0.9). Both were outperformed by ADC (AUC=0.817; P<0.003). Integration of ADC+DCE and ADC+T2 showed equal results (AUC=0.847/0.833, P=0.45). Use of all three parts of the protocol did not further increase diagnostic performance (ADC+T2+DCE: AUC=0.856; P>0.1).

Conclusion: T2 signal-intensity mapping and ADC analysis could allow skipping DCE scans, thus enabling a shorter, saver and cheaper breast MRI examination. This new aspect of abbreviated breast MRI did not sacrifice diagnostic accuracy and should, therefore, be validated in prospective clinical trials.

B-0552 11:26

Correlate of perfusion parameters on dynamic contrast-enhanced MRI with bimolecular factors and subtypes of breast cancers

L. Liu, B. Yin, W. Peng; Shanghai/CN (llbsy@163.com)

Purpose: This study aimed to investigate the correlation between the parameters of dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) and the molecular biological expression of breast cancers.

Methods and Materials: This prospective study enrolled a total of 67 consecutive patients with breast carcinomas. DCE-MRI were performed in all patients before surgery. Correlations among perfusion parameters and prognostic factors, including tumour size, oestrogen receptor (ER), progesterone receptor (PR), Ki67, human epidermal growth factor receptor 2 (HER-2), epidermal growth factor receptor (EGFR) expression, CK5/6 and subtypes of breast cancer were analysed.

Results: Among these 67 lesions, the mean diameter of tumour was 4.48±1.73cm. There was no correlation between perfusion parameters and lesion size; K^{trans} and Kep were positively correlated with Ki67; the Vp values in negative and positive expression of CK5/6 were statistically different; the mean K^{trans} value of HER-2 overexpression was higher than that of Luminal A and Luminal B; the mean Kep value of HER-2-overexpressing lesions was higher than that of Luminal A. The mean Vp value of triple-negative lesions was higher than that of HER-2 overexpression, Luminal A and Luminal B; the TTP value of HER-2-overexpressing lesions was lower than that of Luminal A and Luminal B; the mean MAX Conc value of triple-negative lesions was higher than that of Luminal B, and the mean MAXslope of HER-2 overexpressing was lower than that of Luminal A and Luminal B.

Conclusion: Perfusion parameters of DCE-MRI can non-invasively evaluate the molecular biological expression and molecular subtype of breast cancer.

B-0553 11:34

Can perilesional oedema detected in MRI be considered as a biomarker for breast cancer? The role of T2-weighted sequences

G. Panzironi, G. Moffa, F. Galati, F. Marzocca, E. Collalunga, F. Pediconi; Rome/IT (g_panzironi@hotmail.com)

Purpose: To evaluate whether the presence of perilesional oedema on T2-weighted sequences in magnetic resonance imaging (MRI) is correlated with worse breast cancer prognosis.

Methods and Materials: From August 2017 to March 2018, 68 patients with biopsy-proven breast cancer underwent breast MRI. All breast MR examinations were performed on 3Tesla scanner using a dedicated protocol, including T2-weighted, DWI and T1-weighted sequences, before and after paramagnetic contrast agent administration (0.2 ml/kg ProHance[®], Bracco). 30 patients (mean age of 52 years) with perilesional oedema, detectable as T2-weighted hyperintensity, were enrolled in this study. The patients were divided into 3 groups characterized by different prognostic phenotypes: Luminal A, Luminal B and triple-negative/basal-like, according to molecular profiling (Ki-67 index, hormone receptor status and Her-2 overexpression). Lesion size measurements and histological evaluations were also performed.

Results: On histological examination, 40 lesions were detected: 33 (82.5%) were invasive ductal carcinoma (IDC) and 7 (17.5%) were invasive lobular carcinoma (ILC). Tumour mean size was 25.8 mm. The prognostic phenotype of patients was: Luminal A in 6 (20%), Luminal B in 16 (53.3%) and triple negative in 8 (26.7%). Perilesional oedema was significantly correlated with breast cancer with worse prognosis (Luminal B and triple negative) rather than with those with better prognosis (Luminal A) (p < 0.0001, Chi-squared test).

Conclusion: Perilesional oedema is significantly associated with more aggressive breast cancer. Therefore, surrounding oedema detected on T2-weighted sequences may be useful and could be considered an additional prognostic indicator in the evaluation of breast cancer.

B-0554 11:42

Diagnostic utility of breast DCE-MRI in patients with diagnosis of atypical ductal hyperplasia after percutaneous biopsy

V. Bertani¹, M. La Grassa², L. Balestrieri³, N. Berger⁴, M. Urbani³, T. Frauenfelder¹, A. Boss⁴, M. Marcon¹; ¹ Udine/IT, ² Pordenone/IT, ³ Aviano/IT, ⁴ Zurich/CH (magda.marcon@usz.ch)

Purpose: To evaluate the diagnostic utility of DCE-MRI in predicting upgrade to malignancy (UM) after a percutaneous biopsy (PB) diagnosis of ADH.

Methods and Materials: In this IRB approved study (January 2016-December 2017) 68 women (median age, 51 years; range 31-73 years) with a PB diagnosis of ADH and subsequently undergoing DCE-MRI at 1.5 T were retrospectively included. PB was performed under stereotactic guidance using 8-11 gauge vacuum-assisted-biopsy (VAB) systems in case of mammography-only findings (40 lesions) or under ultrasound-guidance using 14 gauge core-needle-biopsy (CNB) (28 cases). All cases underwent surgical excision and final histologic diagnosis was recorded. Two radiologists in consensus evaluated: a) maximum diameter (MD) of the lesion in images prior to biopsy b) presence of a MRI-correlation to the lesion. MD and biopsy modality were

compared in cases with/without MRI-correlation as well as with/without UM. Comparison between cases with/without MRI-correlation and UM was also performed. Mann-Whitney U test was used to compare median values and X^2 to compare proportions.

Results: Median MD was 18 mm (IQR 11-30 mm, range 6-63 mm) and 12 mm (IQR 8-20 mm, 6-40 mm) for cases undergoing VAB and CNB, respectively ($p=0.054$). A MRI-correlation was present in 17/40 (42.5%) and in 19/28 (67.8%) which underwent VAB and CNB, respectively ($p=0.081$). 17/68 (25%) had UM: 13/17 (76.5%) low-and intermediate grade DCIS and 4/17 (23.5%) invasive carcinoma. 8/40 (20%) cases after VAB and 9/28(32.1%)cases after CNB had UM ($p=0.272$). All but two cases with UM had a MRI-correlation (88.2%) and both cases without were classified as low-grade DCIS (MD at surgical excision 3 mm).

Conclusion: DCE-MRI can be used to predict UM after a PB diagnosis of ADH and should be used in the lesion assessment to avoid unnecessary surgical procedures.

Usefulness of CAD for diagnostic automated breast US in MRI detected lesions

Y. Kim¹, N. Choi¹, B. Kang², J. Lee², N. Jung¹; ¹Bucheon/KR, ²Seoul/KR (yumikim17@gmail.com)

Purpose: To evaluate the diagnostic performance using CAD for ABUS and to analyse the characteristics of CAD-detected lesions and the causes of false marks.

Methods and Materials: Totally 40 breast cancer patients who underwent diagnostic automated breast ultrasound (ABUS) for detecting multiple suspicious lesions found on MRI were included. We applied the CAD (QVCAD™) to all of the ABUS examinations which were performed after breast MRI. We evaluated the diagnostic accuracy of CAD. Then we analysed the characteristics of CAD-detected lesions and the causes of false-positive, false-negative cases, and false marks.

Results: Of the total 122 suspicious lesions found on MRI of 40 patients, 52 daughter nodules near main breast cancer were excluded, and then 71 lesions were analysed. The sensitivity, specificity, PPV and NPV of CAD for ABUS were 75.5%, 90.9%, 94.9%, and 62.5%, respectively. 81.4% invasive ductal cancer was detected by CAD. 85.3% invasive ductal cancer showing mass (exclude non-mass) was detected by CAD. 90.3% invasive ductal cancer, more than 1-cm mass, was detected by CAD. The mean size of true-positive versus false-negative mass was 2.08±0.85cm versus 1.6±1.28cm. False-positive lesion included a sclerosing adenosis and a usual ductal hyperplasia. Additionally, in total 24 false marks, the most common cause was marginal or subareolar shadowing, then 3 simple cysts, a hematoma, and a skin wart. However, false marks did not create confusion determining proper diagnosis.

Conclusion: Promising detection sensitivity was obtained from the CAD for ABUS on invasive ductal cancer showing mass which is more than 1cm in size.

Multifunctional iron oxide nanoparticle-embedded PVP-HEC microparticles as a drug-eluting embolic material

F. Nurullı¹, G. Bekaroglu², S. Isci², A. Bas², I. Caymaz², I. Yurdaisik², S. Özkanlı², H. Cakiroglu², O. Aras¹; ¹New York, NY/US, ²Istanbul/TR (fuatnurullı@gmail.com)

Purpose: To develop MRI-imageable novel HEC-PVP-magnetic embolic particles intended for transcatheter arterial chemoembolisation and magnetic ablation.

Methods and Materials: MRI-imageable novel HEC-PVP-magnetic embolic microparticles were prepared from iron oxides linked with PVP using a bridging flocculation process and HEC were incorporated (coated) onto the particles to load doxorubicin (DOX).16 rabbits were used in a rabbit renal embolisation model. Sustained release was accomplished with 1 mg of HEC-PVP-magnetic

embolic microparticles containing 16 mcg of DOX. In the chemo-TAE group, embolisation was performed after catheterisation of the renal artery with microcatheters. In the control TAI group, 4 mg DOX alone was injected through the renal artery. Imaging and magnetic ablation were performed after embolisation using a 1.5-T high-field MR scanner equipped with high-performance gradients and fast receiver hardware.

Results: All synthesised particles were calibrated in the 40-500-micron range and were easily injectable through a microcatheter. The particles exhibited no cytotoxicity against hFOB cells ($P > 0.05$). In vivo, the particles were capable of occluding the arteries, and imageable with MRI. In the chemo-TAE group, DOX levels in kidney tissue detected after embolisation were significantly higher than that in the control group ($P < 0.001$). Infarction and necrosis in the renal cortex were observed in the chemo-TAE group and TAE group. The maximum temperature achieved within the rabbit kidney was 48±1°C after 20 min with radiofrequency exposures at 25 kW.

Conclusion: These novel microparticles can be loaded with an anticancer drug to be useful for embolisation therapies with traceability and magnetic ablation properties.

B-0557 10:47

Transarterial radioembolisation with Yttrium90 glass microspheres without temporary or permanent occlusion of the cystic artery appears to be safe in terms of adverse effects

O.M. Topcuoglu, N. Selcuk, B. Sarikaya; Istanbul/TR (omtopcuoglu@gmail.com)

Purpose: To present the results of transarterial radioembolization (TARE) treatment regarding radiation-induced cholecystitis when the cystic artery take off was noted within the vicinity of the treatment zone.

Methods and Materials: Patients with primary or secondary malignant liver tumours treated with TARE, in whom cystic artery was located in the vicinity of the treatment zone on 99-Technetium-MAA angiograms were included in this study. Whole liver dose, tumour dose and healthy injected liver dose, lung dose and if applicable the gallbladder dose were all calculated by using the Medical Internal Radiation Dose (MIRD) formula from SPECT-CT images. Qualitative and quantitative assessment of the gallbladder were performed on SPECT-CT. The observed adverse events were classified according to the National Cancer Institute's Common Terminology Criteria for Adverse Events (CTCAE v5.0).

Results: A total of 34 TARE procedures from 29 patients (18 men and 11 women) with a mean age of 65±13.3 years meeting the inclusion criteria, were involved in the current study. The mean tumour dose, healthy injected liver dose, healthy whole liver dose and gallbladder dose were 204.9±66.8 Gy, 70.5±15.7 Gy, 31.1±12.7 Gy and 96.4±53.4 Gy, respectively. The mean follow-up period was 14±5.2 months. Qualitative assessment revealed gallbladder radioactivity on SPECT-CT in 11 (32.3%) patients with 6 mild and 5 moderate-severe radioactivity. There was no detected grade 2 or 3 adverse events.

Conclusion: TARE treatment might be safely performed without cystic artery intervention when the cystic artery was located within the treatment zone by means of SPECT evaluation.

B-0558 10:55

Post-SIRT ⁹⁰Y-PET/CT showing variable deposition of ⁹⁰Y in various liver tumour types

S. Thoduka¹, S. Mercogliano¹, V. Czernohorsky¹, N. Spahr², J.-H. Schier¹, A. Schenk³, N. Abolmaali¹; ¹Dresden/DE, ²Lübeck/DE, ³Bremen/DE (smita.thoduka@gmail.com)

Purpose: Highly selective uptake of radioactive microspheres is central to effective SIRT. The purpose of our study was to compare the variable selectivity of resin particle deposition, with regard to type of tumour and catheter-position at infusion, in tumour vs. healthy liver tissue as recorded in the post-treatment ⁹⁰Y-PET/CT.

Methods and Materials: All SIRT procedures between 01/2017 and 08/2018 in the treatment of hepatocellular carcinoma (HCC, n=37), cholangiocarcinoma (CCC, n=13) and metastatic colorectal carcinoma (CRC, n=14) with post-treatment ⁹⁰Y-PET/CT were reviewed. Pre-therapeutic gadoxetate late-phase MRI including complete segmentations were registered to post-therapeutic ⁹⁰Y-PET/CTs. The selectivity of ⁹⁰Y-uptake by the hepatic tumours, as classified into low, moderate and high by an expert of nuclear medicine and radiology, was compared with regard to tumour type as well as catheter-position during infusion. Quantitative radioactivity-uptake in liver and malignant tissue was calculated.

Results: 33 out of 64 post-treatment PET/CTs showed highly selective tumour ⁹⁰Y-uptake. A high percentage of HCC (54%) and CCC (69%) compared to CRC metastases (28%) showed highly selective deposition. Selective catheter-positioning employed in the treatment of HCC showed a significant ($p = 0.012$) impact on selective uptake in tumour tissue, whereas catheter-position during the treatment of CCC and CRC showed no significant effect on uptake selectivity.

Conclusion: Our study showed the significance of selective catheter-positioning on achieving highly selective uptake in HCC lesions. CCC lesions were well-targeted even without a selective catheter-position. ⁹⁰Y-microspheres were comparatively less selective for CRC metastases in the liver. This has possible implications in planning catheter-position during SIRT.

B-0559 11:03

Intrahepatic mitomycin C infusion in liver-dominant metastatic breast cancer: factors influencing the outcome

B.M. Aarts¹, E.G. Klompenhouwer¹, R.C. Dresen², A. Laenen², R.G.H. Beets-Tan¹, K. Punie², P. Neven², H. Wildiers², G. Maleux²;
¹Amsterdam/NL, ²Leuven/BE (b.aarts@nki.nl)

Purpose: The aim of this study was to determine the safety and efficacy of Mitomycin C (MMC) infusion in chemo resistant liver dominant metastatic breast cancer patients (LMBC) and to determine factors influencing overall survival.

Methods and Materials: We retrospectively analysed 176 LMBC patients treated with MMC infusion between 2000 and 2017. Local response was measured with CT follow-up by RECIST 1.1 criteria after 1-3 cycles. Toxicities were registered by the CTCae version 5.0. Overall survival (OS) and hepatic progression free survival (hPFS) were evaluated using Kaplan Meier methodology. After univariate analysis, a stepwise forward multivariate (MV) prediction analysis was performed to select independent pre-treatment factors associated with OS.

Results: RECIST evaluation (n=132) showed a partial response rate of 20%, stable disease of 57% and progressive disease in 23%. Toxicity grade 3 and 4 levels were reported in 17.5%. Median PFS was 5.5 months (CI:4.5-6.8) and median OS was 7.8 months (CI:6.1-9.8). Significant independent baseline predictors of worse OS on MV analysis included amount of prior systemic chemotherapy (HR=1.2 CI:1.1-1.3), prior liver ablation (HR=5.9 CI:1.8-19.4), higher liver tumour burden (HR=2.4 CI:1.5-3.7), elevated levels of bilirubin (HR=2.18 CI:1.3-3.8) and ALT (HR=1.5 CI:1.01-2.09).

Conclusion: MMC infusion was safe and effective in LMBC patients. MV analysis showed a worse OS in patients with increased amount of prior systemic chemotherapy, prior liver ablation, higher liver tumour burden and elevated levels of bilirubin and ALT.

B-0560 11:11

Bland embolisation as the sole endovascular treatment for unresectable hepatocellular carcinoma: survival analysis of 230 patients observed for seven years in a single centre

E. Lanza, I. Bolengo, D. Poretta, R. Muglia, R. Ceriani, V. Pedicini; Milan/IT (isabella.bolengo@humanitas.it)

Purpose: To assess the overall survival (OS) of patients with unresectable HCC treated with bland embolisation (BE) after a seven-year observation, comparing it with recent chemoembolisation (TACE) literature; to evaluate OS predictors and test whether a modified TAE (TAE-g) with n-butyl-cyanoacrylate changed the OS or procedural time.

Methods and Materials: This was a retrospective single-centre study of 230 patients (M:F = 181:49; mean age = 73) who underwent 543 treatments: 228 TAE-g (42%), 227 TAE (42%), and 88 TAE (TAE + Lipiodol) (16%). TAE and TAE-g were performed using 40µ or 100µ microparticles. We evaluated previous/concurrent percutaneous ablation (PA), Child-Pugh and BCLC scores and survival time from the first treatment. OS and predictors were assessed using log-rank tests and Cox regression analyses.

Results: Observation time ranged from 0.1 to 86.7 months; 116 (50%) patients died, 8 (3%) were lost to follow-up, 106 (46%) were still alive at the end of the observation. Median OS was 28 months (survival at 1, 2, 3 years = 85%, 59%, 38%). Significant predictors of OS were the total number of embolisations received (p = 0.035) and having a history of PA (p = 0.024). No differences were noted between TAE and TAE-g.

Conclusion: BE performed primarily using small microparticles or secondarily with Lipiodol provided high survival rates in patients with unresectable HCC, higher than that reported by recent TACE trials. The most reliable predictor of survival was PA, followed by the number of endovascular treatments. TAE and TAE-g provided similar results in OS and procedural time.

B-0561 11:19

Safety and efficacy of small versus large drug-eluting bead transarterial chemoembolisation for hepatocellular carcinoma

S.Y. Lee, H.-Y. Ou, C.-Y. Yu, Y.-F. Cheng; Kaohsiung/TW (siehyang418@hotmail.com)

Purpose: To compare the safety and efficacy of 100-300 µm versus 300-500µm drug-eluting bead transarterial chemoembolization (DEB TACE) and to identify predictive factors associated with complete response (CR) in the treatment of hepatocellular carcinoma (HCC).

Methods and Materials: This retrospective cohort study enrolled 234 consecutive patients who underwent TACE using 100-300µm DEB (Group A, n=75) and 300-500µm DEB (Group B, n=159) in a tertiary center between August 2012 and March 2017. The treatment response using modified response evaluation criteria in solid tumours (mRECIST) criteria and adverse events were compared between groups.

Results: A total of 704 HCCs in 234 patients were evaluated and the average index tumour size was 3.8cm. The overall CR of all patients was 40.6%. Multivariate analysis demonstrated that CR was associated with tumour size (P=0.004), location in the liver (P=0.014), lobe involvement (P=0.022) and particle size (P=0.018). The overall CR rates in Groups A and B were 56.0% and 32.7% (P=0.001), respectively. Group A has higher CR than Group B in the subgroup of BCLC B with tumour <3cm (57.9% vs 21.1%; P= 0.020) and subgroup of feeding artery ≥0.9mm (55.2% vs 30.9%; P= 0.014). There were no differences in complication rates between two groups (44.0% vs 47.2%; P=0.531).

Conclusion: TACE with 100-300-µm-sized DEB is associated with better response and similar safety compared with 300-500µm, particularly in patients with BCLC B and tumour size <3cm and feeding artery size ≥0.9mm. These findings may help to select an optimal treatment strategy for HCC.

B-0562 11:27

Alternative routes of intraarterial chemoinfusion for intraocular retinoblastoma

L.S.P. Karanam, S.R. Baddam, S. Honavar, V.R. Palkonda; Hyderabad/IN (drklsp@gmail.com)

Purpose: Intraarterial chemotherapy (IAC) is a proven effective treatment for retinoblastoma. Direct catheterisation of ophthalmic artery (OA) is not always possible in cases of intraarterial chemotherapy for retinoblastoma. We intend to discuss our experience where we used alternative routes of drug delivery other than direct catheterisation of OA with emphasis on its safety and efficacy in globe salvage.

Methods and Materials: 96 eyes underwent 284 sessions of IAC in our institution. In 24 eyes we used alternative routes other than direct OA for drug delivery. We used balloon occlusion technique in 23 sessions, Middle meningeal artery in 32 sessions, middle meningeal artery+OA in 8 sessions, balloon occlusion+OA in 7 sessions for chemoinfusion. Triple-drug regimen with Topotecan + Melfalan + Carboplatin was used in all cases. All the procedures were done under general anesthesia using transfemoral access.

Results: 11 patients of group D and 13 patients of group E (International classification of retinoblastoma classification) underwent IAC using alternative techniques. The technique of ophthalmic artery catheterisation is performed by our trained interventional radiologist team safely in all the sessions. The response of the tumour is graded as complete regression, partial regression and no response. In a follow-up period of 2 years, enucleation was done in 4 patients. Complications were all transient.

Conclusion: From our experience, it shows that when direct OA catheterisation is not possible, alternative techniques as described in our series can be safely and effectively used to salvage the eyes especially in cases of advanced retinoblastoma.

B-0563 11:35

Retrospective analysis of a cohort of patients affected by unresectable HCC treated with SIRT and liver transplant

A. Paladini¹, G.E. Vallati², G. Pizzi², F. Cappelli², D. Beomonte Zobel², E.M. Amodeo², A. Borzelli³; ¹Novara/IT, ²Rome/IT, ³Naples/IT (andreapaladini1988@gmail.com)

Purpose: The aim of our study is to evaluate the radiological and clinical results of SIRT and hepatic transplant on 22 patients (pts) affected by unresectable hepatocarcinoma (HCC). We analysed the role of SIRT as "bridge" or "downstaging" endovascular therapy for pts with intermediate/advanced HCC.

Methods and Materials: We evaluated 274 pts affected by unresectable HCC treated with Yttrium-90 resin microspheres between 2008 and 2016. Average delivered dose was 1.6 GBq (1.5GBq-1.9GBq). 22 pts of this cohort had such a good response to treatment (complete or partial) that they became eligible for hepatic transplant. We followed-up pts after SIRT with CT at 1 month, 3 months and 6 months after therapy, and analysed toxicity of SIRT, staging pts from radiological and clinical point of view.

Results: 8.02% of pts affected by intermediate/advanced HCC had a successful transplant after SIRT and they are still alive. In 4.4% of cases, SIRT had a downstaging effect on pathology. PR, SD and PD based on mRECIST criteria were evaluated in all pts. Moreover, we evaluated free-survival rate of pts transplanted, and we noticed that it was very similar to free survival rate of pts affected from a low-grade HCC which had an hepatic transplant.

Deep learning for automatic detection of fractures on chest CT scans after blunt trauma

L. Yan, X. Chuan, C. Xia, S. Wang, K. Chen; Beijing/CN
(xchen@infervision.com)

Purpose: To evaluate the performance of a deep learning algorithm for automatic detection of rib fractures, scapula fractures and clavicle fractures on chest CT scans after blunt trauma.

Methods and Materials: In this retrospective study, we first collected initial chest CT evaluations of 1675 patients (1122 males and 553 females) with blunt trauma (1434 rib fractures, 145 clavicle fractures, 177 scapula fractures) from three collaborating hospitals. Three board-certified radiologists helped to label the three types of fractures on each CT scan. We developed a modified multi-channel deep learning algorithm based on Single Shot Multi-Box Detector and trained the model on all 1675 cases. To evaluate model performance, a test set of 290 chest CT scans (244 rib fractures, 22 clavicle fractures, 35 scapula fractures) from another two hospitals was collected and labeled by the same three radiologists as for the training set.

Results: We utilized sensitivity [TPs/(TPs+FNs)] and precision [TPs/(TPs+FPs)] to evaluate the algorithm. For the detection of rib fractures, the algorithm's sensitivity was 94.97% with a precision of 55.72%. For scapula fractures, the sensitivity was 88.89% with a precision of 72.73%. For clavicle fractures, the sensitivity was 91.67% with a precision of 84.62%.

Conclusion: Results showed that deep learning could help automatically detect different types of fractures on CT scans with high sensitivity and reasonable precision, especially rib fractures for which missed fractures were not uncommon. We expect such algorithms will improve fracture diagnosis in clinical settings by pre-screening trauma examinations and flagging suspicious cases.

Whole-body MRI based lesion prediction in multiple myeloma

R. Licandro¹, J. Hofmanninger¹, M.-A. Weber², B. Menze³, G. Langs¹;
¹Vienna/AT, ²Rostock/DE, ³Munich/DE (roxane.licandro@meduniwien.ac.at)

Purpose: The earliest possible detection of bone lesions of Multiple Myeloma (MM) patients is critical as a trigger for treatment and a prime marker of the disease's progression. We use predictive machine learning, to identify a localized risk estimator for future lesion emergence based on pre-stage infiltration patterns observed in Magnetic Resonance Imaging data (MRI).

Methods and Materials: T₁ weighted whole-body MRI were acquired from 63 patients over several examination points. We propose a lesion risk predictor to identify early signatures of emerging lesions before they reach thresholds for reporting. The method proposed is based on patch-wise training after patient specific accurate image alignment. A predictive random forest was trained to identify bone locations with high-risk of progression to osteolytic lesions.

Results: The prediction of emerging lesions (not reported in the observed scan, but in the subsequent), achieves a mean Area Under the Curve of 0.7425 (thorax), 0.769 (legs). Additionally, the predictor was able to identify progressing lesions (which are annotated over all examination scans but increase in size) yielding a mean of 0.7607 and 0.7221, respectively, when using a patch size of 10x4x10 voxels.

Conclusion: We propose a local lesion risk predictor for identifying regions in the bone marrow with high risk of disease progression. We showed that the predictor is able to predict future osteolytic lesions and at the same time is able to predict progression of already identified lesions. Our findings indicate hidden imaging markers beyond lesion size, currently used for categorization and risk stratification in MM.

Conclusion: SIRT is a very safe and effective loco-regional endovascular therapy. SIRT has a very important role as downstaging and/or bridge therapy in case of intermediate/advanced HCC. Furthermore, pts transplanted after SIRT have the same free survival rate of pts affected by low-grade HCC that had hepatic transplant.

B-0564 11:43

Yttrium-90 radioembolisation in advanced-stage HCC: does portal vein thrombosis affect survival?

F. Fiore, V. Stoina, F. Somma; Naples/IT (doc.fiore1959@gmail.com)

Purpose: Portal vein thrombosis (PVT) is generally recognized as a prognostic factor in HCC. Our purpose is to assess and compare the survival of patients with and without PVT, after Y-90 trans-arterial radio-embolisation (TARE) of unresectable HCC, unresponsive to other loco-regional treatments.

Methods and Materials: Between November 2005 and November 2012, Y-90 resin-based TARE was performed in 89 patients with unresectable HCC in an IRB-approved prospective protocol. 33/89 patients had PVT, the remaining 56 were either elderly patients, resistant-to-cTACE HCC or underwent TARE as a downstaging therapy. All patients were studied with multi-detector computed tomography (MDCT), angiography, 99m Tc-MAA scintigraphy and liver biopsy. Gastro-duodenal artery was embolised in most cases. Proton-pump inhibitors were administered to prevent gastritis and ulcers. c 2 test with Yates correction and log rank test were used to compare the two proportions and Kaplan-Meier survival curves, respectively.

Results: The average activity administered was 1.7GBq. After the treatment, fever and abdominal pain were found in 25 and 16 patients, respectively. No major side effect was observed. According to mRECIST criteria, partial response or complete response was found in 70% of patient three months after the treatment, and in 90.5% nine months after the treatment. No significant difference Yttrium-90 radioembolisation in advanced-stage HCC: does portal vein thrombosis affect survival? found in survival of patients with PVT compared to those without PVT. A complete regression of PVT was observed in more than half patients.

Conclusion: Portal vein invasion does not affect survival in advanced stage HCC patients undergoing TARE using Y-90 resin-based microspheres. This procedure helps retracting the portal thrombus.

B-0565 11:51

Embolisation of rabbit renal arteries to test feasibility and effects of CT-visible doxorubicin-eluting montmorillonite microparticles

F. Nurili; New York, NY/US (fuatnurili@gmail.com)

Purpose: To develop CT-visible doxorubicin (DOX)-eluting montmorillonite microparticles for transarterial embolisation.

Methods and Materials: DOX-loaded montmorillonite particles were synthesised by adsorption method and dispersed in diatrizoate to enable visualisation on CT and to achieve a sustained drug-release profile. Rabbits were used to determine CT imaging properties and DOX release kinetics. Sustained release of the particles into the kidney was accomplished with 1 mg of montmorillonite containing 39.2 ± 0.14 mcg of DOX. In the transarterial DOX-loaded montmorillonite embolisation group, embolisation was performed following selection of the renal artery. Control groups were use of DOX and montmorillonite particles alone in separate groups. DOX levels in the blood were periodically measured. Kidney tissue was isolated 24 hours after injection and DOX levels in the tissue were measured.

Results: Particles were successfully visualised with CT. Manufactured microparticles were compatible with microcatheters. DOX blood levels in the chemo-embolisation group briefly increased 30 min after embolisation but remained low until 24 hours after embolisation. DOX blood levels in the TAI group rapidly reached a peak more than 30 minutes after injection and then was undetectable at further timepoints. DOX levels in the tissue was significantly higher in the chemo-embolization group compared to the TAI group. Pathology revealed swelling of entire embolised kidney, infarction and necrosis in the renal cortex in the embolisation and chemo-embolisation groups. Vascular injury was observed in only the chemo-embolisation group.

Conclusion: CT-visible DOX-loaded montmorillonite maintained high local concentrations but low blood levels of the anticancer drug, showing promise for transarterial embolisation.

Optimising the dataset for deep learning with x-ray images in musculoskeletal radiology

M.F. **Russe**, N. Kocher, E. Kellner, M. Reiser, F. Bamberg, E. Kotter; Freiburg/DE

Purpose: The datasets for classification tasks in x-ray imaging differ from non-medical tasks due to the standardization of image projections, the grey scale and the similarity in anatomy between the different patients. In this study, the effect of the data split between validation and training data was analyzed for deep learning.

Methods and Materials: A dataset of 1900 anterior-posterior images of the wrist was created. The images were classified for fracture or absence of fracture. A test sample with each 50 fracture/no fracture was separated. The remaining dataset contained 450 images with fractures and 1350 without fractures. The training to validation split changed in 6 steps from 50:50% to 90:10%. An established convulsive neuronal network (CNN), GoogLeNet was used. Image distortion to 256*256 pixels was made, but no further data augmentation was performed. The training of the CNN for each split was performed. All datasets were tested on the separate test sample to avoid data leakage.

Results: The best overall accuracy is 92% with a Cohen's kappa value of 0.84 at the 80/20 ratio. The overall accuracy and Cohen's kappa for each split are 50/50: 81%, κ 0.62; 60/40: 89%, κ 0.78; 70/30: 90%, κ 0.8; 75/25: 91%, κ 0.82; 80/20: 92%, κ 0.84; 90/10: 87%, κ 0.74.

Conclusion: Datasets of x-ray images can be used for the creation of deep learning models with a very good agreement and high accuracy. The ratio of the dataset for training and validation deals a great impact to the result of the performance of the deep learning algorithm.

B-0569 10:54

Predicting the incidence of knee osteoarthritis using deep neural networks: data from the osteoarthritis initiative (OAI) and the multicenter osteoarthritis study (MOST)

Z. **Bertalan**¹, T. Paixao¹, R. Ljuhar¹, D. Ljuhar¹, H.-P. Dimai², S. Nehrer³; ¹Vienna/AT, ²Graz/AT, ³Krems/AT (z.bertalan@imagebiopsy.com)

Purpose: To evaluate the performance of a deep neural network to predict OA incidence.

Methods and Materials: We screened conventional posterior-anterior (PA) knee radiographs of men and women from the Osteoarthritis Initiatives Study (OAI) and Multicenter Osteoarthritis Study (MOST) database for modality and digitalization artifacts, resulting in a total of 2904 images. These were classified as incident or non-incident over the observation period, based on Kellgren & Lawrence scoring (KL>1). This dataset was split into train- (1451), validation- (581) and test- (872) datasets. Class imbalance between incident/non-incident images was approximately 1:4 and was controlled by oversampling the minority class. We trained an 8-layer convolutional neural network to predict OA incidence on these images, with or without clinical data (such as JSW and Kellgren & Lawrence score). As a comparison, we trained a simple dense neural network that utilizes only this clinical data.

Results: A classifier based on radiographs alone achieved an accuracy of 78% on the classification task, with a sensitivity of 67% and a specificity of 81%. In contrast, the CNN trained on the clinical data alone achieved an accuracy of 63%, with a sensitivity of 47% and a specificity of 67%.

Conclusion: This study provides strong evidence that applying deep convolutional neural networks has the potential to predict incidence knee-OA based solely on the information contained in a conventional 2D radiograph before any radiographic signs of the disease. Adding additional clinical data could potentially further increase the prediction of OA.

Automatic MRI-based 3D models of hip cartilage using a 3D U-net-like fully convolutional network for improved morphologic and biochemical analyses

F. **Schmaranzer**¹, R. Helfenstein¹, G. Zeng¹, T. Lerch¹, K. Siebenrock¹, M. Tannast¹, Y.-J. Kim², G. Zheng¹; ¹Bern/CH, ²Massachusetts, MA/US (florian.schmaranzer@insel.ch)

Purpose: The time-consuming and user-dependent post-processing of biochemical cartilage MRI has prevented their widespread use. A time-efficient, fully automated analysis of biochemical 3D images could provide more

straightforward and comprehensive information on cartilage thickness, surface area and volume.

Methods and Materials: IRB-approved study on 25 symptomatic hips undergoing a contrast-enhanced MRI at 3T including a 3D dGEMRIC sequence (0.8 mm³). Development of a fully automated deep learning-based approach for 3D segmentation of hip cartilage models was based on two steps: (1) 3D training data of hip cartilage was provided by one reader (manual 3D analysis); (2) a deep neural network for fully automated cartilage segmentation (automated 3D analysis) and a software for 3D analysis was developed. dGEMRIC index, cartilage thickness, surface area and volume were measured in the four joint quadrants and compared. Mean average surface distance and mean Dice coefficient were calculated.

Results: Regional patterns were comparable for manual/automated 3D methods. Highest dGEMRIC indices were found postero-superiorly (602.1±158.4 ms, 601.8±158.4 ms). Thickest cartilage was found antero-inferiorly (5.3±0.8 mm, 4.3±0.6 mm). Smallest surface area was found antero-inferiorly (134±60 mm², 155±60 mm²). Largest volume was found antero-superiorly (2343±492 mm³, 2294±467 mm³). Mean average surface distance was 0.26±0.13 mm and mean Dice coefficient was 85.7±2.7%.

Conclusion: This validation paves way to large-scale use of this method for fully automatic 3D cartilage segmentation for an improved morphological and biochemical analyses of hip cartilage.

Combined traditional image processing and deep learning approach for automated detection of tears of the anterior cruciate ligament: is it the game changer for AI in musculoskeletal MRI?

V. **Venugopal**, Y. Mallya, V. Jagannatha, V. Mahajan, H. Mahajan; New Delhi/IN (vasanthdrv@gmail.com)

Purpose: We propose a novel ensemble approach of traditional image processing combined with deep learning to detect ACL tear on knee MRI.

Methods and Materials: FSPD knee MRI images of 66 patients (16 normal, 50 with full- or partial-thickness ACL tears) done on a 3.0 Tesla MRI were extracted, the intensity values of MRI images were standardized by histogram matching followed by intensity normalization image pre-processing techniques. Automatic delineation of tibia, femur and bounding box of the ACL bundle was achieved by a three-dimensional CNN implemented in the research version of HealthSuite Insights (Philips HealthTech). A total of 88 features comprising the first-order statistics and texture measures were computed from Gray Level Co-occurrence Matrix (GLCM) and Gray Level Run Length Matrix (GLRLM) of the image volume within the ACL bounding box. Feature subset selection was performed by two-sample t test with statistical significance ($p < 0.05$).

Results: The performance of the deep learning approach for segmentation of femur and tibia is evaluated on 20 randomly selected MRI datasets. The ground truth was created by manual segmentation of femur and tibia by a MSK radiologist. The dice score was 0.91 +/- 0.084. The performance of the predictive model for discrimination of ACL tear was assessed by k-fold cross-validation and the accuracy, sensitivity, and specificity were 89.5%, 93.3%, and 81%, respectively.

Conclusion: The proposed machine learning technique gave good performance in the delineation of knee anatomical structures and detection of ACL tears in the knee MRI.

Ante-mortem chest radiograph retrieval for forensic human identification by deep learning

Y. **Li**¹, X. Yang¹, J. Wang¹, H. Xue¹, W.B. Liang¹, Z.H. Deng¹, J. McNulty², J.C. Lv¹, L. Zhang¹; ¹Chengdu/CN, ²Dublin/IE (291846740@qq.com)

Purpose: Chest radiographs hold potentially high value for forensic comparative radiological identification because of the remarkable number of skeletal features offered by this area and the wide availability of chest radiographs across the population. The purpose of this study was to develop a deep learning retrieval model based on chest radiographs and multi-slice computer tomography (MSCT) chest scans for forensic human identification.

Methods and Materials: Data were retrospectively collected from 1052 clinical patients (aged 20-89 years) who had both posterior-anterior (PA) chest radiographs and MSCT scans to develop the model. Before training, the MSCT scans were pre-processed by three-dimensional volume-rendering technique (VRT) to produce the corresponding two-dimensional PA image of the skeletal elements of the chest; the scapulae and clavicles were removed for each case to address potential positional variations. We use a ranking based criterion for evaluation in a test dataset of 263 clinical patients. Mean reciprocal ranking

(MRR) was also used to assess the model performance.

Results: The model has achieved a top-1 ranking accuracy rate of 78.6%, top-2 of 88.2%; top-5 of 98.1%, and top-10 of 98.9%. The MRR value was 0.869, meaning the relevant target chest radiograph was retrieved at average rank 2.

Conclusion: When the MSCT VRT images are used as the query image, the deep learning network model achieves promising results performance, demonstrating the retrieval ability capable of automated searching the ante-mortem chest radiograph based on the post-mortem VRT images of the chest.

B-0574 11:34

Automatic segmentation of the mandible from CT for 3D virtual surgical planning using a convolutional neural network

B. Qiu, J. Guo, J. Kraeima, R. Borra, M.J.H. Witjes, P.M.A. van Ooijen; Groningen/NL (qjubj1990@163.com)

Purpose: Segmentation of mandibles from CT scans is crucial for 3D surgical virtual planning such as in planned tumour resections. Segmentation of mandibles in CT scans is a challenging task due to metal artefacts and large variation in the shape and size between individuals, i.e. the presence or absence of teeth. To address this challenge, we propose a convolutional neural network approach for mandible segmentation in CT scans by considering the continuum of anatomical structures through different planes.

Methods and Materials: The proposed convolutional neural network adopts the architecture of the U-Net and then combines the resulting 2D segmentation from three different planes (axial, coronal and sagittal) into a 3D segmentation. We used 11 patient CT scans, reconstructed with a kernel of Br64 or I70h(s). The data set is randomly split into the training, validation and the test set, each with eight, two and one cases, respectively. Manual mandible segmentation performed by a single trained researcher is taken as the gold standard.

Results: We evaluated the performance of our CNN approach by comparing to that from the gold standard and achieved an average dice coefficient of 88.15% and an average root mean square value of 0.4115 mm by randomly repeating the aforementioned data split procedure four times.

Conclusion: An end-to-end approach for automatic segmentation of the mandible from CT scans is proposed. Experimental results demonstrate the effectiveness of the proposed approach in mandible segmentation and its potential employment in 3D virtual planning of mandibular treatment planning.

18F-FDG-PET/CT-based radiogenomic tumour decoding and phenotyping of non-small cell lung cancer

M. Chodyla, A. Demircioglu, J. Haubold, S. Bogner, K. Herrmann, F. Nensa, L. Umütlu; Essen/DE (Michal-Kamil.Chodyla@uk-essen.de)

Purpose: The aim of this study was to assess the potential of multiparametric 18F-FDG PET/CT imaging accelerated with machine learning and radiomic algorithms to predict the somatic mutational status as well as N- and M-stage in patients with untreated non-small cell lung cancer.

Methods and Materials: 85 patients (mean age 65.85) with histopathological confirmation of primary NSCLC were enrolled in this trial and underwent a whole-body 18F-FDG PET/CT examination. After segmentation of the primary cancer, 3569 textural as well as shape features were extracted from each volume. T-test, F-test, chi-square and randomized logistic regression were used for feature selection. Statistical modeling was performed using Random Forests, Logistic Regression as well as Support Vector Machines. A repeated 5-fold cross-validation was employed for internal validation.

Results: Prediction of the somatic mutational status and N-/M-stage obtained an AUC of 0.58 for prediction of KRAS, 0.64 for PDL1, 0.59 for tp53, respectively. Prediction of M-stage was superior when compared to N-stage, yielding an AUC of 0.73 versus 0.62. In all cases Random Forests performed best, while no single feature selection method stood out.

Conclusion: Radiogenomic analysis of 18f-FDG PET/CT datasets facilitated only insufficient prediction of the somatic mutational status and N- and M-stage in patients with NSCLC, with M-stage showing best predictive values, thus not serving as a template for non-invasive tumor phenotyping using wide feature vectors extracted from PET/CT data. More advanced methods using deep learning, which promise better predictive performance, should be investigated for a larger patient collective in the future.

B-0576 11:50

Comparison of consistency of nodule detection in repeated chest PA X-ray images between radiologists and deep learning model

C. Wu, S. Lee, J. Seo, S. Lee, H. Lee, H. Hwang, Y. Cho, N. Kim; Seoul/KR (njmu_wcj@163.com)

Purpose: To compare nodule detection ability of repeated chest PA from same patient acquired within one week between expert radiologists and deep learning model.

Methods and Materials: Totally 260 pairs of repeated chest PAs (116 chest PAs with 128 nodules and 144 chest PAs without nodule, which were confirmed by their chest CT) within 7 days were enrolled in this study. A deep

learning model (DLM) using the YOLO v2, fine-tuned with a pre-trained model (DenseNet201), and two board-certificated chest radiologists (R1, R2 with 14 and 13 years' experience) reviewed these chest PAs. The sensitivity, specificity and accuracy were calculated and compared with a nodule-based analysis. Reading time was recorded. The intra- and inter-reader consistencies were evaluated by Cohen's kappa.

Results: The sensitivity, specificity, and accuracy of R1 are 0.926, 0.798, and 0.854. While for R2, they are 0.875, 0.831, and 0.850. For the DLM, they are 0.779, 0.866, and 0.827. The Cohen's kappa coefficient of R1, R2 and DLM between repeated chest PAs is 0.578, 0.629, and 0.600. The inter-reader consistency of R1 vs R2, R1 vs DLM and R2 vs DLM is 0.640, 0.501, and 0.488. The average reading time of each case is 18.14 seconds for R1 and 11.66 seconds for R2. While the detection time of DLM is about 0.03 seconds per case.

Conclusion: Our DLM has the comparable detection ability with expert radiologists with higher specificity, lower sensitivity. Consistency of nodule detection in repeated chest PAs should be improved for application in routine clinical practice.

Dynamic magnetic resonance imaging as an outcome predictor for lung-volume reduction surgery in patients with severe emphysema

K. Martini¹, C. Caviezel¹, D. Schneider¹, G. Milanese², I. Schmitt-Opitz¹, W. Weder¹, T. Frauenfelder¹; ¹Zurich/CH, ²Parma/IT (katharina.martini@usz.ch)

Purpose: We hypothesize a significant correlation between preoperative dynamic MRI and postoperative outcomes measured by pulmonary function tests.

Methods and Materials: Dynamic MRI was performed 1 day before and 3 months after lung volume reduction surgery (LVRS). Quantitative measurements were performed on sagittal planes: lung height, anteroposterior diameter, hemidiaphragm height and area as well as perimeter. Additionally, dynamic changes in hemidiaphragmatic area and height were measured. Parameters were normalized by patients' height. Pulmonary function test pre-LVRS and post-LVRS was performed. The cut-off value for treatment benefit was defined as a 30% increase in forced expiratory volume in 1s.

Results: Thirty-nine consecutive patients were included. On expiration, lung area on both sides (Pright=0.001 and Pleft=0.016) and anteroposterior diameter of the right lung (Pright=0.003) improved post-LVRS. Dynamic measurements showed differences pre- and post-LVRS on the right lung but not on the left lung (Pright<0.001 and Pleft=0.090). There were no significant changes in lung height for both sides, in hemidiaphragmatic height on the right as well as diaphragmatic area pre- and post-LVRS (P>0.05). Except for hemidiaphragmatic height on the left lung (P=0.039), no significant differences were found on inspiration. Considering the 30% cut-off for treatment benefit, the receiver operating curve analysis indicated a height-normalized expiratory lung area $\geq 35.793\text{mm}^2$ as the most sensitive preoperative outcome predictor (sensitivity=86%; specificity=61%).

Conclusion: Preoperative dynamic MRI can be used as an additional outcome predictor for patient selection in LVRS. A height-normalized total lung area in expiration $\geq 35.793\text{mm}^2$ correlates with a 30% increase in forced expiratory volume in 1s.

B-0578 10:38

Quantitative assessment of the relationship between spatial distribution of emphysema and pulmonary function in COPD patients by an automatic analysis software

Q. Yu¹, X. Quan¹, X. Lu²; ¹Guangzhou/CN, ²Shenyang/CN (liudehuayujing@163.com)

Purpose: To investigate the relationship between spatial distribution of emphysema and pulmonary function in patients with COPD by an automatic analysis software.

Methods and Materials: Chest MSCT (end-inspiration) was performed in 119 cases COPD patients (> 40 years old). For the quantitative assessment, the percentage of low attenuation areas ($\leq 950\text{HU}$) were automatically calculated for

each lobe by COPD analysis software (Philips Healthcare). According to the pulmonary emphysema heterogeneity index, the patients were divided into no-emphysema group (LAA% \leq 1%) and emphysema group (LAA% $>$ 1%), and the latter was divided into predominantly upper-lobe subgroup and predominantly lower-lobe subgroup by the formula $[HI=(\%LAA_{upper}-\%LAA_{lower}) / (\%LAA_{upper}+\%LAA_{lower})]$. The differences of pulmonary function parameters which include PFT (FVC%, FEV1%, FEV1/FVC), IOS (Z5, X5, R5%, R20%, Fres), DLco (DLco%) between the 2 groups and the 2 subgroups were compared.

Results: Compared with no-emphysema group, PFT and DLco% of emphysema group were higher, while IOS values were lower, and the difference between which were statistically significant ($z=-4.353\sim-2.088$, all $P<0.05$). Comparing the two subgroups of emphysema group, FEV1%, FEV1/FVC of the predominantly lower-lobe subgroup were slightly lower, while FVC%, IOS, DLco% were slightly higher, and the differences of all lung function indicators between the 2 subgroups were not statistically significant ($z=-1.948\sim-0.284$, all $P>0.05$).

Conclusion: COPD software can be used to quantitative analysis of emphysema spatial distribution, which has an effect on pulmonary function. There is no significant difference in lung function between predominantly upper-lobe and predominantly lower-lobe in COPD patients.

B-0579 10:46

Inspiratory/expiratory xenon-enhanced CT with 3D motion analysis: utility for pulmonary functional loss assessment and clinical stage classification of COPD

Y. Ohno¹, Y. Fujisawa², N. Sugihara², Y. Kishida¹, S. Seki¹, T. Yoshikawa¹, H. Koyama³, T. Murakami¹; ¹Kobe/JP, ²Otawara/JP, ³Osaka/JP (yosirad@kobe-u.ac.jp)

Purpose: To evaluate the utility of 3D lung motion assessment on inspiratory/expiratory xenon-enhanced area-detector CT (Xe-ADCT) for pulmonary functional loss assessment and clinical stage evaluation of COPD.

Methods and Materials: 28 consecutive patients with and without COPD underwent inspiratory/expiratory Xe-ADCT examinations as well as pulmonary function tests. Then, all patients were classified by GOLD classification as follows: 'Without COPD', 'Mild COPD', 'Moderate COPD' and 'Severe or Very Severe COPD'. In each subject, xenon ventilation maps such as wash-in (WI), wash-out (WO) and ventilation ratio (VR) maps as well as 3D motion magnitude maps at X-, Y- and Z-axes as well as expansion rate (ER) map were generated by pixel-by-pixel analyses. Then, each regional index was assessed by ROI measurements, and each final value was determined as averaged value. To determine the relationship between Xe- and 3D motion-based indexes, Pearson's correlations were performed. Then, step-wise regression analyses were performed between all indexes and %FEV₁. Finally, discrimination accuracies were performed among all indexes, and combined method by McNema's test.

Results: WO had significant and correlations with all motion magnitudes (-0.53 \leq r \leq -0.39, $p<0.05$), although VR had significant correlations with same factors and ER (0.37 \leq r \leq 0.49, $p<0.05$). %FEV₁ was significantly affected by ER as 1st step and VR as 2nd step ($r^2=0.63$, $p=0.0003$). Moreover, discrimination accuracy of combined method (75 [21/28]%) was significantly higher than that of xenon ventilation-based indexes (53.6 [15/28]%, $p=0.03$).

Conclusion: 3D motion assessment is useful for pulmonary functional loss and clinical stage classification of COPD, when applied with inspiratory/expiratory Xe-ADCT.

CT measurements of expiratory central airway collapse in COPD patients with suspected tracheobronchomalacia: comparison between transverse and MPR images

D.M. Tridante¹, B.H. Heidinger², D.C. DaBreo³, A.A. Bankier¹, D. Litmanovich¹; ¹Boston, MA/US, ²Vienna/AT, ³Ottawa, ON/CA (dani.tridante@gmail.com)

Purpose: To compare two approaches for measuring the trachea and main bronchi in COPD patients with suspected tracheobronchomalacia (TBM) on CT examinations.

Methods and Materials: 97 COPD patients underwent CT imaging with a dedicated airway protocol acquired at inspiration and during dynamic expiration. Transverse images and images perpendicular to the airways' long axis (MPR) were reconstructed. Cross-sectional areas (CSA) were measured in inspiration and expiration at three anatomical levels: trachea, right (RMB) and left (LMB) main bronchus. Decrease of CSA from inspiration to expiration was calculated. Paired t tests and a McNemar test were used for statistical comparison.

Results: Mean CSAs were significantly smaller on MPR images than on transverse images at both inspiration and expiration for the trachea (insp: 250 \pm 61 vs 282 \pm 66, $p=.001$; exp: 92 \pm 52 vs 116 \pm 66, $p=.005$), RMB (insp: 164 \pm 39 vs 210 \pm 47, $p=.001$; exp: 52 \pm 33 vs 71 \pm 43, $p=.001$) and LMB (insp: 133 \pm 31 vs 179 \pm 43, $p=.001$; exp: 50 \pm 25 vs 66 \pm 37, $p=.001$). Mean tracheal collapsibility was significantly greater on MPR than on transverse images (63 \pm 19% vs 59 \pm 20%, $p=.001$). However, for both RMB and LMB, bronchial collapsibility was not significantly different between transverse and MPR (RMB: 61 \pm 26% vs. 62 \pm 25%, $p=.616$; LMB: 61 \pm 26% vs. 61 \pm 21%, $p=.821$). Using a threshold of \geq 80% collapse for TBM diagnosis, more patients were classified with tracheomalacia on MPR than on transverse images without reaching statistical significance (11 vs. 18 patients; 11% vs 19%, $p=.174$).

Conclusion: Using tracheal measurements from MPR rather than from transverse images increased tracheal collapsibility and, therefore, the number of patients with tracheomalacia.

B-0581 11:02

Efficacy of model-based iterative reconstruction in cystic fibrosis assessment on computed tomography

S. Lin, M. Lin, K. Lau; Melbourne/AU (Sandraxiaolin@gmail.com)

Purpose: Cystic fibrosis (CF) is a common life-shortening genetic disease predominantly affecting young adults. Accurate radiological assessment of pulmonary disease is vital for disease surveillance and predicting exacerbations, one of the leading causes of morbidity and mortality. We evaluated the efficacy of model based iterative reconstruction (MBIR) constructed non-enhanced ultra-low dose CT chest (ULD-CT) to evaluate CF pathology.

Methods and Materials: We compared ULD-CT with chest x-ray and standard adaptive statistical iterative reconstructed (ASIR) non-enhanced low-dose CT (LD-CT). Effective radiation dose was calculated from the recorded dose-length product (DLP) values and compared between the two CT methods. We compared identification of pathology between ULD-CT and chest x-ray. We hypothesized that ULD-CT would be superior to chest x-ray in identification of CF pathology at lower doses than LD-CT.

Results: The mean effective radiation dose of ULD-CT was 0.073 mSv, comparable to one chest x-ray which was a 94% reduction compared to LD-CT. Compared to chest x-ray, ULD-CT detected on average, 2.3 more regions of bronchiectasis per study and better delineated varicose and cystic forms of bronchiectasis ($p<0.0001$). ULD-CT identified four times more mucous plugging than chest x-ray ($p<0.000001$) and twice the amount of consolidation ($p=0.0002$).

Conclusion: ULD-CT is superior to chest x-ray in quantifying CF disease and achieves remarkable radiation doses significantly lower than LD-CT, comparable to one chest radiograph. Our results suggest that MBIR constructed ULD-CT is an effective imaging modality for CF surveillance, with potential applications in other disease settings.

B-0582 11:10

Association between small pulmonary vascular area and mild airflow limitation in healthy smokers

H. Jo, M. Park; Jinju/KR (inthepresent@hanmail.net)

Purpose: The cross-sectional area (CSA) of small pulmonary vessels can be useful markers to assess early changes of pulmonary vascular alteration in smokers before parenchymal destruction. We investigated the relationship between mild airflow limitation and small pulmonary vascular area in healthy male smokers.

Methods and Materials: We enrolled 90 healthy male smokers without COPD from January 2016 to September 2017. All smokers underwent chest computed tomography (CT) and pulmonary function test. We excluded the smokers who had pulmonary disease, cardiovascular disease, or cancer. We measured the small pulmonary vessel area by chest CT. Furthermore, we calculated the percentage of total CSA of less than 5 mm² divided by the total lung area (%CSA < 5). We evaluated the correlations of %CSA < 5, pulmonary function, and the other clinical variables.

Results: The %CSA < 5 was significantly correlated with FEV1/FVC ($r = 0.413$, $p < 0.0001$), whereas this was not significantly correlated with FVC and BMI. The pack-years was significantly correlated with FEV1 ($r = 0.401$, $p < 0.001$), and %CSA < 5 ($r = -0.548$, $p < 0.001$).

Conclusion: The small pulmonary vasoconstriction was associated with the amount of smoking and mild airflow impairment in the healthy smoker before lung parenchymal destruction.

B-0583 11:18

Cystic-fibrosis-related lung disease: correlation of HR-CT lung morphology and regional lung function measured by electrical impedance tomography

U.G. Mueller-Lisse¹, S. Krueger-Ziolek², B. Gong², H.A. Zimmermann¹, K. Moeller²; ¹Munich/DE, ²Villingen-Schwenningen/DE (ullrich.mueller-lisse@med.uni-muenchen.de)

Purpose: Electrical impedance tomography (EIT) investigates regional lung function. We studied the suitability of EIT to assess the severity of cystic-fibrosis- (CF-) related lung disease when correlated with high-resolution-computed-tomography- (HR-CT-) scoring results.

Methods and Materials: With ethics-committee approval, 10 CF-patients (3 female, 7 male, age 35.2±8.4 years, weight 63.9±13.0 kg, height 177.0±10.0 cm, mean±SD) were prospectively enrolled in EIT-measurements during both normal tidal breathing and a forced-vital-capacity- (FVC-) manoeuvre, to determine regional impedance-changes within the lung relating to FVC and forced expiratory volume in one second (Δ IFVC and Δ IFEV1). EIT data were collected both at the 3rd and 5th intercostal space (ICS), with a frame rate of 30 Hz. Pulsatile EIT-signal-components were excluded with a low-pass Butterworth-filter. Lung-areas were defined by pixel-values >20% of the maximum regression coefficient within the functional EIT-image resulting from linear-regression-fitting. Within each thorax-section, median regional Δ IFEV1/ Δ IFVC was calculated and correlated with the mean "Total Brody Score" (TBS) deriving from independent retrospective evaluations by two radiologists of available HR-CT-scans.

Results: Mean HR-CT TBS-values of CF-patients showed high linear correlation ($r^2=0.8992$) with EIT-derived median regional Δ IFEV1/ Δ IFVC obtained within the 5th ICS, and lower linear correlation ($r^2=0.6872$) with EIT-derived median regional Δ IFEV1/ Δ IFVC obtained within the 3rd ICS, respectively.

Conclusion: Results imply that EIT is suitable to assess the severity of CF-related lung disease. Since HR-CT-based TBS comprises the whole lung, differences in correlations are most likely based on respective lung volumes captured by EIT at different thorax-sections.

B-0584 11:26

Predictive model of lung severity in children with cystic fibrosis using Brasfield and Chrispin-Norman scoring systems

I. Yasvily, N. Rohovyk, O. Marushchak, M. Rohovyk; Lviv/UA (flos.veris@gmail.com)

Purpose: Considering the fact that chest radiography for lung disease is one of the methods used worldwide for the assessment of cystic fibrosis (CF), we propose a modified approach in retrospective analysis and comparison in dynamics the most commonly used scale systems - Brasfield and Chrispin-Norman. The aim of this study was to build a regression model to predict the lung damage severity using Brasfield and Chrispin-Norman scoring systems by evaluation of chest radiographs in children with CF.

Methods and Materials: 156 chest radiographs from 51 CF children were taken for the retrospective analysis that consisted of a descriptive part and predicting models. We assigned a unique ID to every patient and also included such features as gender, age when the test was taken, number of tests, scores due to Brasfield and Chrispin-Norman scoring systems.

Results: Applying constructed chart to patients' data we detected a correlation between two scoring systems, for example, 2.5 in Brasfield scoring system relates to 3 points in Chrispin-Norman system and 11-18 points in Brasfield system mostly relate to 8-10 points in Chrispin-Norman system. Taking scores of the patient with the ID 38 as an example, we can present a model of linear regression to predict the next possible index in different scale systems.

Conclusion: Analysing scores in both Chrispin-Norman and Brasfield scoring systems, we present a regression model to predict a lung severity in CF children (next possible score due to general tendency).

B-0585 11:34

MRI-derived regional flow-volume loop parameters detect early stage chronic lung allograft dysfunction

T. Moheralsady, A. Voskrebenezv, M. Greer, L. Becker, T. Kaireit, T. Welte, F. Wacker, J. Gottlieb, J. Vogel-Claussen; Hannover/DE (moheralsady.tawfik@mh-hannover.de)

Purpose: Chronic lung allograft dysfunction (CLAD) is a major cause for poor long-term survival rates after lung transplantation (LTx). The goal of this study is to examine whether early stages of CLAD could be detected using MRI-derived parameters of regional flow-volume dynamics.

Methods and Materials: Sixty-two lung transplantation recipients were included in the study, 29 of which had been diagnosed with CLAD at various stages based on pulmonary function testing. MRI datasets were acquired at 1.5T using a spoiled gradient echo sequence. The datasets were preprocessed and analyzed according to the phase resolved functional lung MRI technique (PREFUL-MRI), resulting in fractional ventilation (FV) maps and regional flow-

volume loops (rFVL). Correlation coefficients between rFVL of each lung voxel and the mean rFVL of a healthy region of interest were estimated. The following parameters were calculated: 1) Median and interquartile range of rFVL correlation coefficients, rFVL-CC and rFVL-CC-IQR respectively. 2) FV-based and rFVL-based ventilation defect percentage (FV-VDP and rFVL-CC-VDP).

Results: The following rFVL-based parameters discriminated between the presence or absence of early CLAD: rFVL-CC, rFVL-CC-IQR and rFVL-CC-VDP ($p<0.003$). In accordance with a previous study, FV-VDP could only discriminate between no CLAD and advanced CLAD ($p<0.0001$).

Conclusion: Using the free-breathing, contrast media-free PREFUL-MRI technique, parameters of regional ventilation dynamics and heterogeneity have been shown to be sensitive for the detection of early CLAD.

Author Disclosures:

J. Vogel-Claussen: Research/Grant Support; This work was supported by a grant from the German Federal Ministry of Education and Research (IFB-Tx, reference number 01EO1302) and the German Center for Lung Research (DZL).

Dose reduction in CT emphysema densitometry enabled by iterative reconstruction and post-scan noise reduction: a phantom study

H.J. Wisselink, G. Pelgrim, M. Rook, M. Oudkerk, R. Vliegenthart; Groningen/NL

Purpose: The aim of this study is to determine the minimum radiation dose required for acceptable image quality for CT emphysema densitometry, using different scan parameters and noise suppression techniques in third-generation dual-source CT.

Methods and Materials: The COPDGene phantom was scanned with 16 scan setups (CTDIvol 0.035-10.68 mGy), using CT Force (Siemens Healthineers, Germany) with different kV and mAs settings. Images were reconstructed at 1.0/0.7 mm slice thickness/increment, with three kernels (one soft, two hard), filtered back-projection and three grades of third-generation iterative reconstruction (IR, ADMIRE). Additionally, stand-alone noise suppression software was applied (PixelShine, Algomedica, USA). Outcomes were the overlap in area of the normalized CT density histograms of the emphysema and air inserts, and the radiation dose required for maximum 4.3% overlap, which was defined as acceptable image quality according to QIBA criteria.

Results: In total, 384 scans were analyzed. The two hard kernel reconstructions showed more histogram overlap than the soft kernel reconstructions. Overlap was 62.8% for the lowest dose setting. IR and noise suppression reduced this overlap. The correlation between radiation dose and histogram overlap is an inverse exponential ($R^2>0.95$). Intermediate grade IR combined with noise suppression software allowed for 85% radiation dose reduction (to a CTDIvol 0.19 mGy).

Conclusion: Noise suppression software, IR, and soft reconstruction kernel allow radiation dose reduction by 85% while still allowing differentiation between emphysema and normal lung tissue in a phantom set-up.

Predictors for bronchoalveolar lavage recovery rates derived from preprocedural quantified computed tomography

J.F.M. Gawlitz, J.D. Michels, H. Haubenreisser, T. Henzler, M. Borggrete, S.O. Schönberg, I. Akin, F. Trinkmann; Mannheim/DE (joshua.gawlitz@medma.uni-heidelberg.de)

Purpose: Bronchoalveolar lavage (BAL) is an important diagnostic method. The percentage of fluid extracted after instillation (recovery rate) is crucial for following diagnostic tests. Currently, no preprocedural predictors for a good recovery rate are known. Therefore, we compared quantified airway parameters from preprocedural lung computed tomography (CT) with recovery rates to find possible predictive markers.

Methods and Materials: Recovery rates and patient characteristics were retrospectively acquired from 33 routine procedures. Parenchyma and airway parameters were quantified in preprocedural CT. The bronchial tree was measured in five generations, acquiring eight airway parameters. Recovery rates and patient characteristics were then analysed in context of quantified CT findings.

Results: Significant correlations between airway parameters and recovery rate were found for CT parameters of the 3rd or 4th generation bronchus with highest values for percentage wall area (WA%, $r=-0.56$; $p<0.01$), lumen area ($r=-0.47$; $p=0.01$) and mean inner diameter ($r=-0.49$; $p<0.01$). No correlations were found for recovery rates and CT parenchyma parameters. ROC analysis of 4th generation bronchus values yielded an AUC of 0.75 ($p<0.01$) for distal outer bronchoscope diameter to mean inner diameter ratio. For 3rd generation WA%, we found an AUC of 0.86 ($p<0.001$). A threshold of approximately 60% recovery rate had 89% sensitivity and 80% specificity to distinguish between patients with good (>50%) and poor (<50%) recovery.

Conclusion: Quantified CT parameters, most notably WA% and bronchoscope diameter to inner bronchus diameter, have the potential to identify the ideal location and bronchoscope size for optimal BAL recovery rates in advance, warranting prospective evaluation.

Phenotyping diabetic cardiomyopathy in South Asians and Europeans

E.H.M. Paiman¹, H.J. van Eyk¹, M.B. Bizino¹, I.A. Dekkers¹, P. de Heer², J.W.A. Smit³, I.M. Jazet¹, H.J. Lamb¹; ¹Leiden/NL, ²Amsterdam/NL, ³Nijmegen/NL (e.h.m.paiman@gmail.com)

Purpose: To characterize the impact of type 2 diabetes (T2D) on left ventricular (LV) function, myocardial tissue characteristics and aortic stiffness in South Asians and Europeans.

Methods and Materials: T2D patients and controls with comparable age and sex distribution, of South Asian and European descent, underwent 3 Tesla cardiac magnetic resonance imaging (MRI) and proton-magnetic resonance spectroscopy (¹H-MRS). Differences in cardiac parameters between T2D patients and controls were examined using ANCOVA with adjustment for age, sex, blood pressure and smoking and were reported as mean (95%CI).

Results: A total of 131 individuals were included (54 South Asians (50.1±8.7 years, 33% men, 33 patients vs. 21 controls) and 77 Europeans (58.8±7.0 years, 56% men, 48 patients vs. 29 controls)). The transmitral early and late filling rate ratio was lower in T2D patients compared to controls, in South Asians (-0.20 (-0.36; -0.03), *P*=0.021) and Europeans (-0.20 (-0.36; -0.04), *P*=0.017), whereas global longitudinal strain and aortic pulse wave velocity were comparable. South Asian T2D patients had a higher LV mass (+22 g (15; 30), *P*<0.001) with a lower extracellular volume (-1.9% (-3.4; -0.4), *P*=0.013), whilst European T2D patients had a higher myocardial triglyceride content (+0.59% (0.35; 0.84), *P*<0.001) than their control group.

Conclusion: Diabetic cardiomyopathy was characterized by impaired LV diastolic function in South Asians and Europeans. Increased LV mass was solely observed among South Asian T2D patients, whereas differences in myocardial triglyceride content between T2D patients and controls were only present among Europeans. The diabetic cardiomyopathy phenotype may differ across ethnicities and tailored management may be required.

Independent association of extracellular volume with myocardial strain assessed by CMR in subjects without history of cardiovascular disease from the general western population

C. Storz¹, T. Zitzelsberger¹, S. Rospleszcz², K. Nikolaou¹, F. von Knobelsdorff², A. Peters², J. Schulz-Menger³, F. Bamberg¹, C.L. Schlett⁴; ¹Tübingen/DE, ²Munich/DE, ³Berlin/DE, ⁴Heidelberg/DE (corinna.storz@med.uni-tuebingen.de)

Purpose: To determine the relationship of T1 mapping parameters and myocardial strain, assessed by cardiac magnetic resonance imaging (CMR) in a western general population without prior cardiovascular disease.

Methods and Materials: A comprehensive contrast-enhanced CMR protocol was performed. Subjects with impaired ejection fraction (EF)<50% were excluded. Extracellular volume (ECV) was calculated based on T1-mapping in MOLLI sequence. Radial (*E_r*), longitudinal (*E_l*) and circumferential (*E_{cc}*) global strain was derived from cine-SSFP imaging using feature-tracking. Univariate and adjusted analyses were carried out.

Results: In 322 participants (56.0±9.2 years, 56.2% males), mean ECV was 24.2±2.9%. ECV was positively correlated with *E_r* (*r*=0.18) and negatively correlated with *E_l* and *E_{cc}* (*r*=-0.18 and *r*=-0.21, respectively; all *p*<0.003). The associations between ECV with *E_r* and *E_{cc}* remained after adjustment for clinical and functional cardiovascular confounders and EF (*β*=-0.28 and

β=0.953, respectively; all *p*<0.01). We found a significant correlation between ECV and cardiac strain in hypertensive participants, whereas there was no significant interaction effect between ECV and cardiac strain in participants with diabetes.

Conclusion: Increased ECV is associated with impaired myocardial strain, determined by CMR, independent of cardiovascular risk factors and EF.

B-0590 10:46

Impaired left ventricular function in patients with treatment-resistant arterial hypertension evaluated by feature-tracking myocardial strain CMRI

C. Ozden¹, M.L. Warncke¹, F. Brunner¹, J. Stáreková¹, A. Koops¹, G.K. Lund¹, G.I. Kirova-Nedyalkova², G. Adam¹, E. Tahir¹; ¹Hamburg/DE, ²Sofia/BG (c.ozden@uke.de)

Purpose: Treatment-resistant arterial hypertension (AHT) is defined as blood pressure above target values despite medication with at least three different antihypertensive drugs including a diuretic, posing a great threat to the hypertensive population. The aim of this study was to investigate the effects of AHT on systolic left ventricular function compared to age- and sex-matched controls by myocardial feature-tracking cardiac magnetic resonance imaging (CMRI).

Methods and Materials: CMRI was performed on 28 patients with AHT and 18 controls. Functional and morphological LV parameters were obtained, including end-diastolic volume (EDV) and ejection fraction (EF) using CVI42 (circle cardiovascular imaging). Global peak systolic longitudinal, radial and circumferential myocardial strains were analysed using Segment (Medviso, Sweden).

Results: Indexed left ventricular mass (LVMM) was significantly higher in AHT patients compared to controls (81 ±18 g/m² vs. 61 ±9 g/m², *p*<0.0001). Left ventricular EF in AHT patients was similar to EF in controls (61 ±10% vs. 64 ±7%, *p*=0.309). EDV also did not differ (74 ±16 ml/m² vs. 75 ±12 ml/m², *p*=0.774). Global peak systolic longitudinal (-15 ±3% vs. -19 ±2%, *p*<0.001) and radial LV strains (37 ±11% vs. 48 ±8%, *p*<0.01) were significantly diminished in AHT patients. Circumferential LV strain did not show significant differences between the two groups (-17 ±5% vs. -19 ±4%, *p*=0.247).

Conclusion: An increase in LVMM in patients with AHT and preserved EF is associated with impaired LV systolic function as indicated by decreased LV systolic strain parameters.

B-0591 10:54

Prognostic role of feature tracking in suspected myocardial infarction with non-obstructed coronary arteries (MINOCA): sensitive or senseless?

T. Leckebusch, P. Wenzel, F. Jungmann, M.C. Halfmann, R.M. Brumberg, C. Düber, K.-F. Kreitner, T. Emrich; Mainz/DE (leckebusch@gmail.com)

Purpose: The term MINOCA was established for patients with acute chest pain, elevated troponins and non-obstructed coronary arteries. It is an umbrella term that includes coronary as well as non-coronary causes. The purpose of this study was to investigate prognostic implications of abnormal strain values in MINOCA-patients and its prognostic significance in relation to established risk parameters like EDVI.

Methods and Materials: The study comprised CMR examinations of 145 patients. These patients were followed over a median time of 4.2 years. Primary endpoints were defined as MACE including death, stroke, congestive heart failure, recurrent hospitalization or an interventional/surgical procedure. Regarding strain parameters, we compared these patients with a collective of 62 healthy volunteers. A dedicated software (CVI42®, Circle) tracked the movement of endo- and epicardial contours and calculated strain parameters.

Results: Based on the strain analysis of healthy volunteers, we set a cut-off value for pathologic strain values at mean value (healthy volunteer) ±2*standard deviation. A significantly higher rate of primary endpoints occurred in patients with abnormal strain values (*p*<0.05 for all). Kaplan-Meier analyses in MINOCA patients were performed for normal and pathologic groups of strain in normal and abnormal EDVI. After adjusting for EDVI, only LV global radial strain and RV global longitudinal strain were of significant prognostic value.

Conclusion: Abnormal strain values are correlated with a higher risk of MACE in patients with MINOCA. After adjustment for normal LV volumes, only LV radial and RV longitudinal strains had a significant effect on the prognosis of MINOCA patients thus outperforming traditional risk factors.

B-0592 11:02

Evaluation of left ventricular strain assessment with feature-tracking CMR in STEMI at long term follow-up

F. Cilia, C. Calvieri, F. Catapano, S. Coco, R.M. Ammendola, G. De Rubeis, N. Galea, M. Francone, C. Catalano; Rome/IT (cilia91@hotmail.it)

Purpose: Left ventricular strain assessed by CMR feature-tracking has been recently used to evaluate the benefits of metoprolol administration before primary percutaneous intervention (PCI) at short term follow up (FU). Our aim was to evaluate LV strain assessment at long term FU in STEMI patients.

Methods and Materials: This is a pilot retrospective single center study. Twelve acute STEMI patients (aged 55 ± 12 yrs, 100% male) underwent CMR at 1.5 T, at 2-6 days after PCI and after a median follow up of 10 years (IQ 9-11). Feature-tracking CMR analysis was performed on steady-state free precession cine images with a dedicated software (CVI42 v5.3, Circle Cardiovascular Imaging, Calgary, Canada) for both CMR exams.

Results: No significant changes in LVEF were observed between the first and the last CMR, while LGE extent significantly reduced (11.7 ± 8.4 to 7 ± 4.5 , $p=0.030$) and global longitudinal strain (GLS) significantly improved (-14 ± 3.3 to -17.9 ± 3.6 , $p=0.016$). At first CMR troponin release and heart rate before PCI correlated with acute GLS ($r: -0.699, p=0.011, r: -0.678, p=0.045$, respectively). Ischaemia duration before PCI correlated positively with global radial strain at long term FU CMR ($r: 0.729, p=0.017$). Interestingly, STEMI who received i.v. nitrates before PCI had no difference in LVEF and LGE extent changes but a greater improvement in GLS at long term follow up ($-16 \pm 0.8, -21 \pm 0.8$, $p=0.007$).

Conclusion: LV strain assessment with feature-tracking CMR adds incremental prognostic information on LV remodelling beyond LVEF. Feature-tracking CMR strain could be a sensitive tool to evaluate long term effect of cardioprotective therapies.

B-0593 11:10

Early detection of left ventricular involvement assessed by 3D CMR feature tracking improves risk stratification in patients with arrhythmogenic right ventricular cardiomyopathy

X. Chen, L. Li, S. Zhao; Beijing/CN (cxy0202@126.com)

Purpose: To investigate the diagnostic value of three-dimensional feature tracking cardiac magnetic resonance (3D CMR-FT) for early detection of left ventricular (LV) involvement in arrhythmogenic right ventricular cardiomyopathy (ARVC) patients as well as its prognostic value of predicting adverse outcomes.

Methods and Materials: Fifty-eight ARVC patients and 20 healthy control subjects were prospectively enrolled. CMR with late gadolinium enhancement (LGE) and myocardial strain analysis using CMR-FT were performed in all subjects. Global and regional (basal, medial and apical) LV peak strains as well as global longitudinal strain of right ventricle were measured. All patients were followed for cardiovascular events.

Results: Of the 58 ARVC patients, 31 (53%) had preserved LV ejection fraction (LVEF $\geq 50\%$). In these patients, the LV global longitudinal as well as circumferential, radial and longitudinal strain at the basal level were all significantly reduced compared with the controls (all $p < 0.05$). During a mean follow-up period of 15.0 ± 7.8 months, 13 (22%) patients experienced cardiac events. The extent of LGE and LV global radial strain (GRS) were significantly associated with adverse outcomes, and LV GRS was the only independent predictor according to multivariate analysis. In patients with preserved LVEF, a basal circumferential strain $> -12.77\%$ was significantly associated with outcomes.

Conclusion: LV involvement can be identified by 3D CMR-FT in the absence of LVEF reduction. LV GRS was the only independent predictor of adverse outcomes in ARVC patients. Reduced basal circumferential strain was associated with adverse events in patients with preserved LVEF.

B-0594 11:18

CMR tissue tracking assessment of myocardial strain in non-ischaemic dilated cardiomyopathy patients with and without left ventricular hyper-trabeculations

H. Fu, L. Wen, Y.-K. Guo, Z. Yang; Chengdu/CN (695868312@qq.com)

Purpose: Our study aimed to evaluate the difference of left ventricular strain and function in non-ischaemic dilated cardiomyopathy (NIDCM) with or without hyper-trabeculations.

Methods and Materials: 157 patients of NIDCM were retrospectively enrolled. Patients were divided into two groups according to definition of prominent trabeculations. Cardiac function and myocardial strain were measured based on short-axis, two-chamber and four-chamber cine sequences. Left ventricular ejection (LVEF), peak ejection rate (PER), peak filling rate (PFR) and global peak strain in three directions of radial (GPRS), circumferential (GPCS), longitudinal (GPLS) were obtained.

Results: LVEF (Mean \pm SD: $25.9\% \pm 10.5\%$) was smaller than 50% of all 157 patients. Hyper-trabeculations were presented in 86 patients (54.8%). Although LVEF, PER, PFR and GPRS have no statistically significant between the NIDCM patients with or without hyper-trabeculations ($p > 0.05$), for the myocardial strain, the GPCS and GPLS in patients with hyper-trabeculations lower than that of patients without hyper-trabeculations ($p=0.040$ and $P=0.006$, $p < 0.05$). GPRS, GPSC and GPSL were mild to moderate correlated with LVEF (correlation coefficients were 0.44, -0.564, -0.321 respectively, $p < 0.05$) in Group A. Despite GPSL was not related to LVEF in patients with hyper-trabeculations, GPRS and GPSL were moderate related to LVEF (correlation coefficients were 0.43 and -0.40, $p < 0.05$).

Conclusion: CMR tissue tracking can early detect myocardial strain in NIDCM patients with or without hyper-trabeculations. And patients with hyper-trabeculation may have more severe myocardial deformation. But it's need to do further research to explore whether hyper-trabeculations would affect the prognosis of NIDCM.

Strain analysis in noncompaction morphology: usefulness in assessing an undefined cardiomyopathy

E. Cannizzaro, P. Palumbo, C. De Cataldo, A. Corridore, S. Torlone, F. Cobianchi Bellisari, A. Di Sibio, E. Di Cesare, C. Masciocchi; L'Aquila/IT (estercannizzaro@hotmail.it)

Purpose: To measure left ventricular (LV) myocardial strain with cine-magnetic resonance (MR) imaging to relate LV function to strain values in order to assess the prognostic value of strain analysis and to detect early impairment of the LV function in patients with left ventricular non-compaction (LVNC); to demonstrate that morphology (absence or presence of non-compaction) doesn't influence LV contractility.

Methods and Materials: In this retrospective study, 65 patients with a validated diagnosis of LVNC were re-analyzed in order to avoid selection biases and consider only patients with an isolated LVNC (LVNC), obtaining a final population of 21 patients who underwent a post-processing strain analysis. Strain analysis effectiveness to detect impairment of LV function ($< 50\%$) was analyzed by ROC curves and morphology's influence on LV contractility has been analyzed by Cohen's kappa coefficient.

Results: In our analysis, we found that global circumferential strain was the most reliable value to detect LV function with a sensitivity of 100% and a specificity of 70.6%. (AUC=91.2%, $p < 0.001$; best cut-off > -13.06). Cohen's kappa coefficient didn't show a concordance between the segmental NC/C ratio and segmental circumferential strain values suggesting a non-significant influence of morphology on LV contractility ($k=0.02$, 95% CI -0.07 to 0.12).

Conclusion: Strain analysis seems to be sensible and specific in assessing LV function and in detecting early patients with a poor or mild-impaired LV contractility. The lack of concordance between the segmental NC/C ratio and the segmental strain values conceivably arise the possibility that morphology doesn't affect the contractility.

B-0596 11:34

Assessment of myocardial deformation in a rabbit model of diabetes mellitus by cardiac magnetic resonance tissue tracking

Y. Zhang, Z.-G. Yang, Y.-K. Guo, K. Diao, M.-T. Shen, X. Li, K. Xu, H. Yu, C. Xia; Chengdu/CN (yizhang524@qq.com)

Purpose: To determine the characteristics of myocardial deformation in a diabetes mellitus (DM) rabbit model at different stages by using cardiac magnetic resonance (CMR) tissue tracking.

Methods and Materials: Twenty-eight New Zealand white rabbits, randomly divided into the control group, 4-week ($n=9$), 8-week ($n=6$) DM groups, induced by Alloxan (80 mg/kg), and the control group ($n=8$), underwent CMR examination. A series of SSFP cine sequence were used to calculate left ventricle ejection fraction (LVEF). 2D global peak radial strain (GS_r) and global peak circumferential strain (GS_c) were derived from short-axis slices and 2D global peak longitudinal strain (GS_l) was derived from the 4-chamber and long-axis slices. Spearman's rank correlation analysis was performed to determine the correlation between myocardial strain parameters and the stages of DM.

Results: All groups had preserved and no statistically different LVEF. The GS_r ($19.01 \pm 3.92\%$ vs. $27.28 \pm 9.04\%$) and GS_l ($-9.91 \pm 2.60\%$ vs. $-12.92 \pm 1.91\%$) of 8-week group were lower than those of controls (all $P < 0.05$), whereas the difference of GS_r and GS_l between the 4-week group and the controls did not reach statistical significance ($P=0.079$ and 0.113 , respectively). GS_c showed numeric but no significant difference between either two groups. Additionally, GS_l had a moderate correlation with the stages of DM ($r=-0.534$, $P < 0.01$).

Conclusion: DM rabbits demonstrated GS_r and GS_l reduction during the process of DM, even without change in LVEF. Myocardial strains could work as sensitive indices to assess LV myocardial deformation in DM.

Author Disclosures:

Y. Zhang: Research/Grant Support; National Natural Science Foundation of China (81471721, 81471722, 81641169, 81771887 and 81771897).

Cardiac computed tomography left ventricle myocardial strain analysis

T. Adla, V. Suchanek, M. Polovincak, L. Miksik, Z. Salagovicova, N. Markova, J. Biskup, M. Rocek; *Prague/CZ (theodor.adla@gmail.com)*

Purpose: Myocardial deformation strain analysis is possible from echocardiography and cardiac MRI with different methods. Feature tracking is a relatively new method used for MRI. Purpose of this study was to assess feasibility of using this method for left ventricle (LV) deformation in cardiac CT.

Methods and Materials: Ten patients (60 +/- 17 years old) were examined by cardiac CT (Somatom Force, Siemens), retrospective gating with dose modulation (full dose 30 - 70% of RR interval) protocol. Additionally to standard analysis, cine images (20 phases, 5 mm thickness) were reconstructed in 3 long and 3 short axes of LV. Software Segment (Medviso) was used for feature-tracking analysis. Automatic segmentation during heart cycle was assessed visually. Values of global strains were compared with LV ejection fraction.

Results: Inaccuracies of propagation of myocardial contour were visible in interventricular septum in cases with low or inhomogeneous right ventricle contrast filling. Global strain values were longitudinal -13 +/- 3%, circumferential -16 +/- 5%, radial from long-axis images 22 +/- 8%, and radial from short-axis images 23 +/- 9%. Significant correlations were found between LV ejection fraction and longitudinal strain ($R = -0.69$, $p = 0.03$), circumferential strain ($R = -0.74$, $p = 0.01$), and radial strain from long-axis images ($R = 0.69$, $p = 0.03$).

Conclusion: Strain analysis of LV from cine CT images is technically possible using Segment software and some of global strains values significantly correlate with LV ejection fraction. However, good enhancement of the right ventricle is needed.

B-0598 11:50

Two-dimensional and three-dimensional cardiac magnetic resonance feature-tracking myocardial strain analysis in acute myocarditis patients with preserved ejection fraction

M. Gatti¹, R. Faletti¹, F. Bioletto¹, A. Palmisano², G. Benedetti², A. Esposito², P. Fonio¹; ¹Turin/IT, ²Milan/IT (marcogatti17@gmail.com)

Purpose: To explore the potential role of two- (2D) and three-dimensional (3D) cardiac magnetic resonance (CMR) feature tracking (FT) myocardial strain analysis in identifying sub-clinical myocardial dysfunction in acute myocarditis patients with preserved ejection fraction (EF).

Methods and Materials: Prospective two centre study-control study. Thirty patients (9 female, 37.2 ± 11.8 yrs.) with a CMR diagnosis of acute myocarditis according to the Lake Louise Criteria and preserved EF (>55%) were included in the analysis. CMR data from 24 healthy volunteers (11 female, 36.2 ± 12.5 yrs.) served as control. 2D and 3D LV tissue tracking analysis were performed in a random fashion by two double-blinded operators. Variables were checked for normality and analysed with parametric test.

Results: The baseline characteristics of myocarditis patients with preserved EF and the healthy volunteers were perfectly comparable, except for the LV mass index (60 ± 13% vs. 45 ± 11%; $p < 0.001$). The results of the interoperator variability in the 2D and 3D LVCMR FT myocardial strain analysis were $p > 0.42$, ICC > 0.80 and $\eta^2 > 0.98$. There was no statistical difference in 2D and 3D global radial, circumferential and longitudinal strain peak (%) and both systolic and diastolic strain rate (1/s) between acute myocarditis with preserved EF and healthy volunteers (all $p = n.s.$).

Conclusion: There were no difference in 2D and 3D global radial, circumferential and longitudinal strain peak and both systolic and diastolic strain rate of the LV between acute myocarditis patient with preserved ejection fraction and healthy volunteers.

Feasibility of foetal MRI in the evaluation of foetal congenital heart disease

S.-Z. Dong, M. Zhu; *Shanghai/CN (dongsuzhen@126.com)*

Purpose: To evaluate the feasibility of foetal cardiac magnetic resonance (CMR) in the assessment of foetal congenital heart disease.

Methods and Materials: This retrospective review included 616 pregnant women referred to a children's hospital for a foetal cardiac MRI from January 2011 to June 2018 due to the finding of a congenital heart disease by echocardiogram (echo) and/or technically limited echo. Screening obstetric ultrasound (US), echo by cardiologists and CMR data of all cases were compared with postnatal diagnoses (postnatal imaging, surgery and/or autopsy). Foetal CMR was performed at 1.5 T or 3.0 T (Discovery 750; GE Medical Systems). Sequences included steady-state free-precession (SSFP), non-gated SSFP cine, single-shot turbo spin echo (SSTSE) and non-gated phase contrast (PC) cine sequences. The CMR images were analysed using an anatomic segmental approach by two radiologists and compared with foetal echo and postnatal findings when available.

Results: All 616 cases with congenital heart disease were confirmed by postnatal imaging, surgery and/or autopsy. Obstetric US were correct in 45.8% (282/616), foetal echoes were correct in 83.1% (512/616), CMR were correct in 77.9% (480/616) when compared to postnatal findings. Foetal echoes had a higher specificity for evaluating ventricular size, septal defects and valve anomalies. CMR was more useful in evaluating extracardiac aortic arch, superior vena cava and malposition anomalies, heart diverticulum, and pericardium cyst.

Conclusion: Foetal CMR is a promising diagnostic tool for the assessment of congenital heart disease (especially extra-cardiac vascular anomalies) and can be a useful adjunct when foetal echocardiography is limited.

B-0600 10:38

Diffusion-weighted magnetic resonance imaging of the foetal brain in complex congenital heart disease

S.-Z. Dong, H. Ji; *Shanghai/CN (dongsuzhen@126.com)*

Purpose: The aim of this study was to assess whether ADC values in the foetal brain were different in a group of foetuses with complex congenital heart disease (CHD), compared to normal controls.

Methods and Materials: Foetal brain diffusion MR imaging was performed in 50 foetuses with complex CHD. Foetal brain MRI examinations with single-shot DWI ($b = 0$ and $b = 700$ s/mm²) were performed. ADC values in frontal white matter (FWM), centrum semi-ovale (CSO), thalami (T), basal ganglia and pons were compared with 50 normal controls at the same gestational age.

Results: We found no significant differences between gestational age between our 2 groups (CHD 26.6 ± 3.2w and control 26 ± 2.8w). All foetal brain morphology and signal were normal. Foetuses with complex CHD had higher ADC values in FWM (2.34 ± 0.18 vs 2.19 ± 0.17 × 10⁻³ mm²/sec; $p < 0.05$), thalami (2.20 ± 0.16 vs 2.06 ± 0.19; $p < 0.001$), centrum semi-ovale (2.34 ± 0.19 vs 2.22 ± 0.19 × 10⁻³ mm²/sec, $p < 0.05$), basal ganglia (2.16 ± 0.18 vs 2.03 ± 0.16, $p < 0.001$), and pons (2.14 ± 0.18 vs 2.04 ± 0.15 10⁻³ mm²/sec, $p < 0.05$).

Conclusion: Foetal diffusion MR imaging is a feasible modality of evaluating abnormal brain diffusivity in foetuses with complex CHD.

Foetal dynamic phase-contrast MR angiography using ultrasound gating and comparison with Doppler ultrasound measurements

B.P. Schoennagel, J. Yamamura, F. Kording, R. Fischer, G. Adam, H. Kooijman, C. Ruprecht, K. Fehrs, M. Tavares de Sousa; *Hamburg/DE (b.schoennagel@uke.de)*

Purpose: To investigate the feasibility of foetal phase-contrast (PC)-MR angiography of the descending aorta (AoD) using an MR-compatible Doppler Ultrasound sensor (DUS) for foetal cardiac gating and to compare velocimetry with Doppler ultrasound measurements.

Methods and Materials: In this prospective study 2D PC-MR angiography was performed in ten human foetuses (gestational age 32.4 ± 2.3 weeks) using an MR-compatible DUS for gating of the foetal heart at 1.5T. Peak flow velocities in the foetal AoD were compared with Doppler ultrasound measurements performed on the same day. Reproducibility of PC-MR measurements was tested by repeated PC-MR in five foetuses.

Results: Dynamic PC-MR angiography in the AoD was successfully performed in all foetuses using the DUS, with foetal heart rates of 131 - 163 bpm. Time-velocity curves revealed typical arterial blood flow patterns. PC-MR mean flow velocity and mean flux were 19.7 ± 7.9 cm/s and 7.8 ± 3.4 ml/s, respectively. A positive association between PC-MR mean flux and flow velocity with gestational age was obtained ($r = 0.9$, $p = 0.001$ and $r = 0.65$, $p = 0.06$). PC-MR and Doppler ultrasound peak velocities revealed highly significant correlation ($r = 0.88$, $p < 0.001$). Peak velocities were lower for PC-MR compared with Doppler ultrasound (68 ± 26 vs. 95 ± 28 cm/s, $p < 0.001$). Reproducibility of PC-MR was high with no statistical differences ($p > 0.05$).

Conclusion: The MR-compatible DUS for foetal cardiac gating allows for PC-MR angiography in the foetal AoD. Comparison with Doppler ultrasound revealed highly significant correlation of peak velocities with underestimation of PC-MR velocities. This new technique for direct foetal cardiac gating indicates the potential of PC-MR angiography for assessing foetal haemodynamics.

Role of fetal MRI in diagnosis of genitourinary anomalies: is there an added value?

S. Sefidbakht¹, B. Bijan², S. Bagheri¹, Z. Etemadi¹, S. Esmailian¹; ¹Shiraz/IR, ²Sacramento, CA/US (kmssd87@gmail.com)

Purpose: To retrospectively review fetal MRI's (fMRI) performed over 5 years in our center to establish the added value of fMRI in diagnosis of fetal GU anomalies.

Methods and Materials: IRB approved study. Out of 771 fetal MRI's performed in our center, 65 were done either primarily to evaluate a GU anomaly seen in ultrasound or an anomaly related to the GUT was incidentally detected. Interpretation of MRI's were done by a single radiologist who was not blinded to the ultrasound results. Final diagnosis was established through phone calls and national registry search. Post-delivery images also surgical notes and biopsy results were obtained when available. The added value of MRI was discussed with a pediatric surgeon, pediatric urologist, perinatologist and radiologist.

Results: Final diagnoses included bilateral/unilateral renal agenesis (8/4), multicystic dysplastic kidneys (4), urinary tract obstruction (3), duplicate collecting system with obstruction (2), simple renal cyst (3), adrenal cyst (4), posterior urethral valve (5), crossed fused ectopia (1), autosomal recessive/dominant polycystic kidney disease (3/2), glomerulocystic disease (2), bilateral UPJO and isolated mild bilateral pelvocaliectases, normal outcome (25). fMRI was considered to have an impact on diagnosis/counseling/management in 26 (confirming presence/absence of kidneys in severe oligohydramnios (8 & 9), confirming probable normal renal function in hyperintense/hyperechoic fetal kidneys (3), multicystic dysplastic kidney diagnosed as pelvocaliectasis in ultrasound (3), crossed fused ectopia (1), megacystis microcolon (1), & bilateral UPJO (1).

Conclusion: fMRI had significant additional benefit to ultrasound in congenital genitourinary anomalies which affected either management (27%) or counseling (12%) as a result of more accurate diagnosis.

B-0603 11:02

Abnormalities concomitant with intrahepatic persistent right umbilical vein

A. Ipek, Ö. Ünal, M. Yildirim Erol; Ankara/TR (mel-tem89@hotmail.com)

Purpose: Persistent right umbilical vein is an uncommon intrauterine variation. In our study, it was aimed to determine the anomalies associated with intrahepatic persistent right umbilical vein (I-PRUV).

Methods and Materials: Prenatal ultrasound results of 43 fetuses with I-PRUV were evaluated retrospectively in 15,632 fetuses who admitted to an obstetric ultrasound between 2010 and 2018, and interviewed with their parents. These fetuses were evaluated in terms of other congenital malformations and accompanying negative results after delivery.

Results: 4 of the 43 pregnant women were still pregnant at the end of the study. Additional anomalies detected during prenatal ultrasound: single umbilical artery 4, AVSD 1, tetralogy of Fallot 1, intracardiac echogenic focus 4, ascending aortic dilatation and pulmonary artery stenosis 1, renal pelvicaliectasis 2, bilateral renal agenesis 1, left equinovarus deformity 1, oligohydramnios 2 and polyhydramnios 2 fetuses. 1 had multiple anomalies (serious cardiac malformations, neural tube defect, musculoskeletal anomalies, cleft palate and lip etc.) It was learned that 2 fetuses had died intrauterine and 1 died at 3 years old followed by seizures and liver failure.

Conclusion: The frequency of I-PRUV is reported in the literature in the range of 1/217-1/1250. The frequency of I-PRUV in this study was 1/363 and was consistent with previous studies. Among the fetuses observed with I-PRUV, the frequency of single umbilical artery was 9.3% (healthy population prevalence was 1% in the literature), and the frequency of cardiac anomaly was 6.9% (healthy population frequency in the literature was 0.8%). As a result, echocardiography can be used in intrauterine-postnatal period for concomitant cardiac anomaly.

B-0604 11:10

Prenatal MRI assessment of swallowing and pharyngeal structures in fetuses with facial clefts

S.R. Teixeira, E.R. Arruda, S.M. Saade, O. Jackson, A.N. Pollock, T. Feygin; Philadelphia, PA/US (teixeiras@email.chop.edu)

Purpose: To determine feasibility of dynamic MRI techniques in assessment of swallowing patterns in fetuses with facial clefts; to assess anatomic variations of nasopharyngeal structures in fetuses with facial clefts in comparison to controls.

Methods and Materials: Between 2008 and 2017, foetal MRI, which included dynamic cine sequences, were retrospectively analyzed by 2 paediatric radiologists. Inclusion criteria: suspected foetal facial clefts, ≥ 19 weeks-of-gestation and technically adequate dynamic MR sequences. The phases of swallowing assessed were: Motion of the foetal lips, tongue, soft palate and hypopharynx. Measurements of the anterior nasal-spine-cranial-cervical junction (ANS-CC), anterior nasal-spine-soft-palate (ANS-SP), presence/absence of velopharyngeal incompetence (VPI) and glossoptosis were recorded. The ANS-CC:ANS-SP ratio was regressed versus pathology status, foetal and maternal age. Comparison was done with 35 random controls.

Results: Sixty-five cases of foetal facial clefts were included. The chi-square test (equivalent to the two-proportion z-test) revealed a marked difference in the proportion of fetuses exhibiting VPI (55/65=0.85 in the pathological group versus 0/35=0 in the control group). The incidence of detected glossoptosis was also significantly higher, in more than 80% of cases. Fetuses with facial clefts had a ANS-CC:ANS-SP ratio 12 percentage points higher than the controls, even after controlling for age effects.

Conclusion: Dynamic-cine MRI is a technically feasible and valuable tool in the prenatal assessment of fetuses with facial clefts. It demonstrates statistically significant abnormal patterns of foetal swallowing. Abnormal ANS-CC:ANS-SP ratio may indicate presence of palatal cleft, even in the absence of direct visualization of the cleft on prenatal imaging.

B-0605 11:18

Evaluation of foetal modified myocardial performance index as a predictor of perinatal outcome in gestational diabetes

R. Khurana, S.K. Bajaj; New Delhi/IN (rajat3008khurana@gmail.com)

Purpose: To assess foetal cardiac function (both systolic and diastolic) using modified myocardial performance index by Doppler in gestational diabetic mothers in early third trimester (28-32 weeks) and to assess role of this index in prediction of perinatal outcome.

Methods and Materials: 1. Study design: Prospective observational study 2. Subjects and Inclusion criteria: 30 singleton pregnant females in third trimester (28-32 weeks) with known history of Gestational Diabetes Mellitus and 30 normal singleton pregnant females in third trimester 3. Exclusion criteria: Multiple pregnancy Intrauterine growth retardation Pre-gestational diabetes mellitus Congenital anomalies History of cardiac disease or hypertension 4. ULTRASOUND: The Mod-MPI will be calculated in the foetal left ventricle by placing the Doppler sample in the internal leaflet of the mitral valve and estimating the three time periods as ICT (isovolumetric contraction time), IRT (isovolumetric relaxation time) and ET (ejection time). The Mod-MPI is calculated as (ICT+IRT)/ET.

Results: The cases had significantly higher median MPI compared to controls, p value < 0.0001. 7 abnormal outcomes were recorded in the 30 fetuses in the study group, corresponding to an adverse outcome rate of 23.3% and these fetuses had significantly higher MPI measurements compared to GDM fetuses with normal outcome. The MPI served as an excellent predictor of adverse outcome in GDM fetuses with a total area under the ROC curve of 0.96. MPI z-score greater than 4.0 provided a 100% sensitivity and 80% specificity. No abnormal outcomes were recorded in the control group.

Conclusion: MPI has the potential to improve foetal surveillance in gestational diabetes.

B-0606 11:26

What does perinatal autopsy add after antenatal ultrasound and post-mortem MRI investigations

S.C. Shelmerdine, O.J. Arthurs, A. Wade, R. Jones, W. Norman, A. Taylor, N.J. Sebire, L.S. Chitty; London/UK (susie_c_s@yahoo.co.uk)

Purpose: To determine the value of perinatal autopsy where non-invasive imaging techniques (post-mortem MRI, PMMR) have been performed in fetuses terminated after antenatal detection of sonographic abnormalities.

Methods and Materials: Pre-autopsy PMMR was performed on consecutive fetuses over a 6-year period (2007-2013). Cases were categorised into three groups depending upon whether ultrasound and PMMR findings were concordant, partially concordant or discordant. The yield of new information from autopsy in each of these groups was assessed and diagnostic accuracies for each of five body systems (neurological, cardiac, thoracic, abdominal and musculoskeletal) were calculated using autopsy as the reference standard for

both ultrasound and PMMR.

Results: Eighty-one fetuses were included. PMMR and ultrasound findings were concordant in 44/81 (54.3%) cases, partially concordant in 26/81 (32.1%) cases, and discordant in 11/81 (13.6%) cases. New information was obtained at autopsy in 19/81 (23%) cases overall, 6/44 (13.6%), 10/26 (38.5%), and 3/11 (27.2%) of the different categories, respectively. The diagnostic accuracy rates for all body systems using ultrasound gave a sensitivity of 76.8% (66.6%, 84.6%), specificity of 92.5% (88.9%, 95.0%) and concordance of 89.0% (85.5%, 91.8%). For PMMR the sensitivity was 79.0% (68.9%, 86.5%), specificity 97.9% (95.5%, 99.0%) and concordance of 93.8% (90.8%, 95.8%). Overall PMMR had a significantly higher concordance rate with autopsy than ultrasound (89.0 vs 93.8%; $p < 0.001$).

Conclusion: In the majority of cases, antenatal ultrasound and PMMR were concordant, and there was little added value from autopsy. Where there was partial concordance or discordance, the yield from autopsy was higher.

Reliable evaluation of ADC values in the study of normal foetal brain, using denoising correction: a prenatal MR study

A. Antonelli, L. Manganaro, M.G. Di Trani, S. Capuani, S. Bernardo, R. Petrillo, C. Catalano; *Rome/IT (amanda.antonelli@hotmail.it)*

Purpose: Apparent Diffusion Coefficient (ADC) measurements are useful to evaluate the normal development of foetal Central Nervous System (CNS). Unfortunately, foetal movement artefacts consistently perturb Diffusion Weighted Imaging (DWI) resolution, affecting ADC measurements. Aim of this study was to investigate the potential of denoising DWI to ameliorate the reliability of ADC values in multiple regions of normal foetal brain.

Methods and Materials: 30 normal pregnancies underwent foetal MRI at 1.5T, using DW-Spin Echo EPI with b-values 50,200,700 s/mm². Eight regions of interest (ROIs) were manually placed in Frontal White Matter (FWM), Occipital WM (OWM), Thalamus (TH), Basal Ganglia (BG) Cerebellum (CH), Pons, lateral ventricle Cerebral Spinal Fluid (CSF) and amniotic fluid. Raw data were denoised and DWI were segmented to eliminate CSF. Kruskal-Wallis test was used to calculate the differences of ADC values during second and third trimester, with and without DWI pre-processing. Signal-to-Noise Ratio (SNR) was obtained with and without denoising correction to evaluate the reliability of ADC values. Spearman's test was used to calculate the correlation between ADC and Gestational Age (GA).

Results: SNR considerably increased and significant differences in ADC values were found with and without correction. ADC values of TH, CH and Pons show a progressive decline in mean diffusivity ($p < 0.001$), while a positive correlation was found between ADC and GA in FWM ($p < 0.05$). In FWM, ADC increases during the second trimester and it decreases in the third trimester. ADC mean values of CH, Pons, FWM and TH are significantly different between second and third trimester ($p < 0.01$).

Conclusion: Denoising DWI is an important tool to obtain no-biased ADC values, in order to better characterize normal foetal brain development in second and third trimester, helping also the study of foetal CNS abnormalities.

B-0608 11:42

Assessment of the reproducibility of foetal proton magnetic resonance spectroscopy at different sequence settings

M. Sokurenko, T. Trofimova, A. Khalikov; *St. Petersburg/RU (maria@sokurenko.name)*

Purpose: To evaluate the possibility of obtaining comparable quantitative data of proton magnetic resonance spectroscopy (¹H-MRS) of the foetal brain at various stages of pregnancy with different point-resolved spectroscopy (PRESS) sequence parameters.

Methods and Materials: Imaging of 70 fetuses' brains (19-39 postmenstrual weeks, normal neurodevelopment) were acquired on 3.0T MRI. Methodology included obtaining T2 SSFSE (TE=70-90 ms, TR=1200) in 3 orthogonal planes; slice thickness 3-4 mm. Then PRESS was applied with different TR/TE parameters: 2000/70 ms and 1500/35 ms. The zone of interest was projected posteriorly from the basal ganglia.

Results: The concentration of metabolite (N-acetylaspartate, creatine, choline, inositol) and graphic spectra were obtained. The earliest detection of metabolite concentration was presented at 19 gestational weeks. We did not find a close link between foetal age and the appearance of metabolic concentration. The reproducibility of metabolites was assessed. In the analysis of 70 obtained spectra in 48% of cases it was possible to obtain the values of all 4 metabolites, in 36% - 2 or 3 metabolites, in 16% - 1 or 0 metabolites. Using of PRESS sequence on TR=2000 ms and TE=70 ms has shown higher reproducibility.

Conclusion: Using modern 3.0T MR scanners allows to obtain qualitative ¹H-MR spectra of the foetal brain. Obtaining high-quality graphic spectra of ¹H-MRS is possible not in all cases and depends on a variety of technical difficulties in conducting the research. Use of PRESS sequence on TR=2000 ms and TE=70 ms has shown higher reproducibility.

B-0609 11:50

Assessment of the dynamics of foetal brain metabolites with proton magnetic resonance spectroscopy

M. Sokurenko, T. Trofimova, A. Khalikov; *St. Petersburg/RU (maria@sokurenko.name)*

Purpose: To evaluate changes of foetal brain metabolite concentrations using proton magnetic resonance spectroscopy (¹H-MRS) at various stages of pregnancy with point-resolved spectroscopy (PRESS) sequence.

Methods and Materials: Imaging of 70 fetuses' brains (19-39 postmenstrual weeks, normal neurodevelopment) were acquired on 3.0T MRI. Pregnant women were examined in the supine position (feet first) and no contrast agents or sedatives were used. Methodology included obtaining T2 SSFSE (TE=70-90 ms, TR=1200) in 3 orthogonal planes to evaluate anatomic structures and planning the region of interest; slice thickness 3-4 mm. Then applied PRESS with TR=2000 ms and TE=70 ms. The zone of interest was projected posteriorly from the basal ganglia, capturing the thalamus and hypothalamus, its size was 20 mm³.

Results: The concentration of metabolites (N-acetylaspartate - NAA, Creatine - Cr, Choline - Cho, Inositol - Ino) and graphic spectra were obtained. Over the gestational period the concentrations of NAA, Cr, NAA/Cho, Cr/Cho were increasing; the concentrations of Cho, Ino, NAA/Cr, Cho/Cr were decreasing. Using PRESS on TR=2000 ms and TE=70 ms has shown high reproducibility.

Conclusion: The foetal brain metabolites is changing during pregnancy and this corresponds to brain maturation. This reflects the status of myelination associated with increasing synaptic complexity, increased proliferation and differentiation of cells. Diagnosis of disorders of normal metabolic processes of the foetal brain can be useful in identifying future potential therapeutic strategies.

Volumetric DCE-MRI radiomics nomogram can predict tumour response in patients with oesophageal cancer treated by neoadjuvant chemotherapy

J. Qu¹, L. Ma², Y. Lu¹; ¹Zhengzhou/CN, ²Shanghai/CN (qiryq@126.com)

Purpose: To assess the role of DCE-MRI radiomics nomogram in predicting response to neoadjuvant chemotherapy (nCT) in oesophageal cancer (EC) patients.

Methods and Materials: This study prospectively enrolled EC patients with stage cT1N+M0 or cT2-4aN0-3M0. All patients received DCE-MRI within 7 days before the beginning of chemotherapy followed by surgery. nCT response assessment was graded from 1 to 5 according to the tumour regression grade (TRG). Patients were stratified into responders (TRG1+2) and non-responders (TRG3+4+5). According to 10-fold cross-validation, the half of this cohort was set as the training cohort, and the other half was set as the validation cohort. The Spearman, Lasso and PCA regression model was exploited for dimension reduction and selection of the feature space. The discriminating performance was assessed with AUC. Univariable association analysis was adopted for testing the correlation of radiomics signature and response, and DCA was used for comparing three models.

Results: All included 82 patients underwent surgery and TRG, and 72 tumour radiomics features were acquired from DCE-MRI. Three most significant radiomics features were identified by Spearman and LASSO, which included Ktransmedian, Vemean, Minintensity, 4 components were identified by PCA, and they were selected to create the radiomics signature significantly associated with response. AUC of radiomics signature performance in the training cohort was 0.855 (95%CI: 0.649-1) by LASSO, and in the validation cohort was 0.821 (95%CI: 0.658-0.985). This model showed good discrimination between responders and non-responders.

Conclusion: The study showed DCE-MRI radiomics features could potentially predict response to nCT in EC patients.

B-0611 10:38

Diffusion kurtosis imaging evaluation of histological differentiation and Lauren classification in advanced gastric cancer

J. Fu, L. Tang, Z. Li, Q. Shi, Z. Yan, X. Li, J. Ji; *Beijing/CN*
(18410259295@163.com)

Purpose: To investigate the value of diffusion kurtosis imaging (DKI) in assessing different histological type and Lauren classification in advanced gastric cancer.

Methods and Materials: This study was approved by the local institutional review board. Fifty-two patients with biopsy-proven gastric cancer were enrolled in prospective study before resection. All DKI images ($b=0, 200, 500, 800, 1000, 1500, 2000s/mm^2$) were blindly determined by radiologists, respectively, using software. The region of interest was manually drawn on the specific slice showing the largest area of tumour. Three parameters of DKI were calculated automatically: apparent diffusion coefficient (ADC), kurtosis (K), and diffusivity (D) value. One-way analysis of variance and receiver operating characteristic curves were used for statistical analysis.

Results: Kurtosis was significantly higher in diffuse type (0.741 ± 0.035) than in mixed type (0.629 ± 0.025) and intestinal type (0.571 ± 0.015) of Lauren type ($p < 0.05$). D and ADC were significantly lower in diffuse type than in mixed and intestine type (2.129 ± 0.208 vs. 2.758 ± 0.252 vs. 3.033 ± 0.144 ; 0.974 ± 0.042 vs. 1.167 ± 0.049 vs. 1.235 ± 0.302 , respectively, $p < 0.05$). The specificity for the assessment of diffuse type was greater using K (92.30%, cutoff value=0.688) compared with other parameters. There were also significant differences between different differentiations for ADC ($p=0.000$), MD ($p=0.000$), MK ($p=0.007$). AUC curve of ADC, K and D values in diagnosing low-grade gastric cancer was 0.77, 0.68 and 0.70, respectively. When the cutoff values of ADC, K, D values were set to $1.148 \times 10^{-6} mm^2/s$, 0.612, $2.769 \times 10^{-6} mm^2$, sensitivity of 77.30%, 68.20%, 77.27% and specificity of 73.30%, 56.70%, 60.00% were achieved, respectively.

Conclusion: DKI parameters exhibit potential predicting the gastric cancer aggressiveness before treatment.

B-0612 10:46

The role of intravoxel incoherent motion and diffusion kurtosis imaging in evaluating pathological complete response to neoadjuvant chemoradiotherapy in rectal cancer

I. Yang, B. Wu; *Chengdu/CN* (lqyang95@163.com)

Purpose: To explore the feasibility of intravoxel incoherent motion (IVIM) and diffusion kurtosis imaging (DKI) parameters in assessing pathological complete response (pCR) to neoadjuvant chemoradiotherapy (CRT) in locally advanced rectal cancer (LARC).

Methods and Materials: 32 LARC patients who received neoadjuvant CRT and subsequent surgery were enrolled prospectively. All of them had pre- and post-CRT rectal MRI examinations, including IVIM and DKI sequence with 11 b values. Pathological tumour regression grade (TRG) was the reference standard. Slow diffusion coefficient (D), fast diffusion coefficient (D*), perfusion-related diffusion fraction (f) were calculated with IVIM model. Mean diffusion (MD) and mean kurtosis (MK) were calculated with DKI model. ROIs were manually drawn on three slices with largest tumour on $b=800 s/mm^2$ diffusion imaging, and then were copied to other parameter imaging automatically.

Results: pCR (n=6) patients had a significantly higher post-CRT f ($P=0.003$), MD ($P=0.017$), as well as higher percentage change of f ($P=0.012$) and D* ($P=0.034$) value after treatment than non-pCR (n=26). They showed comparable overall diagnostic performance in selecting pCR with AUCs of 0.808, 0.769, 0.827 and 0.795, respectively. The percentage change of f had a sensitivity of 80.8%, specificity of 83.3%, PPV of 95.55 and NPV of 50%, with the cut-off value of 10.1%. Post-CRT f, MD and percentage change of f and D* also had negative correlations with TRG ($r_s = -0.416, -0.364, -0.442$ and -0.399).

Conclusion: Post-CRT f and MD value, and percentage change of f and D* could help to assessing complete responders to neoadjuvant CRT in LARC.

B-0615 10:54

Quantitative magnetic resonance imaging can predict tumour subtype, therapy response and patient survival in pancreatic ductal adenocarcinoma

G. Kaissis¹, S. Ziegelmayer¹, F. Lohöfer¹, W. Weichert¹, J. Siveke², E.J. Rummeny¹, R. Braren¹; ¹Munich/DE, ²Essen/DE

Purpose: To evaluate the ADC-map histogram-derived quantitative imaging parameter ADC entropy as a biomarker in pancreatic ductal adenocarcinoma (PDAC).

Methods and Materials: We retrospectively analysed 39 cases of resected and 21 cases of metastatic PDAC who underwent clinical 1.5T-MRI assessment. Whole tumour volumes were segmented and quantitative imaging parameters were derived using LifeX. Disease-free (DFS) and overall survival (OS) was compared between patients with ADC entropy above vs. below the median of 6.0. Histopathological heterogeneity and immunohistochemical subtype of tumour samples were determined. The effect of gemcitabine

treatment on survival was compared between ADC entropy groups.

Results: High ADC entropy led to worse median DFS (8.7 vs. 21.6 months) and OS (12.7 vs. 27.5 months) (N=39, $p < 0.0001$) in the surgical patient cohort. Patients in the high ADC entropy group had a 90% increased risk of high morphological tumour heterogeneity ($p=0.09$) and all patients with a quasi-mesenchymal molecular tumour subtype (n=9) belonged to this group. Patients with high ADC entropy who underwent gemcitabine treatment (N=25) had significantly improved DFS (5.5 to 9.5 months, $p=0.04$) and OS (5.5 to 14.6, $p=0.01$) while gemcitabine had no significant effect on DFS or OS in the low ADC entropy group (N=14). All metastatic PDAC cases belonged to the high ADC entropy group. Gemcitabine-based treatment provided a slight DFS benefit to these patients compared to FOLFIRINOX (11.6 vs. 7.6 months, $p=0.15$).

Conclusion: High ADC entropy predicts worse survival, improved gemcitabine-based chemotherapy response and is associated with increased tumour heterogeneity and the quasi-mesenchymal molecular subtype in PDAC.

B-1663 11:02

Clinical impact of lateral lymph nodes at pelvic MRI in patients with rectal cancer

I. Blazic, S. Patil, T. Konishi, N.M. Campbell, J. Garcia-Aguilar, M.J. Gollub; *New York, NY/US* (ivanablazic@yahoo.com)

Purpose: To determine the relationship between baseline lateral lymph nodes (LLN) size measured on pelvic MRI and clinical outcomes in patients with rectal carcinoma.

Methods and Materials: In this IRB-approved, HIPPA compliant retrospective study, we identified 245 patients (157 men, 88 women, median age 53 years) who received neoadjuvant treatment for clinical stage II or III rectal cancer and for whom baseline MR scans were available. Patients underwent surgery (n=216) or nonoperative management (n=29). Lateral node dissection was performed selectively in patients with grossly enlarged pelvic lymph nodes. MRI exams were reviewed for LLN size, characteristics and location by two radiologists blinded to patient outcomes. In a patient-level analysis, LLN size, node roundedness (short-/long-axis ratio ≥ 0.8), border irregularity and heterogeneity were correlated with disease-free-survival (DFS) using the Kaplan-Meier method and log-rank test. LLN was analysed at a literature-based cutoff of 5 mm. The importance of posterior external iliac (PEI) nodes was examined using multivariable Cox regression.

Results: A total of 845 lateral lymph nodes were evaluated on baseline MRI images (median 6mm; range 3-17mm). DFS was worse among patients with LLN size 5 mm or greater ($p=0.027$). Rounded and heterogeneous ($p=0.003, 0.035$), but not irregularly bordered LLN at baseline was associated with worse DFS. No difference in DFS was observed for PEI node size ($p=0.514$).

Conclusion: Lateral lymph nodes of 5mm or greater on baseline MRI in patients with rectal cancer portends worse survival. Round and heterogeneous nodes were also poor prognosticators.

B-0616 11:10

Investigating blood oxygenation level dependent (BOLD) MRI in small renal masses (SRM), and its correlation with dynamic contrast enhanced (DCE) MRI

N. Bogveradze¹, D. Prezzi¹, R. Neji¹, C. Kelly-Morland¹, H. Verma¹, K. Lashkhi², V.J. Goh¹; ¹London/UK, ²Tbilisi/GE (bogveradze.nino@gmail.com)

Purpose: To assess for: 1. Differences in BOLD & DCE MRI parameters between histological groups, including benign & malignant SRM. 2. Differences in BOLD & DCE MRI parameters between SRM & normal renal parenchyma. 3. Within-subject correlations between BOLD & DCE MRI parameters.

Methods and Materials: Following ethical approval and informed consent, 21 prospective adults with SRM planned for surgery underwent 3T MRI, including BOLD and DCE MRI in addition to anatomical sequences. Parametric maps ($T2^*$, AUC_{60} , K^{trans} , k_{ep} & v_e) were analysed by two radiologists in consensus. Differences in imaging parameters were assessed by Kruskal-Wallis and Wilcoxon signed-rank tests. Correlations were assessed using Spearman's rank test. Statistical significance was set at 5%.

Results: After technical exclusions (n=3), our cohort consisted of 18 patients with 19 SRM: 11 clear-cell carcinomas (ccRCC), 4 oncocytomas, 3 papillary carcinomas (pRCC) and 1 metanephric adenoma. Mean $T2^*$ did not differ significantly between histological groups ($P=0.20$), but showed consistent values in oncocytomas (median, 30.26 ms; range, 29.22-32.73). Conversely, $T2^*$ varied substantially among ccRCC (median, 20.44 ms; range, 9.20-53.08 ms) and pRCC (median, 23.85 ms; range, 5.64-26.62 ms). $T2^*$ was lower in SRM than in normal renal parenchyma ($P = 0.02$). Among DCE MRI parameters, v_e differed significantly between groups ($P = 0.03$). BOLD and DCE MRI parameters did not show significant within-subject correlations.

Conclusion: BOLD MRI provides potentially useful information for the diagnosis of renal oncocytoma, in the context of a multiparametric protocol. It captures information that is not directly correlated to DCE MRI.

Does perfusion-metabolic tumour phenotype predict for neoadjuvant therapy response in primary oesophageal tumours undergoing DCE-MRI and ¹⁸F-FDG PET/CT?

S.J. Withey, K. Owczarczyk, C. Yip, M. Siddique, A. Green, J. Bell, G. Cook, V.J. Goh; London/UK (samuel.withey@nhs.net)

Purpose: Oesophageal cancer has poor survival rates despite curative treatment. We hypothesized that a low perfusion-high metabolism phenotype may be associated with poorer response to neoadjuvant therapy. We aimed to assess the relationship between tumour perfusion and metabolism with therapy response.

Methods and Materials: Following ethical approval and informed consent, DCE-MRI and ¹⁸F-FDG PET/CT were performed prior to neoadjuvant therapy in 24 oesophageal cancers (18 male; mean age 64 ± 10 years; 21 adenocarcinoma, 3 squamous cell carcinoma). DCE-MRI transfer constant (K^{trans}) and ¹⁸F-FDG PET/CT maximum standardised uptake value (SUV_{max}) were calculated. Pathological response was defined by Mandart tumour regression grade 1-2; non-response by grade 3-5. K^{trans} & SUV_{max} were compared between pathological responders versus non-responders using Wilcoxon rank test. K^{trans}/SUV_{max} was calculated for each patient and the proportion of responders was calculated for each K^{trans}/SUV_{max} quartile using ChiSquare contingency test. Significance was at 5%.

Results: There was no difference in K^{trans} & SUV_{max} between pathological responders and non-responders ($p=0.8$, 1 and 0.6, respectively). There was no significant difference in pathological response rates between different K^{trans}/SUV_{max} quartiles (50%, 0%, 17% and 33%, respectively; $p=0.13$), however patients below the 25th percentile (low K^{trans} /high SUV_{max}) appeared to have a better response than patients >25% (3/5 versus 3/15, $p=0.1$).

Conclusion: No association was noted between a flow-metabolic phenotype and therapy response in patients. We have, however, highlighted significant variability in response in patients with different flow-metabolic phenotypes that will require characterisation in a larger patient cohort.

B-0618 11:26

Imaging texture features to predict neoadjuvant therapy response in locally advanced rectal cancer

G. Cappello, V. Doronzio, V. Romano, A. Timpani, G. Desi, F. Cortese, V. Giannini, S. Mazzetti, D. Regge; Candiolo/IT (giovanni.cappello@ircc.it)

Purpose: Patients with locally advanced rectal cancer (LARC) usually undergo neoadjuvant chemoradiotherapy (CRT) or radiotherapy (RT) alone, followed by surgical resection. In 15-30% of them pathological complete response is reached, therefore a wait-and-see approach could be a viable option. Aim of the study was to predict CRT response in LARC patients before treatment, using texture features derived from MRI and PET acquisitions.

Methods and Materials: 47 LARC patients with pre-treatment MRI and PET/CT underwent RT (46-55 Gy, 23-30 fractions) or CRT (RT plus 5-FU or Capecitabine) followed by total mesorectal excision. We considered responders (pR+) patients with complete (tumour regression grade, TRG=1) or near complete (TRG=2) regression; non-responders (pR-) patients with moderate (TRG=3) to no regression (TRG=5). Tumours were semi-automatically segmented on T2-w MRI, ADC maps and PET/CT. From each image first-order and 22 second-order parameters derived from Haralick analysis were extracted. Multivariate logistic regression was performed to identify features most correlated with TRG.

Results: 26 patients were classified as pR-, 21 as pR+ after total mesorectal excision. Five parameters were included in the multivariate regression (4 from PET and 1 from MRI), with $p=0.002$. The area under the ROC curve was 0.83, with sensitivity 75% and specificity 76% in detecting pR+.

Conclusion: Texture analysis on pre-treatment imaging could be useful in assessing response to neoadjuvant treatment in LARC patients. If results will be confirmed on larger datasets, the oncological pathway for LARC patients could be personalized delaying or advancing surgery, according to the prediction of treatment response.

B-0619 11:34

CT response evaluation of adrenocortical carcinoma (ACC) during and after chemotherapy: which criteria?

M. Bertuletti, D. Cosentini, S. Cieno, M. Di Terlizzi, S. Grisanti, B. Frittoli, A. Berruti, R. Ambrosini, L. Grazioli; Brescia/IT (bertuletti.med@gmail.com)

Purpose: The use of cytoreductive surgery in patients with locally advanced/metastatic adrenocortical cancer (ACC), where chemotherapy is the standard approach, is conditioned by CT evaluation of resectability and response assessment. The purpose of our study was to assess the prognostic impact on progression-free survival (PFS) of three different response criteria (RECIST 1.1, CHOI and tumour volume).

Methods and Materials: We retrospectively evaluated MDCT scans of 30 patients with pathologically confirmed ACC. Each examination was performed with a MDCT scanner (either Toshiba Aquilion with 160 detectors array or

Philips Brilliance with 64 arrays), before and after i.v. automatic injection of iodinated contrast agents (370 mgI/ml@3ml/s - 1.3 ml/Kg body weight), using a bolus tracking technique and image acquisitions during the arterial and venous phases. Two radiologists performed semiautomatic segmentation of every lesion using a dedicated software (Portal IntelliSpace, Philips), to measure lesional longer axis (RECIST 1.1 criteria), attenuation changes (CHOI) and volume changes after therapies.

Results: 18 patients underwent cytoreductive surgery, with a median PFS of 15.5 months (6.1 months in patients who did not have surgical approach). A statistically significant correlation was observed between CHOI criteria and PFS ($p=0.019$), whereas disease response assessed by RECIST 1.1 and volume variations failed to be associated with patient outcome.

Conclusion: In our early experience, ACC radiologic response evaluation to chemotherapy using CHOI criteria could represent an additional prognostic factor, especially in patients candidate to surgical approach.

B-0620 11:42

CT-response patterns and the role of CT-textural features in inoperable abdominal/retroperitoneal soft tissue sarcomas treated with trabectedin

M. Esser¹, C. Kloth², W. Thaiss¹, C.P. Reinert¹, J. Fritz³, M. Horger¹; ¹Tübingen/DE, ²Ulm/DE, ³Baltimore, MD/US

Purpose: To evaluate CT patterns and textural features of soft tissue sarcomas following trabectedin therapy as well as their suitability for predicting therapeutic response.

Methods and Materials: A total of 31 patients (18 female, 13 male; mean age 58.0 years; range 38-79 years) with sarcoma under trabectedin as a third-line therapy between October 2008 and July 2017 underwent baseline and follow-up contrast-enhanced CT. Response evaluation was based on modified CHOI-criteria and RECIST1.1, classified as partial response (PR), stable disease (SD), progressive disease (PD). For CT-texture analysis (CTTA), mean, entropy and uniformity of intensity/skewness/entropy of co-occurrence matrix (COM) and contrast of neighboring-grey-level-dependence-matrix (NGLDM) were calculated.

Results: Following CHOI-criteria, 9 patients achieved PR, 10 SD and 12 PD. RECIST1.1. classified patients into 5 PR, 15 SD and 11 PD. A frequent ($n=6/31$; 19.3%) pattern of response was tumour liquefaction. In responders, differences in entropy of entropy-NGLDM ($p=0.028$) and uniformity-NGLDM ($p=0.021$), in non-responders entropy of average ($p=0.039$), deviation ($p=0.04$) and uniformity of deviation ($p=0.013$) occurred between baseline and follow-up. Mean intensity and average were higher when liquefaction occurred ($p=0.03$; $p=0.02$), whereas mean deviation was lower ($p=0.02$) at baseline compared to other response patterns. Differences in mean ($p=0.023$), entropy ($p=0.049$) and uniformity ($p=0.023$) of entropy-NGLDM were found between responders and non-responders at follow-up. For the mean of heterogeneity, a cut-off value was calculated for the prediction of response in baseline CTTA (0.12; sensitivity 89%; specificity 77%).

Conclusion: A frequent pattern of response to trabectedin was tumour liquefaction being responsible for pseudoprogression; therefore, modified CHOI should be preferred. Single CTTA feature can be used complementarily for the prediction and monitoring response to trabectedin.

Differentiation of atypical non-functional pNET and PDAC using a CT radiomics-based nomogram

M. He, H. Xue, Z. Jin; Beijing/CN (377174431@qq.com)

Purpose: To develop and validate an effective model to differentiate NF-pNET from PDAC and present it in a nomogram.

Methods and Materials: Between July 2014 and December 2017, 147 patients (80 patients with PDAC and 67 patients with atypical NF-pNET) with pathology results and enhanced CT were consecutively enrolled and chronologically divided into primary and validation cohort. Three models were built to differentiate atypical NF-pNET from PDAC, including radiomics signature alone, clinico-radiological features alone and their integrated model. The diagnosis performance of the three models was estimated and compared with area under the receiver operating characteristic curve (AUC) in the validation cohort. Nomogram was used to present the model with best performance, and its calibration was also assessed.

Results: In the validation cohort, the AUC for the differential diagnosis was 0.884 with the integrated model, which was significantly improved compared with the model based on clinico-radiological features (AUC=0.775, p value=0.004), and comparable with the model based on radiomics signature (AUC=0.873, p value=0.512). The nomogram presenting the integrated model achieved good discrimination performances in both primary and validation cohorts with C-index of 0.960 and 0.884, respectively.

Conclusion: The integrated model outperformed the model based on the clinico-radiological features alone and comparable to the model based on the radiomics signature alone in the differential diagnosis atypical NF-pNET from PDAC. The nomogram incorporated radiomics signature, clinico-radiological features can serve as an easy-to-conduct tool for the differential diagnosis between atypical NF-pNET and PDAC.

Outcome of pneumatosis intestinalis and porto-mesenteric venous gas: a multicentric study

T.A. Auer¹, R. Kloeckner², D. Pinto Dos Santos³, M. della Seta¹, D. Geisel¹, B. Hamm¹; ¹Berlin/DE, ²Mainz/DE, ³Cologne/DE

Purpose: To evaluate outcome and mortality of the radiological finding pneumatosis intestinalis (PI) and porto-mesenteric venous gas (PMVG).

Ethics committee approval: Institutional review board approval of this retrospective study was obtained (EA2/238/17)*

Methods and materials: In this retrospective multicentre study design, the radiology information systems of three tertiary care university medical centres searched for CT reports associated with PI. A total amount of 322 patients (132 women, 190 men) with PI were identified. Additionally, presence of "benign PI", PMVG, outcome and mortality (90d-Follow-up) were evaluated. "Benign PI" was defined as conservatively treated patients with radiologically confirmed PI who did not die within the 90d-follow-up.

Results: Overall mortality for patients with PI was 54.1% within 90d after diagnosis while 53.7% of all patients received surgical treatment. For patients with PI in association with PMVG mortality increased to 68.2% ($p < 0.001$). Ischemia, obstructive bowel dilatation and/or infection were the most frequent causes of PI. Kaplan-Meier-curve showed a shortened survival for patients with PI and PMVG; Log-Rank-test: $p < 0.001$ (Median survival: PI: 59d (2.8± SD; 95% CI 54.2-65.3) / PI and PMVG: 40d (3.6± SD; 95% CI 33.2-47.2).

Limitations: The limitation of this study is the retrospective and unrandomised character.

Conclusion: PI is not strictly associated with ischemia and high rates of mortality. In fact, there are several benign causes or favourable harmless conditions PI is frequently associated with; thus, PI is not inherently connected with an infaust prognosis. Nevertheless, the extension seems to matter as mortality increases significantly when PI comes in association with PMVG.

Diffusion-weighted MRI in the assessment of neuroblastoma: results of a multi-centre trial

A.M. Hötter¹, Y. Mazaheri², A. Lollert³, J.-P. Schenk⁴, C. Düber³, P. Mildnerberger³, O. Akin², N. Graf⁵, G. Staatz²; ¹Zurich/CH, ²New York, NY/US, ³Mainz/DE, ⁴Heidelberg/DE, ⁵Homburg (Saar)/DE (andreas.hoetker@usz.ch)

Purpose: To assess the value of diffusion-weighted MRI in the pre-therapeutic evaluation of paediatric renal tumours, including the identification of histological subtypes of neuroblastoma with known adverse outcomes.

Ethics committee approval: The institutional review board approved this multicentric study and waived the requirement for informed consent.

Methods and materials: This retrospective multicentric study included 122 paediatric patients with 130 renal tumours, who underwent MRI including DWI before neoadjuvant chemotherapy and nephrectomy. Two radiologists independently assessed each tumour volumetrically, and apparent diffusion coefficient (ADC) values were calculated on a voxel-wise basis, including parameters derived from histogram and texture analysis.

Results: Inter-reader agreement was excellent (ICC: 0.717-0.975). For both readers, patients with locally aggressive tumour growth (SIOP 3 stage) or with metastases (M1) had significantly lower 12.5th-percentile ADC values ($p \leq 0.028$) compared to those with lower-stage tumours, and the parameter Energy differed significantly between patients with M1 and those with M0 status ($p \leq 0.028$). Contrast and homogeneity differed significantly between benign neuroblastomatosis and malignant neuroblastoma ($p \leq 0.045$, both

readers). As compared to all other subtypes, the blastemal subtype demonstrated significantly higher skewness ($p \leq 0.022$, both readers) and the diffuse anaplastic subtype demonstrated significantly higher 75th-percentile ADC values ($p \leq 0.042$, both readers).

Limitations: Given the multicentric retrospective approach, technical differences between the MRI examinations could not be accounted for.

Conclusion: Diffusion-weighted MRI may be of value in identifying benign neuroblastomatosis and assessing neuroblastoma subtypes. Therefore, it could play an important role in risk stratification for paediatric patients with renal tumours in the future.

Validation of deep learning algorithms for the detection of critical findings in head CT scans

S. Chilamkurthy¹, R. Ghosh¹, S. Tanamala¹, M. Biviji², N. Campeau³, V.K. Venugopal⁴; ¹Mumbai/IN, ²Nagpur/IN, ³Rochester, MN/US, ⁴New Delhi/IN (swetha.tanamala@qure.ai)

Purpose: To validate a set of deep learning algorithms for automated detection of key findings from non-contrast head-CT scans: intracranial haemorrhage and its subtypes, calvarial fractures, midline shift and mass effect.

Ethics committee approval: Exempt because of retrospective analysis.

Methods and materials: We retrospectively collected a dataset containing 313,318 head-CT scans of which random subset (Qure25k dataset) was used to validate and rest to develop algorithms. Additional dataset (CQ500 dataset) was collected from different centres to validate algorithms. Patients with post-operative defect or age < 7 were excluded from all datasets. Three independent radiologists read each scan in CQ500 dataset. Original clinical radiology report and consensus of readers were considered as gold standards for Qure25k and CQ500 datasets respectively. Areas under receiver operating characteristics curves (AUCs) were used to evaluate algorithms.

Results: After exclusion, Qure25k dataset contained 21,095 scans (mean-age 43; 43% female) while CQ500 dataset consisted of 491 (mean-age 48; 36% female) scans. On Qure25k dataset, algorithms achieved an AUC of 0.92 for detecting intracranial haemorrhage (0.90-intraparenchymal, 0.96-intraventricular, 0.92-subdural, 0.93-extradural, and 0.90-subarachnoid haemorrhages). On CQ500 dataset, AUC was 0.94 for intracranial haemorrhage (0.95, 0.93, 0.95, 0.97, and 0.96 respectively). AUCs on Qure25k dataset were 0.92 for calvarial fractures, 0.93 for midline shift, and 0.86 for mass effect, while AUCs on CQ500 dataset were 0.96, 0.97 and 0.92 respectively.

Limitations: Inclusion of follow-up scans, low concordance between radiologists for fractures in CQ500.

Conclusion: This study demonstrates that deep learning algorithms can identify head-CT scan abnormalities requiring urgent attention with high AUCs.

Patient preference for coronary CT angiography and invasive coronary angiography: results from a randomised controlled trial

G. Abdala Gehling¹, S. Feger¹, M. Rief¹, M. Laule¹, M. Dewey¹, E. Schönenberger²; ¹Berlin/DE, ²Hanover/DE

Purpose: To compare patient preference for coronary CT angiography (CTA) and invasive coronary angiography (ICA).

Ethics committee approval: Institutional review board approval was obtained and all patients provided written informed consent.

Methods and materials: 329 patients with stable chest pain, suspected coronary artery disease, and a clinical indication for ICA were randomly assigned to either CTA or ICA at a single centre. Patient preference was assessed using a previously validated questionnaire completed after CTA or ICA. Assessment included preparation for the tests, concern, degree of helplessness, pain, overall satisfaction, and preference for future testing.

Results: Out of the patients randomised to CT and ICA, 91% (152 of 167 patients) and 81% (140 of 162 patients, $P = 0.19$ NS) completed the assessment. Patients reported that they felt better prepared for CTA ($P < 0.001$), less concerned ($P < 0.001$) and had a lesser degree of helplessness ($P < 0.001$) than during ICA. Subjective pain measurements were significantly lower for

CTA (6.8±2.3) than for ICA (17.1±3.8; P<0.001). Overall satisfaction was in favour of CTA (P<0.001) and the vast majority of patients (79%) would choose CTA over ICA for future decision making and diagnostic management.

Limitations: Incomplete response rate and randomised patient preference assessment.

Conclusion: This randomised study shows that patient preference is in favour of CTA when compared with ICA indicating the potential of coronary CTA to be more widely used.

Perspectives of radiologists and cardiologists about the severity of health events in the multicentre DISCHARGE trial - on behalf of the DISCHARGE investigators

V. Wieske, M. Dewey; Berlin/DE

Purpose: To evaluate physicians' perspectives about the severity of different health events in the context of trial endpoints within the European DISCHARGE trial.

Ethics committee approval: Local amendment of the ethics approval for this study was added for the survey if needed due to local standards.

Methods and materials: We used the DISCHARGE trial network to evaluate perspectives of physicians from different disciplines on the severity of major adverse cardiovascular events. A questionnaire for identification of doctors at all partner sites was followed by designing a questionnaire about health events severity (scale from 1 to 7). Scheduled physicians were chosen based on the number of available cardiologists and radiologists.

Results: A total of 422 physicians from 14 sites were included in this analysis (218 cardiologists, 174 radiologists, 30 other specialists); 63.4 % were male, 36.6 % female doctors. Distribution of severity ranking for cardiovascular death and death of any cause was equal between cardiologists and radiologists. Large discrepancies were observed for hospitalisation for unstable angina which radiologists rating them significantly more severe than cardiologists.

Limitations: Only a sub-group of sites (15 of 26) participated in this analysis.

Conclusion: Our analysis showed the presence of differences between different medical specialists when rating different health events. This topic is important for patient care and future clinical trial design and thus we will compare the results with the patients perspective as a next step to identify potential differences between the groups.

A multi-stage randomised clinical trial to reduce variation in computed tomography radiation dose

Y. Wang, P. Chu, S. Yu, R. Smith-Bindman; San Francisco, CA/US

Purpose: Radiation doses for computed tomography examinations are variable and often higher than necessary for diagnosis, and an RCT was conducted to help sites lower and standardise doses.

Ethics committee approval: IRB approved and no informed consent since data received was de-identified after scan was performed.

Methods and materials: We created a registry of 1.2 million abdomen, chest, head, and combined chest-abdomen (CAP). CT adult exams collected 11/2015-10/2017 from 101 hospitals. We administered two interventions through stepped-wedge design: simple audit, ranking hospital performance and suggesting improvements, and multicomponent intervention, combining another audit with an 8-week course. To assess dose variance, we fit – for effective dose and CTDIvol – a complex variance mixed linear regression model with the background time and intervention stage as fixed effects of interest and constituents of variance structure. Patient characteristics are added as confounding fixed effects and the machine as a random effect.

Results: The variance of effective dose decreased over time for all anatomic areas, though attributability to the intervention varies. Respectively, the multicomponent intervention contributed 6%, 10%, 12%, and 35% dose variance decrease to abdomen, chest, head, and CAP scans, in addition to background time trends. The intervention impact on CTDIvol variance is comparatively modest, with most decrease attributable to background trends.

Limitations: All institutions had one type of dose-monitoring software.

Conclusion: The dichotomy between strong impact on effective dose variance and comparatively weak impact on CTDIvol variance mirrors the study of impact on dose mean, further insinuating that many dose reductions were achieved by reducing multi-phase scanning.

Funding for this study: Funded by PCORI & NIH.

Macrocytic or linear MR contrast agent: are there any differences in detection of local recurrence of prostate cancer after radical prostatectomy?

F. Kossov, B. Olimov, P. Bulychkin, S. Tkachev, G. Akhverdieva, V. Panov, I. Tyurin; Moscow/RU (fil-doc@yandex.ru)

Purpose: Salvage radiation therapy (SRT) is a basic treatment approach in patients with prostate cancer recurrence (PCaR) after radical prostatectomy (RP). Routine diagnostic techniques (THUS, CT, morphological MRI) have a low accuracy in PCaR detection. Multiparametric MRI (mpMRI) significantly improved the detection of clinical PCaR. The aim is to analyse what is the dominant sequence of mpMRI for PCaR detection in patients after RP? Is the efficiency of the dynamic contrast enhancement (DCE) with different MR contrast agents (MRCA) (macrocycle 1.0 mmol/ml and linear 0.5 mmol/ml) equal?

Methods and Materials: 62 men (52-71 years old, median - 64) with biochemical recurrence after RP suspected for PCaR were examined by mpMRI: 1) 33 patients received macrocycle MRCA (gadobutrol, 1,0 mmol/ml); 2) 29 patients received linear MRCA (gadoversetamide and gadodiamide, 0,5 mmol/ml). The response for SRT was declared positive in cases where progressive decrease of PSA was evaluated.

Results: DCE was the dominant sequence of mpMRI for PCaR detection. Tumour tissue sizes in patients with clinical PCaR had statistically significant correlation with PSA level ($R=0.74$; $p<0.0008$). Macrocycle MRCA was significantly more effective in the detection of small ($<8\text{mm}$) clinical PCaR ($p<0.018$). Efficacy of PCaR detection (tumour tissue size $>8\text{mm}$) after 1.0 and 0.5 mmol/ml MRCA injection was equal.

Conclusion: Macrocycle MRCA with concentration 1.0 mmol/ml is more effective in the detection of more smaller clinical PCaR ($<8\text{mm}$) in comparison with linear MRCA. DCE is the dominant sequence of mpMRI in the detection of PCaR.

Contrast-enhanced ultrasonography (CEUS) surveillance of native kidneys in renal transplant patients: a monocentric experience

E. Bertelli, S. Agostini, S. Verna, S. Lucarini, E. Savi, L. Mercatelli, P. Carta, S. Serni, V. Miele; *Florence/IT (elena.bertelli3@gmail.com)*

Purpose: Renal transplant recipients (RTR) are at higher risk of renal cell carcinoma (RCC) in native kidneys, especially if they are affected by acquired cystic kidney disease (ACKD), so a routine screening is recommended. To decrease the use of contrast-enhanced CT (CECT) and thus avoid the risk of contrast-induced nephropathy in RTR with ACKD, we prospectively studied the usefulness of CEUS in characterizing renal lesions.

Methods and Materials: 212 consecutive RTRs underwent routine post-transplant US. ACKD was diagnosed in 68. The patients with questionable US result were enrolled in our study. Native kidneys were studied by CEUS and, in instances of positive CEUS, by CECT. Follow-up (FU) was ≥ 3 years.

Results: US identified 38 suspicious or questionable lesions. According to the Bosniak scheme, CEUS classified these lesions as 19 BI, 4 BII, 6 BIII, 4 BIII and 5 solid. The BIII and solid lesions were further studied by CECT, which confirmed CEUS findings in all the solid lesions. In the 4 BIII, CECT confirmed 2 malignancies, and 2 were degraded to BIIIF. No changes were observed in FU lesions. The statistical analysis has shown no difference between the two series. No patient suffered adverse reactions. CEUS decreased by 76% the use of CECT. The limits of our study are the sample size and perhaps the short FU.

Conclusion: CEUS is safe and it is a useful tool in screening for the selection of patients who need to be further evaluated by CECT.

B-0624 11:03

Iodine in common contrast-enhanced CT protocols does not affect renal function in a high-risk population with chronic kidney disease

M. Koci, A. Graber-Naidich, X.S. Cheng, D. Fleischmann, M.J. Willeminck; *Stanford, CA/US (mkoci@stanford.edu)*

Purpose: Administration of iodinated contrast is considered a risk factor for post-contrast acute kidney injury (PC-AKI) in patients with chronic kidney disease (CKD). We sought to evaluate the effect of clinically used doses of iodinated contrast administration on the kidney function of high-risk patients.

Methods and Materials: We retrospectively identified 362 patients who underwent a contrast-enhanced CT examination of the chest, abdomen, or lower extremities between January 2017 and August 2018, with estimated glomerular filtration rate (eGFR) 30-60 ml/min/1.73m² in the year before the CT. Contrast volumes (CV), serum creatinine (sCr) before and after CT, were available (at least 14 days before and 48-72 hours after CT). The primary endpoint was PC-AKI, defined as $>50\%$ or >0.3 mg/dL increase in sCr after CT. Individual laboratory-defined levels for low, normal, and high sCr values were used to evaluate sCr category changes.

Results: Median age (interquartiles) was 66.9 (58.0-75.9) years. Patients with eGFR 30-45 and eGFR 45-60 ml/min/1.73 m² had similar PC-AKI incidence (10.8% versus 7.7%, respectively; $p=0.34$) and contrast volume (95 [80-121] ml versus 96 [85-123] ml, respectively; $p=0.88$). Pre-CT sCr was high in 38.4% (139/361). We observed sCr increase from normal to high in 8.6% (31/362), and sCr decrease from high to normal in 10.8% (40/362). In 8.6% (31/362) of patients sCr increased by 0.3 mg/dL.

Conclusion: Our study showed that even in a high-risk population of patients with a substantially reduced kidney function (eGFR <45), the incidence of PC-AKI after contrast-enhanced CT was low and comparable to patients with eGFR >45 .

B-0625 11:11

Contrast-enhanced ultrasound (CEUS) efficiency in renal graft complication evaluation

C.G. García Roch¹, F. García García¹, F.X. Aragon Tejada², J. Ciampi Dopazo¹, M. Muñoz Cepeda¹, M. Bernabéu Rodríguez¹, R. Giovanetti González³, A. Roca¹, P.A. Baron Rodiz²; ¹Toledo/ES, ²Madrid/ES, ³Córdoba/ES (carmen.roch@gmail.com)

Purpose: To evaluate contrast-enhanced ultrasound (CEUS) efficiency in the diagnosis of renal graft parenchymal and vascular complications.

Methods and Materials: Retrospective, observational, descriptive study that includes all adult patients transplanted in our centre from January 2011 to January 2015. Patients underwent a first baseline US (B mode and colour and pulsed Doppler US) examination within 24-72 hours post-surgery. In cases with abnormal findings, 2nd generation intravenous US contrast (Sonovue®) was administered as protocolled, to obtain qualitative evaluation of the parenchymal graft and vascular contrast uptake. No complications were observed in any examinations, all of which were performed by the same experienced radiologist.

Results: CEUS was performed in 27 patients (out of 131). 6 grafts presented pathological findings in baseline US but CEUS showed no significant alterations. These cases corresponded to exclusively parenchymal involvement: acute rejection in one patient, with histological confirmation, and 5 cases of acute tubular necrosis. A total of 25 complications were depicted in the remaining 21 patients, with infarction, artery stenosis and necrosis being the most frequent. Complementary imaging studies included 10 CT scans and 3 arteriographies, none of which provided additional information to CEUS.

Conclusion: Qualitative assessment of the parenchymal uptake of US contrast was insufficient for the diagnosis of ATN and rejection since CEUS in these patients was normal despite presenting anomalies in baseline US. On the contrary, CEUS offers rapid and reliable diagnosis of renal infarction, necrosis, and vascular stenosis or thrombosis with precise detail of location and extension.

B-0626 11:19

Comparison of computed tomography (CT) and contrast-enhanced ultrasound (CEUS) for the management of complex renal cysts: a single-centre experience

G. Piccoli; *Conegliano/IT (piccoli.gianluca@gmail.com)*

Purpose: To compare CT and CEUS Bosniak classification for the assessment of cystic renal masses and to gauge the correspondence between CEUS Bosniak classification and clinical/histological outcome.

Methods and Materials: Between March 2017 and February 2018, 35 patients underwent CT and CEUS; 37 complex renal cysts were evaluated.

Results: Bosniak score after CEUS was downgraded in 7 patients (6 to Bosniak I); in 18 it was maintained; in 10 upgraded. Eight complex renal cysts underwent surgery: 2 were a simple renal cyst and an oncocytoma (Bosniak IIF and IV after CT, III and IV after CEUS); 6 were malignant: 1 multilocular cystic renal neoplasm of low malignant potential, 1 papillary renal cell carcinoma (RCC) type 1 and 4 clear cell RCC (2 Bosniak IIF, 3 Bosniak III, 1 Bosniak IV after CT; after CEUS 1 Bosniak IIF, 1 Bosniak III, 4 Bosniak IV). Three complex renal cysts were upgraded from Bosniak III to Bosniak IV, all were RCC. Two Bosniak IV cysts were confirmed after CEUS: an oncocytoma and an RCC. Two patients with Bosniak 4 cysts are waiting for surgery. No side effects were recorded after CT or CEUS.

Conclusion: CEUS is a useful alternative to CT scan for the assessment of complex renal cysts, in particular, when iodinated CT contrast is contraindicated. CEUS can help to better define Bosniak score and to select patients candidates to end the follow-up or to surveillance. Furthermore, CEUS can reduce the ionizing radiation exposure and the CT scanners workload.

Using contrast-enhanced ultrasound to assess diagnostically challenging and indeterminate lesions in native and transplant kidneys

P. Lee, A. Mehdi, A. Alsafi, C. Harvey, A.K.P. Lim; *London/UK (philippa.lee08@gmail.com)*

Purpose: Ultrasound is often the initial modality in detection and assessment of renal lesions which are then commonly characterised further with CT/MR. The use of ultrasound contrast agents (UCAs) allows immediate accurate characterisation without the associated delay, anxiety, cost and potential exposure to nephrotoxic agents which CT/MR entails. This study aims to analyse the role of CEUS in the assessment of diagnostically challenging and indeterminate renal lesions and evaluate if CEUS adds diagnostic value to other imaging modalities.

Methods and Materials: We performed retrospective analysis of patients at a tertiary transplant and renal centre in London between 2004 and 2018. 262 patients who underwent CEUS for renal lesions were identified on PACS and their prior and subsequent imaging following CEUS was reviewed and analysed. The role of CEUS diagnostic value was then evaluated and categorised as "diagnosis provided", "confirmed suspected diagnosis", "added information only" or "no added value".

Results: CEUS added value compared to the initial US in 82% of cases. 37% of the patients had an initial CT and/or MR. In this group, CEUS added value in 75%. Diagnoses in this group included complex Bosniak cysts, differentiation of cystic and solid lesions, pseudotumours, complicated pyelonephritis/

abscesses, infarction/ischaemia and characterisation of benign/malignant lesions.

Conclusion: CEUS adds additional diagnostic value in assessment of focal renal lesions and perfusion abnormalities compared to US and CT/MR. CEUS rivals CT/MR in the characterization of renal lesions and in some cases surpasses them because of real-time imaging and greater spatial and temporal resolution of the microcirculation.

B-0628 11:35

Characterisation of CT-indeterminate renal masses by contrast-enhanced ultrasound and acoustic radiation forced impulse imaging

S. Kaufmann, W. Thaiss, M. Horgler, K. Nikolaou, J. Bedke; *Tübingen/DE*

Purpose: To prospectively characterise CT-indeterminate renal masses (CTIRM) using acoustic radiation force impulse (ARFI) elastography and contrast-enhanced ultrasound (CEUS) and to correlate quantitative imaging findings with histopathology or interim follow-up (FU).

Methods and Materials: 123 patients with CTIRM (longest diameter <4cm) underwent ARFI and CEUS with CT-image fusion (IF). Exclusion criteria included all contraindications for CEUS and IF. Shear wave velocity (SWV), shear wave ratio (SWR), peak intensity (PE), time to peak (TTP) and wash-in rate (Wi) were quantified. In case of a cystic lesion classified as \leq Bosniak 2F, follow-up imaging was performed.

Results: 77 out of 123 patients underwent surgical resection of a lesion due to suspect imaging findings, whereas 46 patients underwent FU, which did not show upgrading in Bosniak category. Histopathology revealed 58 renal cell carcinomas (5 chromophobe (chRCC), 18 papillary (pRCC) and 35 clear cell (ccRCC)), 10 oncocytomas and 9 non-malignant renal lesions (1 minimal fat AML, 3 focal nephritis and 5 infected cysts). SWV and SWR differed significantly between ccRCC, pRCC, chRCC ($p=0.0024$, $F=13.94$) and in SWR also for oncocytoma ($p<0.0001$, $F=14.35$). In CEUS, oncocytoma and ccRCC showed significant higher PE values ($p<0.0001$, $F=77.31$) as well as higher Wi and lower TTP compared to all other solid lesions.

Conclusion: Quantitative CEUS and ARFI imaging can provide relevant information to further characterise CT-indeterminate renal masses to guide urological decision-making and offers the possibility of differentiation between ccRCC from less malignant RCC subtypes and from oncocytoma.

B-0629 11:43

Correspondence analysis between different reference lines used in magnetic resonance defecography of pelvic organs prolapse or the measurement of prolapse of pelvic organs with POPQ

S. Yévenes Aravena, G. Cárdenas Loguerco, J. Casas Muñoz, F. Araya Campos, C. Garrido Inostroza, V. Manríquez Galán, R. Guzmán Rojas, M. Naser Nassar, D. Castro Caperán; *Santiago/CL (syevenes@gmail.com)*

Purpose: The aim of this study was to evaluate which of the reference lines: pubococcygeal (PCL), mid-pubic (MPL) or H (HL), commonly used in Magnetic Resonance Defecography (MRD) for evaluation of pelvic floor dysfunction, has better correspondence with the Pelvic Organ Prolapse Quantification system (POPQ).

Methods and Materials: Observational, cross-sectional study. POPQ stage and demographic data was obtained of fifty-six patients in which MRDs was performed. The MRDs were reviewed by four expert radiologist and prolapse was measured using PCL, MPL and HL. A bivariate correspondence analysis and quantification of the inertia of the two dimensions under study was performed between each line and the POPQ.

Results: The mean age was 45.2 ± 11.1 years. The analysis of the anterior compartment only obtained an adequate correspondence between PCL and HL on POPQ stages I-II. For the middle compartment there is a slight correspondence between PCL and POPQ stages 0-II, there is also correspondence between the MPL and POPQ stages 0-I, with greater correspondence in patients without prolapse. For the posterior compartment no correspondence was obtained for any of the lines.

Conclusion: There is no adequate correspondence between MRD reference lines and POPQ when evaluating the pelvic floor as a whole. When analyzed by compartments, there is better correspondence with PCL and HL in the anterior compartment, and for PCL and MPL in the middle. There is no correspondence for the posterior. These results make us propose that the analysis of MRDs should be done separately, using specific lines for each compartment.

Outcome in 73 patients with benign prostatic hyperplasia treated by an ultrasound guided transperineal laser ablation by interventional radiologists

G. Patelli¹, F. Besana¹, E. Faietti¹, G. Ori Belometti¹, C. Costa¹, A. D'Alessio², G. Mauri³, C.M. Pacella⁴; ¹Seriante/IT, ²Zingonia/IT, ³Milan/IT, ⁴Rome/IT (patellig@yahoo.it)

Purpose: To report results of ultrasound-guided (US-g) Transperineal Laser Ablation (TPLA) in patients with Benign Prostatic Hyperplasia (BPH).

Methods and Materials: seventy-three patients (mean age 72.6 ± 10.4 years, range 58-93) with obstructive syndrome secondary to BPH, were treated by TPLA using continuous wave (CW) diode laser source at 1064nm (Echolaser SoracteLite, Elesta s.r.l., Calenzano (FI), Italy). Under transrectal US-g, one or two 21G introducer needles for each lobe, according to the prostate volume, were inserted with transperineal approach. Each ablation was performed at 3W power for 1800J energy. A pull back was done case by case according to the prostate volume. Major and minor complications were recorded. The efficacy was evaluated on the changes of means of International Prostate Symptoms Score (IPSS), Quality of Life (QoL), post-void residual (PVR), prostate volume and the ejaculatory function. The mean hospital stay was measured.

Results: At a mean follow-up time of 16 months (range 3-45), IPSS improved from 22.9 to 9.6 ($P<0.001$), QoL from 4.5 to 1.2 ($P<0.001$), PVR from 162.3 ml to 64 ml ($P<0.001$) and prostate volume from 73.47 ml to 50.8 ml ($P<0.001$). Of 34 patient evaluated for ejaculatory function, 32 (94%) maintained a satisfactory ejaculation. No major complications occurred. The mean operation time was 42.3 ± 8.7 min, ablation time 15.6 ± 3.4 min, energy deployed $11,540.0 \pm 3,680.5$ J, hospital stay 1.7 ± 0.4 days.

Conclusion: TPLA is a mini invasive treatment for BPH. This therapeutic approach was safe, efficacious and with a satisfactory outcome.

Evaluation of acoustic radiation force impulse imaging in the diagnosis of malignant cervical lymphadenopathy

R. Kamat¹, A. Ramesh², K. Nagarajan²; ¹Chandigarh/IN, ²Puducherry/IN (rohanskmt@gmail.com)

Purpose: B-mode ultrasound though useful in the assessment of cervical nodes cannot measure the tissue elasticity. Elastography helps in non-invasive assessment of tissue stiffness. As malignant nodes are generally stiffer than benign nodes, this technique might be beneficial in differentiating them. Acoustic radiation force impulse (ARFI) imaging used in this study is a technique based on shear wave elastography. ARFI could be valuable in the evaluation of cervical lymphadenopathy as a result of its high specificity. Our aims were 1) to assess diagnostic power of ARFI in differentiating benign and malignant cervical nodes and to compare it with B-mode imaging; 2) to compare the shear wave velocities (SWV) between benign and malignant nodes.

Methods and Materials: A total of 166 cervical nodes from 166 patients were examined using B-mode, Doppler and ARFI, between October 2015 and April 2017. SWV, virtual touch imaging (VTI) and area ratio (AR) were calculated for each node and the results were compared with FNAC/biopsy.

Results: Median SWV of benign and malignant nodes were 1.9 (1.56-2.55) m/s and 6.7 (2.87-9.1) m/s, respectively. A SWV >2.68 m/s helped in identifying a malignant node with 81% specificity, 81.6% sensitivity and 81.3% accuracy. AR and predominantly dark elastograms were useful in identifying malignant nodes. ARFI was found to be inaccurate in tuberculous and lymphomatous nodes.

Conclusion: Malignant nodes had significantly higher SWV, AR and darker elastograms compared to benign nodes. SWV had the highest accuracy amongst all the parameters. ARFI imaging accurately identifies the malignant nodes, hence guiding the FNAC/biopsy.

SUV-based lymph node selection for fine-needle aspiration guided by real-time fused ultrasound and FDG PET in head and neck cancer patients

P. De Koekkoek-Doll, W. Vogel, M.W.M. van den Brekel, L. Smit, R.G.H. Beets-Tan, M. Maas; *Amsterdam/NL (petra.dkd@gmail.com)*

Purpose: FDG PET-CT can detect lymph node metastases in head and neck cancer with high sensitivity and ultrasound (US)-guided fine-needle aspiration (FNA) can provide histological proof with high specificity. We assume that real-time fused US+FDG PET-CT for FNA (Fused-FNA) will provide accurate nodal staging. Aim was to determine the optimal SUV_{max} to select nodes for Fused-FNA.

Methods and Materials: 128 patients (female 30%, male 70%, age mean 63 and range 32-88) were prospectively included. FDG PET-CT was acquired according to clinical diagnostic protocols. Live US was fused with PET-CT and Fused-FNA was performed using the electromagnetic navigation system Percunav on a Philips EPIQ US machine. FNA took place on nodes with visually increased metabolic activity. The reference standard was cytology from FNA performed on all suspect nodes on US. ROC curves were constructed and area under the curve (AUC) was used to assess diagnostic performance.

Results: FDG PET detected a total of 269 suspect nodes in 117/128 (91%) of patients. Live fusion failed in 6 (3%) of these nodes, and Fused-FNA cytology results were inconclusive in 16 (6%) of nodes. In the remaining 247 (94%) FDG-positive nodes 135/247 (55%) Fused-FNA yielded malignant cytology. AUC was 0.887 (95% CI 0,845-0,929). The optimal cut-off for SUV_{max} was established at 4.87, yielding a sensitivity of 90% and specificity of 71%.

Conclusion: Selecting nodes with SUV_{max} ≥ 5 on FDG PET-CT for real-time fusion-guided US-FNA yields a high accuracy for the detection of malignant nodes.

B-0633 10:46

Correlation between preoperative 4D CT parathyroid volumes and perioperative PTH levels

A. Yates, P. Cromwell, N.M. Hughes, S. Skehan, D. Evoy, E. McDermott, R. Prichard; *Dublin/IE (ayates@tcd.ie)*

Purpose: The aim of this study is to examine if there is a correlation between estimated 4D CT volume of a parathyroid gland with perioperative parathyroid PTH level and serum ionised calcium (iCa) levels in patients with a solitary parathyroid adenoma. The secondary aim was to compare the estimated CT parathyroid gland volume against the post operative volume.

Methods and Materials: Data was collected from a prospectively maintained database of adult patients who were diagnosed with a solitary PT adenoma and had a pre-operative 4D CT who subsequently underwent a parathyroidectomy over a 5 year period (2012-2017).

Results: 58 patients were included in the study. The mean age was 59.84 years. There were 16 men (27.6%) and 42 women (72.4%). The median estimated parathyroid gland CT volume was 0.265cm³ (IQR: 0.150-0.522cm³) while the median post op volume was 0.724cm³ (IQR: 0.399-1.47cm³). The median drop in PTH was 97.9 (IQR: 63.7-158.1ng/L). The correlation between CT volume and PTH drop was 0.474 (P<0.001) using the Spearman's Coefficient.

Conclusion: Pre-operative parathyroid weight, as estimated by CT, positively correlates with the post-operative reduction in PTH. Estimating volume using 4D CT imaging is a useful tool in the preoperative workup of parathyroid adenomas.

B-0634 10:54

Evaluation of sensitivity and specificity of elastography for differentiating benign from malignant cervical lymphadenopathy and comparing with B-mode and colour Doppler findings

K. Mittal¹, V. Bansal²; ¹Delhi/IN, ²New Delhi/IN (kapishmittal1989@gmail.com)

Purpose: To evaluate the sensitivity and specificity of elastography for differentiating benign from malignant cervical lymphadenopathy and to compare its findings with B-mode and colour Doppler findings.

Methods and Materials: The present study was conducted on 50 patients with cervical lymphadenopathy. This selection was based on size of the lymph node and other B-mode sonography characteristics. B-mode and colour Doppler findings were recorded. In addition to this, strain elastography was done and five elastography patterns were defined: high elasticity (soft): pattern I represented no or very small hard area while spectrum pattern V presented where almost whole of lymph node showed hard pattern on strain elastography. Additionally, a cine loop of elastography was acquired for calculation of strain ratio using adjacent muscle as reference. A cut-off value of less than two (<2) of strain ratio was used to define benign lymph nodes and more than or equal to two (≥2) was used to define malignant lymph nodes. Final diagnosis of benign versus malignant lymph node was based upon other relevant investigations like FNAC/biopsy findings and/or clinical follow-up after three months.

Results: Of all the B-mode parameters, only lymph node border and hilum showed more than 70% accuracy for correctly differentiating benign from malignant lymph nodes while colour Doppler showed 82% accuracy for the same. Elastography pattern and strain ratio achieved 90% and 94% accuracy for correctly differentiating benign from malignant lymph nodes.

Conclusion: Elastography pattern and strain ratio are useful in addition to B-mode and colour Doppler ultrasound for the evaluation of cervical lymph nodes.

B-0635 11:02

Diagnostic accuracy of image-guided core needle biopsy of lymphoma suspected patients

M. Kazemi, M. Mikalani, H. Sharifian, B. Moradi; *Tehran/IR (Ma-kazemi@sina.tums.ac.ir)*

Purpose: In this study we aimed to evaluate the efficacy of image-guided core needle biopsy (CNB) for the diagnosis of lymphoma.

Methods and Materials: This cross-sectional study during 2016-2018, included 46 consecutive patients with suspicious imaging and clinical findings of lymphoma. They went under image-guided CNB by 16 gauge core biopsy needle. At least 3 cores were obtained from each patient. All the patients were followed at least for 1 year.

Results: Pathologic results showed 3 main groups: 1-lymphoma with specific type (35%), 2-lymphoproliferative or lymphocytic and histiocytic infiltration (22%), 3-other pathologies (as other malignancies, infection, reactive) (43%). All the group 2 patients went under surgical excisional biopsy (SEB) that 40% of them showed lymphoma. So in patients with lymphoma 80% were correctly diagnosed by CNB and treated directly. Another remaining 20% were categorized under group 2 and diagnosed by SEB. No patient with lymphoma was missed.

Conclusion: Image-guided CNB in patients with lymphadenopathy suspicious for lymphoma, is an effective and safe method as an initial diagnostic tool.

B-0636 11:10

Arterial spin labelling (ASL) MRI to assess nodal metastases in head and neck cancer

R. Balaji; *Chennai/IN (ravikanthbalaji@gmail.com)*

Purpose: To evaluate the feasibility of predicting nodal metastases in head and neck cancers using arterial spin labelling (ASL).

Methods and Materials: Twenty-eight patients with various types of locally advanced head and neck cancers (buccal mucosa 14, tongue 10, maxillary sinus 4) were evaluated using ASL on 1.5 T MR scanner (Achieva, Philips Healthcare, Best, The Netherlands) in addition to T2, diffusion and contrast sequences. The ASL maps were fused with fat suppressed T2 weighted images and compared with post contrast T1 weighted images. The primary tumour and suspected nodes were identified on T2 and contrast images and Regions of Interest (ROI) were marked. Necrosis within the nodes that had bright signal on T2WI were avoided. All patients underwent concurrent chemo-radiotherapy after histological analysis.

Results: Tumour blood flow (TBF) within suspected nodes showed significant elevation and was comparable with values within the primary mass. The mean TBF in patients within involved nodes from buccal mucosa cancers was 110+/- 15.8 mL/100g/min, nodes from primary tongue malignancies 124+/- 22.4 mL/100g/min and nodes from primary malignancies of the maxillary sinus 117 +/- 18.8mL/100g/min.

Conclusion: Quantitative assessment of TBF in cervical lymph nodes from primary head and neck cancers is possible with ASL. ASL may be useful for noninvasive assessment of tumour viability in head and neck cancer avoiding use of contrast agents and reducing the danger of allergy and nephrogenic systemic fibrosis (NSF). Fusion of T2WI-FS images would improve morphological description of tumour as ASL images are usually of low spatial resolution.

B-0637 11:18

Role of shearwave elastography in assessment of cervical lymph nodes

S.K. Suganchand Rikabchand, R. Mohammed Kashif; *Jodhpur/IN (Sunilmed@gmail.com)*

Purpose: The purpose of our study was to evaluate diagnostic accuracy of Virtual Touch Imaging Quantification (VTQ) shearwave elastography in differentiation of benign and malignant cervical lymph nodes with pathological results as reference.

Methods and Materials: 148 patients with 231 enlarged cervical lymph nodes were examined by elastography and B-mode ultrasonography in our study which was followed up by ultrasound guided core needle biopsy for pathological correlation. The results were compared and analyzed by appropriate statistical test to check the validity of elastography separately and in combination with b-mode characteristics in determining the nature of the lesion.

Results: Of 231 lymph nodes 161 were benign and 70 were malignant. The mean shear wave velocity (swv) of the benign nodes (2.5 ± 0.72 m/s) was lower than mean swv of malignant nodes (4.3 ± 1.2 m/s). With a swv cut-off value <3.12 m/s for benign lesion the sensitivity and specificity were 85% and 82% respectively, but when used in combination with b-mode characteristics the sensitivity and specificity increases to 92% and 96% respectively. Swv values >3.12 m/s showed 89% sensitivity and 84% specificity in determining malignant nodes and when used in combination with b-mode characteristics the sensitivity and specificity increases to 98% and 92% respectively.

Conclusion: VTQ is an excellent tool for analysis for cervical lymph nodes. There is clear difference in swv values between benign and malignant nodes. Thus when values are used in combination with B-mode characteristics of the cervical nodes they can provide results as good as histopathological findings.

B-0638 11:26

Diagnostic performance of computer-aided quantification of intranodal vascularity in differentiating common neck lymph node diseases

M.T.C. Ying, S.C.H. Cheng, A.T. Ahuja; *Hong Kong/CN*
(htmying@polyu.edu.hk)

Purpose: Ultrasound is a common imaging modality for the assessment of neck lymph nodes. This study aimed to investigate the value of intranodal vascularity, as evaluated by computer-aided quantification method, in distinguishing common neck node diseases.

Methods and Materials: Power Doppler sonograms of 347 patients with palpable neck lymph nodes were acquired (155 metastases, 125 reactive, 44 tuberculous lymphadenitis, 23 lymphoma). Doppler ultrasound images were evaluated using our self-developed computer algorithm and the intranodal vascularity was quantified and expressed as vascularity index (VI). The diagnostic performance of using VI of lymph node in differentiating the four disease groups (metastases, reactive, tuberculous lymphadenitis and lymphoma) was evaluated and compared. The optimum cut-off of VI in distinguishing different groups of lymph nodes was determined using the receiver operating characteristic (ROC) curve.

Results: Metastatic and lymphomatous lymph nodes are more vascular and have higher VI than tuberculous and reactive nodes. Among the comparisons of the four lymph node groups, intranodal VI demonstrated the highest diagnostic accuracy in distinguishing metastatic and tuberculous nodes with a sensitivity of 80%, specificity of 73% and area under the ROC curve of 0.82 when using the optimum cut-off VI of 22%.

Conclusion: Computer-aided quantification provides objective assessment of intranodal vascularity. Intranodal VI is a useful parameter in distinguishing metastatic and tuberculous lymph nodes, but has limited value in differentiating lymphomatous nodes from metastatic and reactive nodes.

B-0639 11:34

The utility of F18-choline PET/CT for the localisation of parathyroid adenomata in patients with primary hyperparathyroidism (PHP) with negative or equivocal conventional imaging

R. Ramaesh, G. Browning, S. Wakelin, E. Ward, F. Gibbs, D. Patel;
Edinburgh/UK (rishi.ramaesh@gmail.com)

Purpose: This retrospective study was performed to assess the accuracy of F18-choline PET/CT in localising parathyroid adenomata in patients with PHP with negative or equivocal ultrasound (US), Tc-99m sestamibi, and 4D CT imaging.

Methods and Materials: Over a 15-month period, F18-choline PET/CT was performed in 83 patients with negative or equivocal conventional imaging. Of the 29 patients who had undergone surgery; surgical notes, pathology reports and post operative outcomes were reviewed and correlated with imaging and pathological findings.

Results: Of the 83 patients, 59 had a positive PET/CT result. Of these, 37 were not detected on ultrasound and 9 were equivocal. Tc-99m sestamibi scan did not locate 47 and was equivocal in 8. SPECT did not localise 47 with 4 equivocal studies. 4D-CT failed to detect 39 of these, with 2 equivocal studies. Of the 29 surgical cases, PET/CT correctly localised the site of the adenoma in 26 patients. There were 2 false-positive cases and one false negative, which was correctly identified on sestamibi imaging. The sensitivity of PET/CT was 96.2%, with a precision of 93%. US detected 7 (24%), Tc-99m sestamibi 4 (14%) and 4D CT detected 6 (17%) cases that were apparent at surgery.

Conclusion: In our cohort, F18-choline PET/CT has been shown to identify a significant number of parathyroid adenomata in patients with PHP with negative or equivocal US, Tc-99m or 4D CT and should be performed for preoperative localisation in those patients being considered for surgery with negative or conventional imaging.

B-0640 11:42

Role of multiparametric 4D-MRI in detection of parathyroid lesions in primary hyperparathyroidism

N. Murugan, D. Kandasamy, R. Sharma, A. Goyal, A.K. Gupta, N. Tandon, S. Vara Taranikanti, S. Agarwal, N. Gupta; *New Delhi/IN*
(narasiman1149@gmail.com)

Purpose: 4D-CT is the modality of choice for detection of parathyroid lesions but suffers from high radiation dose. This study evaluated the role of multiparametric 4D-MRI in the localization of parathyroid lesions in primary hyperparathyroidism (PHPT).

Methods and Materials: In this ethically approved study, 59 patients of suspected PHPT were recruited. 56 patients underwent 4D-MRI on a 1.5T scanner and 3 were excluded because of altered renal parameters. 48 patients underwent surgery and surgical findings and histopathology were used as the reference standard. The MR technique included fat-suppressed T2WI, DWI with three B values (0,400,800) and post contrast T1 dynamic sequences (7 phases)

Results: Among 62 histopathologically proven lesions in 48 patients, there were 41 (89.4%) parathyroid adenomas, 20 (32.2%) parathyroid hyperplasias, and 1 (1.6%) colloid nodule. 4D-MRI detected all parathyroid lesions except 2 which were found only at surgery and another lesion which was diagnosed as parathyroid adenoma on imaging but was found to be a colloid nodule. On Fat-saturated T2WI, 54 (91.5%) lesions were homogeneously hyperintense, 4 (6.7%) were heterogeneously hyperintense and 1 (1.3%) was isointense. On high-b value DWI, 56 (94.9%) lesions were hyperintense and 3 (5.08%) were isointense. On dynamic imaging 54/59 lesions showed type-3 enhancement curve, 5/59 showed type-2 curve. Combining the above sequences the accuracy was 95.16%

Conclusion: Multiparametric 4D-MRI had high accuracy for localization of parathyroid lesions. 4D-MRI may provide a robust and safer alternative to 4D-CT.

Role of ultrasound elastography in differentiating tuberculosis and malignant lymph nodes

A.Y.M. Yee¹, R. Norlisah², L.S. Chng³, ¹Sungai Buloh/MY, ²Kuala Lumpur/MY, ³Selayang/MY (yeeba1@hotmail.com)

Purpose: To assess the diagnostic accuracy of ultrasound elastography and greyscale features in differentiating TB and malignant lymph nodes.

Methods and Materials: 54 patients (7 malignant, 39 tuberculosis, 9 reactive) were examined by both elastography and B mode sonography in this cross sectional study. Elastographic patterns were determined according to the total area and appearance of the hard regions within the lymph node, grade 1 being soft and grade 6 being a hard area occupying the entire lymph node with focal cystic area within.

Results: Sensitivity, specificity, positive predictive value and negative predictive value of elastography of 2 and below as well as a strain ratio of 3.475 to diagnose tuberculosis (TB) were 92.3%, 71.4%, 94.7% and 57.1%. It also found that greyscale features of thin echogenic layer and strong internal echoes were only present in TB lymph nodes and not the reactive or malignant lymph node groups.

Conclusion: This study shows that the accuracy of ultrasound elastography to differentiate TB from malignant lymph nodes is higher than usual B mode parameters. This can expedite treatment and reduce the need for unnecessary biopsies.

Actual dose measurements of assistant during paediatric x-ray examination with a precisely calibrated optically stimulated luminescence dosimeter

T. Asahara¹, H. Hayashi², E. Tomita², Y. Mihara¹, S. Goto², Y. Kanazawa¹, N. Kimoto², T. Asakawa², T. Okazaki³; ¹Tokushima/JP, ²Kanazawa/JP, ³Ibaraki/JP (takashi.asahara.111@gmail.com)

Purpose: During paediatric x-ray examination, a patient often needs to be held in position by assistants. It is important to reduce exposure dose to assistant. Currently, their exposure doses are not often monitored by radiation dosimeter

at an examination. The aim of this study is to measure the actual dose during clinical examinations.

Methods and Materials: The doses to assistants were measured with small-type optically stimulated luminescence dosimeters; the dosimeters were precisely calibrated so as to enable low dose measurement. First, to determine the dosimetric point, a phantom experiment was carried out; 170 dosimeters were attached to the surface of human dummies. Then doses to both hands of assistants during actual paediatric x-ray examinations were measured in 70 cases for 1-35-month-old patients. The typical irradiation conditions were 53 kV and 3.2 mAs. We analysed the relationship between individual dose to assistants' hands and age of patient.

Results: The surface dose distributions suggested that dose to hands shows the highest value; therefore, proper dosimetric position was determined to be both hands. From the result of actual dosimetry, the mean doses to right and left hands were 2.06 +/- 0.17 µGy and 2.15 +/- 0.20 µGy, respectively. We found interesting trend that higher doses were observed for lower age patients. We considered that distance from irradiation area contributed to the dose.

Conclusion: The actual doses to assistants were measured. To reduce assistants' dose, attention should be paid to the distance between irradiation area and the assistants' hands.

Frontiers of periosteal changes: comparison between anthropological data, clinical records and readings of X-ray medical imaging technology
R.M.C.R. Gaspar¹, A.F. Abrantes², V. Matos¹; ¹Coimbra/PT, ²Faro/PT
(rosa.cristina.ramos@gmail.com)

Purpose: To define protocols of study in radiology for palaeopathology; to improve palaeopathological diagnosis criteria; to identify other pathologies defined so far as "periostitis"; to evaluate the best protocol for the collection on periosteal changes; to develop a data system that gathers and articulates the anthropological evaluations and imagiological descriptions of the collections.

Methods and Materials: Our analysis focuses on comparing skeletal findings of the collections in the Research Centre for Anthropology and Health database with a diagnosis of periostitis and the data in the hospital archives of Coimbra Hospital and University that include individuals who have performed a diagnostic bone biopsy and with a positive imaging record of periostitis. Anthropology analysis: observation in ideal conditions. Proposal to classify periosteum changes by Osteoware. Imagiology: systematic analysis by conventional radiology and a complementary study by CT scanner of the lesional area.

Results: Expected results are as follows: the determination of specific protocols and guidelines for anthropology will contribute to the differential diagnosis in palaeopathology. The integration of analytical assessments will enrich anthropology, specifically palaeopathology, and will form the basis for future studies. Furthermore, complementing the analysis of this collection with radiology will support the differential diagnosis, rewriting the history of periostitis in Portugal.

Conclusion: This study, which desires to be innovative in the Department of Life Sciences, aims to contribute to the body of knowledge of palaeopathology, complementing the field of systematic imaging analysis and thus allowing to correlate findings between anthropology and imaging.

Radiation dose associated with patients undergoing upper limb radiographic examination in different patient orientation: a phantom study

M.M. Abuzaid, W. Elshami, Z. Noorajan; Sharjah/AE
(mabdelfatah@sharjah.ac.ae)

Purpose: The patient orientation during radiography is essential to perform accurate images and apply ALARA principle. There is a common practice observed by directing the radiation beam towards the patient eye lens and gonads. It was approved that these organs can be affected by relatively low radiation level. The purpose of this study was to investigate the association between the radiation dose received by eye lens and gonads and the patient orientation during upper limb examinations.

Methods and Materials: An adult phantom was used to simulate an adult patient and the patient positions during a hand, wrist, and elbow radiographic examination. The initial position was set as the patient facing away from the radiation beam, then placed in a position facing the radiation beam. A Philips X-ray machine was used to generate a series of images, and TLD was used to

obtain radiation dose to the eye and gonads.

Results: Reduction of the radiation dose was seen when the patient was not facing the radiation beam as well as reduction of the ESD to the eye and gonads area. Results showed significant reduction of ESD and effective dose when the patient is not facing the radiation beam.

Conclusion: The orientation does not affect the patient comfort as the patient responses will not change whether the patient is facing or sitting beside the table. This study confirmed the relation between dose reduction and patient orientation and it align with the ALARA principle to able all efforts to minimize unnecessary radiation exposure.

B-0645 14:24

Radiation dose comparison study between conventional methods and slot-scanning system (EOS® system) on paediatric patients with scoliosis

H. Laitinen, E. Saukko, E. Svedström, O. Pajulo, H. Niiniviita; Turku/FI
(helena.laitinen@hotmail.com)

Purpose: EOS® system is a slot-scanning system (SSS) for orthopaedic use, especially for observing scoliosis. The purpose of this study was to compare radiation doses of paediatric patients in the imaging of scoliosis with computed radiography (CR), digital radiography (DR) and Finland's first, recently installed SSS technique in Turku University Hospital.

Methods and Materials: The retrospective study was performed with real patient data (n=244) aged 1-18 years with maximum bodyweight of 100 kg including posterior-anterior or anterior-posterior (PA/AP) and lateral (LAT) views. The data was analyzed with key statistics and presented by average DAP (Dose Area Product) of the whole population and classified to weight groups.

Results: The average DAP of SSS (209.2±123.8 mGycm²) was 42 % lower compared with CR (360.9±433.6 mGycm²) and 53 % lower compared with DR (449.3±471.7 mGycm²). When classified to weight groups the DAP of SSS was 47-63 % lower compared with CR and 0-65 % lower compared with DR. The DAP of SSS for 45 kg patient was 81-86 % lower compared with literature.

Conclusion: SSS technique exposes to lower radiation doses and should therefore be the preferred method over CR and DR in the imaging of paediatric patients with scoliosis. Radiation doses using SSS in this study were distinctly lower compared to literature. This study indicates that there is a need to set an international diagnostic reference level for scoliosis imaging, as reported dose values vary substantially.

B-0646 14:32

Improvement of safety and image quality with a self-made airway management device for sedation and anaesthesia in paediatric heart CT

H. Kim, J. Chang, D.-K. Seo; Seoul/KR (dangkukong@naver.com)

Purpose: The purpose of this study was to improve the young patients' safety and CT image quality by making airway management device for paediatric CT under sedation or general anaesthesia.

Methods and Materials: We hollowed out the upper part of solidified polystyrene board into a quadrangle to bend young patients' head back and straighten their upper body. The quadrangle groove was filled with a headrest, which adjusted the height according to the patient's head size. Patient safety during sedation was monitored by anaesthesiologists. The reproducibility of follow-up cardiac CT images was assessed qualitatively by radiologists.

Results: Oxygen saturation was raised and maintained by adequate airway positioning with the device. Sedation-related risk of drop in SpO₂ was decreased. The frequency of additional treatment due to desaturation was also decreased. It was also easier to position the centre of the small patients with the iso-centre of the scanner. Straight supine posture by the device increased the reproducibility of follow-up heart CT imaging. Shorter scan time improved overall satisfaction of patients, guardians, and radiotechnologists.

Conclusion: When performing paediatric CT examinations, it often took 4-5 times longer when they require procedural sedation or general anaesthesia. In these cases, airway management to maintain oxygen saturation is important. Using self-made airway management device, we could improve the patient safety and ensure high image quality, while reducing the amount of sedatives and the examination time required.

B-0647 14:40

Dose optimisation of head CT examinations in paediatrics

M. Dziedatja; Riga/LV (madara.dziedatja@gmail.com)

Purpose: The head is the most commonly examined body part for children in all age groups. During the last 5 years, the number of performed head examinations has increased. It is important to be careful when scanning settings to reduce the possible radiation dose as much as possible, without decreasing the quality of the examination.

Methods and Materials: A 64 slice Philips Ingenuity scanner was used to scan a head sized cylindrical PMMA dose phantom and a head phantom made from a beavers' skull and gelatin for the purpose of this research. Each

phantom was scanned with a different protocol parameter setting of all pre-set age groups to see the difference in image quality, absorbed dose and how much they change by altering the used settings.

Results: Gathered results show a gap between the CT calculated radiation dose and the measured absorbed dose as well as the absorbed dose after using AAPM parameters specifically for 64 slice Philips Ingenuity CT scanner. To evaluate image quality changes during the series of scans performed, we replicated the scan of a PMMA phantom on a beaver skull (16cm/diameter).

Conclusion: Identical scanning settings cannot be used for everyone due to the large variety in head diameter (12-20 cm), volume and density in all age groups. All age-group protocols are calibrated by the same 16cm/diameter PMMA phantom. Inappropriate protocol settings can lead to poor quality images, that aren't interpretable by radiologists. The bone structures give an insight into the difference made by changing scan settings.

B-0648 14:48

Evaluation of dose to risk organ during brachytherapy for cervical cancer using a novel passive rectum dosimeter

E. Tomita¹, H. Hayashi¹, T. Asahara², Y. Shitakubo³, K. Sakuragawa³, H. Ikushima³, Y. Kanazawa³, T. Okazaki⁴, T. Hashizume⁴, ¹Kanazawa/JP, ²Okayama/JP, ³Tokushima/JP, ⁴Tsukuba/JP (emitomita.15@gmail.com)

Purpose: This study aims to confirm the availability of planned dose by measuring the actual dose of rectum during brachytherapy for cervical cancer.

Methods and Materials: We measured doses absorbed by patients' rectum (n=18) using a novel dosimeter made from a piece of OSL sheet and a catheter. To obtain three-dimensional images, cone beam CT (CBCT) examination was performed and image-based treatment planning based on TG-43 algorithm was applied. Measured dose was compared with the planned dose calculated by the therapeutic planning system. Then we investigated the correlation of differences between measured and planned doses, treatment planning times and body mass index (BMI).

Results: Measured doses were in good agreement with planned dose in most cases. We experienced a rare situation in which the patient urinated after CBCT was taken (n=2). In this situation, the patient's organs will move due to shrinking volume of a bladder. Even if the original therapeutic plan was applied, the difference between actual and planned doses was found to be at most +/-1 Gy. Furthermore, we found that differences in doses do not have a correlation with treatment planning times (r=0.28), but it has a strong positive correlation with BMI (r=0.84). This fact means that the higher the BMI is, the further it is from the assumption of the TG-43 algorithm that assumes the structure of the human body as a water-equivalent medium.

Conclusion: Precise dosimetry provided good evidence for dosimetry in brachytherapy. We have evaluated robustness of the planned dose by measuring actual dose.

Assessing dignity of patients undergoing radiotherapy for pelvic cancer

M. Calleja¹, M.E. Grech¹, N. Courtier², J.G. Couto¹, ¹Msida/MT, ²Cardiff/UK (marco.calleja.13@um.edu.mt)

Purpose: Patients undergoing radiotherapy experience physical side effects, but also suffer emotionally, psychologically and socially. All four domains can adversely affect their dignity. The aim of this study was to assess dignity of patients receiving radiotherapy for pelvic malignancies, by identifying the patients' major and minor concerns and comparing any differences in the responses between gender and age groups.

Methods and Materials: The study adopted a non-experimental, quantitative and prospective research design. The patient dignity inventory tool (Chochinov et al., 2012) was distributed to 35 patients. This contained 25 statements related to dignity to be rated between 1 ("not a problem") and 5 ("An overwhelming problem"). The target population consisted of adult patients who were in their last two weeks of radiotherapy to the pelvis.

Results: The rating of certain domains of patient dignity were statistically higher than others (p=0.001): patients identified 'psychological issues' as the most problematic and 'general support during treatment' the least. Females rated three of the statements related to 'psychological issues' significantly higher than males (p = 0.031, 0.033 and 0.046). Age groups had no significant effect for all of the statements.

Conclusion: Patient dignity issues arise mostly from the psychological effects of radiotherapy. In view of this, it is recommended that a psychological assessment of patients is undertaken to identify individuals who require additional psychological support, especially female patients in view of the higher rating in the 'psychological issues domain'. However, these gender differences can be due to resistance by male patients to report psychological issues.

B-0650 15:04

Glioblastoma: 3D-CRT or IMRT/VMAT?

M.J.V. Pereira, B. Gregório, A. Cavaco, J.P. Figueiredo; Coimbra/PT (mjvpereira@hotmail.com)

Purpose: The aim was to compare the dosimetric plans with 3D-CRT and VMAT or 3D-CRT and IMRT in patients with GBM submitted to Stupp Protocol.

Methods and Materials: The patients selected were submitted to Stupp Protocol and treated with 3D-CRT. 11 patients were planned in IMRT and the other 11 in VMAT, conformed to the same target volume. The aim was to achieve the best coverage with the least organs at risk dose. The evaluation was made by homogeneity, conformity and organ at risk doses.

Results: Both special techniques showed a better conformity and homogeneity compared to 3D-CRT. The doses to optical structures were higher in VMAT, except to the right optical nerve and chiasm. The doses to optical structures in IMRT were lower, except to the chiasm. Both special techniques showed a higher dose in 80% of cerebral volume.

Conclusion: Better homogeneity and conformity in VMAT and IMRT, keeping the organs at risk doses lower or slightly higher than in 3D-CRT, complying with the internationally defined tolerance doses.

B-0651 15:12

Thematic analysis of the competencies of the therapy radiographer practising in the linear accelerator

J.G. Couto¹, P. McClure², S. McFadden², P. Bezzina¹, C. Hughes², ¹Msida/MT, ²Newtownabbey/UK (jose.g.couto@um.edu.mt)

Purpose: In view of the movement of radiography professionals in Europe, radiographers should be trained and competent to practise in any country. The literature identifies various competencies for the radiographers practising on the linear accelerator. The aim of this study was to perform a literature review to identify the competencies required by therapy radiographers across Europe. A thematic analysis of these competencies was subsequently performed.

Methods and Materials: A systematic approach was used, where six databases were searched using selected keywords related to "competencies", "radiographer" and "linac". Following the application of inclusion criteria and snowballing, publications were identified, competencies of linear accelerator radiographers were extracted, and a thematic analysis was performed using NVivo (v11.0).

Results: 28 publications were analysed and 363 competencies were identified. Thematic analysis resulted in 16 themes and 72 sub-themes that reflects the competencies of therapy radiographers practising on the linear accelerator. Themes identified included specific competencies for the therapy radiographer (e.g. image verification and treatment delivery) and generic competencies which can be performed by other professionals (e.g. patient care and research).

Conclusion: This study summarises the key competencies that are documented and required of these professionals across European to safeguard the movement of radiography professionals and subsequent patient safety between countries, these professionals should develop competencies that are standardised across Europe. These themes can provide all European stakeholders with a template of the components that should be included in curriculum design of radiographers' education.

B-0652 15:20

Expectations of radiography students regarding the new undergraduate course in medical imaging and radiotherapy

L. Ribeiro¹, A.F. Abrantes¹, S. Rodrigues¹, J.P. Arrais², R.P. Almeida¹, K.B. Azevedo¹, O. Lesyuk³, ¹Faro/PT, ²Vila Nova de São Bento/PT, ³São Brás de Alportel/PT (oksanalesyuk@gmail.com)

Purpose: To evaluate the expectations of undergraduate radiography students about the creation of the new undergraduate course in medical imaging and radiotherapy (MIR).

Methods and Materials: This study was carried out using a self-applied questionnaire to evaluate the students perceptions regarding the skills enhancement in the undergraduate course in medical imaging and radiotherapy. The final sample was composed by a total of 83 radiography students from two different universities. The questions were directed to the sociodemographic data, reasons for choosing the MIR course, the enhancement of skills and the importance of the training process. The data were interpreted and analyzed through descriptive statistics, and correlation tests were performed to evaluate the relationship between variables.

Results: The main motivations to choose the degree was "Healthcare related area, enabling greater interaction with patients" (38,8%). Most of students are not satisfied (53,0%) with the new MIR degree and 44,6 % reported that expectations after the frequency in the course slightly coincide with the beginning. Regarding the contribution of the university, 82% of the students answered that the greatest influence to the acquisition of competences is the "Teaching Methodology".

Conclusion: The students of the first-year degree have high expectations concerning the new degree and the students who are in transition phase have lower expectations due to less expertise and knowledge in the three different areas (Radiology, Nuclear Medicine and Radiotherapy). In the students perspective, the new undergraduate course will reduce the students professional capacity and competences after their graduation.

Impact of decentring patients for abdominal CT scan

S. Moerup¹, H. Precht², S. Foley³, A. Seegert⁴, B.R. Mussmann¹; ¹Odense/DK, ²Middelfart/DK, ³Dublin/IE, ⁴Kolding/DK (sdmo@ucl.dk)

Purpose: To evaluate the effect on skin dose and image quality when decentring in the y- and x-directions for abdominal CT scans.

Methods and Materials: Patient centring data in CT were collected retrospectively from dose management software (DoseWatch, GE Healthcare) from a single university hospital (n=4 scanners) in 2017. Deviations from the isocentre were categorized for both vertical ($\pm 1.5\text{cm}$, $\pm 3.0\text{cm}$, $\pm 4.5\text{cm}$) and horizontal ($\pm 1.5\text{cm}$, $\pm 3\text{cm}$) planes on 498 patients. An anthropomorphic phantom (PBU-60) was subsequently scanned using each deviation on two scanners (Toshiba Prime, GE HD750) to allow dose and image quality (noise and visual grading assessment) comparisons.

Results: Significant skin dose increases (4.3mSv, 50%) were detected anteriorly for both scanners when centred above the isocentre and reductions (2.0mSv, 24%) when scanned below the isocentre. For the HD750, dose decreased up to 8.3mSv in four locations at the -4.5 position. Increased dose were (2.0mSv) noted on the right side with horizontal deviation. With upward vertical deviation noise increased from 13HU (isocentre) to 15HU. No change in standard deviation (SD) was detected with the phantom below isocentre. With left horizontal deviation SD increased up to 14HU while SD decreased to 12HU dextro-laterally. VGA score was lowest at the largest vertical isocentre deviation.

Conclusion: Positioning above isocentre may increase noise and skin dose. Similarly, horizontal deviation may increase dose. Subjective image quality is negatively affected by extreme vertical isocentre deviation.

B-0654 14:08

Exploring academic and social factors' effect on CT dose optimisation: a longitudinal study of radiographers from student to first post

V.T. Major¹, S. Ryan², D. O'Leary³; ¹Northwood/UK, ²Hatfield/UK, ³Keele/UK (vicki.major@stricklandscanner.org.uk)

Purpose: We aimed to identify training requirements for UK CT radiographers, and whether social/academic factors in the clinical environment have a bearing on the students' approach toward CT dose optimisation, before and after qualification. The purpose of this study was to a) explore student radiographer's knowledge and experience of dose optimisation within CT scanning; b) measure their emotional intelligence; and c) explore their educational experience.

Methods and Materials: A mixed methods approach using convergent parallel methods, integrating and connecting quantitative and qualitative data were acquired simultaneously on two separate occasions. Student radiographers were invited to participate in in-depth interviews at two discrete time points: as final year students and post-employment in their first post. Ethics approval was sought and granted. An emotional intelligence (EI) questionnaire (TEIQue-SF tool) and a pre-validated questionnaire on CT parameters and their influence on both patient dose and image quality were completed and scored.

Results: Results were analysed via descriptive statistics and thematic analysis. Six main educational themes were identified: on-the-job training, postgraduate courses, applications training, undergraduate courses, study days and competency assessment. EI did not change over time. Knowledge of CT exposure parameters increased, with a difference in mean scores pre- and post-qualification ($P=0.025$).

Conclusion: In the two-year period from student radiographer to working in their first post, EI remained static although their knowledge of CT dose optimisation increased. The radiographers felt that education was best delivered on the job and supplemented with study days, application specialist talks, medical physics, radiographer and radiologist expert advice.

B-0655 14:16

Is the technology for patient placement in CT really that useful in reducing dose and improving SNR?

L. Lennon¹, S. Tsui², G. Dick³, J. Hislop-Jambrich⁴; ¹North Ryde/AU, ²Box Hill/AU, ³Marooondah/AU, ⁴Notting Hill/AU (LLennon@medical.canon)

Purpose: Contemporary CT scanners employ various technologies to support the minimization of patient dose. Many of these technologies are applied in the background with little or no knowledge of being activated by the operator. Centring of the patient within the bore of the CT however represents an obvious input by the operator, but how much does it impact dose and SNR really? This project aimed to assess the practical utility of the lateral couch centering function on radiation dose and signal to noise ratio (SNR).

Methods and Materials: We scanned an anthropomorphic phantom using offset values (lateral and antero-posterior) established from the evaluation of chest and abdominal series performed at 6 sites not employing centering technology. We then assessed the CTDIVOL, DLP and SNR in the liver and mediastinum using a standard clinical scanning protocol. The chest and abdomen were investigated separately using automatic exposure settings.

Results: CTDIVOL reduces considerably more with a lowered couch height and lateral scout performed first than a higher position within the gantry. Lateral maladjustment serves to exacerbate the dose differential from the standard isocentre findings, though the actual spread of these values across lateral malalignments was larger for a higher couch gantry position for the CT unit tested. SNR results were in line with the dose delivered.

Conclusion: Accurate isocentre positioning is a simple yet highly effective means of achieving dose and image quality optimization.

B-0656 14:24

The unjustified dose behind cropped radiographs

J. Guðjónsdóttir, G.A. Hannesdóttir; Reykjavik/IS (joninag@hi.is)

Purpose: In this study an attempt was made to evaluate how common image cropping, or electronic collimation, is in digital radiography, how large an area of the images is cropped and how high the radiation dose is that corresponds to the cropped area.

Methods and Materials: A sample of images was taken from three medical imaging departments. The images were reviewed and, if cropped, the extent was recorded.

Results: A total of 1270 images was reviewed. 10.6 % of them had been cropped, 19 %, 7 % and 6 % in sites A, B and C, respectively. 26 % of all chest images were cropped as well as 18 %, 13 %, 10 %, 10 %, 3 % and 2 % of lumbar spine, shoulder, hip, knee, hand and foot images, respectively. The proportion of cropped images was significantly different between sites and between examinations ($p < 0.05$). Considering only the cropped images, the average cropped fraction of each image was from 16,0 % to 36,3 % and the corresponding unjustified dose was estimated to be from 19,0 % to 56,9 % of the dose actually needed for the final image. Averaging the cropped area over all images in the same type of examination showed that up to 4,6 % of the dose in the examinations in the study was unjustified.

Conclusion: This study confirms that radiographs are cropped and that the corresponding unjustified dose may be significant. This needs to be considered in the optimization of radiographic imaging procedures.

B-0657 14:32

Scoliosis dose comparison using current clinical protocols

M. Shanahan¹, M. Geso², A. Potter², G. Lennie²; ¹Bruce/AU, ²Melbourne/AU (madeleine.shanahan@canberra.edu.au)

Purpose: Radiography is a valuable diagnostic and monitoring tool for patients with adolescent scoliosis. Radiation dose is important as this patient group is statistically more likely to develop cancer during their lifetime. The purpose of this research was to compare entrance surface dose (ESD) and dose area product (DAP) measurements for scoliosis imaging using current clinical techniques for four image acquisition systems: EOS™-normal (EOS-N), EOS™-microdose (EOS-M), DR-standard (DR-S) and DR-low (DR-L) dose.

Methods and Materials: EOS™ and Shimadzu RADspeed Auto X-ray coupled with Canon CXDI 70C wireless flat panel detector systems were used. PA and left lateral images were acquired of a RSD anthropomorphic phantom using four image acquisition techniques. Dosimeter measurements were obtained using Deschênes et al. (2010) 13 anatomic locations. Three independent image acquisitions were made for each technique and the resultant ESDs for each location, and DAP measurements were averaged to minimise random error.

Results: ESD measurements for EOS-M, EOS-N, DR-L, DR-N ranged from 0-0.09, 0.02-0.57, 0.01-2.48, 0.01-4.54 mGy, respectively, with the highest dose measured on right lateral aspect T10 level. Lower doses were recorded on the breasts (right: 0.01, 0.09, 0.15, 0.29; left: 0.00, 0.04, 0.05, 0.11 mGy). DAP showed similar dose trend across imaging systems (109, 767, 1206, 2380 mGy^{cm}²).

Conclusion: Direct dosimetry (ESD) allows radiation dose to specific anatomic regions to be measured. DAP provides a general indication of dose. Reviewing ESD for clinical protocols allows identification of potential further dose reduction strategies.

Establishment of national diagnostic reference levels for dental radiology
A.Q.L.C. Brito, R.P.P. Almeida, S. Rodrigues, A.F. Abrantes, L. Ribeiro, P. Sousa, K.B. Azevedo, D.M. Simão; *Faro/PT (andreiabrito8@hotmail.com)*

Purpose: Dental radiology is a field where effective dose per exposure is low; however, the frequency of these procedures is high, and professionals must be aware of the dose delivered to the patient. The main goal of this study was to establish the diagnostic reference levels (DRLs) for intraoral and extraoral dental radiology examinations nationwide.

Methods and Materials: Entrance surface air kerma (ESAK) and dose-area products (DAP) were determined for a total of 1001 intraoral and 268 extraoral dental equipment's distributed throughout the national territory. The determined values were averaged and compared according to the type of image receptor system, installation duration, and the type and model of dental X-ray machine.

Results: For intraoral radiology, the National DRLs were established at the 75th percentile of ESAK values (1.55 mGy). For orthopantomography and cephalometry, DRLs were determined at the 75th percentile of DAP values, corresponding to 107 mGy.cm² and 80 mGy.cm², respectively. Most intraoral equipment's has direct-digital receptor systems (81.8%), followed by analog film system (10%) and indirect-digital receptor systems (4.1%). In extraoral X-ray, a total of 28 different equipments was observed. Furthermore, the type and model of the equipment has influence in the radiation dose values.

Conclusion: The establishment of DRLs, as a tool for the optimisation of radiological procedures, is a requirement of national regulations. The proposed national DRLs in this study are in accordance with those established by other countries; however, a constant dose optimisation can reduce these values further.

B-0659 14:48

The impact of different exposure factors on radiation dose of lumbar spine in five different size phantoms: a factorial design study

S.J.M. Alqahtani, J.R. Meakin, R.M. Palfrey, K. Knapp; *Exeter/UK (salbeshri@hotmail.com)*

Purpose: To investigate the impact of tube potential (kVp), source to image distance (SID) and Copper filtration on dose area product (DAP) on lumbar spine radiographs with different size bespoke phantoms (18, 29, 38, 42 and 46 BMI).

Methods and Materials: A factorial design study was conducted using a DR x-ray machine (Multi Fusion Max, Siemens, Germany), and three factors; kVp⁶ x SID³ x Cu filtration³. The collimation was kept identical across all phantoms. The DAP reading was reported directly from the x-ray image. Analysis of variance was used to investigate the impact of each factor on the DAP.

Results: kVp has a significant negative impact on DAP for the 18, 29, 38 and 42 BMI phantoms ($r^2 = 0.53, 0.57, 0.51$ and 0.29) but is non-significant for the 46 BMI phantom. SID has no significant impact on the DAP but rather showed a proportional relationship with DAP in the 18 and 29 BMI phantom and inverse relationship with DAP in the remaining 38, 42 and 46 BMI phantoms. The filtration showed a significant negative impact on the DAP across all phantoms ($r^2 = 0.40, 0.36, 0.38, 0.48, 0.59$).

Conclusion: The kVp has the biggest effect on DAP reduction across all phantoms followed by the Cu filtration. The SID can be used especially in the morbidly obese phantoms. These results need to be taken into account with consideration of image quality.

B-0660 14:56

Radiation dose reduction using copper filters

K. Yagami¹, M. Hirota¹, H. Kato¹, F. Okada¹, S. Suzuki²; ¹Gifu/JP, ²Toyoake/JP (yagami@gifu-u.ac.jp)

Purpose: To measure the patient dose and the scattered radiation dose, when copper filters are added.

Methods and Materials: Using a Shimadzu X-ray system, copper filters were added from 0.0mm to 0.5mm at 0.1-mm interval. For each additional copper filters, an anthropomorphic phantom (Alderson Rando Phantom) with thermoluminescent dosimeters (BeO) positioned was placed at the PA position and exposure was performed under the conditions which had an equivalent transmitted radiation dose and the quality. The SID was set to 140cm, and the irradiation field was from the diaphragm to the symphysis pubis. For each additional copper filter, the entrance surface dose (ESD), the organ dose, the effective dose and the scattered radiation dose were measured.

Results: At the copper filter 0.0mm, the ESD was 1460μGy, the lung-absorbed dose was about 30μGy, the liver 190μGy, the ovary 180μGy, and the effective dose was about 130μSv. By adding 0.1-mm copper filter, the ESD was reduced by about 30%, but the organ dose and the effective dose were almost equal within 10%. By adding a 0.5-mm copper filter, the ESD was reduced by about 40%, the organ dose and the effective dose were reduced by about 10%. As for the copper filter addition, the scattered radiation dose fluctuated within about 10%.

Conclusion: By adding a copper filter, the dose reduction for ESD was observed as being up to 40%. However, a dose reduction in the organ dose, effective dose, and scattered dose was not much recognized.

B-0662 15:12

Stylized phantom used in PCXMC, the validation against hybrid phantom in obesity

S.J.M. Alqahtani, J.R. Meakin, R.M. Palfrey, K.M. Knapp; *Exeter/UK (salbeshri@hotmail.com)*

Purpose: To investigate the behaviour of the PCXMC stylized phantom compared to a hybrid phantom in obesity.

Methods and Materials: Stylized and hybrid phantoms were modified to three different sizes (185.6 cm height with 73 kg, 87 kg and 108 kg weight). The three sizes stylized and hybrid phantoms were exposed to identical dose of area product (DAP) 8 Gy/cm² in supine lumbar spine (AP), with 70 kV, 3 mm Al filtration, and source to skin distance (SSD) of 84.2, 83.3 and 79.4 cm. Correlation of the absorbed doses between determined by PCXMC and CALDose were conducted.

Results: CALDose software shows higher absorbed dose (51%) on average across the three different size phantoms compared to PCXMC. Both programs show a negative trend in absorbed dose as the phantom size increase, -24% and -19% on average for PCXMC and CALDose, respectively. The spearman correlations between the estimated absorbed dose by the two software are significant with $P < 0.01$, with $r = 0.80$ in the normal phantom, $r = 0.81$ in the overweight phantom and $r = 0.71$ in the obese phantom.

Conclusion: PCXMC absorbed dose is lower than CALDose across the different size phantoms. Strong correlations of estimated absorbed dose between the two programs are demonstrated. Both PCXMC and CALDose demonstrated an inverse relationship between absorbed dose and size, which is expected due to the excessive fat acting as a protection layer for the internal organs. This indicates the possibility of using PCXMC in cases of obesity.

B-0663 15:20

Should DR and CR projection radiography have separate LDRLs at a local hospital level?

A.M. Burke, S.J. Foley; *Dublin/IE (andrea.burke@ucdconnect.ie)*

Purpose: DRLs are important optimisation tools for identifying atypical doses either locally (LDRL), regionally or nationally and are set at the 75th percentile of the dose distribution. This study aimed to investigate how CR and DR doses should be accounted in LDRL data for three common radiographic examinations: AP pelvis, AP and lateral lumbar spine, and to determine if DR and CR equipment should have separate LDRLs.

Methods and Materials: Twenty patient DAP measurements of each projection were recorded for both DR and CR imaging systems in five Irish hospitals, which were sampled purposively. Dose distributions for CR and DR equipment in each of the hospitals were analysed and compared using parametric ANOVA and independent-samples T test analysis to determine if there is a need for separate LDRLs for CR and DR systems. LDRLs were analysed on a room by room basis and compared with current NDRLs.

Results: DR systems deliver on average 46-56% lower doses than CR systems ($p < 0.05$) for AP pelvis (average DR LDRL: 1.66 Gy^{cm}², CR LDRL: 2.65 Gy^{cm}²) and lateral lumbar spine (average DR LDRL: 1.82 Gy^{cm}², CR LDRL: 3.25 Gy^{cm}²) projections across all sites. For the AP lumbar spine projection, there is an overall average 8% difference between DR (1.65 Gy^{cm}²) and CR (1.52 Gy^{cm}²) LDRLs, which was not deemed statistically significant

($p > 0.05$) by the one-way ANOVA test.

Conclusion: Separate LDRLs are justified for AP pelvis and lateral lumbar spine projections but not for AP lumbar spine projections and thus facilitate local dose optimisation.

Quantitative 3D analysis of hybrid 18F-FET PET/MR-neuroimaging for differentiation between treatment response and glioma recurrence

J. Lohmeier, B. Hamm, M.R. Makowski; Berlin/DE

(johannes.lohmeier@charite.de)

Purpose: This cohort study investigated quantitative PET/MR-imaging parameters for differentiation between glioma recurrence and post-treatment related effects (PTRE) using volumetric (3D-VOI) lesion analysis in hybrid contrast-enhanced and 18F-fluoroethyl-L-tyrosine (18F-FET) PET/MR-imaging.

Methods and Materials: 45 patients (female/male patients=18/27; age mean \pm SD, 47 \pm 15 a) were retrospectively evaluated regarding glioma recurrence. Histopathology (40%) and conclusive clinical follow-up serial imaging (60%) were used as reference standard (PTRE/recurrence=9/36). PET/MR-imaging was evaluated using semi-automated isocontour (85%) lesion segmentation based on 18F-FET tracer uptake. Standardized uptake-value (SUV), target-to-background ratio (TBR) and (relative) apparent diffusion coefficient (ADC and rADC) were determined and assessed using receiver operating characteristic analysis (ROC).

Results: Cancer relapse showed lower rADCTotal/Vol values than treatment-related changes and presented satisfactory discriminative test performance (AUC \pm SE=0.744 \pm 0.101, p -value=0.016). Quantitative 18F-FET parameters (TBRTotal/Vol, AUC \pm SE=0.799 \pm 0.080, p -value=0.0002; TBRmax, AUC \pm SE=0.877 \pm 0.082, p -value \leq 0.0001; TBRmean, AUC \pm SE=0.877 \pm 0.082, p -value \leq 0.0001) facilitated reliable differentiation between recurrence and PTRE. Multiparametric analysis with quantitative parameters from hybrid PET/MR-imaging demonstrated highest diagnostic accuracy (AUC \pm SE=0.929 \pm 0.048).

Conclusion: The current study introduced TBRTotal/Vol and rADCTotal/Vol as novel parameters for the differentiation between glioma recurrence and post-treatment related effects. We provided evidence that 18F-FET parameters facilitate reliable classification, which reduced the clinical false positive rate. Additionally, we showed that multiparametric analysis with quantitative parameters from hybrid PET/MR-imaging demonstrated highest diagnostic accuracy, showing a benefit of combining both modalities, which provide distinct information about the underlying physiology.

B-0666 14:25

Prediction of patient outcome in head and neck squamous carcinoma following chemo(radiation): comparison of 4 different FDG PET-CT response assessment interpretative criteria

J. Zhong, M. Arunsingh, P. Brown, K. Dyker, R. Prestwich, S. Currie,

S. Vaidyanathan, A. Scarsbrook; Leeds/UK (j.zhong.edinburgh@gmail.com)

Purpose: To assess comparative accuracy of fluorine-18 fluorodeoxyglucose (FDG) positron emission tomography-computed tomography (PET-CT) response interpretation criteria (NI-RADS, Porceddu, Hopkins, Deauville) for predicting recurrence in head and neck squamous cell carcinoma (HNSCC).

Methods and Materials: All patients with histologically confirmed HNSCC treated at a specialist cancer centre with curative-intent non-surgical treatment between August 2008 and May 2017 were included. Patients underwent FDG PET-CT before and 4 months post-treatment. Metabolic response was assessed using 4 different interpretative criteria (IC) harmonised into 4-point scales (complete response, indeterminate, partial response, progressive disease). IC performance metrics (sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), accuracy) were compared.

Results: 570 patients (397 oropharynx, 58 hypopharynx, 51 larynx, 64 other/unknown primary). Median age 58 (range 24-84), 431 (76%) were male. 426 patients received chemo-radiotherapy and 144 had radiotherapy alone. Median follow-up was 26 months (range 0-148). 156 patients (27%) progressed during follow-up. All IC were highly accurate for prediction of

complete response or disease progression (NPV/accuracy (%)) of primary tumour (NI- RADS 96.3/95.7; Porceddu 96.2/93.6; Hopkins 95.9/93.5; Deauville 96.3/93.7) and nodes (NI- RADS 93.5/93.5; Porceddu 94.3/94.4; Hopkins 91.9/92.3; Deauville 92.9/93.8). PPV was significantly reduced for indeterminate uptake with all IC (mean PPV primary tumour 19.5%, nodes 52.4%). No IC had consistently better performance characteristics for outcome prediction.

Conclusion: FDG PET-CT at 4 months post-treatment is highly accurate for prediction of complete response or disease progression. All IC have similar performance characteristics. Individual centres should apply one IC consistently across all patients.

B-0667 14:33

Performance of FDG PET-based textural features for prediction of loco-regional recurrence in advanced larynx and hypopharynx squamous cell carcinoma

J. Zhong, P. Brown, H.L. Nelstrop, R. Prestwich, G.M. McDermott, S. Currie, S. Vaidyanathan, A. Scarsbrook; Leeds/UK (j.zhong.edinburgh@gmail.com)

Purpose: To determine whether metabolic tumour parameters and radiomic features derived from fluorine-18 fluorodeoxyglucose (FDG) positron emission tomography-computed tomography (PET-CT) are prognostic predictors in patients with locally advanced larynx and hypopharynx squamous cell carcinoma (SCC).

Methods and Materials: All patients with advanced stage larynx and hypopharynx SCC treated at a specialist cancer centre that underwent baseline FDG PET-CT between August 2008 and May 2017 were included. Primary tumour and nodal disease were segmented using LIFEX software (University of Paris-Saclay, France) and radiomic analysis (first- and second-order parameters) was performed which included calculation of metabolic tumour volume (MTV). Lesions less than 64 pixels (5 ml) were excluded. Univariate Cox regression was performed using SPSS Statistics (Version 22, IBM Corp, USA) correlating each tumour characteristic and textural feature to progression-free survival (PFS) with two-tailed significance taken as $P < 0.05$.

Results: 101 patients (54 hypopharynx and 47 larynx tumours) with 119 lesions were included (79 tumour and 40 nodes). Median age 62 (range 41-82), 76 (75%) were male. 62 patients received chemo-radiotherapy and 39 had radiotherapy alone. Median follow-up was 26 months (range 0-105). 39 patients progressed during follow-up; 22 at the primary site and 17 within loco-regional nodes. Median loco-regional PFS was 23 months (range 0-105). CT tumour volume (ml), PET MTV and PET-derived grey-level zone length matrix (GLZLM) were independent predictors of PFS ($P < 0.05$). No other features correlated with PFS.

Conclusion: Baseline MTV and PET-derived GLZLM are prognostic predictors in patients with locally advanced larynx and hypopharynx SCC.

B-0668 14:41

Clinical impact of breast and whole body simultaneous PET/MRI for staging of breast cancer lesions >2 cm

V. Romeo, C. Cavaliere, M. Imbriaco, A. Stanzione, R. Cuocolo, A. Pignata, V. Picariello, E. Nicolai, M. Salvatore; Naples/IT (valeria.romeo@unina.it)

Purpose: To assess the added clinical value of breast and whole body simultaneous 2-(18F)FDG PET/MRI over conventional diagnostic imaging techniques in patients with breast cancer lesions (BCLs) > 2 cm.

Methods and Materials: 40 patients with BCLs > 2cm were prospectively enrolled. 38 patients underwent contrast-enhanced breast and whole body simultaneous 2-(18F)FDG PET/MRI; 2 patients prematurely interrupted MRI examinations due to claustrophobia and were therefore excluded. MRI and PET images were evaluated in consensus by a radiologist and a nuclear physician to perform TNM staging. PET/MRI stage was then compared to those obtained using conventional diagnostic imaging techniques (mammography, ultrasound, MRI, chest x-ray and bone scintigraphy) and the possible changes in treatment planning were finally assessed.

Results: In 18% (7/38) cases, PET/MRI had a significant clinical impact: 1) changing surgical strategies in two patients due to the exclusion of contralateral BCLs; 2) switching one patient candidate to surgical excision towards neoadjuvant chemotherapy (NAC) due to the detection supraclavicular pathologic lymph-nodes; 3) contraindicating NAC in four patients due to the detection of additional bone and/or mediastinal lymph-node metastases. Finally, the finding of a contralateral BCL in one patient candidate to NAC, even without modifying the therapeutic approach, was crucial in view of the assessment of the response to treatment.

Conclusion: Breast and whole body simultaneous PET/MRI examination is useful for staging of patients with BCLs > 2cm, allowing to identify or exclude contralateral BCLs as well as to detect distant metastases that may be missed by conventional imaging techniques.

B-0669 14:49

Can we replace sentinel lymph node resection in breast cancer patients by breast MRI, axillary MRI or axillary ¹⁸F-FDG PET/MRI

J. Kirchner¹, O. Martin¹, L.M. Sawicki¹, L. Umutlu², P. Heusch¹, C. Buchbender¹; ¹Düsseldorf/DE, ²Essen/DE (Julian.Kirchner@med.uni-duesseldorf.de)

Purpose: To compare the diagnostic performance of Mamma-MRI, axillary MRI and axillary ¹⁸F-FDG PET/MRI in the detection of lymph node metastases in patients suffering from breast cancer.

Methods and Materials: 27 female patients with breast cancer (mean age 54 ± 10 years) with newly diagnosed, histopathologically proven breast cancer were prospectively enrolled in this trial. All patients underwent dedicated prone ¹⁸F-FDG breast PET/MRI and supine whole-body ¹⁸F-FDG PET/MRI. Sentinel lymph node biopsy (SLNB) and/or axillary lymph node dissection was performed in all patients and histopathology served as reference standard. Sensitivities, specificities, PPV, NPV and accuracy regarding axillary lymph node assessment were calculated for dedicated breast MRI, axillary MRI and axillary ¹⁸F-FDG PET/MRI.

Results: According to the reference standard lymph node metastases were present in 13 patients with a total of 23 metastases. On a patient based analysis dedicated breast MRI identified 6/13 (46%), axillary MRI 5/13 (38%) and axillary PET/MRI 8/13 (62%) of the patients with a positive nodal status. All modalities revealed on false positive finding (7%). On a lesion-based analysis sensitivity, specificity, PPV, NPV and accuracy were 30%, 90%, 88%, 38% and 50% for breast MRI, 22%, 90%, 83%, 36% and 44% for axillary MRI and 48%, 90%, 91%, 45% and 62% for axillary PET/MRI.

Conclusion: Breast MRI or (¹⁸F-FDG PET/ MRI) do not reliably differentiate N-positive from N-negative breast cancer patients. Hence, sentinel lymph node biopsy cannot be replaced by imaging procedures.

B-0670 14:57

Evaluation of a fast protocol for staging patients with bronchial cancer using PET/MRI

O. Martin¹, L.M. Sawicki¹, J. Kirchner¹, G. Antoch¹, K. Herrmann², L. Umutlu², P. Heusch¹; ¹Düsseldorf/DE, ²Essen/DE (Ole.Martin@med.uni-duesseldorf.de)

Purpose: To evaluate the applicability of a fast MR-protocol for whole-body staging of bronchial carcinoma patients using PET/MR.

Methods and Materials: In this prospective study, 52 patients (63.9±8.7years) underwent clinically indicated 18F-FDG-PET/CT and subsequent PET/MRI. For PET/MRI imaging, a fast whole-body MR-protocol was implemented. MRI and PET/MRI datasets were analyzed to identify malignant manifestations. The accuracy for the identification of malignant manifestations was calculated and the tumor stage for each examination was determined. In 26 patients, all available histopathological samples as well as results of prior examinations and follow-up imaging were used for the determination of the reference standard. In the other cases, the results of PET/CT imaging used for reference standard.

Results: Both MRI and PET/MRI have a 100% accuracy to correctly identify the extent of the primary (T-stage). In nodal staging and identification of metastases, PET/MRI revealed higher values of diagnostic accuracy than MRI alone (both p<0.05). The values of correct stage did not differ significantly between PET/CT and PET/MRI (93.5% for PET/CT vs. 86.9% for PET/MRI). Average scan duration of whole-body PET/CT and PET/MRI examinations were 17.5±2.3 min and 29.4±3.9 min, respectively. Estimated mean effective-dose for whole-body PET/CT scans were 61.3% higher than for PET/MRI.

Conclusion: Using 18F-FDG PET data in addition to whole-body MRI leads to a more accurate evaluation of patients with bronchial cancer. With regard to patient comfort related to scan duration and reduced radiation exposure, fast PET/MRI may serve as a powerful alternative to PET/CT for a diagnostic workup of bronchial cancer patients.

B-0671 15:05

Is there a connection between immunohistochemical markers and grading of lung cancer with ADC and SUV of hybrid 18F-FDG PET/MRI?

O. Martin¹, P. Heusch¹, J. Kirchner¹, T. Ullrich¹, C. Buchbender¹, F. Nensa², K. Herrmann², L. Umutlu², L.M. Sawicki¹; ¹Düsseldorf/DE, ²Essen/DE (Ole.Martin@med.uni-duesseldorf.de)

Purpose: To correlate various prognostically relevant immunohistochemical parameters of primary lung cancer with simultaneously acquired standardized uptake values (SUV) and apparent diffusion coefficient (ADC) derived from hybrid PET/MRI.

Methods and Materials: 55 consecutive patients with histologically proven lung cancer (62.5±9.2y) underwent 18F-FDG-PET/MRI. Diffusion-weighted imaging (DWI, b values: 0, 500, 1000) was performed simultaneously with PET acquisition. A region of interest (ROI) encompassing the entire primary tumour was drawn into each patient's PET/MR images to determine the glucose metabolism represented by maximum and mean SUV and into ADC maps to assess tumour cellularity represented by mean and minimum ADC values.

Histopathological tumour grading was available in 43/55 patients. In 15 patients, additional prognostically relevant immunohistochemical markers, i.e. pAKT473, pERK, PTEN and erbB2 were available. Pearson's and Spearman's correlation were used.

Results: We found a significant inverse correlation between the ADCmin and SUVmax (r=-0.58, p<0.001) as well as between the ADCmin and SUVmean (r=-0.44, p<0.001). Tumour grading showed a significant positive correlation with SUVmax and SUVmean (r=0.34 and r=0.31, both p<0.05) and a significant inverse correlation with ADCmin and ADCmean (r=-0.30 and r=-0.40, both p<0.05). In addition, erbB2 showed a significant inverse correlation with SUVmax and SUVmean (r=-0.50 and r=-0.49, both p<0.05). The other immunohistochemical markers did not show any significant correlations.

Conclusion: The present data show significant correlations between SUV, ADC, grading and erbB2-expression of lung cancer. Hence, 18F-FDG-PET and DWI from hybrid PET/MRI may offer complementary information to the histopathology of lung cancer for the evaluation of tumour aggressiveness and treatment response.

B-0672 15:13

Prediction of overall survival using interim 18F-FDG PET-CT and CT for response assessment of patients with Hodgkin lymphoma treated with immune checkpoint inhibitors

F.-Z. Mokrane¹, A. Chen², B. Zhao³, S. Ammani⁴, L. Schwartz³, R. Houot⁵, L. Dercle⁶; ¹Toulouse/FR, ²Nanjing/CN, ³New York, NY/US, ⁴Villejuif/FR, ⁵Rennes/FR, ⁶Paris/FR (mokrane_fatimazohra@yahoo.fr)

Purpose: Anti-programmed death 1 therapy triggers new patterns of response and progression in patients with Hodgkin lymphoma. We aimed to predict overall survival (OS) based on interim imaging.

Methods and Materials: We retrospectively analysed 61 patients treated by anti-PD1 from 2013 to 2017. Concomitant F-FDG PET/CT and CT scans were acquired at baseline and upon treatment. Three radiologists classified blindly and independently patients as immune-responding or immune-refractory based on the first evaluation, using the International Harmonisation Project Cheson 2014 criteria and the Lymphoma Response to Immunomodulatory Therapy Criteria (LYRIC) (2016 revised criteria). Results were compared imaging assessment to OS. Two interim time points were assessed: interim 1 and 2.

Results: After treatment initiation, imaging examinations were acquired at a median time of 3.0 months (n=61 pts) for interim 1 and 6.7 months (n=51pts) for interim 2 evaluations. At the time of analysis, 13 (21%) patients died due to lymphoma progression. Median OS was not reached. The best overall response rate (ORR) with CT1 was 46%, and 59% with PET1. After two years, the OS rates were 50% for progressive disease (PD), 84% for stable disease (SD), 84% for partial response (PR) and 100% for complete response (CR) at PET1. Moreover, PET reclassified patients from SD or PR using CT to CR at interim 1 (31%) and interim 2 (18%).

Conclusion: A complete response assessment using first interim PET evaluation is highly predictive of good OS. 18F-FDG PET/CT shows a significant incremental value comparing to CT alone in the identification of these complete responders' high survivors patients.

B-0673 15:21

Comparison evaluation of the diagnostic potential of PET/MRI and PET/CT using mIBG-Iod-124 in neuroendocrine and neuroectodermal tumours

A. Örnek¹, L. Umutlu¹, J. Kirchner², D. Heber¹, K. Herrmann¹, V. Ruhlmann¹; ¹Essen/DE, ²Düsseldorf/DE (ahmet.ornek@uk-essen.de)

Purpose: To compare the diagnostic potential of PET/MRI and PET/CT using mIBG-Iod-124 in neuroendocrine and neuroectodermal tumors.

Methods and Materials: 20 patients (12 m, 8 w, age 53±16 y) with histopathologically confirmed pheochromocytoma (n=15), paraganglioma (n=2) and ganglioneuroblastoma (n=3) underwent both a whole-body contrast-enhanced PET/CT and PET/MRI approximately 1 day after injection of 48±9 MBq mIBG-Iod-124. Image analyses included the detection and delineation capacity of malignant lesions. Morphological components: transversal maximal tumor diameter and conspicuity (4-point scale (not visible=0 - high contrast=3)). PET images: tumor conspicuity (4-point scale), SUVmax and SUVmean using VOI technique.

Results: 58 malignant mIBG-positive lesions (peritoneal and mesenteric n=22, bone n= 15, lymph node n= 8, liver n=8, lung n=2 pleural space n=2, adrenal n=1) were detected with both PET/CT and PET/MRI with strongly positive correlated mean SUVmax (18.3±11.4 vs. 17.5±9.8; Pearson's correlation r=0.84) and SUVmean (12.1±7.7 vs. 11.1±6.7; r=0.91). Comparable high lesion conspicuity in the PET component of PET/CT (2.9±0.4) and PET/MRI (2.9±0.3; p=0.46) could be assessed with significant higher lesion conspicuity in MRI (2.8±0.6) compared to CT (2.6±0.8; p=0.01). Two small lung lesions were not visible on MRI and five osseous metastases could not be assessed on CT, but showed an unequivocal hyperintensity on MRI.

Conclusion: Integrated mIBG-Iod-124-PET/MRI shows high potential as diagnostic procedure in neuroendocrine and neuroectodermal tumors with in comparison to PET/CT comparable detection rate and high lesion conspicuity in PET. A significant higher lesion conspicuity could be found in MRI compared to CT.

Implementation of an ultra-low-dose CT-protocol for extremities: initial experience with 106 subjects

Z. Alagic¹, R. Bujila², S. Srivastava², S.K. Koskinen³, ¹Solna/SE, ²Stockholm/SE, ³Huddinge/SE (zlatan.alagic@sll.se)

Purpose: To assess if ultra-low-dose Computed Tomography (ULD-CT) is a useful alternative to Digital Radiography (DR) in the evaluation of wrist and ankle fractures.

Methods and Materials: A ULD-CT protocol on a Revolution™ CT was designed for wrist and ankle fractures. Patients admitted to the emergency department with suspected wrist or ankle fractures were evaluated prospectively. After DR obtained on a Discovery™XR650 radiography system, a ULD-CT was performed. Two readers independently analyzed DR and ULD-CT images, and the results were blinded to the readers. Also, the radiation dose (RD), examination time, and time to preliminary report was compared between DR and CT.

Results: In 106 subjects DR and ULD-CT detected 55 and 69 fractures, respectively, corresponding to an odds ratio of 1.7 for ULD-CT vs. DR. Furthermore, ULD-CT provided important additional information about soft tissue in 3 cases (2.8%), non-fracture related findings that explained the symptoms in 10 cases (7.4%), additional fracture-related findings in 22 cases (15.7%) and was able to confirm or rule out suspected fractures on DR in 8 cases (5.6%). The average examination time was shorter for ULD-CT than DR (3.5±1.4 vs. 6.7±3.8 min, p<0.001) as well as the average time to preliminary report (22.6±13.6 min vs. 35.6±33.2 min, p=0.057). The average estimated effective dose was comparable between ULD-CT and DR (0.66±0.45 µSv vs. 0.51±0.47 µSv).

Conclusion: ULD-CT is an excellent alternative to DR for imaging the peripheral skeleton as it provides additional clinically important information at a comparable RD as well as faster examination and reporting times.

B-0684 14:08

Tissue stiffness after self-myofascial release in athletes with different experience in foam rolling assessed by quantitative acoustic radiation force impulse elastography (ARFI)

R. Heiß, I. Mayer, M. Huettel, M.S. May, W. Wuest, M. Kopp, C. Lutter, R. Forst, T. Hotfiel; Erlangen/DE (Rafael.Heiss@uk-erlangen.de)

Purpose: Self-myofascial release using foam rolling (FR) has been developed into a popular preventive and recovery intervention. However, its effects on target tissue with regard to changes in stiffness properties are still poorly understood. The aim was to investigate the role of foam rolling on muscle and ligament stiffness.

Methods and Materials: Acoustic radiation force impulse elastography (ARFI) was performed in 40 volunteers (20 with more than 6 months of experience in FR and 20 without any experience) before and several times (0, 30, 60, 120min, 12h and 24h) after a standardized foam rolling exercise of the lateral thigh. Tissue stiffness was assessed at different compartments of the lateral thigh including superficial and deep muscle tissue (vastus lateralis muscle, VL; vastus intermedius, VM) and connective tissue (distal insertion of the iliotibial band, ITB).

Results: Tissue stiffness of the ITB revealed a significant decrease of 13% in experienced athletes at 30 min post-intervention (p=0.0017). In non-experienced athletes a 6% increase of stiffness was found at 30 min post-intervention at ITB, which was not significantly different to baseline (p=0.16); no significant changes occurred at later time points at ITB. For VLM and VM no significant changes were detected at any time point in both groups.

Conclusion: A significant short-term decrease of connective tissue stiffness in experienced athletes is detectable with ARFI.

B-0675 14:16

Dual-energy CT for assessment of bone marrow oedema in the acute fracture: a systematic review

F.C. Müller¹, J.S. Bovin¹, K.K. Gosvig¹, F. Kainberger², A. Rodell³, M. Østergaard⁴, M. Boesen⁵, ¹Herlev/DK, ²Vienna/AT, ³Ballerup/DK, ⁴Glostrup/DK, ⁵Copenhagen/DK (felix.c.mueller@gmail.com)

Purpose: The aim of this systematic literature review (SLR) was to investigate dual-energy CT (DECT) for the detection of bone marrow oedema (BME) associated with acute fracture.

Methods and Materials: A SLR was done, based on a study protocol in agreement with the PRISM statement, with Medline searched on 01.08.2018. Abstracts were screened by two independent reviewers and studies included based on consensus. Key outcome measures were diagnostic test accuracy, inter-reader agreement, virtual non-calcium (VNCa) values and minimal size for oedema detection.

Results: 11 prospective and 8 retrospective studies were identified and investigated the knee, ankle, hip, wrist and spine using scanners from three vendors with different CT and post-processing parameters. Sensitivity was 61%-100% and specificity 70%-100%. Inter-reader agreement was substantial with $\kappa > 0.7$ in 11 of 13 studies. In the knee, average VNCa values were -53 to -8 in normal regions and -94 to -58 in oedematous regions. In the spine VNCa values were overlapping between the different studies for vertebra with and without acute fracture. No study investigated minimal detectable oedema size.

Conclusion: Results indicate that demonstration of fracture-associated BME with DECT is feasible. Prospective, blinded studies are missing for the wrist and hip. Included knee studies use similar CT-parameters and show high diagnostic test accuracy. Spine studies are technically heterogeneous with high accuracy but inconsistent quantitative results. Bone marrow oedema can be detected on various CT units, but the effect of CT parameters, CT unit and post-processing is still unclear and we suggest that for clinical utilisation and meta-analysis CT parameters should be carefully considered.

B-0676 14:24

A prospective randomised CT analysis of ankle syndesmosis injuries in Weber B and C type fractures

A. Favia¹, M. D'addato², G. Calio¹, C. Campagna¹, V. Favia¹, M. Carrozzo¹, A. Spinarelli¹, A. Scardapane¹, A. Stabile lanora¹; ¹Bari/IT, ²Bisceglie/IT (annafavia@libero.it)

Purpose: To evaluate the role of preoperative computed tomography (CT) scan in patients with programmed stabilisation of ankle syndesmosis injuries in Weber B and C type fractures.

Methods and Materials: Between June 2016 and May 2017, 51 patients with Weber fracture type B and C were divided into 3 groups: 14 (27.45%) without preoperative fractured ankle CT scan in Group A, 19 (37.25%) with preoperative fractured ankle CT scan in Group B, and 18 (35.30%) with preoperative bilateral ankle CT scan in Group C. All the patients underwent to stabilisation of syndesmosis and have been subjected to postoperative bilateral ankle CT scan. Clinical outcomes with American Orthopedic Foot and Ankle Society (AOFAS) score at 3, 6 and 12 months were recorded. Seven measurements on postoperative axial CT scan images were confronted between the injured and uninjured ankles to check the accuracy of reduction.

Results: At 3 months of follow-up, there was no significant difference between groups (p= 0.105). At 6 and 12 months of follow-up, the median AOFAS score was higher in Group C (84.33±1.68 and 93.44± 3.01, respectively) compared to Group B and Group A. The seven variables measured at the CT scan after syndesmotic reduction were statistically different between groups with a better restoration of the tibiofibular distances and the correct ankle anatomy in Group C.

Conclusion: Use of the preoperative comparative CT scan of the injured and uninjured ankle gives the surgeon more accurate informations for the reduction and the intraoperative manoeuvres, allowing a better clinical outcome.

Reliability of ultrasonography measurement of the anterior talofibular ligament (ATFL) length in healthy subjects, based on examinee experience and patient positioning

J. Seilern und Aspang, K.-H. Kristen, H. Platzgummer, F. Hartenbach, J. Wiedermann; Vienna/AT (jesse.seilern@gmail.com)

Purpose: The most common cause of ankle injury is the supination trauma, inflicting a partial or complete rupture of the anterior talofibular ligament (ATFL). Among conventional diagnostic tools and procedures of sports injuries, the method of stress-ultrasonography is reportedly a promising diagnostic tool for examining injuries of the lateral ligaments of the ankle. Preceding studies predominantly examined the comparability of stress-ultrasonography and other established diagnostic tools in terms of efficacy, viability and quality. The

purpose of this study was to assess the reliability of stress-ultrasonography of the ATFL based on varying examinee experience and patient positioning.

Methods and Materials: Sixteen healthy subjects were examined by four examiners with differing levels of skill and experience in ultrasonography, ranging from laymen to specialist. Measurements were recorded and interrater correlation coefficient (ICC) was applied in four positions, including a neutral position (A), medial rotation (B), plantar flexion (C) and inversion of the foot (D).

Results: The correlation of the combined results of all four investigators was 0.333 for position A, 0.386 for position B, 0.320 for position C and 0.517 for position D. The highest ICC (0.811) was recorded between the orthopaedic specialist and the radiology specialist. The lowest ICC (0.299) was recorded between the laymen and the radiology specialist.

Conclusion: The reliability of the ATFL examination seems to be exceedingly dependent on the examiner's experience in ultrasonographic (US) diagnostics. Moreover, the positioning described by the European Society of Musculoskeletal Radiology (ESSR) yielded the highest measurement reliability.

B-0678 14:40

Model-based accelerated T2 mapping of sacroiliac joint with 3-T MRI: a preliminary study of Grappatini

X. Peng, S. Yang, P. Hu, J. Xiao, Y. Pei, W. Liao; *Changsha/CN*

Purpose: The objective of this study was to assess the feasibility of GRAPPATINI in the sacroiliac joints.

Methods and Materials: The sacroiliac joints of 10 healthy volunteers were imaged by 3-T MRI using routine FSE sequence, multi-slice multi-echo spin echo (MESE) T2-weighted sequence, model-based accelerated T2 mapping (GRAPPATINI). ROIs were drawn in sacral-side and iliac-side cartilage to get T2 values. Intra and interobserver reproducibility of T2 values measured using GRAPPATINI by two radiologists independently were calculated. The consistency of T2 values measured by T2 mapping with MESE and GRAPPATINI was calculated using Bland-Altman. The image quality, SNR and CNR was compared between routine FSE T2W image and synthetic T2W image of GRAPPATINI.

Results: Compared to MESE sequence, GRAPPATINI gave a almost 40% reduction of scanning time. Mean (\pm SD) T2 values were 50.2 ± 5.3 ms and 48.2 ± 6.1 ms for observer 1 and 47.9 ± 5.6 ms for observer 2 measured by GRAPPATINI. The intraobserver intraclass correlation coefficient was 0.78, and the interobserver intraclass correlation coefficient was 0.76. Good agreement between T2 values measured with MESE and GRAPPATINI was identified by Bland-Altman plot. No significant difference for overall image quality, image quality, SNR and CNR was demonstrated between the routine FSE T2W image and synthetic T2W image of GRAPPATINI.

Conclusion: Our study shows the feasibility of GRAPPATINI at the sacroiliac joints. Model-based accelerated T2 mapping enable quantitative imaging techniques to proceed in clinical applications.

B-0679 14:48

Feasibility of sub-milliSievert CT of the skeletal pelvis: a human cadaver study

J.M. Weinrich¹, K.J. Maas¹, J. Stárková¹, L. Intert¹, S. Sehner¹, M. Regier², G. Adam¹, A. Quitzke¹; ¹Hamburg/DE, ²Munich/DE

Purpose: To investigate the feasibility of sub-milliSievert (sub-mSv) CT of the skeletal pelvis in human cadavers using a standard-dose (SD) and four different reduced-dose (RD) protocols reconstructed with filtered back projection (FBP) and iterative reconstruction (IR).

Methods and Materials: The pelvis of 25 human cadavers was examined using different RDCT protocols with decreasing reference tube currents (RDCT-1: 80 mAs; RDCT-2: 60 mAs; RDCT-3: 40 mAs; RDCT-4: 10 mAs) at 120 kV. A clinical SDCT protocol (100 mAs, 120 kV) served as reference. Raw data were reconstructed using FBP and two increasing levels of IR (IRL4&6). The anterior pelvic ring, acetabulum and posterior pelvic ring including the iliosacral joints were evaluated for image quality and diagnostic acceptability according to a 5-point-scale.

Results: Image quality of all anatomical structures was rated as diagnostically acceptable for all protocols reconstructed with IR except for eleven cadavers in RDCT-4. Image quality of reconstructions with FBP was generally rated lower and only diagnostic acceptable for SDCT, RDCT-1 and 2. RDCT-3 with IR was the most reduced dose CT protocol allowing diagnostically acceptable image quality for all anatomical structures in all cadavers. Compared to SDCT, application of RDCT protocols resulted in significantly reduced effective radiation doses (SDCT: 2.0 ± 0.7 mSv; RDCT-1: 1.6 ± 0.6 mSv; RDCT-2: 1.2 ± 0.4 mSv; RDCT-3: 0.8 ± 0.3 mSv; RDCT-4: 0.3 ± 0.1 mSv; $p=0.001$).

Conclusion: Diagnostically acceptable sub-mSv CT of the skeletal pelvis is feasible with a reference mAs of 40 at 120 kV using iterative reconstruction. We believe that the presented RDCT-protocol should be implemented in clinical routine as a first-line imaging method.

B-0680 14:56

Quantification and evaluation of pre-post exercise femoral cartilage thickness and T2 changes in ultramarathon athletes

F. Garcia-Castro¹, J. Catala-March², D. Brotons-Cuixat², M. Llobet-Llambrich², E. Sanchez-Osorio², A. Alberich-Bayarri¹; ¹Valencia/ES, ²Barcelona/ES (*fablogarcia@quibim.com*)

Purpose: Articular cartilage MRI allows the assessment of the integrity of the tissue matrix through the quantification of T2 and thickness. The purpose of this work is to evaluate the variation of these image biomarkers in ultramarathon athletes before and after exercising.

Methods and Materials: Thirty-six MRI studies were acquired from both knees of 9 healthy subjects before and after running an ultramarathon (80 km). The MR protocol included a T2 multi-echo sequence with 6 echo times and a high-resolution anatomical sequence (DESS). The multi-echo T2 sequence was registered to the anatomical sequence using an elastic algorithm to achieve spatial consistency. Thickness of the femoral cartilage was calculated using an in-house algorithm based on the distance transform. For the T2-mapping calculation, the voxelwise signal decay across echo times was modelled using a non-linear least-squares fit algorithm. Thickness and T2 parametric maps were aligned to the same spatial reference. Thickness and T2 values were statistically compared before and after exercise, as well as with and without the administration of hyaluronic acid.

Results: Significant differences were obtained in the median ($p=0.037$) and 25th percentile ($p=0.017$) of the T2 values before and after exercising (higher post-ultramarathon values). In cases with hyaluronic acid, these differences disappeared ($p=0.24$ and 0.16). There were no significant differences in cartilage thickness.

Conclusion: T2-mapping provides information on post-ultramarathon alterations. The hyaluronic acid removed differences in T2 values. Femoral cartilage thickness remained invariant during exercise.

B-0681 15:04

Presence of intravascular contrast material after intraarticular injection for CT arthrography

C. von Falck, J.B. Hinrichs, F. Wacker; *Hanover/DE (c.v.falck@gmx.de)*

Purpose: To analyze the appearance of intravascular contrast material after intraarticular injection for CT arthrography

Methods and Materials: A total of 50 CT arthrography examinations were retrospectively reviewed (elbow: 6, wrist: 22, knee: 11, ankle: 8, shoulder: 3). All procedure were conducted under sterile conditions and fluoroscopic guidance according to the institutes standard procedures. The examinations were independently evaluated by two readers for the presence and degree of intravascular contrast enhancement using a 4-point Likert scale.

Results: Intravascular contrast material was seen in 72% (36/50) of the examinations. Grade 1 was seen in 16% (8/50), grade 2 in 34% (17/50) and grade 3 in 22% (11/50) of the scans. Only 28% (14/50) of the examinations did not show intravascular enhancement.

Conclusion: Intravascular contrast material is commonly seen after intraarticular injection of iodinated contrast agents. This should be considered during pre-interventional risk assessment in patients with allergy to contrast agents or hyperthyroidism.

Optimising dual-energy CT parameters for virtual non-calcium imaging: a phantom study

F.C. Müller¹, H. Børgesen¹, K.K. Gosvig¹, A. Rodell², C. Booz³, B. Schmidt⁴, B. Krauss⁴, M. Boesen⁵; ¹Herlev/DK, ²Ballerup/DK, ³Frankfurt a. Main/DE, ⁴Forchheim/DE, ⁵Copenhagen/DK (*felix.c.mueller@gmail.com*)

Purpose: Virtual non-calcium (VNCa) images calculated from -energy CT (DECT) data can characterise bone marrow changes associated with fractures and rheumatoid arthritis. We investigated the relationship between dose, tube voltage combinations, pitch, rotation time and reconstruction kernel regarding accuracy and image noise of VNCa images using a bone marrow phantom.

Methods and Materials: A bone marrow phantom was developed in-house and imaged using a third-generation dual-source CT scanner with various dose and tube voltage combinations, rotation times, pitch and reconstruction kernels. Accuracy was determined by measuring the mean error between VNCa values in identical volumes of interest in free fluid and fluid in bone and spearman rank correlation coefficients calculated between mean error, image noise (standard deviation of VNCa measurements) and scan parameters.

Results: The mean error did not significantly correlate ($p>0.05$) with tube voltage, dose, rotation time or pitch. Increasing sharpness of the reconstruction kernel correlated with mean error ($r=0.83$, $p=0.015$, n (number of experiments)=8). Image noise correlated significantly with tube voltage difference ($r=0.96$, $p<0.001$, $n=29$), dose ($r=0.98$, $p<0.001$, $n=29$) and kernel

sharpness ($r=1.0$, $p<0.001$, $n=8$) but not with rotation time or pitch.

Conclusion: In this study, dose and spectral separation did not affect the accuracy of VNCA images, but correlated with image noise. VNCA reconstructions with similar accuracy and image noise could be achieved using different tube voltage combinations by adjusting the dose. The phantom holds the potential to calibrate image quality across different DECT scanners to be used in multicentre studies of bone marrow changes.

Importance of minimal HU setting in the foot and ankle DECT: frequency and the common site of submillimeter artefact noted in patients in gout free patients

H. Yang¹, Y.-S. Hong², J. Gong Yong³, Y. Lee¹, S. Kim¹, J. You¹, E. Park¹; ¹Jeonju/KR, ²Gwangju/KR, ³Chonju/KR (yphot@naver.com)

Purpose: To evaluate the frequency of cluster of submillimeter artefact in normal foot and ankle DECT and to compare the difference between two different setting of minimal HU.

Methods and Materials: From July to September 2018, 12 normal foot and ankles obtained by DECT were enrolled. Two radiologists reviewed the images and checked if there is a cluster of green pixilation (submillimeter artefact). When it existed, they assessed the volume, site, shape and the width to height ratio of the artefact. Student t-test was used to compared the frequency and volume of DECT with two different minimal HU setting.

Results: The cluster of submillimeter was noted at 75% of normal foot and ankle DECT in setting of minimal HU as 130HU. The volume of artefact significantly decreased from 2.03cm³ to 0.3 cm³. These frequency significantly decreased to 33.3% in setting of minimal HU to 150HU. These were most frequent in forefoot. In setting of minimal HU as 130HU, the most frequent anatomic site was FHL at hindfoot level (12/79) and forefoot level (11/79) and, followed by 2nd flexor tendon at forefoot level (9/79). Other additional sites was FDL at hindfoot level, 3rd flexor tendon at forefoot level.

Conclusion: Even though the submillimeter artefact decreases with the minimal HU setting from 130 to 150HU, it is not rare. This artefact is common in forefoot, and tends to be flat and wider than tall. Radiologist should be aware of the common site of the artefact including FHL, 2-3rd flexor tendon, and FDL.

Using radiomics to identify invisible bone metastases on CT in melanoma patients receiving immunotherapy

Z. Elkarghali¹, T. Nguyen-Kim², J. Spekrijse¹, S. Trebesch¹, J.B. Haanen¹, C.U. Blank¹, W. Vogel¹, R.G.H. Beets-Tan¹; ¹Amsterdam/NL, ²Zurich/CH (z.elkarghali@nki.nl)

Purpose: Bone metastases are associated with advanced tumour progression and poor prognosis, however they are not considered measurable under Response Evaluation Criteria in Solid Tumours (RECIST 1.1, modified iRECIST) and PET Response Criteria in Solid Tumours (PERCIST). While visible on PET scan, some metastatic bone lesions are indistinguishable on CT from surrounding healthy tissue. We hypothesize that non-invasive radiomic features extracted from baseline CTs could be used to discriminate between occult lesions and healthy tissue.

Methods and Materials: 238 patients with metastatic melanoma (receiving anti-PD1 immunotherapy) were retrospectively studied, of whom 61 had PET-confirmed bone metastases. A total of 153 PET-positive/CT-occult lesions were identified (using the PET scan as benchmark) and delineated on CT. The

healthy contralateral bone within the same image examination was delineated symmetrically for each identified lesion and was defined as a control lesion. Radiomic features were extracted and with a multivariate mixed-model analysis, each of the features were tested on their ability to discern PET-positive/CT-occult lesions from the matched healthy contralateral controls.

Results: Of the seventeen non-redundant CT radiomic features, four were found to be predictive of PET-positive/CT-occult lesions. On a coarse scale, more morphological heterogeneity in bone metastases was observed ($coeff.=0.619$, $p<0.001$). This difference in heterogeneity becomes less and less prominent at the medium ($coeff.=2.041$, $p=0.003$) and fine scale ($coeff.=0.721$, $p=0.018$) - suggesting more involvement of larger structures in the bone.

Conclusion: Our findings suggest that, with the use of radiomics, discernible morphological differences exist between PET-positive/CT-occult lesions and their healthy controls, specifically in heterogeneity.

B-0686 14:17

Prediction of immune-checkpoint-inhibitor therapy effectiveness by evaluation of bone marrow activity modifications: an FDG-PET/CT study

G. Ferrero¹, F. Fiz², J. Schwenck³, C. La Fougère³, C. Campi⁴, G. Sambucetti², E. Fabbro⁵, B. Pickler³, M. Kneilling³; ¹Pietra Ligure/IT, ²Genoa/IT, ³Tubinga/DE, ⁴Padua/IT, ⁵Cuneo/IT (giulio.ferrero@gmail.com)

Purpose: Despite its efficiency, immune checkpoint inhibitor therapy (ICIT) fails in 60-80% of metastatic melanoma patients. Increase in lymphocyte counts has been proposed as an early prognostic marker of ICIT response, but data are inconsistent. Aim of our study was to uncover whether determination of bone marrow (BM) metabolic activity by ¹⁸F-FDG-PET/CT can predict efficient response to ICIT.

Methods and Materials: 20 patients, with Stage-IV melanoma (10 responders; 10 non-responders) were retrospectively enrolled. Every subject underwent a whole-body staging PET/CT (PET1) and a second PET/CT (PET2) 118±29 days later, in the course of ICIT. Response was evaluated with PERCIST criteria. A computer algorithm recognized trabecular bone (where BM is housed) in the CT images and extracted the mean SUV from the co-registered PET images; SUV was corrected for background (target-to-background ratio, TBR). Total, axial and appendicular BM was analyzed separately. Bone metastases, previous radiotherapy, high-grade infections and use of BM-stimulating agents were exclusion criteria.

Results: After ICIT, whole-body TBR values increased by 0.52±0.64 in responders ($p<0.05$) and remained stable in non-responders. In axial skeleton TBR increase was 0.5±0.3 in responders ($p<0.01$) and 0.1±0.16 in non-responders ($p=ns$). As a consequence, mean TBR increase was higher in responders than in non-responders, both in total and in axial skeleton ($p<0.05$). Moreover, responders showed a higher baseline TBR in the axial skeleton when compared to non-responders (2.3±0.62 vs 1.61±0.27, $p<0.05$).

Conclusion: Analysis of glucose metabolism by ¹⁸F-FDG-PET/CT in secondary lymphoid organs might be a new sensitive tool in predicting ICIT response. In particular, a higher BM metabolic activity before therapy as well as a higher metabolic increase after therapy was identified in patients who had responded to the ICIT.

B-0687 14:25

Imaging detection and characterisation of bone metastases from neuroendocrine neoplasm with simultaneously acquired Ga-68 DOTATATE PET/MRI

J. Bai, R. Matthews, L. Bangiyev, A.R. Chimpiri, D. Franceschi; Stony Brook, NY/US (james.bai@stonybrookmedicine.edu)

Purpose: The purpose of the study is to evaluate imaging characteristics of bone metastases from neuroendocrine tumour (NET) with simultaneously acquired Ga-68 DOTATATE PET-MRI.

Methods and Materials: We retrospectively identified 35 patients with NET who underwent combined Ga-68 DOTATATE PET-MRI for tumour staging. Each PET-MRI was evaluated in consensus by a nuclear radiologist, a body radiologist, and a neuroradiologist. 61 lesions from 8 patients demonstrated abnormal osseous uptakes of DOTA consistent with bone metastases. 38 of 61 lesions were located in the spine. MR sequences included axial T1 radial view fs, axial T2 haste, and sag T1 Dixon sequences.

Results: 32 of 61 osseous lesions with abnormal DOTA uptake demonstrated variable T1 and T2 signal abnormalities. Of the 32 lesions, 26 lesions showed mild hyperintensity on T1 view fs. 34 of 38 DOTA-positive spine lesions were detected on Dixon. Among the spine lesions, Dixon demonstrated consistent abnormal signal characteristics with hyperintensity on water sequence and hypointensity on fat sequence. 1 cervical spinal lesion from a patient with concurrent prostate cancer demonstrated mild DOTA uptake, but prominent MR abnormalities. 1 lumbar spinal lesion from a patient with rectal carcinoid cancer also demonstrated mild DOTA uptake, but suspicious MRI features.

Conclusion: In this study, Ga-68 DOTATATE was shown to be a highly sensitive molecular marker that can detect bone metastases from NET before signal abnormalities could be identified on simultaneously acquired MRI sequences. The multi-sequential MRI provides incremental diagnostic value to distinguish bone metastases from NET vs bone metastases from other neoplasm and to identify potential complication from bone metastases which would help in clinical management.

B-0688 14:33

Whole-body MRI vs bone scan in the follow-up of oncologic patients

A. Malich, I. Papageorgiou, D. Wiech; Nordhausen/DE
(ismini.e.papageorgiou@gmail.com)

Purpose: The 99mTc-bone scan (BS) is a standard of diagnosis for the skeletal staging in many oncologic guidelines. However, the number of nuclear medicine departments in Germany is steadily decreasing while MRI devices become more available, fast, precise and affordable. Whole-body MRI (WB-MRI) is a promising radiation-free alternative to bone scan with growing popularity in the oncological practice. We compare the diagnostic efficacy of WB-MRI to BS in a large database from our hospital.

Methods and Materials: From a large database of 1797 WB-MRI, we included 285 eligible patients with WB-MRI and BS within a time interval of 12 months. WB-MRIs were evaluated by 2 radiologists blinded to the BS report. Change of the therapeutic decision, confirmation in less than 1 year from the diagnosis or biopic confirmation served as the gold standard.

Results: From the 285 eligible cases a decision agreement between WM-MRI and BS was observed in 222 cases (in 94 cases both methods were true positive and in 128 cases true negative). In 90 cases WB-MRI and BS showed deviating results and the inter-observer agreement was 71.15% with a Cohen's kappa of 0.42, which speaks for a moderate method agreement. The sensitivity, specificity, PPV and NPV of WB-MRI were 98/85/82/99% and were not significantly different compared to the general WB-MRI metrics in our department.

Conclusion: WB-MRI is a radiation-free, reliable and precise bone staging method with equal efficacy compared to the established BS.

B-0689 14:41

Activity concentration in prostate cancer bone metastases predicts the radioisotope therapy outcome: a SPECT/CT study

G. Ferrero¹, F. Fiz², H. Dittman³, C. La Fougère³, C. Campi⁴, G. Sambuceti², S. Sahbai⁵, M. Weissinger³, M. Piana²; ¹Pietra Ligure/IT, ²Genova/IT, ³Tubinga/DE, ⁴Padova/IT, ⁵Parigi/FR (giulio.ferrero@gmail.com)

Purpose: 223RaCl₂ is the only bone-specific radioisotope therapy that showed a benefit in metastatic castration-resistant prostate cancer (mCRPC) patients' survival. However, a variable percentage of patients progresses in course of 223RaCl₂-Therapy. In this study, we applied a computational software analysis to SPECT/CT images from mCRPC patients, to identify automatically the skeletal tumour burden and the activity concentration in bone metastases from prostate cancer and to see if these factors have an impact on the therapy outcome.

Methods and Materials: 76 mCRPC patients were retrospectively enrolled. Each patient underwent a whole-body bone SPECT/CT (99mTc-DPD) for staging, then was treated with 6 223RaCl₂ applications. A second SPECT/CT was carried out after this therapy; patients with new visible bone lesions were classified as having a progressive disease (PD), patients with clearly diminished uptake in known metastases as having a partial response (PR), the remaining a stable disease (SD). The staging SPECT/CT was analyzed with a segmentation analysis software, which identified the volume occupied by metastases (mVol), the one of normal trabecular bone (bVol) and the mean activity concentration within these two volumes.

Results: PD, SD, PR were 21, 35, 20, respectively. Mean counts in mVol of PD patients were significantly lower when compared to the other two groups (715±190, 1058±255 and 975±215 mean counts, for PD, SD, PR, respectively p<0.01). The same pattern (lower mean counts in PD patients) was observed in bVol (p<0.001). Moreover, PD patients had a lower total volume of metastases in comparison with SD and PR patients (p<0.05).

Conclusion: Patients with weaker uptake have a worse therapy response; it seems to be associated with a less extended metastatization. These patients may in fact have less tracer-avid foci and their bone lesions could receive a smaller doses during 223RaCl₂ therapy.

B-0690 14:49

18F-FDG PET/MRI for therapy response assessment of isolated limb perfusion in patients with soft-tissue sarcoma

J. Gruenewald¹, B.M. Schaarschmidt², M. Chodyla¹, O. Martin², Y. Li¹, W. Fendler¹, K. Herrmann¹, M. Forsting¹, L. Umutlu¹; ¹Essen/DE, ²Dusseldorf/DE (johannes.gruenewald@uk-essen.de)

Purpose: To assess the diagnostic potential of simultaneously acquired 18F-FDG PET- and MR-derived datasets for therapy response assessment of isolated limb perfusion with melphalan and alpha-TNF (TM-ILP) in patients with soft-tissue sarcomas.

Methods and Materials: A total of 45 patients with a histopathologically proven soft-tissue sarcoma manifestation were prospectively enrolled for an integrated 18F-FDG PET/MR examination before (1st scan) and after (2nd scan) TM-ILP. Therapy response was assessed based on different MR- and PET-derived morphological (RECIST 1.1., MR-adapted Choi criteria) and metabolic (PERCIST) criteria. Histopathological results after subsequent tumour resection served as reference standard and patients were categorized as responders/non-responders based on the grading scale by Salzer and Kuntschik.

Results: Histopathological analysis categorized 27 patients as therapy responders (Grade I-III) and 18 patients as non-responders (Grade IV-VI). Calculated sensitivities, specificities, positive and negative predictive values and diagnostic accuracies were 22%, 89%, 75%, 43% and 49% for RECIST 1.1., 70%, 44%, 66%, 50% and 60% for MR-adapted Choi criteria and 85%, 78%, 85%, 78% and 82% for the PERCIST criteria. Furthermore, receiver operating characteristic analysis revealed an area under the curve of 0.56 (RECIST), 0.57 (MR-adapted Choi) and 0.81 (PERCIST), respectively.

Conclusion: Our results demonstrate the discrepancy of morphological and metabolic response criteria and underline the superiority 18F-FDG PET over MRI for response assessment of TM-ILP. Considering the essential role of MRI in preoperative diagnostics, integrated 18F-FDG PET/MRI may serve as a useful diagnostic tool for treatment planning and monitoring of initial treatment strategies of soft tissue sarcoma patients.

Histopathologic and radiologic assessment of chemotherapeutic response in osteosarcoma: correlation of ADC with huvos grading

H.S. Mohanty¹, A.K. Chaturvedi¹, A. Jajodia¹, M. Bind², A.S. Rao¹, R. Tripathi¹, V. Mahawar¹; ¹New Delhi/IN, ²Bangalore/IN (drmahawarvivek@gmail.com)

Purpose: Histological necrosis, the current standard for response evaluation in osteosarcoma, is attainable after chemotherapy. To establish the role of surrogate markers of response prediction and evaluation using MRI in the pre-surgical assessment.

Methods and Materials: In a retrospective analysis MRI images of newly diagnosed osteosarcoma patients who received more than three cycles of neo-adjuvant chemotherapy or high dose methotrexate followed by surgery during 2012-2018 were analysed. All patients had undergone post-chemotherapy conventional, diffusion-weighted and contrast-enhanced MRI. Classifying histological response in post-surgical specimens according to Huvos grading of necrosis as the reference standard, ADC was measured in pre-surgical DW MRI study and compared to it. ADC was measured separately in soft tissues and bony component of tumor or only in the bone/soft tissue whichever feasible in the sample and it was compared with Huvos grading of necrosis.

Results: Mean ADC for soft tissue component in 28 samples was 2068.3±382.5 and mean ADC for 55 samples of bony component was 1866.6 ± 357.6. The ADC measured in bony samples of osteosarcoma is significantly correlating with Huvos grading with P value <0.05. However the ADC of soft tissue component is not correlating significantly with Huvos grading.

Conclusion: In osteosarcoma, chemotherapy related grade of bony necrosis can be predicted with the help of DW MRI.

B-0692 15:05

Value of the cinematic rendering from CT data in evaluating the relationship between deep soft tissue sarcomas of the extremities and adjacent major vessels

Z. Li; Kunming/CN (lizhenhui621@qq.com)

Purpose: To assess the value of cinematic rendering (CR) from volumetric computed tomography (CT) data in evaluating the relationship between deep soft tissue sarcomas (STS) of the extremities and the adjacent major vessels.

Methods and Materials: Preoperative contrast-enhanced axial imaging (CEAI) and CT angiography (CTA) with 3D volume rendering (VR) and CR were used to assess adjacent vascular invasion in 43 cases of deep STS of the extremities. All images were evaluated by two musculoskeletal radiologists. The imaging assessments were compared with surgical findings and interpreted as negative (no vascular invasion) or positive (vascular invasion was present).

Results: Thirty-four and nine cases were classified as negative and positive, respectively, in surgery. Intra-reader agreement values for the CEAI, VR, and

Can artificial intelligence identify normal mammograms in screening?

K. Lang, M. Dustler, V. Dahlblom, I. Andersson, S. Zackrisson; Malmö/SE
(kristina.lang@med.lu.se)

Purpose: To evaluate the effect of using a deep-learning algorithm in mammography screening to identify normal exams.

Methods and Materials: 9,588 double-read mammography screening exams including 71 screen-detected cancers and 187 false positives, a sub-cohort from the prospective populations-based Malmö Breast Tomosynthesis Screening Trial, were analysed with a deep-learning-based software. The software is used as a preselection tool that categorizes mammograms with a cancer risk score of 1-10, with 10 indicating the highest risk of malignancy. The effect of excluding cases with low risk scores (≤ 5) from screen-reading was investigated. A panel of three breast radiologists assessed the radiographic appearance, type and visibility of cancers assigned low risk scores.

Results: 5,085 (53.9%) exams, including 8 (11.3%) cancers and 52 (27.8%) false positives had low risk scores. If cases scored 1 were excluded, 1,004 (10.5%) normal exams could be removed, including 6 (3.2%) false positives but no cancers. If cases scored 1-2 were excluded, 1,830 (19.1%) exams could be excluded, including 10 (5.4%) false positives and one cancer, an 8 mm invasive ductal carcinoma. The 8 cancers with low risk scores were all invasive, including the ductal, tubular and lobular type. All, except one, were clearly visible, and the majority (5/8) were spiculated masses.

Conclusion: An artificial intelligence system can reduce the screen-reading workload. With further improvement of the software an even greater exclusion of normal mammograms seems possible since the majority of the cancers with low risk scores were clearly visible.

B-0696 14:17

Artificial intelligence software to improve mammography workflow

A.T. Watanabe¹, R.C. Mayo², L.Q. Chang Sen², M. Kapoor², J. Leung²;
¹Los Angeles, CA/US, ²Houston, TX/US (alyssa90266@gmail.com)

Purpose: To determine whether artificial intelligence (AI)-based software can be used to improve radiologists' workflow efficiency and revenue.

Methods and Materials: A retrospective study was performed on a set of 250 2-D Mammograms. The number of cases marked by AI vs traditional CAD, and the number of cases that were recalled were compared. The potential time saved and revenue benefits from use of AI were calculated.

Results: 52% of cases had no marks by AI while only 17% were free of CAD marks. Both systems had 100% sensitivity for cancer detection. There were 37% fewer cases marked by AI compared with CAD. Fifteen of the 18 false positive cases had CAD marks whereas only 8 of the 18 were marked by AI. Based on an assumption of 100,000 mammograms per year, extrapolated data shows AI would yield a potential time savings of 64% or 375 hours of radiologist reading time per year based on fewer marked cases. Up to 10% more screening mammograms could be read with the saved time with as much as \$1,488,362 per year of increased global revenue based on Medicare Fee schedule rates. In addition, AI software can pre-sort the worklist based on suspiciousness which enhances reader's efficiency and potentially their accuracy.

Conclusion: There is potential for decreased reader time, fewer recalls, and increased revenue with AI based software products.

Author Disclosures:

A.T. Watanabe: Board Member; Chief Medical Officer, Curemetrix.

CR assessments were all excellent (0.984, 0.934, and 0.914, respectively), while the inter-reader agreement for CEAI assessments was greater than that for VR and CR (0.969 vs 0.804 and 0.761). CR showed lower accuracy (0.698), sensitivity (0.778), specificity (0.676), positive predictive values (PPV: 0.389) and negative predictive values (NPV: 0.920) for vascular invasion diagnosis than CEAI or VR; the accuracy, sensitivity, specificity, PPV, and NPV increased to 0.767, 0.889, 0.735, 0.471, and 0.962 for both CEAI and VR. The results were not statistically significant (all $P > 0.05$).

Conclusion: CR shows excellent intra-reader agreement and good inter-reader agreement for assessment of the relationship between tumours and the adjacent major vessels. It has the potential to be used to evaluate vascular invasion in cases of deep STS of the extremities.

B-0693 15:13

Diffusion-weighted MR imaging diagnostic merits in post-therapeutic assessment of musculoskeletal soft tissue sarcoma

S. Shokry, A.F.I. Moustafa, M.A.M. Hawanna, M.M. Hussein, A. Shokry; Cairo/EG (drmeago@yahoo.com)

Purpose: Assessing the diagnostic merits of DWI with ADC mapping in evaluating tumour response to chemoradiotherapy.

Methods and Materials: Study included 36 patients with soft tissue sarcoma, who received chemo-/radiotherapy. Tumour longest dimension according to RECIST 1.1, the longest dimension of the contrast-enhanced portion of the tumour according to (mRECIST), the tumour volume (VOL)(cm³) and DWI with ADC values were recorded.

Results: ADC values in the non-progressive group were higher than those of the progressive group after neoadjuvant treatment (1.63± 0.42 vs 1.24±0.35) with ($P < 0.005$). ADC variations in the non-progressive group were higher than those of the progressive group (27.09±48.09 vs -3.08±23.5)% with ($P < 0.05$). ADC values after neoadjuvant treatment were negatively related to tumour volume variations (VOL%) after neoadjuvant treatment. ADC variations (ADC%) were inversely correlated with morphologic changes, regardless of the effectiveness of anticancer therapy expressed as changes in tumour size based on (RECIST, mRECIST and three-dimensional volumetric assessment). Linear regression analysis revealed a Pearson correlation coefficient of $r = (-0.424, -0.478$ and -0.479), respectively, with ($P < 0.005$). An increase in the ADC value was not always associated with a reduction of tumour volume. The disease control rate (defined as the percentage of CR+PR+SD patients) was 63.8% and 69.4% according to RECIST 1.1 and mRECIST.

Conclusion: Quantitative DW imaging after neoadjuvant therapy provides added value in determining treatment response in soft tissue sarcomas. Therapeutic response to neoadjuvant therapy can be underestimated using RECIST 1.1; therefore, the mRECIST should also be considered.

B-0694 15:21

Bone staging of breast cancer with whole-body MRI: using low field strength without enhancer does not mitigate the diagnostic efficacy

A. Maich, A. Kott, C. Kurrat, J. Feger, I. Papageorgiou; Nordhausen/DE (ismini.e.papageorgiou@gmail.com)

Purpose: Whole-body magnetic resonance imaging (WB-MRI) is a guideline recommendation for the detection of bone metastasis in breast cancer. In this study, we compare the diagnostic efficacy of 1.5T and 3T WB-MRI as well as the diagnostic benefit from gadolinium enhancement.

Methods and Materials: The study was retrospective for 874 patients scanned between 05/2007 and 08/2018. 360 patients were imaged at 1.5T and 514 at 3T with a T1-w FFE and a STIR or a Dixon at the coronal level. The slice thickness was 6mm at 1.5T and 3mm at 3T. In 441 patients, we injected gadoteridol (ProHance) 0.1 mmol/kg. Clinical or bioptic confirmation served as the gold standard.

Results: The sensitivity (Se) and specificity (Spe) for 1.5T was 98/91% and the positive predictive value (PPV)/negative predictive value (NPV) was 86/99%. A field strength of 3T showed Se/Spe 100/93% and a PPV/NPV of 83/100%. Binary logistic regression with Fisher's exact test revealed no significant difference between 1.5T and 3T WB-MRI ($P = 0.83$). The Se/Spe of WM-MRI (merged 1.5T and 3T) without enhancement was 99/92%, with PPV/NPV 87/99%. Upon administration of ProHance the Se/Spe shifted to 100/93% and the PPV/NPV to 83/100%, overall without statistically significant effect compared to non-enhanced scans ($P = 0.83$, Fisher's exact test).

Conclusion: Field strengths of 1.5T or 3T show equal diagnostic efficacy for the diagnosis of osseous metastatic breast cancer with WB-MRI. Gadolinium can be omitted without compromising the WB-MRI diagnostic accuracy.

B-0697 14:25

Artificial intelligence detecting breast cancer on mammography: does breast density play a role?

A. Rodriguez Ruiz, M. Kallenberg, A. Gubern-Merida, N. Karssemeijer, R.M. Mann; *Nijmegen/NL*

Purpose: To analyze the relationship between the breast cancer detection performance of an artificial intelligence (AI) system on mammography and breast density.

Methods and Materials: An independent multi-vendor cancer-enriched database of 1397 mammograms was collected across several institutions in Europe (179 with biopsy-verified cancer, 1218 normal with at least two years of negative follow-up). For each mammogram, an AI system computed a score representing the likelihood of presence of cancer (scale 1-10); while the breast density volume fraction (averaged across views) was computed with previously published and validated software. Linear regression analysis was performed for AI score and density. Subsequently, the population was divided into two groups based on the median density value of the population: high-density mammograms (73 cancers, 626 normals) and low-density mammograms (106 cancers, 592 normals). The area under the receiver operating characteristic curve (AUC) of the AI system was compared between the two groups.

Results: Median density volume fraction in the population was 0.12 (0.09-0.18). The AI score did not correlate with density ($R^2 = -0.09$), with low AI score categories harboring at same proportions high-density and low-density mammograms. The AUC of the AI system was similar for both groups (0.91 vs 0.89, difference = +0.02, 95% CI = -0.03, 0.08).

Conclusion: The AI score may be considered as an independent tool to estimate the likelihood of the presence of cancer on mammograms, to stratify screening populations, and to potentially fasten the reading process by reassuring readers on mammograms that are likely normal, irrespective of breast density.

B-0698 14:33

Improved cancer detection using artificial intelligence: a retrospective evaluation of missed cancers on mammography

A.T. Watanabe¹, V. Lim², E. Weise², H. Vu²; *Manhattan Beach, CA/US, La Jolla, CA/US, San Diego, CA/US (alyssa90266@gmail.com)*

Purpose: To determine whether an artificial intelligence-based computer-aided detection (AI-CAD) algorithm can be used to improve radiologists' sensitivity in breast cancer screening and detection.

Methods and Materials: A blinded retrospective study was performed with a panel of seven radiologists using a cancer-enriched data set from 122 patients that included 90 false negative mammograms obtained up to 5.8 years prior to diagnosis. The mammograms were performed between February 7, 2008 (earliest) and January 8, 2016 (latest) and evaluated using Students T Test statistical analysis.

Results: All radiologists showed a significant improvement in their cancer detection rate (CDR) with the use of AI-CAD (p-value=0.0069, Confidence interval = 95%). With the assistance of AI-CAD, the sensitivity of less experienced general radiologists improved to a level higher than a fellowship-trained academic breast imager. The readers detected between 25% and 71% (mean 51%) of the early cancers without assistance. With AI-CAD, the overall reader CDR was 41% to 76% (mean 62%). Overall, there was less than 1% increase in the readers' false positive recalls with use of the AI-CAD.

Conclusion: There was a statistically significant improvement in radiologists' sensitivity for cancer detection in this set of primarily false negative mammograms with the benefit of the AI-CAD. The percentage increase in CDR for the radiologists in the reader panel, ranged from 6% to 64% (mean 27%) with the use of AI-CAD, with negligible increase in false positive recalls.

B-0699 14:41

False negative on computer-aided detection application in preoperative automated breast ultrasound of breast cancer patients

Y. Kim¹, J. Rim¹, S.M. Kim¹, B.L. Yun¹, S.Y. Park¹, H.S. Ahn², B. Kim³, M.J. Jang¹; *Seongnam/KR, Seoul/KR, Yongin/KR*

Purpose: To analyze the characteristics of ultrasonographic, mammographic, and MRI findings of breast cancers that computer-aided detection (CAD) application missed in automated breast ultrasound (ABUS).

Methods and Materials: Total 133 consecutive breast cancer patients (age in mean ± standard deviation, 52.2 ± 10.3 years) who underwent preoperative ABUS were included in our study. Imaging features of mammography, ABUS, and breast MRI as well as pathology results were assessed. Univariable analyses were performed to identify factors associated with missed breast cancers. Multivariable regression analysis was performed using variables which showed a statistical significance in the univariable analyses.

Results: The CAD application missed breast cancers in 27.1% (36/133) of our included patients. Missed breast cancers had higher frequency of ductal carcinoma in situ in pathology and the following imaging features in ultrasound: size <1 cm, distance to nipple <5 mm, indistinct margin, and heterogeneous background tissue echotexture. None of the variables assessed in mammography or MRI was associated with missed breast cancers. In the multivariable regression analysis, ductal carcinoma in situ in pathology, size <1 cm, indistinct margin, and heterogeneous background tissue composition were associated with missed breast cancers.

Conclusion: Breast cancers missed by ABUS CAD application tended to have size <1 cm, indistinct margin, and heterogeneous background tissue echotexture in ABUS. Understanding the imaging features of CAD application-missed breast cancers would help radiologists to diagnose breast cancer in ABUS more accurately.

B-0700 14:49

Automatic detection of breast lesions on ABUS using a novel transfer learning approach: comparison between three different networks

J. Santinha¹, A. Vourtsis², A. Uysal³, J. Moreira¹, N. Papanikolaou¹; *Lisbon/PT, Athens/GR, Ankara/TR (joao.santinha@research.fchampalimaud.org)*

Purpose: To compare three machine learning models that can automatically identify the presence of a lesion on Automated Breast Ultrasound System (ABUS) images.

Methods and Materials: Coronal ABUS reconstructions from 195 patients that underwent ABUS examination were randomly selected and utilised in the current study. 130 ABUS images containing lesions were used, while another 130 images were randomly selected from 65 patients with negative exams (2 non-consecutive slices per patient). 60% of the exams were used for training, 20% for validation and 20% as a hold out test data set. 2048 deep features were extracted from each ABUS image using a pre-trained Google's Inception V3 network, the VGG-16 and VGG-19 networks that were trained on ImageNet. A logistic regression algorithm was used to classify ABUS images into normal or abnormal.

Results: Testing of the diagnostic performance of the three classifiers was done on 52 images that were kept away from the training-validation phase. Inception V3 network provided with the highest performance (sensitivity, specificity and accuracy were 96.15%, 92.31% and 94.23%, respectively), followed by VGG-16 (sensitivity, specificity and accuracy were 88.46%, 96.15% and 92.31%, respectively) and VGG-19 (sensitivity, specificity and accuracy were 92.31%, 88.46% and 90.38%, respectively).

Conclusion: Transfer learning based on Inception V3 offers very high performance for automatic detection of breast lesions on ABUS images.

B-0701 14:57

Automated volumetric analysis of breast cancer vascularisation enables risk stratification in patients scheduled for neoadjuvant chemotherapy

M. Dietzel¹, S. Ellmann¹, P. Clauser², E. Wenkel¹, M. Uder¹, R. Schulz-Wendtland¹, P.A.T. Baltzer²; *Erlangen/DE, Vienna/AT*

Purpose: Volumetric analysis of breast cancer vascularization (VAV) can be automatically performed on a standard pre-therapeutic breast-MRI examination. We investigated whether breast cancer vascularization (VAV) could be used for risk-stratification in patients scheduled for neoadjuvant-chemotherapy using complete response (CR), distant metastasis (MTX) and disease-specific death (DSD) as study endpoints.

Methods and Materials: Within this retrospective, IRB-approved study, 77 consecutive patients with primary invasive breast cancer received standard breast-MRI before the initiation of neoadjuvant-chemotherapy according to international recommendations. Diagnostic workup, treatment, and follow-up were done at one tertiary care, academic breast center (CR: 13, MTX: 17, DSD: 14; mean follow-up: 56 months). Based on the MRI-scans, VAV was accomplished by commercially available, FDA-cleared software. DSD, CR, and MTX served as endpoints. Potential of VAV to predict all three endpoints was investigated; the potential of clinico-pathological factors (CPF) to predict DSD and MTX was identified and compared to VAV. Finally, we investigated whether integration of VAV into CPF increased prognostic accuracy (logistic/Cox regression, Kaplan-Meier statistics, ROC analysis, area under the curve/AUC; alpha=5%).

Results: VAV was able to predict DSD (AUC= 86.3, hazard-ratio/HR=20.2), MTX (AUC= 80.3), and CR (AUC=79, all $P < 0.001$). CPF enabled the prediction of DSD (AUC= 68.3, HR=2.7; $P=0.01$) and MTX (AUC= 74.4, $P=0.03$), yet with a substantially lower accuracy ($P > 0.04$). Combination of VAV and CPF further increased the accuracy ($P > 0.002$) regarding the prognostication of DSD (AUC= 92.2, HR=35.7) and MTX (AUC=85.7%).

Conclusion: Automated volumetric analysis of breast cancer vascularization enables non-invasive risk-stratification in patients scheduled for neoadjuvant-chemotherapy.

B-0702 15:05

The Kaiser score, a decision rule based on BI-RADS MRI descriptors: is there an impact of histopathology on the diagnostic accuracy?

M. Dietzel¹, S. Ellmann¹, E. Wenkel¹, P. Clauser¹, R. Schulz-Wendtland¹, M. Uder¹, P.A.T. Baltzer²; ¹Erlangen/DE, ²Vienna/AT

Purpose: We investigated, whether the diagnostic accuracy of the Kaiser score is influenced by the underlying histopathology.

Methods and Materials: Consecutive patients with equivocal breast lesions scheduled for breast MRI (standardized protocols @ 1.5T: dynamicT1-GRE before/after Gd-DTPA [0.1 mmol/kg body weight (BW)]; T2-TSE), with subsequent pathological sampling, were investigated. The Kaiser score was assessed by two experienced radiologists in consensus (blinded to pathology). Diagnostic accuracy of the Kaiser score stratified by the underlying histopathology was investigated (ROC analysis, descriptive statistics, $\alpha=5\%$).

Results: There were 1080 lesions in 1080 breasts (malignant/benign: 643/437). Histopathology revealed all major subtypes of benign and malignant lesions. Overall accuracy for the differential diagnosis of malignant vs. benign lesions achieved reported values (AUC=0.88). Performance of the Kaiser score regarding invasive cancers (AUC=0.91) was superior to DCIS (AUC=0.73; $P < 0.001$). The Kaiser score performed equally in the assessment of invasive cancers subtypes (AUC=0.92-0.86; $P=0.13-0.97$). Performance of the Kaiser score in the assessment of papillomas (AUC=86.7) and fibrocystic changes (AUC=88.0) was similar ($P=0.57$). Yet, the Kaiser score performed better in fibroadenomas (AUC= 91.8; $P < 0.05$). The highest accuracy of the Kaiser score was observed within the differential diagnosis of benign phyllodes tumours vs. malignant lesions ($n=10$; AUC=98.2; $P < 0.001$).

Conclusion: In general, the Kaiser score is independent of the underlying histopathology and reaches high accuracy. Even in the presence of challenging tumours (DCIS), the Kaiser score enabled a precise diagnosis, yet with a slightly lower level of accuracy.

B-0703 15:13

Combining artificial intelligence and MRI in the management of equivocal breast lesions: the perfect couple?

M. Dietzel, S. Ellmann, E. Wenkel, C. Bielowski, R. Schulz-Wendtland, M. Uder, T. Bäuerle; Erlangen/DE

Purpose: We evaluated whether combining artificial intelligence (AI) and MRI could be beneficial to the management of equivocal breast lesions.

Methods and Materials: 100 consecutive patients were enrolled. All showed equivocal breast lesions (BI-RADS IV) upon conventional assessment (clinical examination, mammography, and ultrasound) and received histopathological verification. Prior to biopsy we performed a standardized breast MRI in each patient. Six agnostic semantic MRI parameters were extracted by two observers independently (R1/R2: intermediate/no experience in breast MRI). These semi-quantitative parameters were and previously described; they assess geometry, structure, microstructure and vascularity of each lesion. Based on these parameters, AI was used to identify typical MRI thumbprints of certainly benign lesions as defined by a false-negative rate $< 1\%$. An AI-algorithm consisting of a polynomial kernel function support vector machine was used for this purpose. This approach has been previously published including, training and evaluation on breast MRI data ($n > 200$). Statistical evaluation included intraclass correlation coefficient/ICC, Mann-Whitney U test and descriptive methods ($\alpha < 1\%$).

Results: 33 lesions were malignant and 67 benign. Agnostic parameters demonstrated excellent inter-observer variability (ICC > 0.8); every parameter showed significant potential to differentiate BI-RADS IV lesions ($P < 0.001$). AI identified typical fingerprints of certainly benign lesions in 31.3% (21/67).

Conclusion: Combining artificial intelligence (AI) and MRI could be beneficial to the management of equivocal findings: this perfect couple identified thumbprints of "certainly benign" findings in a substantial proportion of equivocal lesions (31.3%). As such thumbprints showed an extremely low false-negative rate ($< 1\%$), biopsy could have been safely avoided in these patients.

B-0704 15:21

Automatic cluster analysis of breast lesions assessed with diffusion-weighted imaging

J. Schaar, H. Dijkstra, M. Wielema, M. Dorrius, P. Sijens; Groningen/NL (j.e.schaar@umcg.nl)

Purpose: To optimize and validate an automatic method for cluster analysis of breast lesions to prevent unnecessary biopsies and compare this method with three already existing methods.

Methods and Materials: This retrospective consecutive study was approved by the hospital's institutional review board and informed consent was obtained. 163 breast lesions with known pathology and BI-RADS classification (BI-RADS 2, 3, 4, 5, 6 with 7, 7, 19, 73 and 33 lesions, respectively) were examined (1.5T MRI) with diffusion-weighted imaging using $b=0$ and $1000s/mm^2$. The lesions were automatically defined into clusters based on the pixel diffusion values using Matlab. For each cluster mean apparent diffusion coefficient (ADC) and area were calculated. Optimal thresholds and minimal cluster area were determined: the cluster algorithm was optimized in a training set of 24 lesions (12 benign) to yield maximum true negatives and minimal false negatives. The cluster algorithm was validated in a subsequent consecutive set of 139 lesions (23 benign) to obtain sensitivity (Se) and specificity (Sp). The cluster algorithm was compared to three existing methods: the minimal and mean ADC of a lesion and histogram analysis using the 10% lowest ADC pixels.

Results: In the training set, optimal thresholds were $1.118 \times 10^{-3} mm^2/s$ (cluster algorithm, $area > 3$ pixels), $0.958 \times 10^{-3} mm^2/s$ (minimal ADC), $1.705 \times 10^{-3} mm^2/s$ (mean ADC) and $1.331 \times 10^{-3} mm^2/s$ (lowest 10%). This resulted in the validation set in Se=97.4% and Sp=43.5% (cluster algorithm), Se=95.7% and Sp=30.4% (minimal ADC), Se=93.1% and Sp=43.5% (mean ADC), and Se=97.4% and Sp=21.7% (lowest 10%).

Conclusion: Automatic cluster analysis of breast lesion diffusion yields a high sensitivity and can potentially reduce unnecessary biopsies.

Cerebrospinal fluid volume as a predictor of malignant middle cerebral artery infarction

F. Kauw, E. Bennink, H.W.A.M. De Jong, L. Kappelle, A.D. Horsch, B.K. Velthuis, J.W. Dankbaar; Utrecht/NL (f.kauw-3@umcutrecht.nl)

Purpose: To investigate the association between intracranial cerebrospinal fluid (CSF) volume and malignant middle cerebral artery (MCA) infarction.

Methods and Materials: Patients with an occlusion proximal to the M3 segment of the MCA were selected from the Dutch Acute Stroke Study (DUST). Admission imaging included non-contrast CT, CT-angiography and CT-perfusion. Malignant MCA infarction was defined as a midline shift larger than 5 mm on follow-up non-contrast CT, which was performed three days after the stroke or in case of clinical deterioration. Clinical characteristics and CT findings were collected. The ratio between CSF volume and intracranial volume (CSF/ICV) was quantified on admission thin slice non-contrast CT. To test the association between CSF/ICV and malignant MCA infarction, odds ratios were calculated for three multivariable models using binary logistic regression. Furthermore, ROC curves were plotted from the models and their AUCs were compared using the DeLong method.

Results: Of the 271 included patients, 34 (13%) developed malignant MCA infarction. CSF/ICV was independently associated with malignant MCA infarction in three multivariable models: 1) with age and admission NIHSS (OR 3.3, 95% CI 1.1-11.3, $p < 0.05$), 2) with admission NIHSS and poor collateral score (OR 5.0, 95% CI 2.2-12.4, $p < 0.001$), 3) with clot burden score and poor collateral score (OR 7.3, 95% CI 2.6-22.8, $p < 0.001$). The performance of all models was improved by adding CSF/ICV, but only model 1 improved significantly (AUC 0.787 vs. 0.819, $p < 0.01$).

Conclusion: CSF volume is associated with malignant MCA infarction and might be of additional value to clinical prediction models.

B-0706 14:08

Improved diagnostic performance of CT perfusion imaging in acute stroke using advanced noise suppression and Bayesian perfusion algorithms

E.J. Smit¹, K. Murayama², T. Galen¹, S. Pegge¹, L. Kluijtmans³, Y. Ikeda⁴, K. Katada², F.J. Meijer¹, M. Prokop¹; ¹Nijmegen/NL, ²Toyoake/JP, ³Malden/NL, ⁴Otawara/JP (ewoudsmit@gmail.com)

Purpose: Current CTP techniques have limited diagnostic performance because of moderate image quality resulting from low signal-to-noise ratios. We tested if advanced noise-suppression and Bayesian probabilistic perfusion techniques allow for more reliable diagnosis of ischaemia in acute stroke.

Methods and Materials: We evaluated 37 consecutive patients with suspected acute stroke who underwent CTP and DWI within 6 hours after each other. Post-processing for CTP was performed with commercial software using a standard processing technique that uses smoothing filters and single value decomposition (SVD) algorithms and an advanced processing technique that uses a 4D-similarity filter for noise suppression followed by Bayesian perfusion algorithms. Three expert observers rated all images for the presence of a perfusion deficit, diagnostic confidence and image quality on a 5-point Likert scale. MR diffusion-weighted imaging (DWI) served as the reference test.

Results: Diagnostic performance was significantly better for the Bayesian-based method compared to the SVD-based method, with area under the ROC curves of 0.88 and 0.72, respectively. At similar sensitivity of 72-73% for detecting DWI infarcts, the Bayesian-based method resulted in a higher specificity with 93% compared to 52% for the SVD-based method. Observers were significantly more confident of their diagnosis using the Bayesian-based method and image quality was rated significantly higher for all perfusion maps.

Conclusion: Bayesian-based processing improves the reliability and diagnostic performance of CT perfusion imaging. Using these methods, CT perfusion imaging seems to allow for the reliable diagnosis of acute ischaemic stroke. However, negative perfusion exams still cannot exclude cerebral ischaemia.

Effect of report length on its clarity in the stroke setting: an AI study

A. Mereu, L. Saba; Cagliari/IT

Purpose: To assess whether a longer text report can hide its meaning when a clear message is critical, such in the case of head CT for stroke.

Methods and Materials: 300 urgent head CT without contrast free-text reports were retrospectively analysed. All clinical requests suspected acute stroke. Findings were categorized (presence or lack thereof) in acute, such as stroke and haemorrhage, and chronic ones, such as lacunae and leukoariosis. Reports' word count was measured. An ensemble of 7 algorithms (based on bagging, boosting, classification trees, maximum entropy, neural networks, random forests and support vector machine) was employed by a supervised AI to predict the findings. Statistical analysis was performed with the multinomial logistic regression and significance was set at $p < 0.05$. All the main tasks involved were handled with the free and open source programming language R.

Results: Report length did not correlated significantly with the probability of a correct prediction of acute findings only ($p = 0.5103$), chronic ones only ($p = 0.4258$) or both at the same time ($p = 0.5221$). The whole model was not significant too ($p = 0.4876$).

Conclusion: Study results showed that wordy reports did not significantly impair AI predictions. Thus, neither an attentive human reader might be impaired by the amount of information provided.

B-0708 14:24

Evaluation of pial collaterals on multiphase CT angiography: impact on the prediction of infarct size and outcome in acute ischaemic stroke

E. Puqelli, G. Manente, M. Assetta, P. Pulsone, V. Di Mizio; Teramo/IT (edopug@hotmail.com)

Purpose: Pial collaterals may vary in CTA single phase (sCTA) depending on whether the CTA is arterial (A), arterio-venous (AV) or venous (V) weighted. We investigate the impact of sCTA weighting on the evaluation of collaterals using the classic MAAS, Tan and Menon methods and their ability to predict infarct size and outcome.

Methods and Materials: 162 consecutive patients (mean age of 45 years, April 2009-September 2018) with classical onset, underwent to endovascular therapy, in a single center. Basal CT, CTP and sCTA were used for imaging. The sCTA weighting was determined by comparing the AV ratios between torcula with those obtained from concomitant CTP temporal density curves at the attenuation of the arterial peak or of the venous contrast. Two readers studied infarct volume on imaging of the three collateral scores stratified by

sCTA weighing with age, gender, aetiology, symptoms, NIHSS, clot burden score (CBS) and mRS. For primary analysis, we used ordinal logistic regression.

Results: Median NIHSS score at presentation was 13 (range 3-36) and the onset to treatment time were 128 (66-181) minutes. sCTA scans were AV-weighted in 105/162 (64.8%) and A-weighted in 57 (35.1%). No association was demonstrated between sCTA weighting and sCTA technique. No association was shown between sCTA weighting, collateral grade and clinical outcome ($p < 0.005$).

Conclusion: After recanalization the sCTA weighting did not significantly impact collateral grade analysis with the three common collateral scores and there is lack of evidence of their ability to predict final infarct size.

B-0709 14:32

Extracted computed tomography angiography measurements as a screening tool for obstructive sleep apnoea in acute stroke patients

T.J. Jeffery, D. Gibson; Perth/AU (tim.jeffery@inet.net.au)

Purpose: Obstructive sleep apnoea (OSA) is reportedly a common co-existent disorder in stroke patients. The presence of OSA could significantly hinder neurological recovery. Radiological correlative measurements on cross-sectional neck imaging correlates characterise both the presence and severity of OSA. There are limited published studies exploring the frequency of these adverse parameters in acute stroke patients. This case series explores the incidence of three robust radiological surrogate measures in routine contrast-enhanced CT imaging of acute stroke patients.

Methods and Materials: The imaging for 50 sequential acute stroke presentations from a major tertiary hospital was reviewed. Three measurements were routinely performed on computed tomography extra- and intracranial angiogram (CTA) studies: mandibular plane to hyoid distance (MPH), oropharyngeal length (OPL) and minimal transverse dimension of the retropalatal airway (RPA).

Results: Of the 50 cases analysed, 74% had at least one measure exceeding defined thresholds. An inferiorly placed hyoid bone (MPH>18mm) was the most frequent adverse finding at 58%. An elevated OPL and a reduced RPA were less frequent at 42% and 26%, respectively. Only two of the fifty cases were documented as having diagnosed OSA upon discharge.

Conclusion: Radiological indicators of sleep apnoea are frequently present in our acute stroke population. The results of this case series suggest that these measurements should be performed routinely on admission CTA studies and be included in radiology reports. This can alert treating teams to consider in patient polysomnography studies for confirmation of OSA and early institution of continuous positive airway pressure support.

B-0710 14:40

Comparison of accuracy for the prediction of infarct tissue volumes between arrival-time insensitive and arrival-time sensitive CT perfusion algorithms

L. Pennig, F. Thiele, M. Perkuhn, C. Kabbasch, M. Schlamann, J. Borggreffe; Cologne/DE (lenhard.pennig@uk-koeln.de)

Purpose: Stroke-thrombectomy (ST) can be performed up to 24 hours after onset if a significant CT-perfusion (CTP) mismatch is present. CTP maps can be calculated by arrival-time-sensitive (TSP) and arrival-time-insensitive (TIP) algorithms. This study compared performances of TSP and TIP and investigated optimal parameters of TIP for the prediction of final-infarct-volume (FIV) and penumbra.

Methods and Materials: Retrospective study including 54 patients receiving Stroke-CT/CTP-imaging between 2010-2018 with follow-up-imaging as reference standard. CT scans were conducted at 4 different CT-scanners. FIV was obtained using CT and MRI. Patients were stratified as a) not-treated (mTICI 0, n: 25) and b) successful ST (mTICI 2b/3, n: 29). IntelliSpace Portal (Philips, NL) was used to calculate CTP-maps for both TSP and TIP. TSP (default settings) and TIP (full-range of threshold settings for CTP parameters) results were coregistered in 3D with FIV using IntelliSpace Discovery (Philips, NL), and voxel-wise overlap was measured.

Results: Baseline characteristics: NIHSS=15.34 (SD±6.8), 67.02 years (SD±13.11), 37/17 m/f, average follow-up-imaging after 2.63 days (SD±2.67). Regarding TIP, penumbra (group A) was best predicted using Tmax (AUC 0.9), FIV (group B), was determined best using relative CBF (AUC 0.8). TIP's prediction of penumbra and FIV was comparable to previous literature. There was a broad range of thresholds of optimal TIP-settings in both groups.

Conclusion: Both algorithms showed a comparable performance, with TIP yielding a slightly better, but statistically non-significant prediction of FIV. TIP showed a broad range of optimal thresholds. Thus, exact thresholds regarding TIP should be evaluated in further studies.

Prediction of motor recovery after stroke by assessment of corticospinal tract Wallerian degeneration using diffusion tensor imaging

R. Elshafey¹, H.S. Darwish², H.A. Kamel¹; ¹Tanta/EG, ²Ismalia/EG (darwish.hoda@yahoo.com)

Purpose: To predict motor recovery after stroke by detection of diffusion tensor (DTI) imaging fractional anisotropy changes of corticospinal tract and correlate findings with clinical scores to provide more effective treatment and rehabilitation.

Methods and Materials: 30 patients with cerebral stroke were included, 18 males (60%) and 12 females (40 %); mean age was 58 +/- 11.5 years. The patients underwent conventional MRI, diffusion tensor imaging at admission as well as one month after stroke. Mean diffusivity (MD), fractional anisotropy (FA), fractional anisotropy ratio (rFA) and fibre number (FN) values of corticospinal tract (CST) were calculated at the pons at admission and after one month of stroke. Three-dimensional reconstruction of bilateral corticospinal tract and the structural changes of fibrous bands were observed. Severity of limb weakness was assessed using the motor sub-index scores of the National Institutes of Health Stroke Scale (NIHSS) at admission, and after 1, 6 and 9 months for severity of limb weakness.

Results: Significant negative correlation was found between rFA and FN in the ipsilateral CST of the cerebral infarction at the rostral part of pons after one month of infarction and NIHSS score at 6 months ($r = -0.377$, $P = 0.04$) ($r = -0.237$, $P = 0.02$), respectively, while positive insignificant correlation was observed between MD and NIHSS ($r = 0.345$, $P = 0.635$).

Conclusion: DTI is a sensitive tool for the early detection of Wallerian degeneration (WD) in the CST after stroke and can predict motor performance and outcome to provide more effective treatment and rehabilitation and improve quality of life.

B-0712 14:56

Arterial transit artefacts on ASL perfusion MRI in patients with carotid artery stenosis are a better predictor of recent symptoms than degree of stenosis or carotid plaque morphology

A. Di Napoli¹, S. Cheng², G. John², M. Brown², M. Sokolska², H.R. Jäger²; ¹Rome/IT, ²London/UK (adnapoli7@hotmail.com)

Purpose: The most commonly assumed mechanism by which carotid artery stenosis (CAS) causes a stroke or TIA is artery to artery embolism. Carotid plaque imaging allows to assess the component of atherosclerotic plaques and to detect intra-plaque haemorrhage (IPH); Arterial Spin Labelling (ASL) is a non-invasive method of assessing haemodynamic effect of CAS and Arterial Transit Artefacts (ATAs) indicate brain regions with delayed arrival of blood. The aim of this study is to identify imaging parameters that distinguish best between asymptomatic and symptomatic patients and to obtain new evidence by which mechanism carotid stenosis causes clinical symptoms.

Methods and Materials: 44 patients with cervical ICA stenosis (22 symptomatic and 22 asymptomatic) underwent MRI at 3T including pseudocontinuous arterial spin labelling (pCASL) had carotid plaque imaging sequences. Degree of stenosis, plaque morphology, intra-plaque haemorrhage and extent of ATAs were evaluated.

Results: ATAs were present only in patients with >70% stenosis ($p < 0.0001$). Presence of symptoms correlated with ATAs ($p = 0.004$) and with their severity ($p = 0.002$), but not with degree of stenosis ($p = 0.537$), plaque morphology ($p = 0.537$) or intra-plaque haemorrhage ($p = 0.310$).

Conclusion: The presence of ATAs on ASL imaging correlated best with symptoms in patients with ICA stenosis, suggesting that cerebral haemodynamics play a greater role than previously thought and have to be considered alongside embolic mechanisms.

Clinical decision support based on automated non-contrast CT density measurements in patients with acute ischaemic stroke

P. Reidler¹, D. Pühr-Westerheide¹, M.P. Fabritius¹, L. Rotkopf¹, D. Apel¹, S. Tiedt¹, F.A. Wollenweber¹, K. Thierfelder², W.G. Kunz¹; ¹Munich/DE, ²Rostock/DE (Paul.Reidler@med.uni-muenchen.de)

Purpose: To examine the clinical value of automated non-contrast CT (NCCT) density measurements in Alberta-Stroke-Program-Early-CT-Score (ASPECTS) regions to support decision-making in acute ischaemic stroke.

Methods and Materials: We included consecutive patients with follow-up-confirmed middle cerebral artery infarction and available NCCT and CT perfusion (CTP) data. ASPECTS region density was assessed using automated software. Relative Hounsfield units (rHU) were defined as ratio of ipsilesional by contralesional region density. Ischaemic core was measured on CTP maps. Regression coefficients from a linear regression analysis on the association of regional rHU and infarction core volume were used as weighting factors to calculate a composite rHU score of all regions. Receiver operating characteristics (ROC) analyses were performed to test this score's discriminative value regarding current thrombectomy selection criteria and

subacute stroke complications.

Results: In total 121 patients were included. The composite rHU score resulted in significant classification of patients who meet CTP selection criteria of ischaemic core size <70 mL and target mismatch >1.8 (AUC=0.759, $p < 0.001$). The score discriminated between patients with and without subsequent space-occupying oedema development (AUC=0.771, $p < 0.001$). ROC curves are shown in Figure 1. The score could not classify patients by occurrence of haemorrhagic infarction or parenchymal haematoma (both $p > 0.05$).

Conclusion: Automated NCCT density measurements have the potential to act as observer-independent imaging biomarkers that could support decision-making in centres without CTP. The composite rHU score allowed classification of patients with current CTP imaging criteria for extended time window thrombectomy selection. The score also identified patients with subsequent space-occupying oedema development.

B-0714 15:12

Pattern of leptomeningeal collateral circulation on perfusion computed tomography in patients with acute ischaemic stroke

A. Singh¹, U.B. George², J.D. Pandian²; ¹Delhi/IN, ²Ludhiana/IN (appysingh05@gmail.com)

Purpose: To correlate grade of leptomeningeal collateral circulation with clinical outcome in patients with acute ischaemic stroke.

Methods and Materials: Leptomeningeal collateral (LMC) scores were defined for 71 patients presenting within 24 hours of stroke onset on perfusion CT baseline images: 0-absence of vessels; 1- <50%; 2-50-100%; 3-more prominent; as compared with contralateral hemisphere. A score of 0/1 and 2/3 were distributed in poor and good collateral groups respectively. LMC scores were correlated with clinical outcome as early neurological recovery (drop of ≥ 4 NIHSS score points at 24 hours) and Modified Rankin score at 3 months (favourable ≤ 2). A p value of <0.05 was taken as significant.

Results: 64.7% and 35.3% had good and poor collateral status. No significant difference in early neurological recovery by NIHSS scoring was noted in the two collateral groups; 30.4% and 36% in good and poor collateral group; p value-0.63. A favourable MRS of ≤ 2 was higher in good (59.01%) than poor collateral group (44%), with p value - 0.23. More number of patients had favourable MRS with good (59%) than with poor collaterals (44%). NIHSS score was significantly lower for thrombolysed patients (p value <0.005); however, there was no difference in clinical outcome in two collateral groups. (p value -0.92).

Conclusion: Early neurological recovery and long term recovery outcome was favourable in patients with good collaterals, however results were not statistically significant. Though Intravenous thrombolysis resulted in significantly lower NIHSS score, results were not significant between the two collateral groups.

B-0715 15:20

Ultra-low-dose cerebral CT perfusion for the diagnosis of acute ischemic stroke using iterative model reconstruction combined with optimised temporal resolution

X. Fang¹, R. Wang¹, Y. Liu¹, C. Yuan¹, X. Chen², Z. Wang¹; ¹Nanjing/CN, ²Shanghai/CN (fmmfangxk@163.com)

Purpose: To evaluate the diagnosis performance of ultra-low dose cerebral CT perfusion (CTP) in patient with acute ischemic stroke using iterative model reconstruction (IMR) combined with low tube voltage.

Methods and Materials: 80 consecutive patients with suspected ischemia stroke were enrolled in this study and randomly divided into two groups (n=40 each): Regular dose GroupA, 80kVp, 100mAs, 45 passes were performed with 2 varied intervals (1 second interval for the first 30 passes and 2 seconds for the following 15 passes), reconstructed with iDose(level-3); Ultra-low dose GroupB, 80kVp, 50mAs, 18 passes were performed with 3 varied intervals (2 seconds for the first 3 passes, 1.7 seconds for the next 13 passes and 7.5 seconds for the left 2 passes), reconstructed with IMR(level-1). Perfusion maps of CBF, CBV, and MMTT were created for both groups and values were quantitatively compared by using independent t-test. Perfusion maps were qualitatively rated on a 5-point scale (5-excellent, 1-not diagnostic) for both groups and compared by using Mann-Whitney test. Mean CTDIvol and DLP were recorded and compared. Mean effective dose (ED) was estimated and compared.

Results: For the overall image quality, no significant quantitative or qualitative differences were found between two groups (all $P > 0.05$). Differences in mean CTDIvol, DLP, and ED between two groups were statistically significant (all $P < 0.01$). There was an 81% ED reduction of Group B (0.662mSv) in comparison to Group A (3.312mSv).

Conclusion: Ultra-low dose cerebral CTP can be achieved using IMR in combination with optimized temporal resolution while preserving image quality.

Decrease in unnecessary biopsy recommendations by the application of quantitative multiparametric breast ultrasound: a prospective study

P. Kapetas, P. Clauser, R.A. Woitek, G.J. Wengert, M. Lazar, K. Pinker-Domenig, M. Bernathova, T.H. Helbich, P.A.T. Baltzer; *Vienna/AT* (panagiotis.kapetas@meduniwien.ac.at)

Purpose: To evaluate quantitative breast multiparametric ultrasound (mpUS) using B-mode, elastography (Virtual Touch IQ-VTIQ), Doppler and contrast-enhanced US (CEUS) in different combinations of 2, 3 or 4 parameters for the differentiation of benign and malignant lesions and investigate a possible variation according to the reader experience level.

Methods and Materials: 124 patients, each with one biopsy-proven breast lesion were included in this prospective, IRB-approved study. Each lesion was examined with B-mode, VTIQ, Doppler and CEUS. Different quantitative parameters were recorded for each modality. 4 readers (2 experienced breast radiologists and 2 residents) independently evaluated B-mode images of each lesion and assigned a BI-RADS score to it. Using ROC curve analysis, the quantitative parameter with the best diagnostic performance for each modality was chosen. The BI-RADS scores of all readers were then combined with the results of the quantitative parameters. Diagnostic performance of mpUS was evaluated with descriptive statistics. Histology was the reference standard.

Results: 65 lesions were malignant. MpUS with three parameters (B-mode, VTIQ and CEUS or Doppler) showed the highest diagnostic performance irrespective of the reader experience level (averaged AUC 0.812 vs. 0.789 vs. 0.683 for B-mode, p value=0.0001). All other combinations showed a lower AUC. MpUS with three parameters was able to significantly reduce the number of false-positive biopsy recommendations up to 47% ($p < 0.0001$).

Conclusion: Quantitative breast mpUS with 3 parameters (B-mode, VTIQ elastography and CEUS or Doppler) significantly improves the diagnostic performance of B-mode, irrespective of the reader experience level and can obviate unnecessary biopsies.

B-0717 14:08

Diagnostic performance of fifth BI-RADS edition ultrasound lexicon for prediction of malignancy in breast masses with histopathological correlation

K. Gupta¹, T. Chandra², B. Venkatesan³; ¹Chennai/IN, ²Orlando, FL/US, ³Pondicherry/IN (hikanika@gmail.com)

Purpose: The fifth edition of Breast Imaging Reporting and Data System (BI-RADS) was released in 2013 with several changes in the descriptors for breast ultrasound. The purpose of this study was to compare the diagnostic performances of fifth BI-RADS edition ultrasound lexicon for prediction of malignancy in breast masses, in comparison with fourth BI-RADS edition.

Methods and Materials: Using a prospective study design, 256 solid breast masses were assessed by ultrasound, out of which 174 underwent core biopsy and 160 masses had definitive histopathological results. The ability of individual descriptor of ultrasound in fourth and fifth BI-RADS editions to differentiate between a benign and malignant lesion in the breast was assessed using statistical analysis.

Results: The descriptor 'intraductal calcifications' was very useful for prediction of malignancy and had the highest sensitivity (97%) among all ultrasound descriptors of fifth BI-RADS edition. The presence of spiculated and indistinct margins were predictive of malignancy- 94.4% of masses with spiculated margins and 100% masses with indistinct margins were found malignant. 'In rim vascularity' and 'internal vascularity' were found useful in differentiating benign from malignant lesions. 'Internal vascularity' depicted a high PPV of 86% in predicting malignancy in a breast mass.

Conclusion: Some new descriptors used in fifth edition of BI-RADS, such as intraductal calcifications and internal vascularity, in addition to established descriptors of spiculated/indistinct margins and anti-parallel orientation of the mass result in improved diagnostic performance of ultrasound lexicon in predicting malignancy in breast masses

B-0718 14:16

Does establishing preoperative nomogram including ultrasonographic findings help predict the likelihood of malignancy in patients with microcalcifications?

H. Wang, J. Lai, J. Li, R. Gu, F. Liu, Y. Hu, X. Jiang, J. Mei, F. Su; *Guangzhou/CN* (whonglii@163.com)

Purpose: To investigate whether establishing preoperative nomogram including ultrasonographic findings helps predict the likelihood of malignancy in patients with microcalcifications.

Methods and Materials: Between May 2012 and January 2017, 475 patients with suspicious microcalcifications detected on mammography (MG) underwent ultrasonography (US). The χ^2 test was used to screen risk factors amongst the variables. Then, a multivariate logistic regression analysis was performed to identify independent predictors of malignant microcalcifications. A mammographic nomogram (M nomogram) and mammographic-ultrasonographic nomogram (M-U nomogram) were established based on multivariate logistic regression models. The discriminatory ability and clinical utility of both nomograms were compared by the receiver operating characteristics curve and decision curve analysis. The calibration ability was evaluated using a calibration curve.

Results: Among the cases, 68.2% (324/475) were pathologically diagnosed as breast cancer and 31.8% (151/475) were benign lesions. Based on multivariate logistic regression analysis, age, clinical manifestation, morphology and distribution of microcalcifications on MG and lesions associated with microcalcifications on US were confirmed as independent predictors of malignant microcalcifications. In terms of discrimination ability, the C-index of M-U nomogram was significantly higher than that of M nomogram (0.917 vs 0.897, $p=0.006$). The bias-corrected curve was close to the ideal line in the calibration curve. Decision curve analysis suggested M-U nomogram were superior to M nomogram.

Conclusion: Combining mammographic parameters with ultrasonographic findings into a nomogram performed better than M nomogram alone, which highlighted the value of ultrasonographic findings for individualized risk prediction in patients with microcalcifications.

B-0719 14:24

How should we manage breast ultrasound masses that do not enhance on MRI?

D. Avendano¹, E.J. Sutton¹, E.A. Morris¹, M.A. Marino², P. Gibbs¹, D. Martinez¹; ¹New York, NY/US, ²Messina/IT (dilahh1@gmail.com)

Purpose: Assess incidence of malignant breast masses on ultrasound where magnetic resonance imaging (MRI) correlate does not enhance in women with a new diagnosis of breast cancer.

Methods and Materials: IRBA this HIPAA-compliant retrospective study and waived informed consent. Consecutive women identified between June 2017 and March 2018 who a) have new diagnosis of breast cancer b) underwent US where an additional mass (distinct from index cancer) was identified and categorized as either BI-RADS 3/4, and c) underwent bilateral breast MRI where the US correlate didn't enhance. A benign mass was pathologically proven or defined as showing 2-y imaging stability. A malignant mass was pathologically proven. Sensitivity, Specificity and predictive values were calculated on a per-lesion level by using proportions. Descriptive statistics were also assessed.

Results: 230 women (mean age 52) with 309 additional lesions (mean size 9 mm) were identified. Of the 309 breast masses, 140 in 105 women (mean age 54) did not enhance on MRI. The mean size of these masses on US was 16 mm (range 3-74 mm). In 89/140 cases (64%) the patient underwent biopsy and in 51/140 (36%) had 2-year follow-up. None of the 140 masses were malignant, with a NPV of 100%.

Conclusion: All breast masses on US that did not enhance on MRI were benign. The results suggest that biopsy or follow-up is not required.

Contrast-enhanced ultrasound in breast cancer and its role in predicting immunohistochemical subtype: a novel prognostic approach

S.B. Grover¹, H. Grover², P. Jain¹, A.K. Nag¹, A. Katyan¹, N. Antil¹, S.K. Jain¹, A.K. Mandal¹; ¹New Delhi/IN, ²Bridgeport, CT/US (shabnamgrover@yahoo.com)

Purpose: Breast cancer prognostication is based on biopsy evaluated receptor subtyping. This study in breast cancer patients aimed to correlate contrast enhanced ultrasound (CEUS) parameters with immunohistochemical (IHC) markers, as a non-invasive alternative for prognosis prediction.

Methods and Materials: Fifty consenting female patients with newly diagnosed, biopsy proven breast cancer were included in this prospective institutional review board approved study. CEUS was performed using a 4-9 MHz transducer and both qualitative and quantitative CEUS parameters were

recorded. Qualitative parameters included enhancement order, type and margins, and presence of perfusion defects. Quantitative parameters documented were time to peak, mean transit time, peak intensity and area under time intensity curve (AUTIC). IHC parameters including oestrogen receptor (ER), progesterone receptor (PR) and HER2 status were assessed on histopathology. Diagnostic test, Independent t test and receiving operating characteristics (ROC) were used for statistical analyses. p value < 0.05 was considered as statistically significant.

Results: Presence of perfusion defects was significantly associated with negative ER and PR status, $p < 0.05$. A higher AUTIC was the only quantitative parameter significantly related to ER and PR negativity, $p = 0.05$, with a ROC cut-off of 566 predicting ER/PR negativity with a sensitivity and specificity of 84.21% and 51.51% respectively. None of the qualitative or quantitative parameters showed association with HER2 status.

Conclusion: CEUS has reprised the use of conventional sonography, providing additional tumour characterization, even at the molecular level. Significant CEUS parametric and ER/PR status association can provide accurate non-invasive prognostic information and in future could guide treatment protocol decisions.

B-0721 14:40

Preliminary study of real-time three-dimensional contrast-enhanced ultrasound of sentinel lymph nodes in breast cancer

M. Lu; Chengdu/CN (graceof@163.com)

Purpose: To investigate the clinical value of real-time three-dimensional contrast-enhanced ultrasound (3D-CEUS) in the detection of sentinel lymph nodes (SLNs) and drainage lymphatics in breast cancer patients.

Methods and Materials: The prospective study was performed in 187 women with pathology-confirmed T1/2 breast cancer between June 2016 and December 2017. 146 in 187 patients were randomly divided into two groups: 73 patients received two-dimensional contrast-enhanced ultrasound (2D-CEUS, 2D-CEUS group), the other 73 patients immediately received three-dimensional CEUS (3D-CEUS, 3D-CEUS group). The number, size, location, enhancement pattern of SLNs and the lymphatic drainage patterns were reviewed; the routes, location of SLNs and lymph channels (LCs) on the surface were marked. All patients underwent blue dye-guided sentinel lymph node biopsy (SLNB) finally.

Results: According to the postoperative pathology findings and the blue stained lymphatic drainage routes, the coincidence rates of the 2D-CEUS group and the 3D-CEUS group were 97.3% and 98.6%, respectively ($p > 0.05$); the LN detection rates were 90.4% and 95.6% ($p > 0.05$); the correct diagnosis rates were 88% and 90.8% ($p > 0.05$); the times of operation was 15.42 ± 1.10 and 13.49 ± 0.94 min ($P < 0.05$).

Conclusion: Compared to the 2D-CEUS, the 3D-CEUS can show the stereo direction of SLNs and lymph drainage routes including the angle, help the clinicians recognize the spatial location and depth of SLNs and reduce the time of finding the SLNs during operation.

B-0722 14:48

Role of ultrasound in the SOUND trial: can we move away from sentinel lymph node biopsy?

F. Pesapane, M. Grimaldi, A. Rotili, D. Lepanto, E. Cassano; Milan/IT (filippopesapane@gmail.com)

Purpose: Our purpose is to evaluate the negative predictive value (NPV) of axillary ultrasound (AUS) in early breast cancer (BC) patients to propose this non-invasive examination as a credible substitute of sentinel lymph node biopsy (SLNB) in the axillary lymph node (ALN) staging.

Methods and Materials: We conducted preoperative AUS in 685 consecutive patients enrolled in the SOUND trial, in our institution, evaluating the frequently used signs of suspicious ALN on AUS. NPV of AUS was calculated first considering all false negatives, including micrometastases and isolated tumoural cells (ITC), and then considering macrometastases alone. We used 3 mm as a threshold to assess US-detectable metastases.

Results: Preoperative AUS resulted in 4.8% of false positives and 15.5% of false negatives, which is reduced to 8.1% excluding ITC and micrometastases and to 4.9% considering only metastases > 3 mm, which are the only lesions that AUS can reliably detect. The NPV was estimated 92% (90-94%, 95% CI) including all cases of positivity to histopathological examination. Excluding ITC and micrometastases, the NPV was 95% (94-97%, 95% CI). Finally, including metastases that can be detected by AUS (namely metastases > 3 mm) alone, the NPV was 97% (95-98%, 95% CI). Specificity of AUS in our population was 95% (93-97%, 95% CI).

Conclusion: Our results show that in early BC patients, the AUS may represent an effective, non-invasive diagnostic tool for axillary staging, and due to its high NPV, it allows to select women who can benefit from observation only as a treatment approach, replacing the SLNB.

Predictive factors on ultrasound for the early tumour recurrence of breast cancer after breast-conserving treatment

S.G. Yun, Y.Y. An; Suwon/KR (sgdream88@gmail.com)

Purpose: To evaluate the clinicopathologic and imaging factors associated with early tumour recurrence in breast cancer patients who underwent breast-conserving treatment.

Methods and Materials: We retrospectively reviewed the clinicopathologic data and imaging features (MG, US, and DCE-MRI) of 529 breast cancer patients who underwent breast-conserving surgery and adjuvant therapy at our hospital between January 2009 and December 2014. A total of 36 patients recurred within 3 years after surgery (early tumour recurrence). Risk factors associated with the early tumour recurrence were analysed by univariate and multivariate logistic regression analyses.

Results: In univariate analysis, large tumour size ($p = 0.004$), advanced stage ($p = 0.025$), high histologic grade ($p = 0.002$), high nuclear grade ($p = 0.001$), presence of lymphovascular invasion ($p = 0.044$), high Ki-67 proliferation index ($p = 0.023$), Her2-enriched and triple-negative subtypes ($p = 0.005$), ER positive ($p < 0.0001$), and PR positive ($p = 0.021$) were associated with early tumour recurrence. Among imaging characteristics, multifocality ($p < 0.0001$) on US and presence of vessels in the rim on colour Doppler exam ($p = 0.017$) were significantly related to early recurrence. Multivariate logistic regression analysis showed that the multifocality (odds ratio = 3.2, 95% CI 0.547-3.803, $p = 0.003$) on US and the vessels in the rim on colour Doppler exam (odds ratio = 3.1, 95% CI 1.314-7.352, $p = 0.0098$) were independently associated with early tumour recurrence.

Conclusion: The multifocality on US and vessels in the rim on colour Doppler exam are independent factors for predicting the early tumour recurrence of breast cancer after treatment.

B-0724 15:04

The value of automated breast ultrasound (ABUS) coronal view

S. Schiaffino, A. Tagliafico, L. Gristina, E. Massone, S. De Giorgis, A. Garlaschi, M. Calabrese; Genoa/IT (schiaffino.simone@gmail.com)

Purpose: To evaluate the value of automated breast ultrasound (ABUS) in women with dense breast, focusing on the potential assessment of coronal images alone, compared to the complete multiplanar (MPR) views.

Methods and Materials: From August 2017 to October 2017, consecutive patients with dense breast that referred to our institute for post-mammography ultrasound assessment, pre-operative assessment or follow-up of known benign lesions were invited to perform an additional study with ABUS. Three radiologists, with different levels of experience in breast radiology (5, 15 and 25 years), reviewed the exams twice: the first with the assessment of reconstructed coronal plane alone and the second with complete MPR views. Reporting times, diagnostic performance and interobserver agreement were assessed.

Results: 188 women were included in the study, for a total of 67 breast lesions, 25 (37%) malignant and 42 (63%) benign lesions. Compared to MPR, coronal view was associated with lower reading times, respectively, for the three readers: 83 ± 37 , 84 ± 43 and 76 ± 30 versus 163 ± 109 , 131 ± 57 , 151 ± 42 seconds ($p < 0.035$); lower sensitivity: 44.8%, 62.1%, 55.2% vs. 69.0% ($p = 0.059$), 65.5% ($p = 0.063$), 72.4% ($p = 0.076$), respectively; better specificity: 94.1%, 93.7%, 94.2% vs 89.5% ($p = 0.093$), 87.4% ($p = 0.002$), 91.6% ($p = 0.383$), respectively. Agreement between the most and the least experienced rater was fair for categorical variables and significant for continuous.

Conclusion: The coronal view allows significantly lower reading times, a valuable feature in the screening setting. The assessment of this plane alone could be considered as "fly through" first assessment, completed with targeted analysis in all the available views.

Diagnostic performance of automated breast ultrasound (ABUS) after breast-conserving surgery

C. Depreto, A. Primolevo, F. Cartia, C. Ferranti, G. Scaperrotta; Milan/IT (cathe.dp@gmail.com)

Purpose: To assess the non-inferiority of automated breast ultrasound (ABUS) compared to handheld ultrasound (HHUS) in terms of detection rate of local recurrences after breast-conserving surgery (BCS).

Methods and Materials: In our study, between April and June 2016, we invited 154 consecutive patients with dense breasts (ACR C or D) coming for scheduled imaging after BCS to undergo ABUS. Mean age was 62 years (range 34-90) and BCS had been performed on average 8 years prior (range 5-31). ABUS images were analysed by two independent radiologists blinded to conventional imaging.

Results: There was interreader agreement between ABUS and HHUS in terms of BI-RADS assessment in 134/154 cases (87%). In this subset, 66 exams were negative (BI-RADS 1), 64 showed benign findings (BI-RADS 2) and 4 cases were suspicious (BI-RADS ≥ 4), subsequently confirmed histologically as malignant. ABUS detection rate for recurrences was equal to HHUS. All the 20 cases of readers' disagreement were small benign findings, not detected by ABUS. 2 further cases were parenchymal distortions detected only by HHUS (one of which resulted negative at biopsy and the other remained unchanged at follow-up after 6 months).

Conclusion: ABUS detected all cancers found by HHUS, which suggests its non-inferiority to HHUS in terms of detection rate.

B-0726 15:20

Targeted ultrasound as first-line examination in women with focal breast complaints

L. Appelman¹, P. Appelman², P. Bult¹, R. Mann¹; ¹Nijmegen/NL, ²Tienhoven/NL (Linda.Appelman@radboudumc.nl)

Purpose: To determine the relative contribution of ultrasound and mammography for tumour detection in women with focal breast complaints.

Methods and Materials: We performed a retrospective evaluation of women who visited our radiology department in 2016. All 482 consecutive women undergoing targeted ultrasound for new focal breast complaints were included, patients undergoing ultrasound for other reasons were excluded. The radiological assessment for mammography and ultrasound was obtained from the reports generated at the time of diagnosis. Ground truth was obtained from histopathological reports when available, or one year of negative follow-up when no biopsy was performed. We compared cancer yield and frequency of false-positive findings between mammography and ultrasound using chi-square and McNemar tests.

Results: Based on the targeted ultrasound assessment, 72 biopsies (15%) were performed, of which 47 yielded breast cancer. Forty-five of these cancers were also visible on the concurrent mammogram ($p=0.47$). Mammography led to the detection of only 1 additional breast cancer in women without cancer at the symptomatic site. In addition, mammography prompted 22 biopsies for additional benign findings. Sensitivity of targeted ultrasound was, therefore, 98% with NPV 99.7%, and for mammography 96% and 99.5% ($p=1.0$). Mammography also prompted 10 additional biopsies in women with cancer at the symptomatic site, of which 9 proved to be malignant.

Conclusion: For initial cancer detection in women with focal breast complaints the interpretation of targeted ultrasound alone by breast radiologists is highly sensitive. In women with cancer at the focal complaint mammography appears useful for staging purposes.

Results: The mean pulmonary arterial opacification of the main pulmonary circulation was (343.88 ± 73 HU), right lung: upper (316.51 ± 23 HU), middle (312.5 ± 39 HU) and lower (315.23 ± 65 HU) lobes and left: upper (318.76 ± 83 HU) and lower (321.91 ± 12 HU) lobes. The mean venous opacification of all pulmonary veins was below 182 ± 72 HU. Subsequently, the AVCR was observed at all anatomic locations ($p < 0.0002$) where this ratio was calculated. Mean contrast volume of 33 ± 9 mL. Larger lung volumes were significantly correlated to larger volumes of contrast ($r=0.89$, $p < 0.03$). Inter-observer variation was observed as excellent ($\kappa = 0.71$).

Conclusion: Increased lung volume is significantly correlated with increased contrast media volume and radiation dose when employing a patient-specific contrast formula.

B-0728 14:17

Age-adjusted D-dimer and risk-stratification in acute pulmonary embolism for reduce the unnecessary CT imaging

A. Pandur, D. Sipos, B. Banfai, J. Betlehem, B. Radnai; Pécs/HU (attila.pandur@etk.pte.hu)

Purpose: Pulmonary embolism is connected with high morbidity and mortality. Prognostic assessment is important for the management of patients with pulmonary embolism. To assess the percentage of CTPA which could have been avoided by use of risk-stratification scores with age-adjusted D-dimer testing in patients with suspected PE.

Methods and Materials: We conducted a retrospective study of ED patients undergoing CTPA for suspected PE. In our study we analyzed 659 patient-documentation. Every patient were admitted to the ED and sent for pulmonary CTA. We calculated Wells-score and followed the European Guideline for PE.

Results: Our study included 659 patients (407 women, 252 men), admitted to three ED. In the 659 cases all over 105 D-dimer assays, 51 CT angiograms and 212 chest X-ray examinations were carried out rudlessly, which could have mean saved money to the hospitals and less radiation to patients. The age adjusted D-dimer threshold was more specific (70 % versus 60 %) but less sensitive (95% versus 98 %). The sensitivity of the combination (risk-stratification and age adjusted D-dimer test) was 100 %.

Conclusion: An age adjusted D-dimer limit has the potential to reduce diagnostic imaging. This is more accurate than a standard threshold of 500 ng/dl. The combination of the risk stratification and the age adjusted D-dimer we can safely diagnose the pulmonary embolism. Finally we can conclude that risk-evaluation in acute PE is indispensable and the appropriate use of guidelines results in lower costs.

B-0729 14:25

Real-time patient specific scan delay in CTA of pulmonary embolism: impact on image quality

F.R. Schwartz¹, J.C. Ramirez Giraldo², R. Gutjahr³, D. Marin¹, D. Boll⁴, L. Hurwitz¹; ¹Durham, NC/US, ²Rochester, MN/US, ³Nürnberg/DE, ⁴Basle/CH (fidesreginadorotheaann.schwartz@duke.edu)

Purpose: To assess whether real-time modulation of scan initiation based on patient specific haemodynamics improves contrast enhancement in the pulmonary arteries when using fluoroscopic triggering in pulmonary embolism (PE) computed tomographic angiogram (CTA) compared to fixed delay time.

Methods and Materials: HIPAA-compliant, IRB-approved QI project. Exams were performed on a 3rd generation dual-source MDCT scanner. Contrast administration was monitored in the main pulmonary artery (MPA). The delay prior to initiation of the diagnostic scan was adjusted by a real-time patient specific modulation (RTPSM) software, incorporating time to threshold and the slope of the enhancement curve. 150 patients (cohort 1) were scanned using RTPSM triggering of scan delay in pulmonary embolism CTAs. A BMI and age matched reference cohort of 150 patients (cohort 2) was identified with exams on the same scanner in the preceding 18 months, using a fixed diagnostic delay (FD). Patient demographics and HU values in the MPA, the bilateral posterior lobe segmental and sub-segmental arteries (750 segments per cohort) were collected. Descriptive statistics and student's t-tests were applied.

Results: Percentage of females (58.7 vs 61.3%) was similar between cohorts. The average scan delay was statistically significantly longer (9.8 ± 2.4 vs 5 sec; $p < 0.01$) using RTPSM. Average HU values were significantly higher in the RTPSM cohort (409.1 ± 22.2 vs 367.7 ± 20.8 HU; $p < 0.01$) and the number of non-diagnostic segments was significantly reduced in segmental and sub-segmental arteries (-3.6% ; $p < 0.05$).

Conclusion: RTPSM results in higher HU values and fewer non-diagnostic segments in the pulmonary arteries.

Patient lung volume is significantly related to contrast media volume during CT pulmonary angiography when employing a patient-specific contrast protocol

C. Saade, F. El-Merhi; Beirut/LB (charbel.saade@aub.edu.lb)

Purpose: To investigate the effect of patient lung volume and contrast volume on pulmonary artery opacification using a patient-specific contrast formula during pulmonary CTA.

Methods and Materials: IRB approved this retrospective study. CTA of the pulmonary arteries was performed on 200 patients with suspected PE using a 256-channel CT and a dual-barrel contrast injector. The contrast media volume was calculated by employing a patient-specific contrast formula. Both contrast media and saline were injected at a flow rate of 4.5 mL/s. The mean cross-sectional opacification profile of eight central and eleven peripheral pulmonary arteries and veins were measured for each patient and arteriovenous contrast ratio (AVCR) calculated for each lung segment. Mean body mass index (BMI) and lung volume were quantified. Receiver operating (ROC) and visual grading characteristics (VGC) measured the confidence intervals and image quality, respectively. Inter- and intra-observer variations were investigated employing Cohen's kappa methodology.

B-0730 14:33

Contribution of CT lung perfusion in diagnosis of acute pulmonary embolism

A. [Oganesyan](#), E. Mershina, V.E. Sinitsyn; *Moscow/RU (talilen@mail.ru)*

Purpose: To study the contribution of CTA iodine maps (IMPS) to the diagnosis of acute pulmonary thromboembolism (PE) and compare the pulmonary perfusion defects severity with other signs and biomarkers of PE.

Methods and Materials: 42 patients (f/m - 19/23; age 65 ±10) with suspected PE were performed pulmonary CTA. Single-tube dual-energy scan (DECT) and wide-detector scanner were used. Pulmonary IMPS were reconstructed using DECT (n=29) and lung subtraction (n=13) options. For CTA analysis the number and level of vessel occlusions were marked. Presence of lung perfusion defects on IMPS, signs of right heart failure were studied.

Results: CTA signs of PE were found in 42 patients. Defects of lung perfusion on IMPS were present in 83% cases. 6 patients had PE without perfusion defect and signs of right heart overload. The area of lung perfusion defects in IMPS correlated with the Quanadly index ($r=0,8$, $p<0,05$) and it had a weak correlation with severity of right heart failure ($r=0,3$, $P<0,05$). In 3 patients with segmental and subsegmental PE it was found due to the presence of a defect on IMPS and retrospective analysis of CTA.

Conclusion: Addition of IMPS to pulmonary CTA contributes to the improvement of acute PE diagnosis and assessment of its severity. The prognostic value of this biomarker needs to be further studied.

B-0731 14:41

Virtual non contrast imaging of aortic intramural hematoma for replacing the non contrast CT imaging

S.A. Si-Mohamed¹, N. Dupuis¹, D.C. Rotzinger², S. [Boccalini](#)³, Y. Yagil⁴, P. Coulon⁵, N. Shapira⁴, P. Douek¹, L. Bousset¹; ¹Bron/FR, ²Lausanne/CH, ³Genoa/IT, ⁴Haifa/IL, ⁵Paris/FR (sara.boccalini@yahoo.com)

Purpose: The purpose was to assess *in vitro* and *in vivo* whether Virtual Non-Contrast (VNC) images could replace true non-contrast images (TNC) for intramural hematoma (IMH) diagnostic.

Methods and Materials: A phantom of IMH was placed in a semi-anthropomorphic phantom (ORM GmbH, Germany) and imaged on the DLCT (iQonCT, Philips, Israel) at different CT DIvol using iDose 0, 3 and an extension ring. Attenuation, iodine density, image noise, contrast-to-noise ratio (CNR) between the hematoma and lumen were measured. 22 patients with IMH were included. CNR values were compared using t-test. Diagnostic confidence on a 4-point Likert scale was done by two radiologists using a Kruskal-Wallis rank sum, then with inter-agreement analysis using Cohen kappa test.

Results: CNR were not significantly different for both phantom sizes ($p = 0.78$ and 0.65). CNR between blood and hematoma were not lower in VNC compared to TNC images ($\Delta\text{CNR } 95\% \text{ CI} = -0.81; 0.85$). For both images, higher CT DIvol, iDose 3 and smaller phantom were associated with better CNR. *In vivo*, CNR were found to be significantly different with a higher value for VNC images ($\text{CNR}_{\text{TNC}} = 0.89 \pm 0.73$ and $\text{CNR}_{\text{VNC}} = 1.04 \pm 0.83$, $p = 0.04$). The mean diagnostic confidence scores for the TNC and VNC images were diagnostic to exemplary and not significantly different (3.13 ± 0.74 and 3.22 ± 0.73 respectively, $p = 0.56$).

Conclusion: DLCT offers similar performances with virtual non-contrast images for IMH diagnosis without any compromise in radiation dose or diagnostic image quality.

B-0732 14:49

Contrast-enhanced US (CEUS) of lung abscess: how it can help

C.L. [Piccolo](#)¹, D. Cozzi², M. Trinci³, M. Galluzzo³, M. De Cicco³, V. Miele³, S. Ianniello³; ¹Aversa/IT, ²Florence/IT, ³Rome/IT (clapiccolo@libero.it)

Purpose: The aim of this prospective study is to evaluate the contribution, in improving diagnostic accuracy, provided by the use of second-generation ultrasound contrast media (Sonovue®) in the diagnosis of lung abscesses.

Methods and Materials: At the three emergency departments, 32 patients (28-76 y.o) with signs of fever, cough and chest x-ray positive for limited opacity (suggestive for intrapulmonary abscess), were evaluated from January to september 2018. We evaluated with lung ultrasound (L-US), both the anterior and posterior regions (patients seated or supine our gold standard was contrast medium lung CT; we have described every opacity/abscess with diameters, eco-structural aspect of the wall and of the content, presence of associated pleural effusion. Exclusion criteria: recognition of a not-well delimited consolidation. CEUS was performed immediately after ultrasound with intravenous injection of 2.4 ml of Sonovue® (in 2 boluses) followed by each of 5ml of physiological solution.

Results: We identified with L-US 30/32 inhomogeneous sub-pleural round formations (diameters from 3 to 7 cm); we had 2 false-negative exams due to abscesses that did not reach the pleural surface. In 13/32 there was ipsilateral

pleural effusion. In 30/32 cases studied with L-US, we performed CEUS which better defined the wall (with intense and persistent contrastographic impregnation) and the content of the abscess.

Conclusion: Our limited-experience LUS, integrated with CEUS exam, has shown to contribute significantly in the improvement of diagnostic accuracy and in the best assessment of lung abscesses in patients with clinico-radiological suspect, with interesting perspectives about their follow-up.

B-0733 14:57

Lung ultrasound in the diagnosis of pneumothorax in paediatric stable major trauma: chest x-ray is still useful?

D. [Cozzi](#)¹, C.L. [Piccolo](#)², M.L. De Cicco³, M. Trinci³, M. Galluzzo³, V. Miele³, S. Ianniello³; ¹Florence/IT, ²Aversa/IT, ³Rome/IT (dilettaozzi@gmail.com)

Purpose: The aim of this retrospective study is to evaluate the diagnostic accuracy of lung ultrasound in the diagnosis pneumothorax in paediatric stable polytrauma in Emergency room, to try to avoid chest X-ray. All patients underwent multislice computed tomography (MS-CT) exam that represented the "gold standard".

Methods and Materials: From January 2017 to September 2018, 46 paediatric patients (mean age 14 yo, range 8-16 yo, 31 males, 15 females) with haemodynamically stable severe trauma (AP > 90 mmHg, injury severity score >15) underwent lung ultrasound. All the exams were performed with portable ultrasound machine in all three emergency rooms, with patients lying on the spinal board. Then all patients underwent a MS-CT immediately after lung ultrasound. No chest x-rays were performed.

Results: Among the enrolled patients (46 patients; 92 hemithorax compared), 11/12 pneumothoraces were found with lung ultrasound, while 12/12 were reported with MS-CT; the single false-negative exam reported with lung ultrasound consisted of a pneumothorax with a thickness <5 mm in anterior-inferior para-mediastinal left region. Lung ultrasound did not report any false positive (PPV 100%, specificity 100%, sensitivity 91.6%, NPV 98.7%). Diagnostic accuracy was 98.9%.

Conclusion: Our data regarding accuracy of pneumothorax ultrasonographic diagnosis in severe paediatric trauma (within five minutes from arrival) highlighted its important role in the early identification of a potentially lethal pathology, which needs to be diagnosed as soon as possible. Instead of chest X-ray, lung ultrasound represents a promising scenario that could reduce radiation exposure in paediatric patients.

B-0734 15:05

Accuracy of a new system score based on lung ultrasound and clinical data in the decision of a drainage tube necessity in polytrauma patients pneumothorax

M.L. [De Cicco](#)¹, C. Andreoli¹, B. Sessa², V. Miele¹, S. Ianniello¹; ¹Rome/IT, ²Chieti/IT (marialuisa.decicco@tiscali.it)

Purpose: The aim of this study is to evaluate the validity of a new score system and its utility in the ER to establish the necessity to drainage the pneumothorax diagnosed by ultrasound in adults polytrauma.

Methods and Materials: This is a retrospective observational study that involved from January 2015 to June 2018, 315 patients with pneumothorax, evaluated by lung ultrasound lung during primary survey. All ultrasound were performed in ER. It was applied a system score which included the evaluation of the lung point site (parasternal: 1; emiclavare: 2; axillary: 3), the presence of pleural effusion (><300ml: 1/0), pericardial effusion (0/1), heart dislocation (1/0), contusion areas (1/0), F/T ratio (><200ml 1/0). Cut-off established was 6. All patients underwent to MDTC and the results were compared.

Results: Among the enrolled patients with pneumothorax 235/315 had a score >6 and the necessity of a drainage was indicated. Of these in 208/235 the necessity was confirmed by CT, while in 27 the patients were just observed and in only two patients during the follow-up the tube was placed. Among the 25 false positives, 12 had an high BMI, 5 had a subcutaneous emphysema, in 8 there was an overvaluation by the US.

Conclusion: Our data regarding the validity of a new system score showed its utility in deciding the necessity of a draining tube in polytrauma patients. This score would allow an early diagnosis and a promptly therapeutic choice, avoiding wasting time, essential in patients with many traumatic lesions and above all with serious pneumothorax.

B-0735 15:13

Iatrogenic injuries and misplaced foreign material found in whole-body CT: a retrospective analysis in over 1000 resuscitation room patients

S. [Sudarski](#), D. Schäfer, T. Henzler, T. Terboven, T. Viergutz, S.O. Schönberg, H. Haubenreisser; *Mannheim/DE (sonja.sudarski@medma.uni-heidelberg.de)*

Purpose: Whole-body computed tomography reveals beyond findings related to the suspected diagnosis often additional incidental findings. Aim of this investigation was the systematic assessment of these findings in patients admitted via the emergency room after suffering potential major trauma or life-threatening medical conditions.

Methods and Materials: 1362 consecutive patients admitted via the resuscitation area were included retrospectively if they had received a whole-body computed tomography scan at admission. 197 patients were excluded because of missing data, the final cohort consisted of 1165 patients (1038 trauma and 127 internal-neurological patients). Reports from the whole-body computed tomography scans were screened for iatrogenic injuries and misplaced foreign material.

Results: In 43 (3.7%) patients a total of 46 iatrogenic injuries or misplaced foreign material were reported. The most common findings were too deeply placed endotracheal tubes. Five transurethral catheters placed in the emergency room were found to be blocked within the urethra.

Conclusion: Whole-body CT in our retrospective consecutive cohort of around 1000 patients admitted via the resuscitation area diagnosed iatrogenic injuries and misplaced foreign material in around 4% of the study patients.

B-0736 15:21

Incidental findings in thoracic CTS performed in trauma patients: an underestimated problem

E.J.M. Barbosa Jr., O. Osuntokun; Philadelphia, PA/US
(eduardo.mortani@gmail.com)

Purpose: Whole-body CT scans are commonly performed to assess trauma patients, and often reveal incidental findings (IF) the patient may be unaware of. We assessed the prevalence, associations and adequacy of follow up of IF.

Methods and Materials: We retrospectively identified 1,113 patients who had a chest CT to assess for traumatic injuries (6-years interval). We coded the radiology reports for IF, and queried our EMR regarding clinical history and adherence to follow-up recommendations for IF mentioned in the reports.

Results: IF are much more likely (62.2%) to be found in a Chest CT scan than acute traumatic findings (ATF, 32.4%), in patients being evaluated for potential traumatic injuries. 86.4% of patients who had IF also had another relevant diagnosis (RD). Lung nodules were the most common IF (45.7%). A multivariate logistic regression model (MLR) demonstrated accuracy of 89% to predict IF; the 3 statistically significant predictors ($p < 0.05$) were any RD (FDR logworth 68.6), followed by smoking history (29.8) and age (4.1). Radiologists recommended follow-up for IF 53.5% of the time, but only 13.9% of patients ever received a follow-up imaging study or procedure.

Conclusion: IF are much more common than ATF, and can be accurately predicted based on MLR utilizing only 3 clinical variables. While radiologists often recommend follow-up for IF in trauma patients, most are never effectively followed up or addressed, leading to increased risk of poor outcomes. Clinicians should be aware of the high prevalence of IF and develop systems for appropriate, evidence-based recommendations and effective management.

Catheter-directed gastric artery embolisation with octreotide acetate-loaded PLA/PLGA (poly(lactide-co-glycolide) acid) microspheres with slow sustained release properties

F. Nurili¹, T. Acar², S. Derman², A. Bas², I. Caymaz², S. Özkanlı², H. Cakiroglu³, I. Yurdaisik², O. Aras¹; ¹New York, NY/US, ²Istanbul/TR, ³Adapazari/TR
(fuatnurili@gmail.com)

Purpose: The objective of the present work was to formulate slow and sustained release octreotide acetate-loaded PLA/PLGA (poly(lactide)(poly(lactic-co-glycolic) acid) microspheres and prospectively test the effects of catheter-directed gastric artery administration of these microspheres on plasma ghrelin levels and body weight in swine. Octreotide is an octapeptide with pharmacologic properties mimicking those of the natural hormone somatostatin. In the GI system it inhibits secretin, gastrin, vasoactive intestinal peptide, motilin and ghrelin. Slow-release local high-dose therapy might significantly decrease all these hormones, especially ghrelin.

Methods and Materials: Twelve healthy growing swine were tested. Transcatheter embolisation with octreotide-loaded microspheres was performed selectively in the gastric arteries that supply the fundus and corpus. Six swine underwent embolisation with octreotide-loaded microspheres, while six control animals underwent a sham procedure with saline. 18 mg of total octreotide per procedure was used. Weight and fasting plasma ghrelin levels were obtained

in the animals at baseline and at weeks 1-8. Necropsy was performed to assess mucosal integrity, fibrosis and ghrelin-expressing cells.

Results: Ghrelin levels over time was significantly decreased in experimental animals ($P < 0.001$). Weekly ghrelin levels were measured in control and experimental animals as a change from baseline ghrelin values. The average post-procedure weight loss in experimental animals was significantly ($P < 0.001$) higher than that in control animals. The ghrelin-immunoreactive mean cell density was significantly lower in the fundus in the embolised animals compared with control animals.

Conclusion: Gastric artery embolisation with biodegradable octreotide-loaded PLA/PLGA microspheres with sustained release properties can significantly suppress ghrelin and significantly affect weight loss.

B-0738 14:08

Prevention of post-partum haemorrhages in patients with morbidly adherent placenta: a monocentric experience

F. Capasso, M. Coppola, M. Caruso, S. Stilo, A. Stanzone, P. Venetucci; Naples/IT (francesco.capasso@gmail.com)

Purpose: To evaluate the performance of various interventional radiology techniques in the prevention of post-partum haemorrhages in patients with MAP.

Methods and Materials: Between January and December 2017, 16 pregnant women were referred to our institution due to metrorrhagia and MAP. Among them, 7 underwent cesarean delivery assisted by occlusion balloon catheters located in both hypogastric artery (group 1); in 6 patients an embolisation procedure in leading uterine artery before delivery was performed (group 2); finally, in 3 patients an observational approach was adopted, positioning prevention catheters in both hypogastric artery (group 3). All procedures were performed by mobile C-arm angiograph in gynaecology surgery room. Primary endpoints were haemoglobin reduction and transfusion requirement whereas the secondary ones were hysterectomy rate and hospitalization time.

Results: Haemoglobin average reduction was of 0,7 g/dl for group 1 and 2 and 0,9 g/dl for group 3. No blood transfusions were need for patients of group 2 and 3; only one patient of group 1 need transfusion of 1000 mL of blood but her haemoglobin value before delivery was 9,0 g/dL. Hysterectomy was essential in 3 patients of group 1, in 3 patient of group 2 and in 1 patient of group 3. Mean hospitalization time was 7 days.

Conclusion: No significant differences were found in both primary and secondary endpoints when comparing the three groups, although our experience might suggest not to adopt an observational approach.

B-0739 14:16

Partial splenic artery embolisation using ethylene vinyl alcohol copolymer in patients with portosplenomesenteric thromboses and portal hypertension

W. Uller¹, W.A. Wohlgemuth², H. Goessmann¹, R. Müller-Wille¹, G. Kirchner¹; ¹Regensburg/DE, ²Halle/DE (wibke.uller@ukr.de)

Purpose: Partial splenic artery embolization (PSE) may be a therapy option in patients with symptomatic portal hypertension not eligible for TIPS. The purpose of this study was to evaluate PSE using the permanent liquid embolic agent ethylene vinyl alcohol copolymer (EVOH) for treatment of varices and thrombocytopenia in patients with chronic portomesenteric thrombosis and portal hypertension.

Methods and Materials: Data of 11 patients with portal hypertension who underwent PSE with EVOH between 2012 and 2017 were retrospectively analysed. 40-70% of splenic infarction was induced by EVOH. Thrombocyte, leukocyte counts and haemoglobin were measured prior to and 6 months after PSE and follow-up upper gastrointestinal endoscopy was performed. P-values were calculated using the Wilcoxon matched-pairs signed rank test.

Results: Causes of portal hypertension included chronic thrombosis of the portal/mesenterial/splenic vein system (n=9) and liver cirrhosis with severe thrombocytopenia (n=2). All patients developed extensive, multiple varices (esophageal, gastric, duodenal). Eight patients suffered from additional hypersplenism. Thrombocytes, leucocytes counts and haemoglobin increased significantly 6 months after the procedure ($p=0.0078$, $p=0.001$, $p=0.014$, respectively). Absence of variceal bleeding and decrease of grade of varices was achieved in 10/11 patients during follow-up (24.7±17.7 months, median 18). All patients developed a mild post-embolization syndrome. Two patients experienced abscesses of the spleen.

Conclusion: PSE with EVOH is an efficient technique that decrease varices, variceal bleeding, improves sequels of hypersplenism significantly and prevents recanalization via extra- and intrasplenic arterial anastomoses. The risk of splenic abscess seems to increase with embolization rates of more than 70% of the spleen parenchyma.

B-0740 14:24

Shattered spleen in blunt trauma: clinical results of trans-arterial embolisation, four years' experiences in a single regional trauma centre
R. Lee, C.H. Jeon, C.W. Kim, H. Kwon, H.M. Cho; *Busan/KR*
(fkdzja@gmail.com)

Purpose: To evaluate the benefits and risks of splenic artery embolisation (SAE) for patient with high-grade blunt spleen injury (BSI), especially "shattered spleen".

Methods and Materials: A retrospective electronic medical record review of all patients undergoing SAE from April 2013 to March 2017 at a Korean regional trauma care centre was performed. Reviewed results included patient demographics, initial and follow-up CT scan results, angiographic findings, embolisation techniques, and clinical outcomes including splenic salvage rate and procedure-related complications.

Results: A total of 89 patients were reviewed. CT scan was used to give the American Association for the Surgery of Trauma (AAST) grade of BSI. A total of 31 patients with shattered spleen were identified with a median (SD) age of 42.0 (24.7), including 3 patients of age under 15 years. 28 (90.3%) patients were males and the major mechanism of injury was motor vehicle collision. These patients had mean (SD) Injury Severity Scores (ISS) of 27.0 (9.3); systolic blood pressure of 92.0 mmHg (18.1) and 11 patients were haemodynamically unstable. The rate of successful embolotherapy was 90.3% (n=28) and only 3 patients underwent post-embolisation splenectomy. The spleen salvage rate was 96.4% (n=27). Major complications included rebleeding in 3 embolotherapy patients; 1 splenic abscess. There was no patient with sepsis during follow-up duration (237.0±198.2 days).

Conclusion: SAE is a safe and feasible procedure in extremely high-grade BSI and effective for not only haemorrhage control but also spleen salvage.

B-0741 14:32

Preoperative transarterial embolisation using a gelatin sponge for benign prostatic hyperplasia: initial feasibility test
K.Y. Kim, M.G. Shin; *Jeonju/KR* (kky2kww@gmail.com)

Purpose: To assess the safety and effectiveness of preoperative prostatic artery embolisation (PAE) in relation to the decrease in haemoglobin level, requirement of amount of blood transfusion, hospital days, and procedure-related complications after surgery.

Methods and Materials: From the database search, eight patients were identified from May 2017 to September 2018 (embolisation group). For statistical analysis, consecutive patients with large prostate volume (≥ 70 ml) who were operated during the same period without preoperative PAE (non-embolisation group; n=8) were reviewed from hospital record. The outcomes of interest were technical success, complication related to embolisation, haemoglobin reduction, need of blood transfusion, operating time, and hospital admission days after surgery.

Results: PAE was technically successful in 87.5% (7/8) patients. Partial success was gained in 1 patient due to prolonged vasospasm of right prostatic artery. The mean haemoglobin reduction was lower in embolisation group compared to non-embolisation group (1.24±0.29 g/dl vs. 2.85±0.45 g/dl, respectively; p=0.021). Median hospital admission days after surgery was 6.5±0.7 days (range, 4-10 days) in embolisation group, and 9.5±1.4 days (range, 2-13 days; p=0.110) in non-embolisation group.

Conclusion: Preoperative PAE is safe and may have a preventive effect on blood loss during prostate surgery. It leads to decrease in reduction of haemoglobin without procedure-related complications.

B-0742 14:40

Gastric variceal recurrence after balloon-occluded retrograde transvenous obliteration
K. Kato, K. Kawashima, T. Suzuki, M. Hamano, S. Ehara; *Morioka/JP*
(kkato@iwate-med.ac.jp)

Purpose: Balloon-occluded retrograde transvenous obliteration (B-RTO) is an effective treatment for gastric varices (GV); however, reports on the GV recurrence were limited. Therefore, this study aimed to evaluate the recurrence factors of GV after B-RTO.

Methods and Materials: B-RTO was performed in 54 patients with GV between October 2007 and December 2017. GV recurrence was evaluated based on follow-up contrast-enhanced CT (CE-CT) and clinical course. GV recurrence was also compared according to the gastro-renal shunt patency, size of the spleen, and afferent gastric vein classification.

Results: The appropriate technique for B-RTO was successfully performed in 53 patients. Complete thrombosis of GV was achieved in 43 patients, partial thrombosis in 6, and non-thrombosis in 4. Among the 43 patients, who had complete obliterated GV, follow-up CE-CT was performed in 34 patients during a mean observation period of 33.3 (range, 3-121) months, which revealed GV recurrence in six patients, and two of them had GV haemorrhage. Developed afferent veins on the recurrent GV were short gastric vein in four patients and left gastric veins in two. Gastro-renal shunt patency was statistically correlated

with GV recurrence (p<0.05). However, the size of the spleen and afferent gastric vein classification were not correlated with GV recurrence.

Conclusion: Residual gastro-renal shunt seems to cause revascularization of the GV afferent veins, which can result in GV recurrence. Therefore, obliteration of the gastro-renal shunt and GV would support the long-term therapeutic effect of B-RTO.

B-0743 14:48

Trans-arterial embolisation of the prostate with biodegradable flutamide-loaded PLA/PLGA microspheres for benign prostatic hyperplasia: a preliminary study in normal swine model

F. Nurili¹, T. Acar², S. Derman², A. Bas², I. Caymaz², I. Yurdaisik², H. Cakiroglu², S. Özkanlı², O. Aras¹; ¹New York, NY/US, ²Istanbul/TR
(fuanurili@gmail.com)

Purpose: To prospectively evaluate whether transarterial embolisation with biodegradable flutamide-loaded PLA/PLGA microspheres with sustained release properties in the prostate of swine can induce shrinkage in the volume of prostatic tissue. Flutamide is a strong nonsteroidal antiandrogen that acts as selective, competitive and silent antagonist.

Methods and Materials: Sustained release flutamide-loaded poly(lactide)/poly(lactide-co-glycolic acid) (PLA/PLGA) microspheres were successfully fabricated using the single emulsion (o/w) solvent evaporation method in our preliminary study. Twelve male swine were randomly assigned to either the experimental group (n=6) or control group (n=6). Selective angiography was performed to deliver microspheres. In the experimental group, 200-700-micron-diameter flutamide-loaded microspheres were used for embolisation. 250 mg of total flutamide was used per procedure. 6 weeks later animals were euthanised for necropsy, the prostates were removed for size measurement and histopathologic examination. Paired Student's t test was used for statistical analysis.

Results: All procedures were technically successful. The mean prostate volume after embolisation in the experimental group was significantly (P<0.001) diminished compared with the mean prostate volume for the control group. Microscopic examination showed that normal gland structure was partially replaced by fibrosis and atrophy in the residual gland tissue.

Conclusion: Embolisation of the prostatic arteries with flutamide-loaded PLA/PLGA microspheres can induce strong shrinkage of the prostate. This study shows that transarterial targeted embolisation of prostatic arteries with flutamide-loaded PLA/PLGA microspheres with sustained release properties may provide an effective alternative approach to the treatment for benign prostatic hyperplasia in humans.

The application of hepatic artery-targeting guidewire technique combined with indirect portography to transjugular intrahepatic portosystemic shunt

S. Wang, N. Li, C. Yu; *Tianjin/CN* (wase1255@163.com)

Purpose: This study evaluated the value of combined hepatic artery-targeting guidewire technique with indirect portography to transjugular intrahepatic portosystemic shunt (TIPS) for the puncture step.

Methods and Materials: We retrospectively reviewed 11 consecutive patients (5 men and 6 women, aged 46-76 years (mean 64 years)) with portal hypertension in whom the TIPS procedure was performed. As the first step in the TIPS procedure in all cases, a micro-guidewire was inserted into the hepatic arterial branch accompanying the portal venous branch through a microcatheter coaxially advanced from a 5-French catheter positioned in the coeliac or common hepatic artery. At the puncture step, the tip of the metallic cannula was aimed 1 cm posterior to the distal part of this micro-guidewire, after which the TIPS procedure was performed. Success rate, number of punctures and complications were evaluated.

Results: The TIPS procedure was successfully performed in all 11 patients. The mean number of punctures until success in entering the targeted portal venous branch was 5 (range 1-14). In 3 patients (27%), the right portal venous branch was entered at the first puncture attempt. The hepatic artery was punctured once in one patient and the bile duct was punctured once in another patient. No serious procedure-induced complications occurred.

Conclusion: The TIPS procedure can be accomplished safely, precisely and relatively easily using the hepatic artery-targeting guidewire technique.

What makes a difference between life and death in patients with NOMI? Analysis of clinical data and contrast-enhanced dynamic CT findings before angiography

R. Miyazawa, M. Kamo; *Tokyo/JP*

Purpose: The purpose of this study was to investigate prognostic factors of computed tomography (CT) findings and clinical data in patients with non-occlusive mesenteric ischemia (NOMI).

Methods and Materials: This was a retrospective, IRB-approved study, reviewing 21 consecutive patients diagnosed as NOMI on angiography. By chart review, patients were divided into either "survivor" group or "non-survivor" group. Clinical data such as laboratory data or time from taking CT to injecting papaverine were also obtained. Assessment on contrast-enhanced CT images was performed by consensus of two radiologists in following items: defect of mural enhancement, pneumatosis intestinalis, hepatic portal venous gas, paralytic bowel dilatation, bowel wall thinning, and diameter of the vessels.

Results: 8 patients belonged to "survivor" group, 11 allocated to "non-survivor" group. Neither of CT findings showed significant difference between alive group and dead group (defect of mural enhancement: 75% and 100% (p=.16), pneumatosis intestinalis: 50% and 45.5% (p=1.00), hepatic portal venous gas: 37.5% and 45.5% (p=1.00), paralytic bowel dilatation: 12.5% and 63.6% (p=.06), bowel wall thinning: 50% and 45.5% (p=1.00)). There was also no significant difference in the diameter of the vessels. Time from taking CT to injecting papaverine was significantly shorter in alive group (207.6 ±126.2 minutes and 578.8 ±506.6) (p=.038). None of laboratory data showed significant difference between each group.

Conclusion: It may be difficult to estimate the prognoses of NOMI patients by preceding CT findings or laboratory data. Prompt action to angiography could save lives of the patients.

Temporary balloon occlusion of the internal iliac arteries as a prevention of massive haemorrhage during cesarean delivery among patients with abnormal placentation

M. Milnerowicz, J. Garcarek, M. Miś, M. Miś, A. Kacala; Wroclaw/PL
(gosia.milnerowicz@gmail.com)

Purpose: To investigate the efficacy and safety of temporary balloon occlusion of the internal iliac arteries (IIAs) in the prevention of haemorrhage during cesarean delivery among patients with placenta previa and placental accretism.

Methods and Materials: From 2013 to 2017, 16 patients diagnosed with placenta previa and coexisting placental accretism using ultrasound imaging underwent elective cesarean delivery preceded with temporary balloon occlusion of the IIAs. Depending on penetration of the placenta into the uterine wall, placental extraction with curettage or hysterectomy was performed. Intraoperative blood loss, amount of transfusions, haemoglobin level and procedure complications were analyzed.

Results: The mean age was 33.7 years with a mean of 2.9 previous gestations, 80.6% of them were delivered by cesarean. Abnormal placentation was confirmed intraoperatively in all cases. All of the patients had placenta previa and all but one had coexisting placental accretism. 12 patients underwent hysterectomy and the remaining 4 patients required only curettage. Blood loss was assessed by the surgeon in a 3-point scale (low, moderate, significant) and in 13/16 (81.2%) cases was estimated as low. The mean amount of transfused packed red blood cells was 1.1U and haemoglobin drop was 1.7g/dl in the first day postoperatively. One patient underwent nephrostomy due to postoperative urinary stasis. There were no other procedure-related complications, neither maternal nor fetal mortality.

Conclusion: Temporary balloon occlusion of the IIAs during cesarean delivery is a safe method and appears to reduce blood loss and transfusion requirements in patients diagnosed with placenta previa and placental accretism.

Prospective evaluation of a deep learning algorithm deployed in an urban imaging centre to notify clinicians of head CT scans with critical abnormalities

S. Tanamala¹, S. Chilamkurthy¹, M. Biviji², R. Ghosh¹, P. Rao¹; ¹Mumbai/IN, ²Nagpur/IN (swetha.tanamala@qure.ai)

Purpose: Non-contrast Head-CT scans are primary imaging modality for evaluating patients with trauma or stroke. While results of deep learning

algorithms to identify head-CT scans containing critical abnormalities has been published in retrospective studies, effects of deployment of such an algorithm in a real-world setting, with mobile notifications to clinician remain unstudied. In this prospective study, we evaluated performance of such an automated triage system in an urban 24-hour imaging facility.

Methods and Materials: We developed an accurate deep neural network algorithm that identifies and localizes intracranial bleeds, cranial fractures, mass effect and midline shift (defined as critical abnormalities) on non-contrast head-CT scans. The algorithm is deployed in clinical imaging facility in conjunction with an on-premise module that automatically selects eligible scans from PACS and uploads them to cloud-based algorithm for processing. Once processed, cloud algorithm returns an additional series, viewable as an overlay over the original, and a text notification to radiologist with preview images. Mobile notifications facilitated confirmation of the detected abnormalities. We studied performance of the automated system over 60 days.

Results: 194 non-contrast head-CTs were filtered amongst 748 CT images acquired over 60 days. The head-CTs were evaluated by senior radiologist to generate ground-truth. Sensitivity, specificity, AUC and average time to notification of head-CT scans with critical abnormalities were 0.90(95% CI 0.74-0.98), 0.86(0.80-0.91), 0.97(0.92-1.00) and 3.2 minutes respectively.

Conclusion: An automated triage system in a radiology facility results in rapid notification of critical scans, with high sensitivity and this may be used to expedite treatment initiation.

Extracranial determinants of white matter lesion volume: a machine learning-based top 10 list

S. Grosu¹, S. Rospleszcz¹, F. Bamberg², C.L. Schlett³, A. Peters⁴, M. Heier¹, F. Schöppe¹, B.B. Ertl-Wagner², S. Stöcklein¹; ¹Munich/DE, ²Freiburg/DE, ³Heidelberg/DE, ⁴Neuherberg/DE, ⁵Toronto, ON/CA
(sergio.grosu@med.uni-muenchen.de)

Purpose: Numerous extracranial, potentially interrelated factors have an impact on the development of white matter lesions (WML). The aim of this study was to train a multifactorial composite score of extracranial parameters using machine learning algorithms to identify the variables that best predict WML volume.

Methods and Materials: 400 subjects of the KORA study cohort underwent comprehensive 3T-MRI. Cerebral WML were manually segmented on 3D-FLAIR-images. 90 extracranial parameters including measures of sociodemographics, anthropometrics, diabetes-related issues, behaviour, somatic/depressive symptoms, blood pressure, laboratory values, adipose tissue, medication intake and sleep were collected in a standardized method. To identify relevant predictor covariates associated with WML volume penalized zero-inflated negative binomial (ZINB) regression models based on elastic Net (EN) regularization were calculated.

Results: The final study population consisted of 370 participants (58% male; age: 55.72 ± 9.11 years). WML were found in 236 (63.78%) participants (57% male). The EN model was evaluated based on 1000 data splits. The ten variables that were most often selected were age (N=224), controlled hypertension (N=169), HbA1c (N=148), widowed marital status (N=145), prediabetes assessed by OGTT (N=135), antiplatelet medication (N=134), unknown hypertension (N=106), NSAID medication (N=65), physical activity of less than 2h/week (N=46) and alcohol consumption 1g-20g/day (N=46).

Conclusion: In this reference population without prior cerebrovascular disease, a systematic machine learning-based analysis of a wide range of extracranial parameters showed that the most powerful determinants for WML volume are age, hypertension, pre-/diabetes, widowed marital status, antiplatelet/NSAID medication, low physical activity and moderate alcohol consumption.

B-0750 14:16

Deep learning for infarct detection and localisation from head CT scans

R. Ghosh¹, S. Chilamkurthy¹, P. Rao¹, S. Tanamala¹, N. Campeau²; ¹Mumbai/IN, ²Rochester, MN/US (swetha.tanamala@qure.ai)

Purpose: The purpose of this study was to use a deep learning algorithm to detect and localize subacute and chronic ischemic infarcts on head CT scans for use in automated volumetric progression tracking.

Methods and Materials: We sampled 308 head CT scans (11840 slices) which were reported with chronic or subacute infarct. The infarcted regions in 11840 infarct-positive slices were marked. We trained segmentation algorithm to predict a heatmap of infarct lesion. The heatmap was used to derive scan level features representative of lesion density and volume to train a random forest to predict scan-level probabilities of chronic infarct. Area under receiver operating characteristics curves (AUC) were used to evaluate scan level predictions.

Results: The algorithm was validated on an independent dataset of 1610 head CT scans containing 78 chronic & 9 subacute infarct, 45 chronic ICH, 6 glioblastomas. The distribution of infarct affected territories was - 52.9% MCA, 33.3 % PCA, 9.3% ACA and 4.7% verteobasilar territories. The algorithm yielded AUC of 0.8474 (95% CI 0.7964 - 0.8984) for scan level predictions. It identified 8 of 9 subacute infarcts (88.89% recall) and 70 out of 78 chronic infarcts (89.74% recall). The eight missed chronic infarcts constituted of 3 lacunar and 2 hemorrhagic. The volumes of predicted infarct lesions ranged from 1 mL - 526 mL with mean prediction volume as 55.60mL.

Conclusion: The study demonstrates the capability of deep learning algorithms to accurately differentiate infarcts from infarct mimics.

Estimation of intracranial haemorrhage volume with the deep learning method

Q. Gong, Y. Deng, C. Xia, R. Zhang, C. Wu, Z. Wang, Y. Zhang, J. Ma;
Beijing/CN (dr.junma@foxmail.com)

Purpose: Brain haemorrhage is one main cause of stroke. The current standard to estimate bleeding volume is ABC/2, which is an approximation applied to the bleeding regions. We developed a deep learning approach to estimate brain haemorrhage volume by training CNN.

Methods and Materials: Our model automatically segments haematoma from brain CT images. It uses DenseNet to extract features from CT images and propagate the features through U-Net for the segmentation. The model was trained on a brain CT dataset that consisted of 3000 brain CT sequences, including 1000 intracerebral haemorrhage (ICH), 1000 extracerebral haemorrhage (EDH) and 1000 subdural haemorrhage (SDH) cases. The test dataset consisted of 217 brain CT sequences (67 ICH, 87 EDH, and 63 SDH). The gold standard was obtained from manual segmentation by 3 neuro-radiologists with more than 5 years of experience.

Results: The ABC/2 method resulted in inaccuracies up to 40 ml. The volume difference between DL model and the gold standard was 1.44 ± 1.91 , 1.06 ± 2.04 and 1.44 ± 2.34 ml for ICH, EDH and SDH. Another attending neuro-radiologist performed manual segmentation, and achieved similar performance compared to the DL model. The computation time for the DL model was 4 second per case, as compared to 12 seconds for ABC/s method, and 1 minute by manual segmentation.

Conclusion: The results demonstrated that our DL model achieved high accuracy in ICH, EDH, and SDH volume estimation, which significantly outperformed the current standard ABC/2 method. The computational time of the DL model was 4 second, which was 15 times faster than human segmentation.

Brain disease classification based on routine MRI using a deep learning algorithm

Y. Liu, P. Gao, Y. Duan; *Beijing/CN (asiaeurope80@gmail.com)*

Purpose: To develop and evaluate the efficacy of a deep learning algorithm using clinical routine sequences to classify patients into one of four broad neurological disease classes: normal, tumor, ischemic cerebral vessel disease (ICVD), and multiple sclerosis (MS).

Methods and Materials: A deep learning algorithm was trained on MR images from 4507 randomly selected cases restricted to one of the four classes. Each subject's diagnosis was validated by an experienced radiologist in Beijing TianTan Hospital. After training, the model performance was tested in 1167 cases that included the following diagnosis distribution: 212 normal, 739 tumor cases, 111 ICVD, and 105 MS. Sensitivity, specificity, accuracy for classifying each case into its respective disease categories, in a separate test set.

Results: Taking the predicted class with the highest probability for each case, the deep learning algorithm achieved an overall accuracy of 94.1%, with a sensitivity and specificity of 85.2% and 95.7%, respectively. Sensitivity for specific classes were: 91.5% (normal), 89.7% (tumor), 83.7% (ICVD), and 76.2% (MS). Specificities for specific classes were 91.3% (Normal), 93.9% (Tumor), 98.4% (ICVD) and 99.0% (MS).

Conclusion: The algorithm achieved high sensitivity and specificity across normal cases and several broad classes of neurological disease classes, indicating its potential usefulness in automatic neurological disease detection and diagnosis. Optimization of the algorithm and the extension to other neurological diseases would have to be carried out to enable it to be used in clinical settings to aid radiologists and doctors in their diagnosis of patients.

B-0753 14:40

Detection of intracranial haemorrhage on CT of the brain using a deep learning algorithm

D. Desbuquoit, S. Dekeyzer, J. Huyskens, S. Nicolay, E. De Smet, J. Van Goethem, L. Van den Hauwe, P.M. Parizel; *Edegem/BE (damien.desbuquoit@gmail.com)*

Purpose: This prospective study aimed to evaluate the use of a commercially available deep learning algorithm for the detection of intracranial haemorrhage on non-contrast enhanced CT of the brain.

Methods and Materials: 500 non-contrast enhanced CT's of the brain performed in June, July and August 2018 were independently analysed on the presence of pathological hyperdensities by a deep learning software package (Aidoc, Tel Aviv, Israel) and a 4th-year radiology resident. Their results were compared to a "gold standard analysis", performed by a senior neuroradiologists with access to clinical information and, when available, previous or follow-up imaging studies.

Results: Pathological hyperdensities were present in 134/500 patients, the majority of which were haemorrhages (128/134; 95.5%). Pathological hyperdensities were correctly identified by Aidoc-software in 125/134 cases (93.3%), compared to 133/134 (99.3%) for the resident. Aidoc's false-negative ratio was 9/134 (6.7%). When no pathological hyperdensities were present, the exam was rated negative by Aidoc-software in 345/366 cases (94.3%), compared to 362/366 (98.9%) for the resident. Aidoc's false-positive ratio was 21/366 (5.7%).

Conclusion: The use of a deep learning algorithm for the detection of pathological intracranial hyperdensities helped to detect urgent cases more quickly. False positive results occur in a limited number of cases (5,7%) and are mainly due to beam hardening artefacts, hyperdense dural sinuses, or calcine or basal ganglia calcifications. False negatives were slightly more frequent (6,7%) and mainly seen in small or subtle haemorrhages.

B-0754 14:48

Development and validation of a deep neural network-based computer-assisted detection system for cerebral aneurysms in CT angiography

Z. Shi¹, C. Pan², C. Zhou¹, D. Fan², X. Li², G. Lu¹, L. Zhang¹; ¹Nanjing/CN, ²Beijing/CN (fmrishiz@126.com)

Purpose: To develop a CAD system for intracranial aneurysms on computed tomography angiography (CTA) images based on a deep convolutional neural network (CNN) and a volume rendering (VR) algorithm, and to demonstrate the usefulness of the system by training and evaluating it using a large dataset.

Methods and Materials: There are 209 cases (159 for training and 50 for the validation) with intracranial aneurysms that diagnosed by both computed tomography angiography (CTA) and invasive cerebral angiography in the dataset. The CNN was trained in advance using manually inputted labels in bone-removal images of CT angiography and the corresponding VR algorithm. 3D patches were randomly cropped with or without aneurysms, and kept the ratio between positive and negative about 1.0. The architecture contains an encoder to extract features and a decoder to output a volumetric segmentation. And we added a classification path to determine whether the patch contains aneurysm(s). The diagnostic performance of the system was assessed using Dice coefficient and receiver operating characteristic (FROC) analysis.

Results: Our system showed a good performance in detection of intracranial aneurysms with a dice score of 0.65, 92.2% (47/51) of aneurysms with 1.36 false positives per case (FPs/case). At a sensitivity of 73.4%, the number of FPs/case was 0.40. The area under the ROC curve (AUC) is 0.974 for the detection of aneurysm in a voxel.

Conclusion: We demonstrated that the combination of a CNN and VR algorithm is useful for the detection of intracranial aneurysms based on the CT angiography images of head.

B-0755 14:56

Automated detection of midline shift and mass effect from head CT scans using deep learning

S. Chilamkurthy¹, R. Ghosh¹, S. Tanamala¹, M. Biviji², N. Campeau³, V. Venugopal⁴; ¹Mumbai/IN, ²Nagpur/IN, ³Rochester, MN/US, ⁴New Delhi/IN (sasank.chilamkurthy@qure.ai)

Purpose: Mass effect and midline shift are most critical and time sensitive abnormalities that can be readily detected on head-CT scan. We describe development and validation of deep learning algorithms to automatically detect mentioned abnormalities.

Methods and Materials: We labelled slices from 699 anonymized noncontrast head-CT scans for the presence or absence of mass effect and midline shift in that slice. Number of scans(slices) with mass effect were 320(3143) and midline shift were 249(2074). We used these labels to train a modified ResNet18, a popular convolutional neural network to predict softmax based confidences for the presence of mass effect and midline shift in a slice. We modified network by using two parallel fully connected(FC) layers in place of a single FC layer. The confidences at slice-level were combined using random

forest to predict the scan-level confidence for presence of mass effect and midline shift. A separate dataset (CQ500 dataset) was collected for the validation of the algorithm. Three senior radiologists independently read each scan in this dataset. Consensus of the readers' opinion was used as the gold standard. We used areas under receiver operating characteristics curves (AUC) to evaluate the algorithm.

Results: CQ500 dataset contained 491 scans of which number of scans with mass effect and midline shift were 99 and 47 respectively. AUC for detecting mass effect was 0.92 (95%CI 0.89-0.95) and for detecting midline shift was 0.97 (95%CI 0.94-0.99).

Conclusion: We show that a deep learning algorithm can be trained to accurately detect mass effect and midline shift from head CT scans.

A deep learning method for analysing post-operative MRI scans of glioblastoma patients

M. **Perkuhn**, P. Stavrinou, R. Shahzad, F. Thiele, G. Shakirin, D. Garpis, C. Kabbasch, J. Borggreffe; *Cologne/DE (michael.perkuhn@uk-koeln.de)*

Purpose: Cytoreductive surgery is the cornerstone of glioblastoma (GB) therapy and residual tumour volume is considered to be an important outcome measure. The MRI analysis of the contrast-enhancing residual tumour (CE-RT) is challenging e.g. due to small tumour volumes. Detection and segmentation of CE-RT suffers from high inter-rater variability. Our objective was to train and evaluate a deep learning model (DLM) for fully-automatic detection, localisation and segmentation of CE-RT, Oedema (ED) and tumour cavity (TC) on routine postoperative MRI data.

Methods and Materials: 94 post-operative GB patients were included. T1, T2, FLAIR, CE T1 sequences were obtained 24-48 hours after surgery. ED, TC and CE-RT were manually delineated by experts (radiologist, neurosurgeon). Ground truth (GT) was obtained by consensus. A DLM for GB segmentation was trained using 5-fold-cross-validation based on transfer learning of a pre-operative model.

Results: For CE-RT detection, the DLM achieved 82% sensitivity and 72% specificity (AUC=0.83). ED, TC compartments were detected in all patients. Volume correlations (R) were 0.63 (CE-RT), 0.95 (ED), 0.76 (TC). Inter-rater agreement kappa for CE-RT before consensus was 0.43, and 0.54 between the DLM and GT. Automatic segmentation achieved dice coefficients of 0.33±0.23 (CE), 0.67±0.18 (ED) and 0.59±0.21 (TC), outperforming published methods.

Conclusion: The proposed fully-automatic approach is robust in detecting CE-RT on routine postoperative data and its accuracy is comparable to inter-rater variability. This makes the method suitable for automatic CE-RT segmentation reviewed by the radiologist in postoperative GB analysis. ED and CE-RT segmentations can also serve as baseline for GB follow-up.

A radiomics strategy for amide proton transfer imaging in predicting isocitrate dehydrogenase genotype within grade II/III gliomas

Y. **Han**, Y.-Z. Sun, L.-F. Yan, W. Wang, G.-B. Cui; *Xi'an/CN (hanyu0920@163.com)*

Purpose: To evaluate the diagnostic performance of radiomics analyses in predicting isocitrate dehydrogenase (IDH) genotype of grade II/III gliomas based on amide proton transfer weighted (APT_w) imaging.

Methods and Materials: Fifty-nine grade II/III glioma patients with known IDH mutation status were prospectively included (IDH-wild type, 16; IDH mutation, 43). Cases were randomly assigned to the training (n = 49) and test cohort (n = 10). A total of 1044 quantitative radiomic features were extracted from APT_w images. Support vector machine with recursive feature elimination (SVM-RFE) and synthetic minority oversampling technique (SMOTE) were adopted to select the optimal feature subsets and to solve the adverse impact of the imbalance dataset in the training cohort, respectively. The trained SVM prediction model for IDH genotype was validated on both train and test cohort.

Results: Our SVM model was established using 19 features selected by SVM-RFE. The AUC and accuracy for IDH genotype on training set were 89.2%, 0.952, while on the testing set were 70%, 0.84, respectively.

Conclusion: A radiomics strategy integrating SVM model and APT image features are predictive for IDH genotype in grade II/III gliomas.

B-0758 15:20

BRAIMS: an incoming open source MR imaging dataset for brain instance-aware metastases segmentation

W.-Y. **Guo**, S.-Q. Zheng, H.-M. Wu, P.C. Liu, I.-J. Sun, S. Hong, W.-Y. Chung, W.H. Yang, Y.-C. Tu; *Taipei/TW (wyguo@vghtpe.gov.tw)*

Purpose: Depicting brain metastases (for number counting and size measuring) is challenging and critical for patient management. A novel dataset for automated instance segmentation of brain metastases and a benchmark model for feasibility evaluation of metastases detection are introduced.

Methods and Materials: Brain MR images of 1100 patients (at least, T1-weighted (pre- and post-gadolinium contrast, T1-Gd) and T2-weighted) were acquired for radiosurgery of brain metastasis between 1993 and 2017 in our institute. The current dataset enrolled 308 of them, who had naïve brain metastases. Tumour detection done by an interdisciplinary team served as the ground truth. The BET of FMRIB Software Library was utilized for skull-stripping. Contrast limited adaptive histogram equalization was used for image enhancement for model training. Finally, the benchmark model was based on 2D Mask R-CNN, best known for instance segmentation. Only T1-Gd were used for feasibility evaluation by model.

Results: The dataset comprised 308 folders, with each containing three series images in NIFTI format and one segmentation mask volume in 3D TIFF format. Each tumour instance was annotated with an exclusive value. There were 100 tumours of 38 patients in testing set. By patient, the recall of model was 100%. By tumour, the recall was 86%, and the precision was 67.7%.

Conclusion: This is a groundbreaking work on dataset and model for instance segmentation and biometric measurements of MR Images. T1-Gd images of brain metastases present clear spatial information and typical texture for automatic tasks. A competition with release of the dataset is planned currently.

MRI principles and techniques: how and where do radiologists and radiology residents look for?

F.M. **Doniselli**, M. Zanardo, L.M. Sconfienza, F. Sardanelli; *Milan/IT (fabio.doniselli@gmail.com)*

Purpose: To investigate where and how MRI principles and technical issues are searched by radiologists and radiology residents (RR).

Methods and Materials: We proposed a European online survey with 8 multiple-choice questions. We investigated how often radiologists have doubts about MR principles or technical issues, where and what kind of information they search, in which language and in which websites. Chi-squared test was used.

Results: We obtained 122 answers (40 radiologists, 82 RR, from 6 different European countries). Radiologists and RR search information in English rather than their native language (75% vs. 68%, respectively, $p=0.761$). RR recognises to have frequently (51%) or often (32%) doubts about MRI principles while radiologists sometimes (45%) or rarely (25%), with a statistically significant difference ($p=0.002$). Post-processing details are equally searched by RR and radiologists (30%, $p=0.953$) as well as advanced/new techniques (49% vs 40%, $p=0.518$). Clinical protocol settings are more searched by RR than radiologists (68% vs 35%, $p=0.014$) as well as basic sequences details (66% vs 10%, $p<0.001$). Regarding source of information, RR uses more internet (90% vs 60% of radiologists, $p=0.005$), books (49% vs 20%, $p=0.031$) or directly ask to same-age colleagues (32% vs 10%, $p=0.065$) or to older colleagues (54% vs 40%, $p=0.316$). Website evaluation described a situation dominated by radiopaedia.org, both for technical and clinical issues (75% and 46%, respectively), mriquestions.com (43% and 30%) and mrimaster.com (16% and 15%).

Conclusion: Radiologists and RR search information about MRI principles and technical issues with different frequency. Differences were also found regarding the means, the kind of information searched and the web sources.

Design and testing of a novel complex flow phantom for medical imaging

S. Ambrogio¹, A. Walker², P. Verma¹, A. Narracott¹, J. Fenner¹; ¹Sheffield/UK, ²Boroughbridge/UK (simoambr@gmail.com)

Purpose: Calibration and quality control of medical flow imaging scanners is essential and, to that end, a novel, portable, cost-effective, multimodal, complex flow phantom design is presented. This is relevant to recent medical imaging technologies, such as Doppler ultrasound vector flow imaging, which enable real-time quantitative and qualitative analyses of complex blood flow patterns. The phantom has the potential to establish a flow benchmark for comparative studies and for validation of advanced velocity estimation algorithms developed for medical imaging at research level.

Methods and Materials: The vortex ring is the reference flow upon which the design of the phantom is based, because it offers patterns that resemble physiological flows and has been demonstrated to be stable, reproducible, predictable and controllable. The phantom is motor-driven and vortex rings with different features can be generated on demand. The design is validated, comparing results obtained from three independent measurements methods, namely optical/video, laser-PIV and pulsed-wave Spectral Doppler ultrasound.

Results: Vortex rings with travelling velocities from approximately 1cm/s to 80cm/s and different sizes were produced with a reproducibility typically better than +/-10%. At best, differences of +/-2% were found for peak velocity estimations with laser-PIV and Spectral Doppler. Errors refer to average and standard deviation values calculated on 10 vortex ring acquisitions.

Conclusion: Construction and characterisation of an innovative flow phantom, able to produce stable complex flow patterns, was described. The design, currently compatible with Doppler ultrasound modalities, could be adapted for comparative studies with different medical imaging technologies, such as X-rays and magnetic resonance.

Phantom for independent global head SAR assessment of MRI-induced temperature change

G. Oluniran, J. Blackwell, B. Tuohy, N. Colgan; Galway/IE (g.oluniran2@nuigalway.ie)

Purpose: Underestimation of SAR in MRI poses potential risks to patients and individuals with compromised thermoregulation. EU standardization imposes a head SAR limit of 3.2W/kg and SAR effects are negligible at up to 3W/kg. We developed a phantom and protocol where heating due the RF pulse is measured and verified against scanner-displayed SAR.

Methods and Materials: The spherical 3-litre glass phantom comprised of agar (60 g/L), NaCl (10 g/L) and CuSO₄ (1 g/L) dissolved in distilled hot water. The phantom was manufactured to achieve thermal equilibrium and T1 properties of the phantom were determined at room temperature using a STIR sequence. A baseline image was acquired using a 2D fast gradient echo. SAR loading is generated with a clinical 3D FLAIR sequence followed by a repeat 2D fast gradient echo. Our phantom is non-perfused, and the period of heating is relatively short. Thus, physiological and conduction effects are ignored, i.e. $SAR \approx C_{\text{agar}} \Delta T/\Delta t$. Temperature maps were generated using Proton Resonance Frequency Shift (PRF) thermometry. Global SAR was estimated by averaging temperature changes over the whole phantom and compared to the scanner's SAR display. Procedure was repeated for five independent scanners.

Results: In the format scanner model/scanner readout [W/Kg]/our calculation [W/Kg]/error [%]: GE 1.5T Signa Explorer/0.42/0.41/2.3, Siemens 1.5T Symphony/1.88/1.90/1.0, Philips 3T Achieva/1.52/1.52/0, GE 1.5T Signa Explorer/0.56/0.55/1.7, Siemens 1.5T Magnetom Sola 1.5/1.49/0.7. Our SAR estimates are in good agreement with scanner displayed data.

Conclusion: We have developed a phantom that can independently verify MRI head SAR.

Hotspot temperatures leading to burn in 3T MRI in pigs

C.-H. Cho¹, C. Grosse-Siestrup¹, G. Brinker¹, J. Nadobny¹, S. Niehues¹, M. Taupitz¹, B. Hamm¹, P. Schlattmann²; ¹Berlin/DE, ²Jena/DE (choch@gmx.ch)

Purpose: Magnetic Resonance imaging (MRI) is based on radiofrequency which induces heat in tissue. Areas of overlapping radiofrequency leads to hotspots and elevated body temperature. The International Electrotechnical Commission (IEC), IEC 60601-2-33:2010 has defined limits of heat exposure, quantified as specific absorption rate (SAR). The aim of this project was to investigate the temperature behavior in vivo online.

Methods and Materials: Invasive temperature measurements in pre-calculated hotspots and in the rectum of 20 pigs were performed prior, during, and post radiofrequency exposure in 5 exposure levels (sham, low-2.7W/kg, moderate, high4.8W/kg, extreme 11.4W/kg) in a whole body resonator (60 cm diameter) of a 3T MRI system (123 MHz).

Results: Rectal temperatures increased continuously by 2.1±0.9°C independently of the hotspot temperatures which ranged from 40.5°C to 55.9°C. When a core body temperature of 39°C is reached, hotspot temperature may be already 40.5°C within 29 minutes in the low-, 41.6°C within 20 minutes in the moderate-, and 41.4°C within 21 minutes in the high-exposure group. The hotspot temperature curves showed four characteristic patterns, sinusoid, parabola like, plateau reaching, and linear.

Conclusion: SAR is may not be sufficient to define safe temperatures and prevent burns. While the pig model is limited (anatomy, different thermoregulation), our results may improve the understanding of potential burns. Special care is needed for thermoregulatory impaired persons (anesthetized and pharmacologically treated patients, infants and children).

Accuracy and reproducibility of magnitude-based proton density fat fraction quantification with resolved water-fat ambiguity

A. Bagur, C. Hutton, M.L. Gyngell, M.D. Robson, M. Brady; Oxford/UK (Alexandre.Bagur@perspectum-diagnostics.com)

Purpose: Proton density fat fraction (MRI-PDFF) is the leading imaging biomarker for the early diagnosis and monitoring of non-alcoholic fatty liver disease (NAFLD). Typically calculated using chemical shift-encoded (CSE) water-fat separation, it can be complicated by clinical MRI phase images being inaccessible or containing errors. We introduce a confounder-corrected, magnitude-based CSE method that is robust to artefacts and unambiguous over the entire 0-100% MRI-PDFF range.

Methods and Materials: The method embodies multi-peak fat spectral modelling and model fitting with multipoint search optimisation. Simulations evaluated the feasibility of the method in multi-echo gradient echo protocols. Publicly available phantom data was used to evaluate bias, linearity and reproducibility of the method across manufacturers, field strengths and acquisition settings. Abdominal human acquisitions at 3T that generated artefacts in our implementation of IDEAL were used to evaluate the robustness of the new method to clinical practice.

Results: Excellent MRI-PDFF accuracy and reproducibility observed across manufacturers, field strengths and acquisition settings in the phantom experiment (linear regression: mean r-squared = 0.999, mean slope = 0.995, mean intercept = 0.298% MRI-PDFF). The water-fat ambiguity that typically challenges magnitude-based methods was resolved using our method. Increased robustness to local variability and fat-water swap artefacts was observed in the previously challenging 3T human acquisitions.

Conclusion: The introduced magnitude-based MRI-PDFF reconstruction method is accurate and robust across manufacturers, field strengths and acquisition settings. The method shows potential for standardisation and enables increased accessibility to MRI-PDFF in the clinic, notably because it does not require access to phase images.

Quantification of abdominal subcutaneous adipose tissue in MRI of obese patients

N.P. Linder, K. Solty, A. Hartmann, M. Blüher, R. Stange, H. Busse; Leipzig/DE (linder@uniklinik-leipzig.de)

Purpose: To evaluate a novel approach for segmentation of abdominal subcutaneous tissue (ASAT) in obese patients. Gantry size often limits full imaging of obese patients. We hypothesized that the equal distribution of subcutaneous adipose tissue on both sides of the body enables ASAT prediction from one-sided segmentation.

Methods and Materials: Abdominal MRI was performed at 1.5T using a 2-point Dixon sequence and complete images were segmented within the Dicomflex framework (Stange et al. 2018). After segmentation, the total volumes were divided into half resulting in hemiASAT-R and hemiASAT-L. Results were blotted against the total volume of ASAT (vASAT) and corresponding conversion factors yielded estimated total volume of ASAT (eASAT). Statistical measures of agreement were the coefficient of determination R^2 of a linear regression through the origin as well as the standard deviations of the differences between measured and predicted volumes.

Results: A total of 26 patients (13 females, mean BMI was 34.0 kg/m²) was identified and all images could be included into the analysis. Mean vASAT was 12,466 (range 7,170 - 23,741) cm³. Correlation between total and half-side ASAT yielded good results ($R^2 > 0.99$), slightly better for the left side of the body. Mean eASAT was 12,721 (7,491-23,951) cm³. Standard deviations of the differences between vASAT and eASAT were 359 cm³.

Conclusion: The observed, equal distribution of ASAT holds promise for the prospective analysis of half-side MRI of subcutaneous adipose tissue.

MR imaging relaxation times of pancreatic tissue measured in vivo at 7.0 Tesla

M. Damen¹, M.S. van Leeuwen², A. Webb¹, D.W. Klomp², C. Arteaga de Castro²; ¹Leiden/NL, ²Utrecht/NL

Purpose: Distinction of pancreatitis from pancreatic cancer is challenging with conventional MRI. High field MR offers higher SNR, CNR and resolution than lower fields, potentially offering better diagnostic imaging. However, at 7T image artefacts occur, particularly in the abdomen, ultimately hampering image quality. By using a multi-transmit system, these artefacts can be reduced using optimized channel combination. Though, MR protocols for 7T still need to be optimized. Here, we determine the mean T1 and T2 relaxation times of pancreas at 7T, and optimize T2-weighted protocols for high-resolution imaging of the pancreas.

Methods and Materials: 24 healthy volunteers were scanned with a 7T MR system using eight parallel transmit antennas, each with two additional receive loops, positioned around the abdomen. RF phase shimming was performed to maximize the transmit field in the pancreas region. A Look-Locker-sequence (TFE) was used to obtain images for T1 determination, while T2 was determined from the images acquired with different echo times in one slice. T1 and T2 times were calculated using a mono-exponential fit of the average magnitude signal from an ROI contained in the pancreas. Optimized T1-weighted images were acquired using DIXON sequences, and T2-weighted MRI using multi 2D single-shot TSEs.

Results: The average T1 and T2 relaxation times found in healthy pancreas were 896±145ms, and 27±5ms, respectively.

Conclusion: We determined the T1 and T2 relaxation times for healthy pancreas at 7T and optimized imaging protocols, that can be used to discriminate healthy from pancreatic cancer tissue based on its T2 differences.

B-0767 15:13

Magnetic resonance 4D-flow derived mean pulmonary arterial pressure at 3T: a validation study

U. Reiter¹, G. Kovacs¹, C. Reiter¹, C. Kräuter¹, A. Greiser², H. Olschewski¹, M.H. Fuchsjaeger¹, G. Reiter¹; ¹Graz/AT, ²Erlangen/DE (ursula.reiter@medunigraz.at)

Purpose: A close linear relationship between mean pulmonary arterial pressure (mPAP) measured with right-heart catheter (RHC) and duration of vortical blood flow along the main pulmonary artery was reported from 1.5T magnetic resonance 4-dimensional (4D) flow imaging. We hypothesized that this relationship is also valid at 3T, and tested accuracy for the diagnosis of pulmonary hypertension (PH) at 3T in a prospective study.

Methods and Materials: 133 patients with known or suspected PH (PH/nonPH, 87/46) underwent RHC and time-resolved, 3-directional phase-contrast imaging covering the main pulmonary artery at 3T. Duration of vortical blood flow along the main pulmonary artery (t_{vortex}) were assessed from velocity vector-fields using prototype software (4DFlow, Siemens Healthcare), and

were used to determine $mPAP_{MR} = 16 + 0.63 \cdot t_{vortex}$. Relationships between mPAP and mPAP_{MR} were analyzed by correlation and Bland-Altman analysis. The diagnostic performance of mPAP_{MR} to diagnose PH (mPAP_{MR} ≥ 25 mmHg) was investigated by receiver operating characteristic curve analysis.

Results: mPAP and mPAP_{MR} revealed no bias (35±15 mmHg vs. 35±13 mmHg, p=ns), standard deviation of errors was small (4 mmHg), and the correlation between mPAP and mPAP_{MR} was very strong ($r=0.96$). Area under the curve for the diagnosis of PH using mPAP_{MR} was 0.99. Employing 25 mmHg as cut-off value for PH, mPAP_{MR} predicted PH with a sensitivity/specificity of 0.98/0.89 (confidence intervals, 0.92-1.00/0.76-0.96).

Conclusion: Results confirm that the 1.5T relationship between RHC-derived mPAP and duration of vortical blood flow along the main pulmonary artery is also valid at 3T, and that PH can be diagnosed at 3T with equivalent accuracy.

Contrast-enhanced MR images employed in stereotactic radiosurgery: does susceptibility-related distortion pose a significant problem?

D.P. Dellios¹, E.P. Pappas¹, I. Seimenis², P. Karaiskos¹; ¹Athens/GR, ²Alexandroupolis/GR (d.dellios@med.uoa.gr)

Purpose: This study aimed at characterizing and evaluating MR image distortion stemming from susceptibility effects associated with the uptake of gadolinium diethylenetriamine pentaacetic acid (Gd-DTPA), a paramagnetic contrast agent routinely used for target localization and delineation in stereotactic radiosurgery (SRS).

Methods and Materials: A custom-made, head-sized phantom incorporating 947 control points and two cylindrical inserts was imaged at 1.5T. The inserts were filled with Gd-DTPA solutions (0-20 mM) to simulate small brain lesions. The read gradient polarity reversal and field mapping techniques were employed to assess total sequence-dependent distortion at the insert locations and B_0 inhomogeneity-related distortion, respectively. The net centroid offset stemming from Gd-DTPA susceptibility alone was deduced by subtracting the B_0 inhomogeneity-related distortion from the estimated total distortion. The same methodology was applied to Gd-enhanced images with brain metastases.

Results: Both techniques provided detailed distortion maps, although the reversed gradient method proved extremely straightforward and efficient. In the phantom study, Gd-DTPA presence significantly affected insert positions, whilst severe warping was observed at specific locations for concentrations >5mM. Under the imaging conditions studied, an average insert centroid offset of 0.068mm/mM (0.204ppm/mM) was estimated. In patient images, the observed total distortion magnitude, ranging from 0.35mm to 0.87mm, was mostly affected by the location dependent relative signs of the B_0 inhomogeneity and susceptibility-related distortion components.

Conclusion: Target mispositioning in contrast-enhanced MR images could adversely affect the efficiency of SRS treatment planning, especially in locations where Gd-DTPA-induced susceptibility and B_0 inhomogeneity add to each other, thus resulting in increased overall distortion.

Radiogenomics of non-small cell lung cancer (NSCLC): association between CT-based imaging features and EGFR and K-RAS mutations in 122 patients: an external validation

C. Fanciullo¹, F. De Piano¹, E. De Jong², S. Raimondi¹, V. Buscarino¹, S. Rizzo¹; ¹Milan/IT, ²Maastricht/NL (cristiana.fanciullo@unimi.it)

Purpose: To validate previously identified associations between semantic radiomic features and clinical features with EGFR/KRAS alterations in patients with NSCLC.

Methods and Materials: CT images of 122 patients with NSCLC tested for EGFR/KRAS alterations were included. Clinical and semantic radiomic features were recorded. Univariate and multivariate analyses were performed to look at the associations of the studied features with EGFR/KRAS alterations. Previously calculated model parameters for each gene alteration prediction

were applied to the validation cohort and ROC (receiver operating characteristic) curves were drawn according to each significant characteristic in the training cohort and the full model. The area under the ROC curve (AUC) with 95% confidence intervals (CI) was calculated and compared between different models.

Results: At univariate analysis, EGFR+ confirmed an association with an internal air bronchogram, pleural retraction, emphysema and smoking; KRAS+ with round shape, emphysema and smoking. The AUC (95%CI) for the validation cohort was confirmed to be high for EGFR+ prediction, resulting in 0.82 (0.69-0.95) vs. 0.82 in the training cohort, whereas it was smaller for KRAS+ prediction, resulting in 0.60 (0.48-0.72) vs. 0.67 in the training cohort. Looking at single features in the validation cohort, we found that the AUC for the models including only smoking was similar to that of the full model (including semantic and clinical features) for both gene alterations.

Conclusion: This study validated the significant association of internal air bronchogram, pleural retraction, lack of emphysema and smoking with the EGFR+ mutation; round shape and smoking with KRAS rearrangement.

B-0770 14:08

Correlation between EGFR gene mutation and CT, clinical features and pathological subtypes in ground glass lung adenocarcinoma

L. Kang, X. Zhang, X. Chen, H. Li; *Zhengzhou/CN (18558267@qq.com)*

Purpose: To investigate the relationship between epidermal growth factor receptor (EGFR) and CT, clinical features and pathological subtypes in ground glass lung adenocarcinoma.

Methods and Materials: 108 Ground Glass lung adenocarcinomas confirmed by pathology were included. All cases were divided into two groups: effective mutation group and null mutation group. The patient gender, age, history of smoking, lesion location, size and CT features (including border, shape, margin, bubble-like lucency, air-bronchogram, pleural retraction, GGO proportion) and histological subtype were assessed. The comparison of size between two groups was performed by rank sum test. Two independent sample T test was used for comparison of age, and the chi square test was used for other indicators. *P*-values <0.05 were considered significant.

Results: In 108 cases of glass lung adenocarcinoma, 93 cases of effective mutation group, 15 cases of null mutation group, the mutation rate was 86.1%. The average age of effective mutation group (93 cases) and null mutation group (15 cases) was 49 ± 10.62, 60.75 ± 8.18, respectively. There was significantly different between two groups (*t*=-4.945, *P*<0.05). Patient gender, CT features and histological subtype were not significantly different between the two groups (*P*>0.05).

Conclusion: The mutation rate of EGFR gene was higher in patients with ground glass lung adenocarcinoma, and the mutation was more likely to occur in patients with (49 ± 10.62) years old. There was no relationship between EGFR mutation and gender, history of smoking, CT features and histological subtype in ground glass lung adenocarcinoma.

B-0771 14:16

Evaluation of pre-treatment FDG PET-CT-based imaging parameters and textural features as prognostic indicators in non-small cell lung carcinoma

G.M. McDermott¹, P. Brown¹, A. Scarsbrook²; ¹Leeds/UK, ²York/UK (*garry.mcdermott@nhs.net*)

Purpose: To determine whether metabolic tumour parameters and radiomic features (RFs) derived from fluorine-18 fluorodeoxyglucose (FDG) positron emission tomography-computed tomography (PET-CT) are prognostic predictors in patients with non-small cell lung carcinoma (NSCLC).

Methods and Materials: Patients with NSCLC who underwent FDG PET-CT before lung biopsy and pre-treatment at a single cancer centre were studied. Primary tumour segmentation using semi-automated thresholding based on mean liver standardised uptake value (SUV_{mean}) and radiomic analysis (first- and second-order feature extraction) were performed using LIFEX software (University of Paris-Saclay, France). Lesions less than 64 pixels (5cm²) were excluded. Uni- and multi-variate analyses were performed to assess RF prediction of progression-free survival (PFS).

Results: 81 patients were included in analysis, mean age 69 (range 41-89), 40 (49%) were male. Tumours were staged T1-T4 (7%, 59%, 10% and 24%, respectively), N0-3 (37%, 15%, 31% and 14%, respectively) and M0-1 (81% and 19%, respectively). Patients were censored at time of recurrence, progression, death or loss-to-follow up, median 10.0 months (IQR: 4.0 - 38.5 months). 51 (63%) patients were censored due to progression/death during follow-up. Metastatic status and 4 CT-derived RFs (CT entropy, CT energy, CT grey-level co-occurrence matrix (GLCM)-homogeneity and CT grey-level run length matrix-short-run emphasis (GLRLM-SRE)) were statistically significant predictors (*p*<0.05) of PFS on multi-variate analysis. Tumour stage, nodal status and all PET-derived RFs were not statistically significant predictors.

Conclusion: CT-derived RFs may be better prognostic predictors of outcome than PET RFs in patients with NSCLC.

B-0772 14:24

Value of TSCT features in differentiating pre- and minimally invasive from invasive adenocarcinoma presented as ground-glass nodules smaller than 3 cm

J. Qi, Q. Weng, H. Wang, S. Fang, X. Wu, M. Chen, Z. Wang, M. Xu; *Lishui/CN (lshrijs@163.com)*

Purpose: To distinguish the invasive adenocarcinoma (IA) from pre-invasive (AIS/AAH) and minimally invasive adenocarcinoma (MIA) appearing as solitary ground-glass nodules (GGNs) less than 3cm by thin-section computed tomography (TSCT) features to guide therapeutic approach.

Methods and Materials: A total of 154 lesions histopathologically confirmed with pre-/minimally invasive adenocarcinoma (hereafter pre/MIA) or IA presented as part-solid GGNs (mGGNs) or pure GGNs (pGGNs) were retrospectively reviewed. The TSCT features, including diameter, area, density, shape, vacuole sign, vessels passing, air-bronchogram, margin, and location were compared and assessed thoroughly. Receiver operating characteristic (ROC) analyses were conducted to determine the cut-off values for the qualitative variables and their diagnostic performances.

Results: Of 154 nodules, 89 AI, 53 MIA, 8 AIS, and 4 AAH were found. Univariate and multivariate logistic regression of the pre/MIAs and IAs were analysed in mGGNs and pGGNs, respectively. In pGGNs, the significant difference was found in the area (*P*=0.004, *OR*=0.124, 95%*CI*: 0.30-0.515) between pre/MIA and IA groups. In mGGNs, significant differences were found in diameter (*P*=0.001, *OR*=0.171, 95%*CI*: 0.063-0.467), density (*P*=0.001, *OR*=0.996, 95%*CI*: 0.993-0.998) and shape (*P*=0.102, *OR*=0.188, 95%*CI*: 0.25-1.397) between pre/MIA and IA groups. According to the corresponding ROC curve, the optimal cut-off tumour area in pGGNs to differentiate pre-/minimally invasive adenocarcinoma from invasive adenocarcinoma was 0.59cm². Higher CT values of lesion (≥ -298.5HU) and larger diameter (≥1.45cm) in mGGNs were significantly associated with IAs.

Conclusion: Imaging features of TSCT is able to distinguish IAs from pre/MIAs in GGNs and may contribute to guide the clinical management of lesions.

B-0773 14:32

CT bronchovascular bundle thickening sign as a predictor of survival in patients with peripheral small cell lung cancer 3 cm or smaller

P. Sung, S. Yoon; *Seoul/KR*

Purpose: To determine whether bronchovascular bundle thickening (BVB) sign on pretreatment CT images help predict the survival in patients with peripheral small cell lung cancer (SCLC) 3cm or smaller.

Methods and Materials: We retrospectively reviewed the pretreatment CT scans of 79 consecutive patients who had pathologically proven peripheral SCLC 3cm or less in diameter (TNM stage I, 21; II, 13; III, 22; IV, 23). The CT characteristics of the nodule and associated findings including the BVB sign were evaluated. We compare the overall survival (OS) and progression-free survival (PFS) using Kaplan-Meier and Cox-regression analysis between the patients with BVB sign and those without it.

Results: Among 79 the patients, 34 (43%; 95% CI, 33-54%) had BVB sign. Patients with BVB sign had more frequent mediastinal lymph node metastasis and distant metastasis than those without (50.9% vs 22.7%; *p*=0.041: 60.9% vs 35.7%; *p*=0.049). Those without BVB sign showed better PFS and OS, however they were statistically insignificant (mean, 838 vs 344 days, respectively; *p*=0.058: mean, 1898 vs 1258 days, respectively; *p*=0.120). For 21 patients with TNM stage IA, 16 patients (76%) without BVB sign showed better PFS and OS (mean, 1630 vs 483 days, respectively; *p*=0.023: mean, 2243 vs 1328 days, respectively; *p*=0.038). Multi-variate Cox proportional hazard model showed that BVB sign and associated idiopathic pulmonary fibrosis are poor prognostic factors for PFS (*p*=0.045; *HR*=5.001; 95% CI, 1.036-24.131: *p*=0.028; *HR*=10.536; 95% CI, 1.288-86.175).

Conclusion: The absence of BVB sign was potentially associated with better PFS in stage IA peripherally located SCLC.

B-0774 14:40

Computerised texture analysis predicts histological invasiveness within lung adenocarcinoma manifesting as pure ground-glass nodules

Y. Yang, H. Liu; *Shanghai/CN (yang_yang61@126.com)*

Purpose: To investigate the value of computerised texture analysis for predicting histological invasiveness of pulmonary adenocarcinoma that manifests as pure ground-glass nodules (pGGNs).

Methods and Materials: The study consisted of 138 patients with 142 pathologic analysis-confirmed pGGNs who had undergone computed tomographic (CT) imaging. Each nodule was manually segmented and its computerised textural features were extracted. Seven best features were chosen using hierarchical cluster analysis and the ReliefF method. Multivariate logistic regression analysis was performed to distinguish adenocarcinoma in situ (AIS) and minimally invasive adenocarcinoma (MIA) from invasive adenocarcinoma (IAC). Performance of the logistic regression was evaluated by receiver operating characteristic (ROC) curve analysis.

Results: Pathologic analysis confirmed 26 AISs, 71 MIAs and 45 IACs. Seven best features (10 percentile, maximum 3D diameter, surface volume ratio, elongation, maximum probability, large area low gray level emphasis and zone entropy) were chosen using hierarchical cluster and the ReliefF method. Multivariate logistic regression analysis revealed larger maximum 3D diameter, lower surface volume ratio and higher zone entropy as independent differentiators of IACs (adjusted odds ratio [OR]=1.59, P=0.011; OR=0.47, P=0.002; OR=6.78, P=0.001, respectively). The accuracy based on the logistic regression model using these features for differentiating IAC from AIS/MIA reached 78.7% with ROC analysis (AUC, 0.861; sensitivity, 78.0%; specificity, 80.0%).

Conclusion: In patients with pGGN, computerised texture analysis has the potential to differentiate histological invasiveness, especially maximum 3D diameter, surface volume ratio and zone entropy are independent differentiators of IACs from AISs and MIAs.

B-0775 14:48

The comparison of hook wire vs coil localisation for video-assisted thoracoscopy surgery

D. Kim, Y. Song; Changwon/KR (tobealight@naver.com)

Purpose: A hook wire has been widely used for CT-guided localisation before video-assisted thoracoscopic surgery (VATS). However, microcoils have been suggested to replace wires. The purpose of this study was to compare the efficacy, VATS procedure time, and excised volume of specimens of CT-guided localisation using a hook wire and microcoil.

Methods and Materials: The medical records of 106 patients with 110 pulmonary nodules who underwent CT-guided localisation using a hook wire (group A) or microcoil (group B) before VATS performed between March 2013 and January 2017 were retrospectively reviewed.

Results: The procedure success rate was 100% in both groups. Dislodgement occurred in four patients in group A and not in group B. Patient pain score was significantly lower for group B than group A (4.0 vs. 6.3; P < 0.001). The VATS success rate was higher in group B than in group A (98.1% vs. 91.1%; P = 0.174). The VATS procedure time was significantly shorter for group B than group A (18.8 vs. 23.6 minutes; P = 0.004). The excised volume of surgical specimens was significantly smaller for group B than group A (8.5 vs. 11.7 cm³; P = 0.043). No major complications related to the localisation procedure were noted in either group.

Conclusion: This study showed similar effectiveness of VATS localisation between groups. However, microcoil is superior to hook wire for localisation of pulmonary nodules in terms of VATS procedure time and excised volume of surgical specimens, with the advantages of no dislodgement and less patient pain

B-0776 14:56

Hook-wire localisation vs lipiodol localisation for patients with pulmonary lesions having ground-glass opacity: the LOGIS trial

J. Hur¹, C.H. Park¹, S.M. Lee¹, J.W. Lee¹, S.H. Hwang¹, J.S. Seo¹, K.H. Lee¹, W. Kwon², D.J. Im¹; ¹Seoul/KR, ²Wonju/KR (khuhz@yuhs.ac)

Purpose: The aim of this study was to compare the usefulness and safety of the lipiodol and hook-wire localisation techniques.

Methods and Materials: This prospective, non-randomised comparative study was conducted between April 2014 and December 2016 at 8 qualifying university teaching hospitals. Two hundred and fifty patients with pulmonary lesions having GGO were included based on the following criteria: pulmonary lesion < 3 cm with GGO >50%; persistence or growth of the lesion during the 3-month follow-up. Patients were assigned in a 1:1 ratio to either the lipiodol (n=125) or hook-wire group (n=125) for preoperative localisation procedures. The primary endpoint was the procedure success rate. Secondary endpoints were procedure-related complication rate, localisation procedure duration, and the resected specimen's safety margin from the lesion.

Results: The procedure success rates (hook-wire vs lipiodol group) were 94.40% vs 99.16% (P=.084); complications occurred in 53.60% vs 48.33% of patients (P=.487). Haemorrhage and dislodgement rates were significantly higher in the hook-wire group (21.6% and 5.6%) compared to lipiodol group (5.83% and 0%) (p<.001, and p=.024, respectively). The lipiodol procedure time was significantly longer than that of the hook-wire technique (20.69±9.34 vs 17.15±7.91 min, P=.001). The initially positive surgical resection margin was significantly higher in the hook-wire group (10.53% vs 2.86%, P=.048).

Conclusion: There was no significant difference in success rate between the hook-wire and lipiodol methods. However, the haemorrhage and dislodgement rates were significantly higher in the hook-wire group, while the hook-wire group showed higher initially positive surgical resection margins.

B-0777 15:04

Diagnostic accuracy of F-18 FDG PET/CT in mediastinal lymph nodal staging of recently diagnosed carcinoma lung

R. Kumar^E, R. Verma, A. Dhamija, E. Belho, V. Gupta, H. Mahajan, V. Mahajan; New Delhi/IN (ramji2k8@gmail.com)

Purpose: The aim of the study is to evaluate the diagnostic accuracy of FDG PET/CT in mediastinal lymph nodal staging in carcinoma lung patients.

Methods and Materials: A total of 120 recently diagnosed lung carcinoma patients, who underwent pre-treatment staging FDG PET/CT between March 2016 and May 2018 were included in the study. Lymph nodes more than 1cm in short axis and SUV max more than 3.0 in F-18 FDG PET/CT scan were considered suspicious for metastasis and correlated with their pathological reports. Clinical TNM staging assessed with PET/CT was compared with pathological TNM staging using appropriate statistical methods.

Results: A total of 3117 lymph nodes with a mean of 26 lymph nodes per patient were resected. 179 nodes were reported metastatic, 37 as granulomatous and rest non-specific. FDGPET/CT staged 68 (56.7%) patients as N0, 18 (15%) as N1, 28 (23.3%) as N2, 6 (5%) as N3. The overall per nodal station basis sensitivity, specificity, positive predictive value, negative predictive value and accuracy was 51.2%, 98.3%, 84%, 92.2% and 91.4%. On comparing N staging on PET CT with pathological N staging, 85 (70.8%) patients were staged accurately, 22 (18.3%) were over-staged and 13 (10.8%) were under-staged.

Conclusion: FDG PET/CT is an accurate imaging modality for mediastinal lymph nodal staging in carcinoma lung patients. However, in view of low sensitivity due to limited spatial resolution of the PET scanner and low positive predictive value in granulomatous disease epidemic regions, like India, it is not an alternative to pathological staging.

B-0778 15:12

Dual-energy CT (DECT) lung tumour perfusion: can we distinguish features that can reflect prognosis?

J. Dewaguet¹, M.-C. Copin¹, J.-B. Faivre¹, V. Deken¹, M. Sedlmair², J. Remy¹, M. Remy-Jardin¹; ¹Lille/FR, ²Forchheim/DE (martine.remy@chru-lille.fr)

Purpose: To investigate potential relationships between DECT perfusion characteristics and prognostic histopathologic features.

Methods and Materials: A two-phase DECT scanning protocol was obtained in the presurgical evaluation of 49 tumours (squamous cell carcinomas: n=12; adenocarcinomas: n=37), including (a) an early phase over the entire thorax (ROI within the ascending aorta) (i.e., intravascular phase of tumoural perfusion); (b) completed by a delayed acquisition over the tumour, 50 s later (i.e., interstitial phase of tumoural perfusion). The first-pass and delayed iodine concentration (IC; mg/mL) and the arterial enhancement fraction (AEF=first pass IC/delayed IC x 100) were calculated over the entire tumour and within the most peripheral 2-mm-thick tumour layer, automatically segmented. The expression of the membranous carbonic anhydrase IX (mCAIX), an immunohistochemical marker of hypoxia, was assessed in tumour specimens.

Results: 33 tumours were mCAIX positive (Group 1) and 16 mCAIX negative (Group 2), the former showing a statistically significantly larger volume (p=0.04). At the level of the whole tumour, the delayed IC was significantly higher than that at first pass (median: 1.53 vs 1.4; p=0.04), suggestive of extravascular leakage within the interstitial space; there was no difference in DECT perfusion parameters between the two groups. Compared to Group 2, the outer layer of Group 1 tumours had significantly higher median values of IC (0.53 vs 0.21; p=0.02) and AEF (102.6 vs 65.6; p=0.02) with a trend toward higher delayed IC (0.48 vs 0.39; p=0.35).

Conclusion: DECT can provide insight into perfusion characteristics at the level of the tumoural invasion front.

The effect of different monochromatic image choices on the accuracy of CT perfusion values for lung tumour in one-stop spectral and perfusion CT scan

H. Wang, S. Yue, P. Lu, W. Li; Zhengzhou/CN (1508249322@qq.com)

Purpose: To assess the effect of monochromatic images with different energy levels on the accuracy of CT perfusion data in one-stop spectral and perfusion CT scan.

Methods and Materials: One-stop spectral and perfusion CT scan(including whole tumour perfusion CT and whole lung contrast-enhanced CT) was performed in 42 patients with lung tumour. Monochromatic images with energy level from 40 to 140 keV (group A1 to A11) generated from spectral CT were used to reconstruct CT perfusion images with primary perfusion data. CT perfusion parameters including blood volume (BV), blood flow (BF),mean transit time (MTT) and permeability surface (PS) were measured to compare

between benign (n=20) and malignant (n=22) tumours by using independent-t test. Receiver operating characteristics (ROC) analysis was performed to calculate cut off values for the differentiation between benign and malignant tumour.

Results: BV, BF values of group A1 to A11 and PS values of group A1 to A7 was significantly higher in malignant tumour than in benign tumour. ROC analysis for differentiation between benign and malignant tumours showed larger area under the curve (AUC) of BV, BF value in group A5 and PS in group A6. Sensitivity, specificity were 88.2% and 93.3% respectively at a cut-off value of 6.89 ml/100g for BV and 103.4 ml/(100g*min) for BF in group A5. The cut-off value of PS in group A6 was 10.27 ml/(100g*min), generating sensitivity of 83.9% and specificity 73.3%.

Conclusion: Use of 80 keV for reconstruction of one-stop spectral and perfusion CT showed higher value of differentiation between benign and malignant lung tumour.

Value of fractional flow reserve computed from triple-rule-out CT angiography data in the emergency department

S.S. Martin¹, M. van Assen², A.M. Fischer³, C.N. De Cecco¹, M. Bauer¹, A. Varga-Szemes¹, D. Mastrodicasa¹, U.J. Schoepf¹; ¹Charleston, SC/US, ²Groningen/NL, ³Mannheim/DE (simartin@outlook.com)

Purpose: The aim of this study was to evaluate the additional value of non-invasive fractional flow reserve (CT-FFR) derived from triple-rule-out (TRO) coronary computed tomography angiography (CTA) data in the emergency department (ED).

Methods and Materials: On-site CT-FFR was calculated in 159 of 226 (70%) eligible patients with coronary artery diseases (CAD) who had undergone TRO-CTA. The agreement of CT-FFR (≤ 0.80) with stenosis on coronary CTA ($\geq 50\%$), as well as additional cardiac diagnostic testing, was investigated. Furthermore, the predictive value of CT-FFR and CTA for coronary revascularization and major adverse cardiac events (MACE) was retrospectively assessed during a one-year follow-up period.

Results: CT-FFR results showed agreement with coronary CTA in 70% (111 of 159) of all cases. CT-FFR (≤ 0.80) served as a better predictor for coronary revascularization or MACE than assessment of stenosis ($\geq 50\%$) on coronary CTA (hazard ratio [HR], 3.0; 95% CI, 1.0-9.6 vs. HR, 2.5; 95% CI, 0.8-7.9) ($P = 0.03$). Further diagnostic cardiac testing was performed in 58% (92 of 159) and included SPECT ($n = 60$), stress echocardiography ($n = 31$), and stress MRI ($n = 1$). The agreement with additional diagnostic testing was significantly higher for CT-FFR (63%; 58 of 92) than for coronary CTA results (49%; 45 of 92) ($P = 0.01$).

Conclusion: CT-FFR derived from TRO coronary CTA was a better predictor for coronary revascularization or MACE and showed better agreement with additional diagnostic testing than significant stenosis on CTA. Therefore, CT-FFR may improve the efficiency of the workup in patients presenting to the ED.

CT-FFR profiles in patients without coronary artery disease: the effect of location and lumen area

R.R. Baver¹, M. van Assen², S.S. Martin¹, R.H. Savage¹, R. Steinbach¹, A.M. Fischer³, L.P. Griffith¹, U.J. Schoepf¹; ¹Charleston, SC/US, ²Groningen/NL, ³Mannheim/DE (bayer@muscu.edu)

Purpose: To evaluate the influence of measurement location and lumen diameter changes on CT-FFR values in normal patients.

Methods and Materials: Patients were included who underwent Calcium scoring (CACS) and CCTA with CT-FFR. Patients were excluded if the CACS was not zero, if there were increased troponin levels or any other cardiac abnormality on the CT-images. On-site CT-FFR was computed for each coronary artery at proximal, mid and distal segments. At each measurement location, the lumen area was measured. CT-FFR was considered positive < 0.75 . The relationship between CT-FFR and lumen areas were evaluated for each coronary artery and each location.

Results: 106 patients were included with corresponding CT-FFR measurements. An overall of 99 (31%) coronary arteries had CT-FFR values < 0.75 , all at distal locations. In 42 (40%) patients the LAD had distal CT-FFR values < 0.75 (mean 0.62 (SD 0.10)). The RCA shows similar results with distal CT-FFR values < 0.75 in 65 (61%) patients (0.61 (0.12)). The Cx shows only a limited number of patients (16, 15%) with distal CT-FFR values < 0.75 (0.65 (0.09)). CT-FFR and lumen area showed good correlation: 0.728 (p -value < 0.001) for the LAD, 0.660 (p -value < 0.001) for the Cx and 0.712 (p -value < 0.001) for the RCA. The lumen areas were not significantly different between the > 0.75 and < 0.75 group (p -value < 0.001).

Conclusion: CT-FFR values in patients without coronary artery disease can become positive at a distal location without indicating flow-limiting stenosis independent of lumen area. CT-FFR values measured distal should always be interpreted in combination with the CCTA images.

High-risk and lipid-rich, but not calcified, plaque predicts ischaemia in non-obstructive lesions (ANOCA): a CTA/CTFFR study

G. Feuchtner, C. Langer, F. Barbieri, C. Beyer, G.J. Friedrich, F. Plank; Innsbruck/AT (Gudrun.Feuchtner@i-med.ac.at)

Purpose: ANOCA (angina in the absence of obstructive coronary stenosis) is frequent in patients referred to coronary CTA. The morphological correlate is unclear. Aim was to assess which plaque types by coronary CTA predict ischaemia in ANOCA.

Methods and Materials: 106 patients with low-to-intermediate risk referred to 128-slice dual-source CT angiography (atypical chest pain, 89.1%) were included. CTA data were transferred to coronary fluid dynamics (CFD) modelling (Heartflow Inc.); lesion-based and distal FFR_{CT} were calculated. CTA analysis included 1) stenosis severity (CADRADS); 2) plaque composition 1-4 (non-calcified, mixed or calcified) total (SIS), mixed (G-score) plaque burden; 3) High-risk plaque criteria (Napkin-Ring sign, plaque density (HU), positive remodelling, spotty calcification); 4) coronary calcium score; 5) qCTA stenosis.

Results: 89 non-obstructive lesions with $< 70\%$ stenosis (40 high-risk-plaque, 40 calcified and 9 non-calcified) matched for qCTA (%area, %diameter stenosis) were included. In high-risk plaque, lesion-based and distal FFR_{CT} were lower as compared to calcified ($p < 0.001$ and $p = 0.002$), respectively. Prevalence of ischaemia (FFR_{CT} < 0.8) (25% vs. 2.5%, $p = 0.007$ for lesion based), and 40% vs 17.5% for distal FFR_{CT} was higher in high-risk plaque compared to calcified. Lower plaque density (HU) ($p = 0.024$) predicted ischaemia in low-attenuation plaque (LAP) < 300 HU, with an strengthened correlation for all lesions (LAP+calcified) ($p = 0.003$) on linear regression analysis. Positive remodelling was associated with lower FFR_{CT} distal ($p = 0.042$), and an increasing non-calcified plaque burden (G score) ($p = 0.008$), but not total (SIS) and calcium score.

Conclusion: High-risk plaque and an increasing lipid-necrotic core and total non-calcified plaque burden predict ischaemia in non-obstructive lesions and explain ANOCA, and while an increasing calcium-density acts contrary.

Comparison between stress CT perfusion versus FFRCT in the evaluation of suspected CAD: PERFECTION prospective study

A. Baggiano¹, M. Guglielmo¹, G. Muscogiu¹, M. Soldi¹, A. Del Torto¹, A.I. Guaricci², M. Pepi¹, G. Pontone¹; ¹Milan/IT, ²Bari/IT (andrea.baggiano@gmail.com)

Purpose: The PERFECTION study is a longitudinal, prospective and consecutive cohort study to compare the feasibility and accuracy of FFRCT versus stress-CTP for the diagnosis of functionally significant CAD.

Methods and Materials: 147 consecutive symptomatic patients for chest pain referred for clinically indicated ICA plus invasive FFR were enrolled. The primary endpoint was to compare the diagnostic accuracy of cCTA versus cCTA+FFRCT versus cCTA+stress-CTP for the detection of significant CAD defined by ICA and invasive FFR.

Results: Rest cCTA was successfully performed in all patients, FFRCT was performed in 143/147 patients, stress-CTP was performed in 144/147 patients. cCTA demonstrated a vessel and patient-based sensitivity (SE), specificity

(SP), negative predictive value (NPV), positive predictive value (PPV) and diagnostic accuracy (ACC) of 99%, 76%, 100%, 61%, 82% and 95%, 54%, 94%, 63%, 74%, respectively. The diagnostic performance of integrated protocol of rest cCTA+FFRCT showed a vessel and patient-based SE, SP, NPV, PPV and ACC of 88%, 94%, 95%, 84%, 92% and 90%, 85%, 92%, 83%, 87%, respectively. Finally, the diagnostic performance of integrated protocol of rest cCTA+stress-CTP showed a vessel and patient-based SE, SP, NPV, PPV and ACC of 92%, 95%, 97%, 87%, 94% and 98%, 87%, 99%, 86%, 92%, respectively. Both FFRCT and stress-CTP significantly improved SP, PPV and overall ACC in both per-vessel and per-patient based model when added to cCTA, while no differences were found between cCTA+FFRCT versus cCTA+stress CTP.

Conclusion: Both FFRCT and stress-CTP are valid tools in addition to cCTA to evaluate the functional relevance of CAD.

B-0784 14:41

Coronary computed tomography angiography-derived fractional flow reserve in anomalous origin of the right coronary artery from the left coronary sinus

C. Tang¹, M. Lu¹, U.J. Schoepf², C. Tesche², M. Bauer², J.W. Nance², L. Griffith², C. Zhou¹, L. Zhang¹; ¹Nanjing/CN, ²Charleston, SC/US (522956587@qq.com)

Purpose: To examine fractional flow reserve derived from computed tomographic angiography (CT-FFR) in patients with anomalous origin of the right coronary artery from the left coronary sinus (R-ACAOS) with interarterial course, its relationship with anatomical features of R-ACAOS with interarterial course on coronary CT angiography (CCTA), and its clinical relevance.

Methods and Materials: Ninety-four patients with interarterial R-ACAOS undergoing CCTA were retrospectively included. Anatomic features (including proximal vessel morphology [oval or slit-like], take-off angle, take-off level [below or above pulmonary valve], take-off type, intramural course, %proximal narrowing, length of narrowing, minimum lumen area (MLA) at systole and diastole, and vessel compression index) on CCTA were analysed. Receiver operating characteristic analyses were performed to describe the diagnostic performance in detecting R-ACAOS with interarterial course with CT-FFR ≤ 0.80 .

Results: Significant differences were found in proximal vessel morphology, take-off level, intramural course, %proximal narrowing area, MLA at diastole (all $p < 0.05$) between normal and abnormal CT-FFR groups. Take-off level, intramural course, and slit-like ostium (all $p < 0.05$) predicted lesion-specific ischaemia (CT-FFR ≤ 0.80) with accuracies of 0.69, 0.71, and 0.81, respectively. Patients with CT-FFR ≤ 0.80 had a higher prevalence of typical angina (29.4% vs 7.8%, $p = 0.025$) and atypical angina (29.4% vs 6.5%, $p = 0.016$).

Conclusion: Take-off level, intramural course, and slit-like ostium were the main predictors of abnormal CT-FFR values. Importantly, patients with abnormal CT-FFR values had a higher prevalence of typical angina and atypical angina, suggesting CT-FFR as a potential tool to gauge the clinical relevance of patients with interarterial R-ACAOS.

Diagnostic performance of fractional flow reserve derived from coronary computed tomography angiography in myocardial bridging: a comparison with invasive fractional flow reserve

F. Zhou¹, Y. Wang², U.J. Schoepf³, C. Tesche⁴, L. Xu², Y. Hou⁵, J. Yan⁶, J.Y. Zhang⁶, L.J. Zhang¹; ¹Nanjing/CN, ²Beijing/CN, ³Charleston, SC/US, ⁴Munich/DE, ⁵Shenyang/CN, ⁶Shanghai/CN (nuzhout@126.com)

Purpose: To investigate the diagnostic performance of machine learning-based coronary CT angiography-derived fractional flow reserve (CT-FFR) to detect lesion-specific ischaemia in myocardial bridging (MB) using invasive FFR as reference standard.

Methods and Materials: This retrospective multicentre study included 107 MBs in 106 patients. An FFR value ≤ 0.80 was considered to be ischaemia-specific. MB was classified as either superficial or deep, while all MB vessels were further divided into 30%-69% and $\geq 70\%$ groups according to diameter stenosis on invasive coronary angiography. Diagnostic performance of CT-FFR to detect lesion-specific ischaemia was assessed on a per-vessel level, using invasive FFR as reference standard. Pearson's correlation analysis and Bland-Altman plots were used for agreement measurement.

Results: Of 107 MBs, 92 were classified as superficial. 49 MB vessels (45.8%) showed ischaemia by invasive FFR. Sensitivity, specificity, accuracy of CT-FFR to detect lesion-specific ischaemia were 0.94 (confidence interval [CI] 0.82-0.98), 0.84 (0.72-0.92), and 0.89 (0.81-0.94), respectively, in all MB vessels. There were no differences in diagnostic performance between superficial and deep MB (all $p > 0.05$). The accuracy of CT-FFR was 0.96 (0.85-

0.99) in $\geq 70\%$ stenosis and 0.82 (0.66-0.91) in 30%-69% stenosis ($p = 0.023$) with corresponding AUCs of 0.99 (0.91-1.00) and 0.86 (0.74-0.94) ($p = 0.013$). Bland-Altman analysis showed a mild systematic underestimation of CT-FFR values when compared to invasive FFR (mean difference = 0.014, 95% LoA: -0.12-0.15). The correlation coefficient was $r = 0.77$ ($p < 0.001$).

Conclusion: CT-FFR demonstrated high diagnostic performance for identifying lesion-specific ischaemia in vessels with MB when compared to invasive FFR, regardless of MB depth.

Coronary CT based on-site FFR might be a useful tool to identify haemodynamically relevant non-culprit lesions in patients who suffered myocardial infarction

J. Simon, B. Szilveszter, A. Ahres, M. Kolossvary, B. Jablonkai, B. Merkely, P. Andrassy, P. Maurovich-Horvat; Budapest/HU (juditsimon21@gmail.com)

Purpose: Prior studies demonstrated that CT-derived fractional flow reserve (CT-FFR) has excellent diagnostic accuracy for the identification of ischaemia-causing lesions in patients with stable chest pain. Non-invasive assessment of non-culprit lesions in patients who suffered myocardial infarction (MI) could improve risk stratification and guide therapy.

Methods and Materials: We enrolled 33 patients (58.24 \pm 9.3years, 33.3% female) who suffered MI with 47 non-culprit coronary lesions. CT-FFR was calculated with an on-site algorithm and values were compared to invasive FFR measured at the index event. FFR value < 0.80 was considered haemodynamically significant in both cases.

Results: The mean FFR-CT value was 0.85 \pm 0.10 while the mean invasive FFR value was 0.82 \pm 0.08. The sensitivity, specificity, positive predictive value and negative predictive value of FFR-CT versus invasive FFR was 33.3%, 89.7%, 66.7% and 68.4%, respectively (AUC=0.70). Correlation coefficient between CT-FFR and invasive FFR was 0.43 ($p = 0.002$).

Conclusion: The majority of non-culprit lesions of MI patients are in the grey-zone for FFR-CT and therefore the diagnostic performance of FFR-CT for the detection of lesion-specific ischaemia in post-MI patients is moderate. However, the high specificity of FFR-CT in this patient population might be useful test characteristics to identify patients who need revascularization.

The prognostic value of CT myocardial perfusion and CT-FFR for MACE in patients with coronary artery disease

M. van Assen¹, C.N. De Cecco², M. Eid³, M.J. Bauer⁴, M. Scarabello⁵, P. von Knebel Doeberitz⁵, M. Oudkerk¹, R. Vliethart¹, U.J. Schoepf⁶; ¹Groningen/NL, ²Atlanta, GA/US, ³Charleston, SC/US, ⁴Munich/DE, ⁵Milan/IT, ⁶Heidelberg/DE (m.van.assen@umcg.nl)

Purpose: To determine the prognostic value of dynamic CT perfusion and CT-derived fractional flow reserve (CT-FFR) for the prediction of major adverse cardiac events (MACE).

Methods and Materials: Patients from 4 institutes who underwent CCTA and stress dynamic myocardial perfusion CT (CTMPI) were included with a follow-up period of 18 months or until MACE occurred. On-site CT-FFR was computed for each coronary artery. A myocardial blood flow (MBF) index was calculated, for which each vessel territory was normalised to global MBF. The lowest CT-FFR and MBF index was selected for each patient. The prognostic value of CCTA, CT-FFR, and CTP was investigated with univariate and multivariate Cox proportional hazards regression models.

Results: 243 vessels in 81 patients were interrogated by CCTA with CT-FFR and 243 vessel territories (1,296 segments) were evaluated with dynamic CTP imaging. Of the 81 patients, 25 (31%) experienced MACE during follow-up. In univariate analysis, a positive index-MBF resulted in the largest risk for MACE (HR 11.4, 95%-CI: 3.4-38.2) compared to CCTA (HR 2.6, 95%-CI: 1.2-5.9) and CT-FFR (HR 4.6, 95%-CI: 2.0-10.5). In multivariate analysis, including clinical factors, CCTA, CT-FFR, and index-MBF, only index-MBF significantly contributed to the risk of MACE (HR 10.1, 95%-CI: 2.1-48.8), unlike CCTA (HR 1.2, 95%-CI: 0.4-3.5) and CT-FFR (HR 2.2, 95%-CI: 0.8-6.4).

Conclusion: Our study provides initial evidence that dynamic CTP alone has the highest prognostic value for MACE compared to CCTA and CT-FFR individually or a combination of the three, independent of clinical risk factors.

Iodine images in dual-energy CT: benchmarking quantitative iodine concentration values of the healthy liver

S. Beck, D. Deniffel, I. Riederer, E.J. Rummeny, D. Pfeiffer; *Munich/DE*
(stef.kaiser@gmail.com)

Purpose: To define quantitative reference values of iodine concentrations in portal venous phase Material Density (MD) iodine images in Dual Energy CT (DECT) for normal liver parenchyma.

Methods and Materials: The iodine concentration in the liver parenchyma as well as of the abdominal aorta and main portal vein were obtained in n= 182 patients in MD iodine images, obtained with a dual layer CT scanner. The iodine uptake was evaluated as the absolute iodine concentration and as a blood-normalized value. The influence of age and gender on the iodine uptake was examined.

Results: A significant difference could be observed for the absolute liver iodine concentration between genders (male: 1.928 mg/ml, female 2.310 mg/ml), yet not for the blood-normalized iodine concentration (male: 2.133 mg/ml, female 2.097 mg/ml). For the analysis of age, there was a significant negative correlation between the blood-normalized iodine concentrations and the patient age ($r = -0.269$). Standard iodine values for absolute iodine concentration ranged between 1.022 and 2.834 (male) and between 1.344 and 3.274 (female) and for blood-normalized iodine concentration between 1.451 and 2.783 (± 0.0054 / year).

Conclusion: The ranges for absolute iodine uptake vary with the patients' gender whereas the ranges for blood-normalized iodine uptake vary with the patients' age. Standard value ranges for normal quantitative iodine concentration in portal venous phase DECT images were defined for both, absolute and blood-normalized values.

DECT in the diagnosis of the efficiency of chelation therapy in patients with iron overload

A.M. Titova, V.A. Fokin, G.E. Trufanov, M.O. Ivanova; *St. Petersburg/RU*
(anisa33@mail.ru)

Purpose: The assessment of liver iron concentration (LIC) by MRI is the most accurate method of controlling chelation therapy in patients with iron overload. However, some patients cannot undergo MRI procedures, liver biopsy is invasive and has several limitations, and measurement of serum ferritin is unreliable. Therefore, DECT as a non-invasive, easily tolerated, low-dose and accurate method for quantitative monitoring of chelation therapy efficiency may be more appropriate.

Methods and Materials: We conducted T2* MRI study of the liver in 75 patients with suspected iron overload by 1.5T scanner for LIC assessment. We performed DECT procedures with 80kV and 140kV on the limited area of the liver of the same patient group with the slice thickness of 5mm. We ran a regression analysis to assess the prognostic capabilities of dual-energy ratio, dual-energy index and dual-energy difference (DED) and based on the best indicators, constructed a mathematical model for LIC quantification. A year later, we repeated the same procedures with calculation of dual-energy indicators to 26 of the examined patients receiving iron chelators.

Results: DED demonstrated the largest correlation with LIC ($r=0.93$). Based on the data of 75 patients, we obtained a regression equation. Using the mathematical model of 26 patients after chelation, in all cases using DED, we established the conformity of our findings to the MRI data.

Conclusion: DECT with using DED is a useful technique for the quantitative assessment of iron overload in patients who need a control of chelation therapy but cannot undergo MRI procedures.

A patient specific lumped parametric model based approach to fractional flow reserve derived from coronary computed tomography angiography

R.W. van Hamersvelt¹, M. Voskuil¹, P.A. de Jong¹, M.J. Willemink², T. Leiner¹;
¹Utrecht/NL, ²Menlo Park, CA/US (R.w.vanhamersvelt-3@umcutrecht.nl)

Purpose: The purpose of this study was to evaluate an on-site patient specific lumped parametric model based approach to fractional flow reserve derived from coronary computed tomography angiography (FFR-CT) for the detection of hemodynamically significant stenosis.

Methods and Materials: Patients who received a coronary computed tomography angiography (CCTA) within 60 days before invasive fractional flow reserve (FFR) were retrospectively selected. Hemodynamically significant coronary artery stenosis was defined as invasive FFR \leq 0.8. The diagnostic performance of the on-site FFR-CT method was evaluated and compared to that of degree of luminal coronary stenosis assessment on CCTA.

Results: In total 57 patients (mean age 58.5 \pm 9.2 years, 74% men) and 77 vessels were included. Hemodynamically significant stenosis was present in 37 vessels (48%). FFR-CT showed an improved diagnostic performance compared to degree of stenosis evaluation on CCTA with an area under the receiver operating characteristic curve (AUC) of 0.87 compared to 0.70 (difference in AUC of 0.17, $p < 0.01$), respectively. Sensitivity was similar between FFR-CT (89.2%) and degree of stenosis on CCTA (89.2%), while specificity substantially improved with FFR-CT (77.5% versus 42.5%, respectively).

Conclusion: Analysis with an on-site FFR-CT method improved diagnostic performance for the evaluation of hemodynamically significant stenosis compared to stenosis degree evaluation on CCTA.

Relationship between coronary CT angiography-derived fractional flow reserve and dynamic CT myocardial perfusion imaging in patients with coronary artery disease

M. van Assen¹, C.N. De Cecco², S.S. Martin³, A. Fischer³, R. Steinbach³, M. Oudkerk¹, R. Vliagenthart¹, U.J. Schoepf²; ¹Groningen/NL, ²Atlanta, GA/US, ³Charleston, SC/US (m.van.assen@umcg.nl)

Purpose: To investigate the correlation between functional parameters describing lesion-specific ischaemia obtained from CT perfusion and CT-FFR at various measurement vessel locations.

Methods and Materials: Patients who underwent CCTA with CT-FFR analysis as well as dynamic CTMPI were included. On-site CT-FFR was computed for each coronary artery at proximal, mid and distal segments. Perfusion was analysed per vessel territory by calculating a myocardial blood flow MBF index (MBFI), the ratio between territory MBF and global MBF. Correlations between CT-FFR, MBF, and MBFI were analysed with Pearson's correlation coefficients for all three-vessel territories and for the proximal, mid, and distal CT-FFR locations. Differences in MBFI values between patients with positive (<0.75) and negative CT-FFR values at different vessel locations were evaluated.

Results: A total of 100 patients (mean age 61 \pm 10 years, 75 male) were included for analysis. The CT-FFR and MBFI values in the left anterior descending territory showed low to moderate correlation (0.36-0.62), with decreasing correlation distally. The CT-FFR and MBFI values from the circumflex territory and right coronary artery territory exhibited the same trend although the mean correlation was lower (0.30-0.40 and 0.28-0.42, respectively). Overall, significant proximal and mid stenosis according to CT-FFR, resulted in a significant decrease in MBF and MBFI values, whereas distal stenosis did not.

Conclusion: Our study provides evidence that CT-FFR and MBFI correlate only moderately. Depending on the measurement location of CT-FFR, a significant CT-FFR value reflects a decrease in myocardial perfusion. This effect is less pronounced in distal CT-FFR measurements.

iodine-independence was evaluated using patients who had contrast-enhanced multiphase CT.

Methods and Materials: MAD plot fat fraction accuracy was determined using an anthropomorphic phantom and vials containing different ratios of homogenized bovine liver/lard (0, 25, 50, and 100% fat by volume). The phantom was scanned on a Philips IQon dual-layer CT (120 kVp and 140 kVp) and a Philips Ingenia 3.0T MRI (3x/system) with the MRI fat fraction measurements (mDIXON Quant) used as the reference standard. ROI data from the CT and MRI fat fraction maps were compared to the known fat fraction. For proof of concept *in vivo*, MAD plot fat fraction iodine-independence between pre- and post-contrast dual-layer CT was determined in four patients with varying degrees of hepatic steatosis. Pre- and post-contrast MAD plot fat fraction maps were compared using three ROIs per image, placed in similar liver locations.

Results: Bland-Altman analysis showed the mean difference between the known and measured phantom fat fraction percent was $CT@120kVp = 0.52 \pm 1.77\%$, $CT@140kVp = 0.80 \pm 1.94\%$, and $MRI = 1.61 \pm 1.23\%$. Similar Bland-Altman analysis for the *in vivo* liver data showed that the mean difference between the pre- and post-contrast measured fat fraction percent was Venous = $0.21 \pm 1.57\%$ and Delayed = $-0.61 \pm 1.78\%$.

Conclusion: MAD plots provide an accurate method for measuring liver fat fraction with dual-layer spectral CT *ex vivo*, with the potential to do so for *in vivo* contrast-enhanced CT.

B-0793 14:24

Preliminary study for intra-abdominal liquids characterisation based on dual-energy CT

O. Meyrignac, R. Losco, R. Moreno, A. Sewonu, H. Rousseau; *Toulouse/FR*

Purpose: This study aimed for differentiation and characterization of intra-abdominal liquids based on parameters issued from dual-energy CT.

Methods and Materials: In vitro, monocentric, prospective study. Forty-six intra-abdominal liquids samples were divided into 5 groups according to their provenance: 12 from proven or strongly suspected infected liquids (I); 7 from bile (B); 6 from serous effusion (SE); 11 from lymphoceles (L); 10 blood samples (S). Acquisition were made on Toshiba One Genesis CT scanner using dual-energy technology with sequential acquisition, with samples placed in a water tank to simulate body surroundings. We analyzed: native densities at 80kV and 135kV, density in virtual monochromatic reconstruction at best CNR (= bCNR), dual-energy dissociation coefficient with water (DCw), atomic Z and electronic density. DCw being defined by the ratio between density differences between sample and water at 30 keV and 135 keV.

Results: The overall densities of the S group were significantly higher than the other groups (135kV=55UH, 80kV=58UH, bCNR=56UH; $p < 0.05$). Within these groups, group I had a significantly higher density than all other groups (135kV=28UH, 80kV=35UH, bCNR=35UH; $p < 0.05$). The DCw of group B was 3.9, significantly higher than the other groups ($p < 0.05$) and DCw of group S, lower than the others (1.5, $p < 0.05$). Average electronic density of the S group was significantly higher than that of other groups ($3.4810 \times 10^{-23} / \text{cm}^3$ $p < 0.05$).

Conclusion: Using dual-energy we can differentiate bile and infected fluids from the other intra-abdominal liquids.

B-0794 14:32

Multi-energy CT quantification of first-pass perfusion in hypervascular liver lesions: potential to differentiate hypervascular metastasis from hepatocellular carcinoma

B. Kaltenbach¹, J.L. Wichmann¹, I. Yel¹, M.H. Albrecht¹, T.J. Vogl¹, S.S. Martin²; *Frankfurt a. Main/DE*, ²Charleston, SC/US
(benjamin.kaltenbach@outlook.de)

Purpose: To investigate the diagnostic accuracy of first-pass static perfusion quantification for the differentiation of hypervascular hepatic metastasis from hepatocellular carcinoma (HCC) in non-cirrhotic liver patients undergoing multi-energy computed tomography (CT).

Methods and Materials: 46 patients (mean age, 64.9±10.1 years; 28 male and 18 female) with either hepatic metastasis due to gastropancreatic neuroendocrine tumour or HCC, who had undergone multi-energy CT of the upper abdomen, were included in this retrospective study. For each lesion, arterial-phase attenuation and fat fraction values, as well as quantitative parameters indicating first-pass perfusion including iodine uptake and normalised iodine uptake (NIU) were measured. Lesion-to-liver-parenchyma ratio (LPR) values were calculated. Histopathology, MRI, and/or PET/CT served as the reference standard for all liver lesions. In addition, the diagnostic accuracy of contrast-enhanced and perfusion analysis for the differentiation of hypervascular hepatic metastasis and HCC was assessed using receiver operating characteristics (ROC) curve analysis.

Results: Hypervascular hepatic metastasis and HCC showed significant differences in arterial attenuation ($p=0.003$), iodine uptake ($p<0.001$), NIU ($p<0.001$), and LPR ($p=0.003$). No significant differences were found for unenhanced attenuation and fat fraction values ($p=0.686$ and $p=0.892$, respectively). NIU showed superior sensitivity (100%; iodine uptake, 71%),

whereas both iodine uptake and NIU revealed superior specificity (100% and 90%, respectively) compared to LPR (sensitivity, 96%; specificity, 80%) and arterial attenuation analysis (sensitivity, 79%; specificity, 80%) ($p=0.016$).

Conclusion: Quantitative analysis of first-pass perfusion in multi-energy CT can differentiate hypervascular hepatic metastasis from HCC in non-cirrhotic liver, with NIU showing the strongest diagnostic accuracy.

B-0795 14:40

Double low-dose spectral liver CT in patients at high risk of HCC

J. Yoon¹, E. Lee¹, S.M. Lee², W. Chang³, J. Lee¹; ¹Seoul/KR, ²Anyang/KR, ³Seongnam/KR

Purpose: To investigate the clinical feasibility of simultaneous reduction of radiation and contrast doses using spectral CT in a high-risk group of HCC.

Methods and Materials: Participants at risk of HCC and body mass index (BMI) less than 30 were enrolled and randomly assigned to standard dose (SD, $n=32$) and double low-dose (DLD, $n=35$) groups. Liver CT was performed at spectral CT scanner. DLD group targeted 30% of reduction of radiation and contrast media doses of SD group. Image quality and lesion conspicuity of arterial phase (AP) and portal venous phase (PVP) of FBP images of SD group and 50keV images of DLD group were determined on a five-point scale and compared with each other.

Results: Compared with SD group, $CTDI_{vol}$ (8.8 ± 1.7 vs. 6.1 ± 0.6 , $P < 0.001$) and the amount of contrast media (116.9 ± 15.7 ml vs. 83.1 ± 9.9 ml, $P < 0.001$) were significantly lower in DLD group. BMI was not significantly different between the two groups (24.5 ± 2.3 vs. 24.2 ± 2.4 , $P = 0.58$). Image quality was significantly higher on 50keV images of DLD group than FBP images of SD group (4.0 ± 0.5 vs. 3.1 ± 0.4 on AP and 4.2 ± 0.4 vs. 3.2 ± 0.4 on PVP, $P_s < 0.001$). Lesion conspicuity was significantly higher on 50keV images of DLD group than FBP images of SD group on AP (1.83 [95% CI: 1.56, 2.11] vs. 2.62 [95% CI: 2.31, 2.93], $P < 0.001$) and PVP (1.80 [95% CI: 1.57, 2.02] vs. 2.39 [95% CI: 2.11, 2.67], $P = 0.001$).

Conclusion: Low monoenergetic image (50keV) was able to provide better lesion conspicuity at low radiation and contrast media doses in patients with BMI < 30.

Estimation of the right posterior section volume in live liver donors: semi-automated CT volumetry in conjunction with portal vein segmentation

S.Y. Jeong, J. Lee, K.W. Kim, J.K. Jang, H.-J. Kwon, G.W. Song, S.G. Lee; *Seoul/KR* (jungsy27@hanmail.net)

Purpose: To determine the accuracy of semi-automated CT volumetry in conjunction with portal vein (PV) segmentation (RPSV_{SCTV}) to estimate the volume of right posterior section (RPS) graft compared with intraoperative measured weight (W) in live liver donors.

Methods and Materials: The study protocol was approved by the Institutional Review Board at our institution. Among 23 donors who donated RPS grafts for liver transplantation in our institution from April 2003 to August 2016, 17 donors (11 men, six women; age, 31.7±7.7 years) were included. CT scans were acquired within 3 months before liver procurement, and PV anatomy was type I-II. RPS volumes were retrospectively evaluated by RPSV_{SCTV} and by measurement of standard liver volume (SLV) and PV area ratio (RPSV_{SLV-PVAR}). RPS volumes were compared with W for correlation coefficients, difference (absolute difference), and percentage deviation (percentage absolute deviation). Regression analysis was performed to identify the method that yielded greatest correlation with W.

Results: Mean values of RPSV_{SCTV}, RPSV_{SLV-PVAR}, and W were 452.4 ± 175.8 (209.0-839.3), 516.54 ± 146.20 (274.06-776.32), and 518.8 ± 122.4 (370.0-789.0), respectively. RPSV_{SCTV} was strongly correlated with W ($r=0.9414$; $P < 0.001$), whereas RPSV_{SLV-PVAR} was only moderately did ($r=0.5899$; $P=0.127$). RPSV_{SCTV} showed a significantly smaller absolute difference (35.20 ± 30.82 vs. 104.79 ± 60.27 , $P = 0.004$) and absolute percentage deviation (6.61 ± 4.90 vs. 19.92 ± 10.37 , $P < 0.001$) from W, by paired *t* tests. Equation correlating RPSV_{SCTV} and W was $W = -74.7191 + 1.1791 \cdot RPSV_{SCTV}$ ($R^2 = 0.8862$; $P < 0.001$).

Conclusion: RPSV_{SCTV} is more accurate than RPSV_{SLV-PVAR} for estimating RPS weight in live liver donors, with a mean absolute percentage deviation of 6.61 ± 4.90 .

B-0797 14:56

Feasibility of volume index to assess liver volume: comparison of ultrasound and computed tomography

D. Seppelt¹, T. Ittermann², A. Haubold¹, D. Fedders¹, R.-T. Hoffmann¹, C. Kolb¹, J.-P. Kühn¹; ¹Dresden/DE, ²Greifswald/DE (danilo.seppelt@uniklinikum-dresden.de)

Purpose: Volume index measurement (VI) is based on simple measurement of liver diameters to estimate liver volume. The purpose was to evaluate the feasibility of VI based either on ultrasound (US) or computer tomography (CT) by comparison with CT based volumetry.

Methods and Materials: Fifty-nine patients, 21 women, mean age of 66.8±12.6 years underwent an abdominal CT followed immediately by US of the liver. Liver diameters: anterior-posterior, medio-lateral, and cranio-caudal in their maximum extension were assessed by two observers in CT and US imaging. VI was calculated by multiplication of diameters divided by a constant (3.6). As gold standard served the liver volume determined by a manual segmentation of liver by CT ("true liver volume"). True liver volume and calculated VI determined by CT and US were compared using a Bland-Altman analysis.

Results: Liver volumes determined by manual segmentation, CT-based VI, and US-based VI were as follows: 1.500±347cm³, 1.509±432cm³, 863±371cm³. Mean differences of VI between observers were 1.1 (-16.1;18.2)% for CT-based technique, -34.7 (-90.1;20.7)% for US-based VI, respectively. There was an excellent agreement between CT-based VI and true liver volume with a mean bias of 4.4±28.3%, and a high discrepancy for US-based VI; mean bias 58.3±66.9%.

Conclusion: Volume index based on measurements of liver diameters is a simple and straightforward approach to estimate true liver volume. CT-based volume index turns out to be a very reliable parameter and can be recommended for clinical usage. Use of US-based volume index should be discouraged from due to its unacceptable low accuracy.

B-0798 15:04

Dose optimisation in multiphasic computed tomography imaging of the liver with high-concentration contrast media

S. Cavalieri¹, A. Ferrari, R. Villa, M. Brambilla, A. Stecco, A. Carriero; *Novara/IT (sergiocab451@gmail.com)*

Purpose: To reduce radiation dose to patients undergoing multiphasic CT of the liver by exploiting the intrinsic properties of iodine enhancement at low kVp.

Methods and Materials: 32 oncology patients underwent multiphasic CT of the liver using a Philips Brilliance iCT scanner and either a standard acquisition protocol (100 kVp in all phases; N=8) or an optimised weight-based acquisition protocol in the arterial phase (80 kVp in patients ≤80 kg; N=16 and 100 kVp in patients >80 kg; N=8). High-concentration contrast agent (Iomeprol 400 mg/ml) and automatic tube current modulation were used in all patients. The standard dose and the optimised protocols were compared with t test for average CTDI_{vol}, liver dose, and peak aortic enhancement measured in the aorta at the level of the coeliac trunk (significance threshold p <0.05).

Results: When the optimised protocol was used, patients ≤80 kg showed a significant increase in peak aortic enhancement (507±69 HU vs 324±59HU; p=0,01) and a significant reduction in average CTDI_{vol} (from 12.5±2.6 to 8.3±1.3 mGy; p=0,005) and liver dose (from 17.4±4.1 to 10.9±1.6 mSv; p=0,005) for the arterial phase. As expected, patients ≥80 kg did not show any significant difference in aortic enhancement and radiation dose compared to the standard protocol.

Conclusion: Our optimised protocol with use of 80 kVp and high iodine concentration resulted in a substantial improvement of aortic attenuation and radiation dose reduction in patients ≤80 kg.

Multidetector liver CT: improved image quality, decreased radiation and contrast media dose with peristaltic contrast media injection system

C. Saade, S. Khalifeh, L. Karout, L. Naffaa; *Beirut/LB (charbel.saade@aub.edu.lb)*

Purpose: To compare hepatic vascular and parenchymal opacification between direct and peristaltic drive contrast media (CM) injection systems and its effect on image quality and pathology detection.

Methods and Materials: IRB-approved retrospective study consisted of 182 patients who underwent CT of the abdomen and pelvis in both groups; Group A: employed direct drive injector, and Group B: utilized the peristaltic injector. Quantitative opacification measurements of the vasculature, parenchyma, contrast-to-noise ratio (CNR) and signal-to-noise ratio (SNR) and each hepatic segment (n=8) were compared by employing paired t test and Pearson's correlation. Receiver operating (ROC) and visual grading characteristics (VGC) measured the confidence intervals and image quality, respectively. Reader

agreement employed Cohen's kappa methodology.

Results: Mean opacification of the vasculature and liver segments demonstrated no statistical difference between each group. CNR in the liver compared to hepatic vein was higher in Group B (2.17 ±0.82) compared to A (1.83±0.64). SNR in Group B (5.89±1.63 HU) was higher than A (4.95±1.59HU) (p<0.001). Radiation dose and CM volume were significantly lower in Group B than A (p<0.0001). VGC showed no significant difference in qualitative image quality assessment. ROC demonstrated pathology detection in Group B than A (p<0.0001). Inter- and intra-observer variation showed that there is a strong relationship between liver vasculature and parenchymal opacification (Protocol A: κ=0.25-0.76 and Protocol B: κ=0.39-0.91).

Conclusion: Significant improvements in quantitative and qualitative assessments of liver pathology can be achieved with low CM and radiation dose when employing peristaltic CM injection system.

A reduced contrast media injection protocol significantly improves the visualisation of liver vasculature at reduced radiation dose during hepatic CTA

C. Saade, A. Haydar; *Beirut/LB (charbel.saade@aub.edu.lb)*

Purpose: To investigate the opacification of liver vasculature and radiation dose by employing a patient-specific (PS) contrast administration protocol during hepatic CTA (HCTA).

Methods and Materials: This hybrid retrospective (protocol A) and continuous prospective (protocol B) study was IRB approved. HCTA was performed in 216 consecutive patients, with one of two protocols: protocol A, 100 mL of contrast material injected intravenously; and protocol B, employing the patient-specific contrast media protocol. Each protocol employed contrast material and saline flow rate of 4.5 mL/sec. Attenuation profiles of the hepatic arteries and veins were measured. Effective dose was calculated. Data were compared with the independent sample t test. Visual grading characteristic (VGC) analyses were performed.

Results: Arterial opacification demonstrated no significant increases in arterial opacification in protocol B, except for right main hepatic artery (p<0.001), segment VI of the right hepatic artery (p<0.036), left main hepatic artery (p<0.002), proximal segment of the gastroduodenal artery (p<0.014). The abdominal aorta and celiac trunk were significantly higher in protocol B compared to A (p<0.007), celiac trunk (p<0.004). In the veins, inferior vena cava, portal (all branches) and proximal splenic veins demonstrated a significant reduction in opacification protocol B compared to A (p<0.001). Effective dose was significantly reduced in protocol B (p<0.001). Contrast media volume in protocol B (57.60±12.25 mL) was significantly lower than in protocol A (p=0.001). VGC demonstrated no significant differences between protocols, with reader agreement increasing from moderate to excellent (p<0.001).

Conclusion: Employing a PS injection protocol demonstrates significant improvements in the visualization of the liver vasculature at reduced radiation and contrast media dose.

Assistant effects of a computer-aided diagnosis system based on 3D convolutional neural network on LDCT reading

S. Wang, Z. Wang, S. Zhang, Y. Fu, T. Hu, W. Peng; *Shanghai/CN (shengpingwang2007@126.com)*

Purpose: To compare the difference of diagnostic performance between radiologists with and without computer-aided detection (CAD) system based on depth learning algorithm in detecting lung nodules in low-dose computed tomography (LDCT).

Methods and Materials: Seventy-nine patients (whether or not lung nodules were found) were enrolled. First, three radiologists randomly read these cases and assessed the risk score without a CAD system. Then, 4 weeks later, the three radiologists read the cases randomly and assessed the risk score again with the aid of a CAD system based on a 3D convolution neural network. The results obtained by one expert chest radiologist with the aid of CAD system is

used as the ground truth.

Results: Number of detected nodules increased in CAD group by 53.22% ($p < 0.01$). The average absolute difference between reader and ground truth was decreased from 0.96 to 0.43 ($p < 0.01$). And the average standard error (SE) of cases between readers decreased from 0.45 to 0.34 ($p = 0.11$) when using CAD system for assistance. The average SE of risk score was from 0.25 to 0.10 ($p < 0.01$) when using CAD system.

Conclusion: This study compared the reading results of different radiologists with and without in-depth learning of CAD system. The results showed that with the aid of CAD system, radiologists discovered more lung nodules and obtained better consistency.

Automatic prostate segmentation of magnetic resonance images using convolutional neural networks

N. Aldo, F. Biavati, M. Rutz, S. Stober, M. Dewey; *Berlin/DE*
(nader.aldoj@charite.de)

Purpose: To develop a fully automatic and accurate tool for prostate segmentation using 2D convolutional neural networks.

Methods and Materials: A dataset of 188 patients with T2-weighted images was used in this study (PROSTATEx challenge). All T2-weighted axial images (256x256 pixels) were manually segmented and examined by an experienced radiologist. The training set consisted of 143 patients (a total of 2982 slices) and the test set of 45 patients (a total of 912 slices). The developed Dense U-Net was based on the U-Net architecture with six stages. We replaced the classical convolutional layers with a Dense net-like architecture which consists of two small Dense blocks separated by transitional layers and each of which comprised four convolutional operations. Results of the developed network were compared for all test images with the classical U-Net using the dice score.

Results: The Dense U-Net achieve an average dice score of 0.89 and a median dice score of 0.90 which was higher in comparison to the classical U-Net with average and median dice scores of 0.885 and 0.89, respectively. Both networks achieved accurate segmentation in the middle region of the prostate with an average dice score of 0.94 for the Dense U-Net and 0.93 for classical U-Net. Both networks resulted in relevantly lower dice scores for the apical and basal region of the prostate (Dense U-Net: 0.72 and 0.79; Classical U-Net: 0.70 and 0.79), respectively.

Conclusion: The developed Dense U-Net architecture outperformed the classical U-Net by achieving more accurate prostate segmentation on axial T2-weighted sequences.

B-0803 14:08

Automated x-ray bone segmentation using a conditional adversarial network

J. Haubold, A. Demircioglu, M. Forsting, L. Umutlu, F. Nensa; *Essen/DE*
(johannes.haubold@uk-essen.de)

Purpose: To train and evaluate a conditional adversarial network (pix2pix) for automated bone segmentation in x-ray images.

Methods and Materials: The bone tissue in 40 x-rays of the left elbow was segmented manually using the 3D Slicer software. The segmentations were used as ground truth for the training of a conditional adversarial network comprising a convolutional and a deconvolutional neural network (pix2pix) on automated bone segmentation. To validate the segmentation efficiency a 5-fold cross validation was performed and therefore the dataset was randomly split into five subsets each containing eight x-rays. In each of five tests the network was trained on 32 images and evaluated on the remaining eight images. Segmentation efficiency was evaluated using the Jaccard similarity coefficient.

Results: Overall Jaccard mean was 0.94 ± 0.03 (Jaccard mean for split 1=0.96; split 2=0.96; split 3=0.95; split 4= 0.94; split 5=0.89) showing an overall good similarity of automatically segmented images compared to manually segmented images. Default training epoch value of 100 showed the best Jaccard similarity coefficient compared to 25, 50 and 250 epochs in pix2pix.

Conclusion: Using only 40 segmented x-ray images of the elbow a conditional adversarial network could be trained for automated bone segmentation with an overall good similarity coefficient compared to manually segmented images.

B-0804 14:12

Small (< 4 cm) renal masses: convolutional neural network-based deep-learning approach in differentiating fat-poor renal angiomyolipoma from renal cell carcinoma at MSCT

X. Li, L. Wang; *Nanjing/CN* (lixiao19901020@yeah.net)

Purpose: To investigate diagnostic performance using a deep learning method with a convolutional neural network for the differentiation of fp-AML and RCC at dynamic contrast agent-enhanced computed tomography.

Methods and Materials: Approved clinical retrospective study from January 2013 to July 2017, patients with fp-AML and RCC were identified from the pathology database. 42 patients with fp-AML (no visible fat at unenhanced CT)

and 158 patients with RCC. All patients were examined with a 320-slice dynamic volume CT by using same four phase renal protocol. This study is composed of two stages: A training stage, in which 10-fold validation was performed and a testing stage to evaluate the performance of the models with new pictures to each model. A testing stage which is simply done by loading the testing image dataset into the classifier.

Results: The mean AUC for differentiating fp-AML from RCC using model unenhanced, model corticomedullary, model nephrographic, model excretory, model enhanced and model quadruple with the test data sets was 0.64 (95% confidence interval [CI]: 0.58, 0.69), 0.83 (95% CI: 0.81, 0.85), 0.83 (95% CI: 0.81, 0.85), 0.81 (95% CI: 0.79, 0.83), 0.85 (95% CI: 0.84, 0.86), 0.84 (95% CI: 0.83, 0.85).

Conclusion: The CNN models except model unenhanced exhibited a high diagnostic performance in distinguishing fp-AML from RCC at dynamic CT. Further research might focus on the application of this tool in other benign renal lesions, such as oncocytomas.

B-0805 14:16

Computed tomography-based radiomics analysis to assess treatment response after perioperative neoadjuvant therapy

Q. Xu¹, C. Zhou¹, C. Ye¹, G. Tao¹, W. Zhao¹, D. Ren², X. Li², L. Zhao², G. Lu¹;
¹Nanjing/CN, ²Beijing/CN (DZ1735002@smail.nju.edu.cn)

Purpose: To assess the value of computed tomography (CT)-based radiomics for diagnosis of good response (GR) to perioperative neoadjuvant chemotherapy (NCT) in patients with locally advanced gastric cancer (GC).

Methods and Materials: This retrospective study includes 189 patients (170 in the primary cohort and 19 in the validation cohort) with GC who had a CT scan after NCT between July 2014 and December 2017. Surgical histopathologic analysis was the reference standard for GR. In total, 1232 radiomics features were extracted from portal venous-phase CT of GC for each patient. F test was adopted during feature selection and linear support vector classification was used to build the classifier model. The combination model was implemented within a nested cross-validation structure. The performance of the radiomics model was assessed by its calibration, discrimination, and clinical usefulness with independent validation. Statistical analysis was performed using the Mann-Whitney U test, Chi-square test and logistic regression analysis.

Results: The radiomics model consisting of 20 selected features showed good discrimination performance and good calibration. The area under the receiver operating characteristic curve was 0.8354 (sensitivity, 0.7559; specificity, 0.7457; accuracy, 0.7521) for the assessment model of GR. Decision curve analysis confirmed the clinical utility of the radiomics model.

Conclusion: Contrast-enhanced CT-based radiomics showed good classification performance for preoperative assessment of GR in patients with locally advanced gastric cancer after NCT and has a prospect for application.

B-0807 14:20

A preliminary study of predicting molecular subtypes of breast cancer by the radiomics features of contrast-enhanced ultrasound

L. Tang, W. Chang, M. Chen; *Shanghai/CN* (13661657380@163.com)

Purpose: To analyse the quantitative features of contrast-enhanced ultrasound (CEUS) imaging of breast cancer (BC) through computer image extraction and to explore the preoperative prognosis of different molecular subtypes of BC.

Methods and Materials: CEUS images of 189 patients with surgical pathology and molecular typing results of BC were analysed. Through mapping border on the images, the entire internal area of tumour was determined. High perfusion within the lesion area was defined as a high brightness area. Temporal and special features of CEUS images in different areas were extracted by computer and the time-intensity curves (TIC) were drawn. From TIC, the features were extracted such as wash-in rate (WIR), wash-out rate (WoR), rise time (RT), base intensity (BI) and peak intensity (PI) and EI (=PI-BI). The parameters of each area were calculated in different molecular typing groups.

Results: The patients' number of Luminal A, Luminal B, HER2+ and triple-negative BC (TNBC) in different molecular subtypes were 46, 75, 37 and 31. The extracted effective features included EI and WoR of internal bright area, WoR and RT of internal overall area. The cutoff value 1.566 of WoR in internal bright area might help to find Luminal A, with specificity in 82.61%. When finding TNBC, the cutoff value of EI at internal bright area was 0.3494; the sensitivity and specificity were 64.52% and 68.99%. When distinguishing between Her2+ and TNBC, WoR of internal overall had a cutoff of 5.7496 and sensitivity of 74.19%.

Conclusion: The radiomics features of CEUS could contribute to preoperative prediction of BC molecular subtypes.

B-0808 14:24

The diagnostic value of texture analysis in predicting WHO grades of meningiomas based on ADC maps: an attempt using decision tree and decision forest

Y. Lu, B. Yin; *Shanghai/CN (06307070008@fudan.edu.cn)*

Purpose: The preoperative prediction of the WHO grade of a meningioma is important for further treatment plans. This study aimed to assess whether texture analysis (TA) based on apparent diffusion coefficient (ADC) maps could non-invasively classify meningiomas accurately using tree classifiers.

Methods and Materials: A pathology database was reviewed to identify meningioma patients who underwent tumour resection in our hospital with preoperative routine MRI scanning and diffusion-weighted imaging (DWI) between January 2011 and August 2017. A total of 152 meningioma patients with 421 preoperative ADC maps were included. Four categories of features, namely clinical features, morphological features, average ADC values and texture features, were extracted. Three machine learning classifiers, namely classic decision tree, conditional inference tree and decision forest, were built on these features from the training dataset. Then the performance of each classifier was evaluated and compared with the diagnosis made by 2 neuroradiologists.

Results: The ADC value alone was not able to distinguish 3 WHO grades of meningiomas. The machine learning classifiers based on clinical, morphological features and ADC value could achieve equivalent diagnostic performance (accuracy 62.96%) compared to 2 experienced neuroradiologists (accuracy 61.11% and 62.04%). Upon analysis, the decision forest that was built with 23 selected texture features and the ADC value from the training dataset achieved the best diagnostic performance in the testing dataset (Kappa 0.64, accuracy 79.51%).

Conclusion: Decision forest with the ADC value and ADC map-based texture features is a promising multiclass classifier that could potentially provide more precise diagnosis and aid diagnosis in the near future.

B-0809 14:28

Automated stroke detection and profiling on initial non-contrast CT via machine learning and textural analysis

J.M.A. Alghamdi, S. Raja; *Riyadh/SA (jmalghamdi@kfmc.med.sa)*

Purpose: To explore the utility of machine learning and texture analysis for possible automatic detection and temporal profiling of suspected stroke.

Methods and Materials: We reviewed stroke-code patients at King Fahad Medical City in Riyadh, who presented between January 2015 and September 2017. We got a total of 826 patients. After applying the exclusion criteria, we chose 567 patients. Baseline cases were reviewed and staged by 3 radiologists. As a result, we identified subsets of hyper-acute (42), acute (39), and sub-acute (23). Baseline and follow-up CT scans were co-registered on a dedicated review workstation. Evolving stroke on follow-up CTs was contoured on in 3D. The 3D-contours were mirrored on to contralateral normal region. Simultaneously, contours were duplicated on co-registered baseline CTs. Pixel level data from the flagged regions on baseline CT and follow-up were exported to Matlab. Utilizing home-built algorithms, 42 textures were computed. Textural features were analysed in SPSS modeller for classification.

Results: Utilizing the 42 textural scalars, among various machine learning algorithms, Decision Trees (C5.1) was found to be the most optimal differentiator between stroke (hyper-acute/acute/sub-acute) versus contralateral normal brain tissue, as well as classifying temporal profiling the stages of stroke. The decision trees were good to excellent in classifying hyper-acute (71%), sub-acute (82%), and modest for acute (60%) stroke.

Conclusion: It is feasible to differentiate and chronologically profile stroke utilizing textural analysis and machine learning. We seek to increase the accuracies in a larger series and also utilize additional textures and machine learning algorithms.

B-0810 14:32

A novel improved deep learning framework for liver lesion detection

Y. Chen¹, J. Ma², J. Wang¹, F. Wang¹, S. Feng¹; ¹Guangzhou/CN, ²Beijing/CN (chen-yingxi@163.com)

Purpose: Hepatocellular carcinoma (HCC) is the second most frequent cause of malignancy-related death in the world. Early detection of HCC is the key issue in clinical imaging. Computer-assisted diagnosis can help for early detection of lesion in many other organs. There is still lack of an effective deep learning framework for liver lesion detection. This study aims to find out an improved framework for liver lesion detection.

Methods and Materials: A new framework has been improved by the following ways: 1) using more numbers of layers in the neural network framework; 2) developing a 2.5D-like structure; 3) using a multi-scale-based deep learning network; 4) fusing the information of multi-phase images. Totally 621 patients were used to train the model, and the training set included 910 hepatic cysts, 495 haemangiomas and 173 HCCs. Other 60 patients were used to test the model, including 98 hepatic cysts, 38 haemangiomas and 30 HCCs. All the

images contained tri-phasic sequences. All the lesions were labelled jointly by two experienced radiologists as standard.

Results: Before the improvement, the predictive accuracy of hepatic cysts, haemangiomas and HCCs were 69.23%, 64.29% and 70.96%, respectively. After using the improved framework, the predictive accuracy of hepatic cysts, haemangiomas and HCCs rose to 82.76%, 78.98% and 77.88%, respectively.

Conclusion: The novel improved deep learning framework has a relative better predictive ability of liver lesion detection, which provides an effective measure for computer-assisted imaging diagnosis. This framework is also helpful for the early detection of HCC.

B-0811 14:36

Evaluation of intra-scanner test-retest variability of machine learning features in low-dose computed tomography of interstitial lung disease

F. Prayer, S. Röhrich, J. Hofmanninger, A. Willenpart, G. Langs, H. Prosch; *Vienna/AT*

Purpose: To investigate the robustness of machine learning imaging features of patients with interstitial lung disease (ILD) in repeated low-dose computed tomography (LDCT) examinations on a single scanner.

Methods and Materials: Thirty consecutive ILD patients, after written declaration of consent, received repeated non-contrast LDCT of the chest on a single CT scanner within 15 to 60 minutes. Images of test and retest scans were reconstructed using one- and three-millimeter slice thickness, and soft tissue and lung kernels (i30f, i50f, and i70f). Imaging features used for machine learning-based diagnosis and progression prediction (Haralick texture features) were extracted after isotropic voxel resampling to 0.7mm resolution. Local features were quantized to volume descriptors and used to assess visual similarities between volumes. We evaluated the effect of retest and reconstruction parameters on the visual similarity by varying one parameter while keeping all other parameters fixed.

Results: Visual similarity between test and retest yield 0.02 mean (SD 0.01), 0.03 (0.01), 0.46 (0.16), 0.51 (0.02), and 0.12 (0.02) between i30f and i50f kernels, i50f and i70f, i30f and i70f and 1mm and 3mm slice thickness, respectively. Two-sample t tests revealed significantly higher influence of varying reconstruction parameters on visual descriptors compared to test-retest (all $p < 4.2e-11$).

Conclusion: LDCT imaging features of ILD used for machine learning obtained by repeated scans on a single scanner are reproducible. However, variability is introduced by reconstruction parameters, with slice thickness exhibiting higher influence than reconstruction kernel despite isotropic resampling.

B-0812 14:40

Accurate pulmonary nodule detection in CT images using multi-stage 3D deep convolution neural networks

X.J. Chen; *Zhengzhou/CN (chenxuejun1967@163.com)*

Purpose: To evaluate the application of a new method of computer-aided pulmonary in diagnosing the accuracy and efficiency of lung cancer.

Methods and Materials: CT images were acquired from 980 lung cancer patients. Manually marked pulmonary nodule location and pathology results are taken as gold standard. The dataset consists of 7336 nodules in which 3169 are malignant. The detection rate of pulmonary nodules and the malignant prediction rate were evaluated through manual detection and the computer-aided detection. Computer algorithm of computer-aided detection adopted multi-stage strategy. In the first stage, CT images were preprocessed to reduce variances such as CT thickness caused by different manufactures. Second, self-designed neural network mimicking zooming in and out the image was used to extract multi-scale image features and generate region of interest (ROI). Finally, another 3D deep convolution neural network is applied to classify whether the ROI is true or false positive.

Results: Compared with the manual detection, the detection of nodules of computer-aided detection was high, which was statistically significant (84.71% vs 95.76%), and false-positive rate of between the computer-aided detection and the manual detection was not statistically significant $P > 0.05$. The malignant prediction result of computer-aided detection shows 95.28% recall rate and 98.56% precision rate in patient level, and the malignant prediction result of manual detection shows 94.7% recall rate and 98.00% precision rate in patient level which were not statistically significant $P > 0.05$.

Conclusion: The multi-stage 3D deep learning method verified by large clinical dataset shows greater efficiency helping detect pulmonary nodules and offer better accuracy.

B-0813 14:44

Deep learning for prostate cancer segmentation and detection: diffusion MRI U-net compared to clinical PI-RADS assessment
 P. Schelb, S. Kohl, J.-P. Radtke, M. Hohenfellner, H.-P. Schlemmer, K. Maier-Hein, D. Bonekamp; Heidelberg/DE (david@bonekamp.de)

Purpose: To compare the performance of DWI-only convolutional neural network (CNN) machine learning with full multiparametric clinical PI-RADS assessment.

Methods and Materials: A U-net CNN was trained on ADC maps and b value 1500s/mm² images from 316 consecutive men with segmentations of clinical PI-RADS lesions yielding Gleason grade group ≥ 2 on targeted biopsy. The CNN was trained on 253 patients (4-fold 3-times repeated cross validation, training/validation=190/63 patients). Ensemble predictions were evaluated on the held-out test set of 63 patients. Radiologist and CNN performances were evaluated on combined extended systematic and targeted biopsy mapping using different net ensemble (CNN) and PI-RADS thresholds.

Results: On a per patient basis both, radiologists (at PI-RADS ≥ 3) and CNN (at net ensemble threshold (NET) ≥ 2) achieved sensitivity of 0.96 and specificity of 0.22. Radiologists achieved sensitivity of 0.85 at specificity 0.50 for PI-RADS ≥ 4 , while CNN achieved sensitivity of 0.81 and specificity of 0.44 at NET ≥ 6 . On a per lesion basis, radiologists achieved sensitivity of 0.63 and specificity of 0.61 at PI-RADS ≥ 3 , while CNN achieved sensitivity of 0.52 and specificity of 0.65 at NET ≥ 2 . For PI-RADS ≥ 4 radiologists achieved sensitivity of 0.54 and specificity of 0.77, CNN sensitivity of 0.41 and specificity of 0.78 at NET ≥ 6 .

Conclusion: A U-net CNN using diffusion MRI information only for prostate lesion segmentation and detection demonstrated a promising performance compared to clinical radiologist interpretation. These findings highlight the ability of computer vision to closely model the clinical task with fewer data and encourage development of the method in larger cohorts.

A whole-tumour histogram analysis of apparent diffusion coefficient maps obtained using 3.0T MRI for distinguishing uterine endometrial carcinoma from endometrial polyps

W. Wang, J. Cheng; Zhengzhou/CN (weijianwang520@163.com)

Purpose: We explored the role of a whole-tumour histogram analysis of apparent diffusion coefficient (ADC) maps for discriminating uterine endometrial carcinoma and endometrial polyps.

Methods and Materials: We retrospectively evaluated findings in 40 patients with uterine endometrial polyps and 50 patients with endometrial carcinoma who underwent diffusion-weighted imaging ($b = 0,800 \text{ s/mm}^2$) at 3T with acquisition of corresponding ADC maps. We derived histogram data from regions of interest drawn on all slices of the ADC maps in which tumour was visualised, including areas of necrosis and haemorrhage in the tumour. We used the Mann-Whitney test to evaluate the capacity of histogram parameters (mean, skewness, kurtosis, 50th, 90th percentiles) to discriminate uterine endometrial carcinoma from endometrial polyps and analysed the receiver operating characteristic (ROC) curve to determine the optimum threshold value for each parameter and its corresponding sensitivity and specificity.

Results: Uterine endometrial carcinoma demonstrated significantly higher mean values of ADC, skewness, kurtosis, 50th, 90th percentiles than endometrial polyps ($P < 0.05$). ROC curve analysis of the 90th percentile yielded the best area under the ROC curve (AUC; 0.92), sensitivity of 90%, and specificity of 95%, with a cutoff value of 198.

Conclusion: A whole-tumour Histogram analysis of ADC maps might be helpful for discriminating uterine endometrial carcinoma from endometrial polyps.

B-0815 14:52

A computer-aided detection (CAD) system on low-dose chest CT images in concurrent-reader and second-reader modes: radiologist performance and reading time

Q. Hu; Wuhan/CN (qjhu@outlook.com)

Purpose: To assess the value of a CAD system in second-reader (SR) and concurrent-reader (CR) models for the detection of pulmonary nodules and time efficiency of radiologists on low-dose chest CT images.

Methods and Materials: A total of 117 patients with extra-thoracic malignancies, were prospectively included. 9 observers independently evaluated images, first without CAD, then using CAD as SR at both dose settings. Furthermore, 8 observers independently interpreted these datasets thrice, once with CR, twice without CAD, and third with SR. True positive rates (TP), false positive rates (FP) and reading times were recorded. Free-response receiver operating characteristic analysis was also used for the statistical analysis.

Results: The sensitivities without CAD for detection of nodules (41.06% and 37.02%) were less than those using CAD as SR (60.57% and 60.39%) in both two dose settings ($P < 0.001$). Reading times were significantly shorter in CR mode (165s) than those without CAD (235s) and in SR mode (294s) ($P < 0.01$). Sensitivity of reading with CAD as CR (64.92%) was significantly higher than reading without CAD (44.71%, $p < 0.001$) and not statistically different in SR mode (66.86%; $P > 0.05$) in the low-dose setting. The FOM in the CR mode was statistically significant better than that without CAD (0.58 vs 0.47, respectively; $P < 0.001$), and not statistically different compared with using CAD in the SR mode (0.61, $P = 0.259$).

Conclusion: CAD benefited all readers including small nodules, which both significantly improved diagnostic performance and shortened the reading times, especially for interns, in the low-dose setting.

Reproducibility of fully automated liver volumetric analyses with artificial intelligence: towards laboratory radiology

D.J. Winkler¹, G. Chabin², J. Cyriac¹, B. Stieltjes¹, T.J. Weikert¹, ¹Basle/CH, ²Princeton, NJ/US (Thomas.Weikert@usb.ch)

Purpose: Laboratory radiology conveys the vision of a norm-based quantitative disease detection in radiology. Thereto, automated imaging quantification pipelines are mandatory both for large-scale norm-collective creation and disease-related outlier detection. Here, we test such a pipeline in terms of reproducibility and stability using an AI-based algorithm trained for liver volumetric analyses.

Methods and Materials: Using a RIS/PACS search engine, we obtained 100 CT datasets with six series for each patient, totaling 600 series: non-contrast (nc), portal venous (pv) and arterial phase (art) with both 1.5mm and 5mm slice thickness. The data were analysed using multi-scale deep-reinforcement learning for 3D body marker detection and adversarial deep image-to-image learning for 3D anatomical structure segmentation. Variations of liver volumes were compared using Cohen's coefficient K. Variations of liver volumes were compared using univariate general linear model analyses with the liver volume as the dependent variable and contrast phase and slice thickness as fixed factors.

Results: The liver volumes for the different scan phases, averaged for 1.5 and 5 mm, were 1903 \pm 599, 1908 \pm 585 and 1928 \pm 595 ml (nc, pv, art). The two cycles of analysis yielded identical liver volumes for the given datasets ($K = 1$). The liver volume was neither dependent on the contrast phase ($p = 0.938$) nor on the slice thickness ($p = 0.605$).

Conclusion: Fully automated AI-based liver volumetry is a reproducible, stable and precise method. The results of our study provide the necessary confidence for future applications of automated abdominal organ volumetric analyses in the sense of laboratory radiology.

Automated detection of lung cancer at ultralow dose PET/CT by deep neural networks: initial results

M. Schwyzer, D. Ferraro, U. Mühlematter, A. Curioni-Fontecedro, M. Hüllner, G.K. Von Schulthess, P.A. Kaufmann, I.A. Burger, M. Messerli; Zurich/CH (moritz.schwyzler@usz.ch)

Purpose: The purpose of this study was to assess the accuracy of a deep learning algorithm for automated detection of lung cancer on FDG-PET scans. Additionally, we simulated reduced FDG dose injection and evaluated its impact on the performance of the deep learning algorithm.

Methods and Materials: We retrospectively included 50 patients with histologically proven lung cancer and a control group of 50 patients without lung cancer. For deep learning analysis, we performed a binary classification for a total of 3936 slices: Slices, in which the lung tumour is visually present versus slices of locations in the lung where no lung tumour is seen. Besides the standard, full-activity reconstructions, simulated tenfold and thirty-fold reduced dose injection reconstructions were additionally analysed by the deep learning algorithm.

Results: The AUC of the deep learning algorithm for the full-activity reconstructions was 0.989, showing no significant difference to the AUC (0.983) of the tenfold reduced dose injection reconstructions. The thirty-fold reduced dose injection reconstruction AUC (0.970) was significantly lower.

Conclusion: In this study, we could show that it might be possible to detect lung cancer fully automatically with very low effective radiation doses of 0.11 mSv (3.3% of current clinical routine). Further improvement of this technology might enhance the specificity of lung cancer screening efforts and could lead to new applications for FDG-PET.

Automated lung cancer detection in PET/CT using a deep learning approach

M. Müller, C.P. Reinert, K. Nikolaou, C. La Fougère, C. Pfannenber, S. Gatidis; *Tübingen/DE*

Purpose: To evaluate the feasibility of automated lung cancer detection in patients undergoing clinically indicated Position Emission Tomography/Computed Tomography (PET/CT) using a deep learning approach.

Methods and Materials: Anonymized FDG-PET/CT data sets of 275 patients with histologically proven lung cancer ("pathologic scans") and 225 patients without a thoracic malignancy ("non-pathologic scans") were retrospectively analyzed. Manual segmentations of tumours were performed using MITK (German Cancer Research Center) and used for evaluation. Sagittal, coronal and transversal maximum intensity projections of PET data were generated prior to further analysis. Two different deep learning approaches were implemented: A seven layer convolutional neural network for classification of examinations into pathologic and non-pathologic and a U-Net architecture for classification and additional spatial segmentation of hypermetabolic cancer lesions. The testing was performed on 50 pathologic and 50 non-pathologic data sets. The classification accuracy was computed as the relative number of correctly classified data sets and the segmentation accuracy was quantified by computing dice coefficients between automated and manual tumour segmentation.

Results: The first proposed classifications network was able to distinguish between pathologic and non-pathologic data sets with relatively high accuracy (83 %). Using the U-Net architecture classification accuracy could be improved to 90% and subsequent segmentation accuracy reached 98% dice coefficient. The false positive classification rate dropped to 2%.

Conclusion: Neural networks are feasible approaches for automated lung cancer detection in PET/CT. In order to yield clinically usable results and limit the false positive rate, the use of larger training data bases will be helpful.

Non-invasive tumour decoding and phenotyping of cerebral gliomas utilizing multiparametric ¹⁸F-FET PET-MRI and MR fingerprinting

J. Haubold, A. Demircioglu, M. Gratz, K. Wrede, M. Glas, K. Herrmann, M. Forsting, F. Nensa, L. Umutlu; *Essen/DE (johannes.haubold@uk-essen.de)*

Purpose: The introduction of the 2016 WHO classification of CNS tumours has rendered the combined molecular and histopathological characterization of tumours as a pivotal part of glioma patient management. Recent publications on radiogenomics-based prediction of the mutational status have demonstrated the predictive potential of imaging-based, non-invasive tissue characterization algorithms. Hence, the aim of this study was to assess the potential of multiparametric ¹⁸F-FET-PET MR imaging including MR fingerprinting accelerated with machine learning and radiomic algorithms to predict tumour grading and mutational status of patients with cerebral gliomas.

Methods and Materials: 42 patients with therapy-naïve cerebral gliomas underwent an 18F-FET-PET-MRI examination. Surgical biopsy or resection served for histopathological sampling. To differentiate the mutational status and the WHO grade of the cerebral tumour we trained a support vector machine and random forest with the radiomics signature of the multiparametric PET-MRI data including MRI fingerprinting. As a gold standard, surgical acquired histology and mutational status were used.

Results: The 5-fold cross-validated area under the curve in predicting the ATRX mutation was 85.1%, MGMT mutation was 75.7%, IDH1 was 88.7% and 1p19q was 97.8%. The area under the curve of differentiating low-grade glioma vs. high-grade glioma was 85.2%.

Conclusion: 18F-FET PET-MRI and fingerprinting enable imaging-based tumour decoding and phenotyping with a good performance in differentiating low-grade vs. high-grade gliomas and in predicting the mutational status of ATRX, IDH1 and 1p19q. These initial results underline the potential of 18F-FET PET MRI to serve as an alternative to invasive tissue characterization.

Deep learning-based automated calcium scoring for cardiac computed tomography

S.S. Martin¹, M. van Assen², A.M. Fischer³, S. Rapaka⁴, P. Sahbaee¹, C. Schwemmer⁵, M.A. Gulsun¹, P. Sharma⁴, U.J. Schoepf¹; ¹Charleston, SC/US, ²Groningen/NL, ³Mannheim/DE, ⁴Princeton, NJ/US, ⁵Forchheim/DE (AndreasMarco.Fischer@googlemail.com)

Purpose: The aim of this study was to evaluate a deep learning-based automated calcium scoring application for cardiac computed tomography (CT).

Methods and Materials: We analysed an automated calcium scoring application that is composed of multiple deep learning models, including voxel segmentation and computing the likelihood of a voxel being coronary calcium. The software automatically identifies the coronaries and calcified lesions, whereas aortic plaques are excluded in the calculations using a model for aorta segmentation. This algorithm was trained on 2000 annotated electrocardiography-gated cardiac CT scans. Thereafter, the application was evaluated on 263 consecutive patients undergoing cardiac CT. Results were compared to coronary calcium scores (CCS) obtained by standard manual assessment of independent cardiovascular radiologists.

Results: Mean CCS revealed no significant differences between the automated algorithm (102.2) and the reference standard (114.2) ($P=0.156$). Moreover, CCS using the automated application showed an excellent correlation with the reference standard (Pearson, $r=0.97$). Overall, 243 of 263 patients (92.4%) were classified into the correct risk category (0, 1-10, 11-100, 101-400, or >400).

Conclusion: Deep learning-based automated calcium scoring for cardiac CT shows a high accuracy compared to reference scores.

Whole-body MRI for detecting bone metastases in treatment naïve high-risk prostate cancer: cracking nuts with a sledgehammer?

E. Rud, F. Ottoson, T. Flatabo, E. Baco; *Oslo/NO (erik.rud@ous-hf.no)*

Purpose: The aim of this study was to evaluate the anatomical sites of bone metastases in patients with high-risk prostate cancer.

Methods and Materials: This retrospective quality control study analysed the prospective results of all whole-body MRIs performed in 2016 and 2017. All patients were treatment naïve, and all had high-risk prostate cancer defined as biopsy Gleason score $\geq 7b$ and/or PSA $\geq 20-100$ and/or cT $\geq 2c$. The MRI sequences included 3DT1, diffusion-weighted images and T2 STIR from C1 to the proximal femur. Results were dichotomized as bone metastasis positive (M1) or negative (M0), and the anatomical sites of metastases were registered. PSA in those with M0 and M1 was compared using Mann-Whitney U test, and the area under the curve (AUC) for PSA was calculated when using M1 as a state variable.

Results: 153 patients were included. Median age (interquartile range) was 71 years (64-76) and PSA was 13 ng/ml (7.9-25.0). Gleason score 6: 4 (3%), 7a: 24 (16%), 7b: 38 (25%), 8: 50 (33%), 9: 31 (21%) and 10: 3 (2%), missing in three. Bone metastases were found in 7 out of 153 patients (4.6%, 95% CI: 1.8-9.4), all occurring in the pelvis. The median (IQR) PSA in M0 and M1 disease was 51 (37-71) and 12 ng/ml (7.8-22.5), respectively ($p=0.006$). All metastases were found in patients with PSA >22 ng/ml and Gleason score ≥ 8 . AUC for PSA was 0.917 (95% CI: 0.85-0.99).

Conclusion: All cases of bone metastases were found in the pelvis suggesting that whole-body MRI is excessive in patients with high-risk prostate cancer.

B-0822 14:08

Detection of extracapsular extension in high risk prostate cancer patients: multiparametric MRI vs. ⁶⁸Ga-PSMA-11 PET/MRI

U.J. Mühlematter, K. Schawkat, A. Becker, J. Müller, A.M. Hötter, N.J. Rupp, C.S. Reiner, I.A. Burger, O.F. Donati; *Zurich/CH*

Purpose: To compare the diagnostic accuracy and inter-reader reliability of multiparametric MRI (mpMRI) and ⁶⁸Ga-labeled prostate-specific membrane antigen (⁶⁸Ga-PSMA-11) PET/MRI for detection of extracapsular extension (ECE) in patients with prostate cancer.

Methods and Materials: Retrospective analysis of 40 consecutive men that underwent mpMRI and ⁶⁸Ga-PSMA-11 PET/MRI within 6 months for suspected prostate cancer that underwent radical prostatectomy between April 2016 and July 2018. Two readers (R1/R2) blinded to clinical and histopathologic findings rated the probability of ECE on mpMRI and PET/MRI in 4 anatomical regions (anterior/posterior on right/left side) using a 5-point Likert-scale. An interval of >3 weeks between readings was maintained to avoid recall bias. Prostatectomy specimen served as reference standard. Accuracy was assessed by calculating the Area under the receiver-operating-characteristics curve (AUC). Sensitivity/specificity was calculated on dichotomized data. Inter-reader reliability was assessed by intra-class correlation coefficient (ICC).

Results: Mean age was 63 years (range 51-78). 14/40 (35%) patients had ECE. For mpMRI versus PET/MRI, the region-specific results were as follows: AUC 0.67/0.71 (R1), 0.70/0.77 (R2); sensitivity 0.26/0.37 (R1), 0.47/0.53 (R2); specificity 0.93/0.93 (R1), 0.91/0.89 (R2). For mpMRI versus PET/MRI the patient-specific sensitivity was 0.42/0.55 (R1) and 0.55/0.60 (R2) and specificity was 0.68/0.66 (R1) and 0.62/0.63 (R2). There was no significant difference in ICC of mpMRI (ICC=0.72, CI=0.69-0.75) and PET/MRI (ICC=0.74, CI=0.71-0.77) between the two readers.

Conclusion: Our results suggest that ⁶⁸Ga-PSMA-11 PET/MR could improve the sensitivity of mpMRI for the detection of ECE in prostate cancer patients.

B-0823 14:16

Prostate cancer local staging: a comparison of short dual pulse and biparametric MRI vs multiparametric MRI

A. Stanzione, A. Ponsiglione, S. Coccozza, R. Cuocolo, S.G. Picchi, V. Romeo, S. Stilo, A. Brunetti, M. Imbriaco; *Naples/IT (arnaldostanzione@yahoo.it)*

Purpose: Local staging plays a pivotal role in the stratification of risk for patients affected by prostate cancer (PCa). Multiparametric MRI (mpMRI) is currently considered the most accurate imaging modality for pre-operative assessment of PCa local stage. Abbreviated unenhanced protocols have been proposed as a cheaper and faster alternative to mpMRI for the detection of PCa. Aim of our study was to evaluate the diagnostic accuracy in PCa local staging of two different abbreviated MRI protocols, in comparison to mpMRI.

Methods and Materials: Fifty patients were retrospectively enrolled (35 affected by PCa who underwent radical prostatectomy and 15 patients with negative biopsy results). A short dual pulse (dpMRI) protocol (axial T2-weighted and DWI) and a biparametric (bpMRI) protocol (triplanar T2-weighted and axial DWI) were obtained from the original images of the mpMRI standard protocol. Two experienced and two novice radiologists evaluated each protocol in a blinded, randomised fashion. The radiologists' performances were correlated with the reference standard using a Spearman correlation analysis, and each correlation coefficient was compared between MRI protocols using a paired t test.

Results: The correlation analysis showed that all MRI protocols were highly correlated to the reference standard (p<0.001). A significant difference emerged when dpMRI was tested in comparison with mpMRI (p=0.009), while no differences emerged when bpMRI was compared with the standard mpMRI (p=0.27).

Conclusion: The bpMRI protocol appears a feasible tool for assessment of PCa local stage, with a comparable diagnostic performance to the standard mpMRI.

B-0824 14:24

Local staging in prostate cancer (PCa): the role of capsular bulging and the length of capsular contact (LCC) to predict the risk of extracapsular extension (ECE) at final pathology

G. Stranieri¹, G. Gallo¹, A. De Pascale¹, D. Gned², M. Bini¹, D. Basile¹, E. Checcucci¹, F. Porpiglia¹, A. Veltri¹; ¹Turin/IT, ²Saint Pierre/IT (giuseppestranieri92@gmail.com)

Purpose: Multiparametric Magnetic Resonance (mp-MRI) had widespread diffusion in preoperative management of PCa in order to guide target biopsy and for local staging. Capsular bulging and LCC_{max} at mp-MRI has shown to be related to ECE. We evaluate the role of capsular bulging and LCC_{max} as biomarkers for predicting ECE.

Methods and Materials: We extracted retrospectively patients with PCa from a prospective robot-assisted radical prostatectomy (RARP) database. We included 162 patients who underwent preoperative mp-MRI followed by RARP from January 2016 to December 2017. ECE was assessed by an expert uro-pathologist. One expert reader, blinded from histological response, manually drawn LLC_{max} and estimated capsular bulging on T2 sequence. LLC_{max}≥20mm, LLC_{max}≥15mm and capsular bulging was chosen as predictors of ECE. We used chi-square-test (CSQ) and ROC curve for statistical analysis followed by calculation of diagnostic-test values.

Results: Among 162 patients, ECE was observed in 97. We evaluated ROC curve for LCC_{max} which showed AUC of 0.8026 (p<0.0001) and best accuracy (ACC) for 19.3mm. Both LCC_{max}≥20mm and LCC_{max}≥15mm had significant correlation with ECE (p<0.001 at CSQ). LCC_{max}≥20mm had specificity (SP) of 0.77 (50/65) and positive predictive value (PPV) of 0.82 (71/86); LCC_{max}≥15mm had sensitivity (SN) of 0.89 (87/97) and negative predictive value (NPV) of 0.79 (39/49). Capsular bulging is associated with ECE (p<0.001 at CSQ) and had SN of 0.86 (84/97) and PPV of 0.79 (84/106).

Conclusion: According to our preliminary evaluation both LCC_{max} and capsular bulging at preoperative mp-MRI seems to play a role in predicting ECE.

B-0825 14:32

Multiparametric MRI of the bladder: interobserver agreement and accuracy with the vesical imaging-reporting and data system (VIRADS) at a single reference centre

G. Barchetti, R. Campa, M. Pecoraro, I. Ceravolo, C. Catalano, V. Panebianco; *Rome/IT (giovanni.barchetti2@gmail.com)*

Purpose: To evaluate the accuracy and interobserver variability of the Vesical Imaging-Reporting and Data System (VI-RADS) for discriminating between non-muscle-invasive bladder cancer (NMIBC) and muscle-invasive bladder cancer (MIBC), in patients undergoing multiparametric MRI (mpMRI) before transurethral resection of bladder tumour (TURBT).

Methods and Materials: 75 patients referred to our institution for bladder cancer underwent mpMRI before TURBT. All mpMRI were reviewed by two radiologists, blinded to clinical history and histopathology. Correlation between mpMRI diagnosis and histopathology was estimated using the Kendall T. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated for both readers, considering scenario 1 (VI-RADS 3 classified as MIBC) and scenario 2 (VI-RADS 3 classified as NMIBC). The K statistics was used to estimate inter-reader agreement.

Results: 53 patients were diagnosed with NMIBC and 22 with MIBC. The correlation analysis yielded the following results for the overall VI-RADS score: T= 0,54 for reader 1 and T= 0,51 for reader 2. Both readers obtained a better sensitivity (91% and 82% vs 82% and 64%) and NPV (96% and 92% vs 92% and 86%) in scenario 1. A lower specificity (91% and 87% vs 96% and 94%) and PPV (80% and 72% vs 89% and 82%) were obtained in scenario 1. Area under curve was 0,918 for reader 1 and 0,897 for reader 2. Inter-reader agreement was good for the overall VI-RADS score (K= 0,731).

Conclusion: In conclusion, mpMRI with the use of VI-RADS is accurate in differentiating MIBC from NMIBC.

B-0827 14:40

Magnetic resonance imaging findings differentiate among periurethral bulking agent, urethral diverticulum and periurethral cyst, preventing misdiagnosis

T. Chulroek¹, D. Wangcharoenrun¹, K. Cattapan², K. Hamed³, A.J. Mitchell³, M.G. Harisinghani³, E.J.B. De³; ¹Bangkok/TH, ²Songkhla/TH, ³Boston, MA/US (thitinan.c@chula.ac.th)

Purpose: To evaluate magnetic resonance imaging findings to differentiate periurethral bulking agent, urethral diverticulum and periurethral cyst.

Methods and Materials: In this retrospective study, we searched radiologic department database. A total of 50 patients with periurethral cystic lesions and magnetic resonance imaging between 2001-2017 were included with 68 lesions (27 bulking agents, 29 urethral diverticula and 12 periurethral cysts) were found. Two abdominal radiologists blinded to clinical history, independently evaluated T1, T2, and post-contrast images. The readers assessed number, morphological features, location, connection to urethra and mass effect, signal intensity, and enhancement for each lesion. Logistic regression analysis was performed for each univariate significant feature. Operative and pathologic reports were the reference standard.

Results: Magnetic resonance imaging findings in bulking agents which helped differentiate from urethral diverticulum were more cases with multiple lesions (P=0.021), upper or upper-mid urethral location (P=0.003), lack of both internal fluid/fluid level (P=0.029) and urethral connection (P=0.038), T1 isointensity, T2 mild hyperintensity compared to muscles but lower T2 signal than urine (P<0.0001). Most cases of urethral diverticula and periurethral cysts were detected at mid and lower urethra. Urethral diverticula were larger than bulking agents and periurethral cysts (P=0.005 & P=0.023) (mean diameter=24, 16, and 15mm, respectively). Most bulking agents (93%) and urethral diverticula (90%) showed mass effect upon urethra while periurethral cysts (75%) did not (P<0.0001).

Conclusion: Signal intensity and lesion characterisation on magnetic resonance imaging can significantly differentiate bulking agent from urethral diverticulum and periurethral cyst. These findings may help guide clinicians when considering operative intervention.

B-0828 14:48

MP-MRI can exclude prostate cancer progression in patients under active surveillance

L. Schimmöller, T. Ullrich, F. Mones, M. Quentin, R. Rabenalt, P. Albers, G. Antoch, C. Arsov; *Düsseldorf/DE*
(lars.schimmoller@med.uni-duesseldorf.de)

Purpose: To assess the ability of multiparametric MRI (mp-MRI) of the prostate to exclude prostate cancer (PCa) progression in patients under active surveillance.

Methods and Materials: One hundred and forty-seven consecutive patients under active surveillance with known PCa with a Gleason score of 3+3=6 or 3+4=7a were initially enrolled and received mp-MRI (T2WI, DWI, DCE-MRI) of the prostate at 3T. Of these patients, fifty-five received follow-up MRI after a minimum interval of 12 months with subsequently targeted MR/US fusion-guided (FUS-GB) plus systematic transrectal ultrasound-guided (TRUS-GB) biopsy. Primary endpoint was negative predictive value (NPV) of the follow-up mp-MRI to exclude tumour progression. Secondary endpoints were positive predictive value (PPV), sensitivity, specificity, and cancer upgrade after initial mp-MRI.

Results: Of 55 patients 28 (51%) had a Gleason score upgrade in the re-biopsy. All of the 28 patients showed findings in the follow-up mp-MRI that were suspicious of tumour progress. 16 of 55 patients (29%) showed signs of tumour progress in the follow-up MRI but had a stable re-biopsy. 11 of 55 patients (20%) showed no signs of progress in follow-up MRI and none of these patients had a Gleason score upgrade in the re-biopsy. NPV was 100%. PPV was 64%. Sensitivity was 100% and specificity 59%.

Conclusion: mp-MRI can reliably exclude PCa progression in patients under active surveillance. Over 60% of the patients with signs of tumour progress in follow-up mp-MRI had a Gleason score upgrade in repeat biopsy.

B-0829 14:56

PSAD and ADC values improve the diagnostic accuracy of PI-RADS v2

A.C. Westphalen, F. Fazel, H. Nguyen, M. Cabarrus, K. Hanley-Knutson, K. Shinohara, P.R. Carroll; *San Francisco, CA/US*
(antonio.westphalen@ucsf.edu)

Purpose: To determine if PSAD and ADC values improve the accuracy of PI-RADS v2 and identify patients likely to have high-grade cancer on areas without mpMRI visible lesions.

Methods and Materials: This is a single-reference-centre, cross-sectional, retrospective study of consecutive men with suspected or known low- to intermediate-risk prostate cancer who underwent 3T mpMRI and TRUS-MRI fusion biopsy from 07/15/2014 to 02/17/2018. Cluster-corrected logistic regression analyses were utilized to predict high-grade prostate cancer (Gleason score $\geq 3+4$) at targeted mpMRI lesions and on systematic biopsy.

Results: 538 men (median age=66 years, median PSA=7.0 ng/ml) with 780 mpMRI lesions were included. High-grade disease was diagnosed in 371 men. PI-RADS v2 scores of 3, 4, and 5 were high-grade cancer in 8.0% (16/201), 22.8% (90/395), and 59.2% (109/184). ADC values, PSAD, and PI-RADS v2 scores were independent predictors of high-grade cancer in targeted lesions (OR 2.25-8.78; P values < 0.05; AUROC 0.84, 95% CI 0.81-0.87). Increases in PSAD were also associated with upgrade on systematic biopsy (OR 2.39-2.48; P values < 0.05; AUROC 0.69, 95% CI 0.64-0.73). Study limitations include its retrospective single-institution design and use of biopsy rather than prostatectomy specimens of standard of reference.

Conclusion: ADC values and PSAD improve characterization of PI-RADS v2 score 4 or 5 lesions. Upgrade on systematic biopsy is slightly more likely with PSAD ≥ 0.15 and multiple small PI-RADS v2 score 3 or 4 lesions.

Dynamic contrast-enhanced MRI perspectives in the assessment of aggressiveness of urinary bladder cancer

R.T. Abouelkheir, M.E. Abou El-Ghar, T. El-Diasty; *Ei-Mansoura/EG*
(dr_rasha_taha@hotmail.com)

Purpose: To investigate role of dynamic contrast-enhanced MRI in non-invasive assessment of staging and aggressiveness of bladder cancer correlating with tumour microvessel density measurement as indicator of angiogenesis.

Methods and Materials: 81 consecutive patients were referred from our outpatient clinic of Urology and Nephrology Center, Mansoura University, with suspected diagnosis of bladder cancer. Morphologic evaluation, dynamic MRI

staging and analysis of "Time- Signal Intensity curves" were done, compared with histopathological staging. Tumour micro-vessel density was identified using CD34 immunoreactivity. Kappa statistics, Spearman's correlation test and ROC curves were used for statistical analysis.

Results: High positive correlation was found between dynamic MRI staging and histopathological staging ($r = 0.965$, $p = 0.001$), also between the type of time-SI curve and pathological grading ($r = 0.727$, $p = 0.001$). High positive correlation was found between the tumour micro-vessel density and pathological staging ($r = 0.606$, $p = 0.001$), also between the micro-vessel density and tumour grading ($r = 0.773$, $p = 0.001$). Among the 81 cases, 71 cases were pathologically proven as malignant and 10 cases were pathologically proven as cystitis. Dynamic MRI with "Time-SI curve" succeeded in differentiating malignant bladder tumours from cystitis. 58% of malignant tumours showed type III (descending) curve, 31% showed type II (plateau) and 11% showed type I (ascending) curve, depending on tumour stage, grade and angiogenesis. However, cases diagnosed as cystitis had type I curve.

Conclusion: Dynamic MRI can increase diagnostic accuracy of bladder tumour staging, angiogenic activity and assessment of tumour aggressiveness; it also can differentiate between malignant bladder tumours and cystitis.

B-0831 15:12

Radiomic analysis of multiparametric MRI for preoperative evaluation of pathological grade in bladder cancer

H. Wang, F. Zhang, W. Fu, J. Guan, Y. Guo; *Guangzhou/CN*
(fzhang1105@163.com)

Purpose: To develop and validate a MRI-based radiomics strategy for the preoperative estimation of grading for bladder cancer(BC).

Methods and Materials: A total of 100 BC patients were divided into a training set (n=70) and validation set (n=30). Radiomics features were extracted from MR images (including T2WI, DWI and ADC maps) of each patient and 5 feature subsets were constructed. The 5 feature subsets were subjected to least absolute shrinkage and selection operator (LASSO) algorithm respectively and logistic regression (LR) analysis was applied to develop 5 corresponding radiomics models (T2WI_Model, DWI_Model, ADC_Model, Joint_Model and MaxFea_Model). The diagnostic performance of the 5 models was evaluated using accuracy, sensitivity, specificity as well as AUC (area under the receiver operating characteristic curve) in the independent validation cohorts.

Results: The accuracy, sensitivity, specificity and AUC of the Joint_Model in both training and validation cohorts was 0.8657, 0.8433, 0.8800, 0.9150 and 0.8333, 0.7692, 0.8824, 0.9276 respectively. The AUC of the remaining four models in training and validation cohorts was 0.8300, 0.8083, 0.8983, 0.9183 and 0.8235, 0.7692, 0.8824, 0.9186 respectively, all of which were significantly lower than that of Joint_Model.

Conclusion: The multiparametric MRI based radiomics approach has the potential to be used as a non-invasive imaging tool for preoperative grading in BC. Multicenter validation is needed to acquire high-level evidence for its clinical application.

Perfusion MRI prediction of progression-free survival in patients with hepatocellular carcinoma treat with TACE

Z. Zhu, X. Zhao, C. Zhou; *Beijing/CN*

Purpose: To predict the value of perfusion weighted imaging (PWI) in progression-free survival (PFS) of hepatocellular carcinoma (HCC) after transcatheter arterial chemoembolization (TACE).

Methods and Materials: Ninety patients were enrolled in this study from Sep 2014 to Sep 2017. A total of 10 parameters including 4 clinical indexes: gender, age, size of lesion, tumour thrombus; and 6 functional MRI indexes: pretreatment and posttreatment volume transfer constant (K^{trans}), exchange rate constant (K_{ep}), and extravascular extracellular space volume ratio (V_e) were analyzed by multivariate analysis. Using independent sample t test, ANOVA, the Kaplan-Meier survival curve, Log-Rank test and Cox regression analysis to determinate the prognostic value of DCE-MR parameters and clinical indicators.

Results: Age, pretreatment K^{trans} and posttreatment K^{trans} were 3 indicators in the prognosis of HCC after TACE ($P_{age}=0.027$, $P_{pretrans}<0.001$,

$P_{\text{postK}^{\text{trans}} < 0.001}$). Using median as cut-off value, found that age > 53 yrs, pretreatment $K^{\text{trans}} > 1.165/\text{min}$ and posttreatment $K^{\text{trans}} > 1.077/\text{min}$ predicts poor prognosis of HCC. Others (gender, thrombus, size, preK_{ep} , postK_{ep} , preV_e and postV_e) showed no statistical significance.

Conclusion: Age, pretreatment K^{trans} and posttreatment K^{trans} value can predict the prognosis of TACE treatment for HCC.

B-0833 16:04

Evaluation of mismatch diameter between radial versus distal radial artery in patients suitable for vascular peripheral procedures

D. Meo, D. Falsaperla, A. Modica, M.C. Calcagno, C. Desiderio, F. Libra, P. Foti, S. Palmucci, A. Basile; Catania/IT (alessandromodica86@gmail.com)

Purpose: To describe the variability of the diameter of the radial artery (RA) measured at both levels used for percutaneous approach: proximal (whitin 2 cm) to the styloid process (pRA) and distal at the snuff box (dRA) correlating them to cardiovascular risk factors (CRF), sex, and age.

Methods and Materials: We enrolled 460 patients (221 female, 239 males) from July to September 2018. The diameter of left and right RA were studied with Ultrasound (US) and Color-Doppler Ultrasound (CD-US). Diameters of pRA and dRA were compared between different sex, age, and CRF (tabagism, hypertension, dislipidemia, BMI > 30, diabetes); the possibility of a snuff box approach was also evaluated considering a diameter $\geq 2\text{mm}$ as a cut-off for the feasibility.

Results: The average proximal diameter founded for the pRA were 2.73mm (SD=0.53mm) at the right arm and 2.72mm (SD=0.56mm) at the left arm. The calibre of the dRA was about 32% lower than the proximal one, with an average diameter of 2.07mm (SD=0.51mm) and 2.05mm (SD=0.53mm) for the left and right side respectively. Female patients showed smaller diameters than male patients, in particular at the dRA. We did not found significative differences related to CFS. Among the 460 patients studied, 360 (66%) were eligible for dRA approach.

Conclusion: dRA approach is a relatively new technique with many advantages compared to "traditional radial access"; the evaluation of the feasibility with US and CD-US is a fast and accurate way to decide if the "snuff box approach" can be performed.

Image-guided percutaneous techniques in the treatment of aggressive vertebral haemangiomas: clinical outcomes and therapeutic strategy

A. Ricoeur¹, J. Caudrelier², X. Buy³, J. Garnon², G. Koch², R. Cazzato², A. Gangi²; ¹Lyon/FR, ²Strasbourg/FR, ³Bordeaux/FR

Purpose: To evaluate the safety and the clinical efficacy of a therapeutic strategy consisting in image-guided percutaneous techniques for treating symptomatic aggressive vertebral haemangiomas (SAVHs).

Methods and Materials: This retrospective study identified all the patients affected by SAVHs who had undergone image-guided percutaneous vertebroplasty (PVP) alone or in combination with prior percutaneous intrasclerosant instillation (sclerotherapy) in one institution between 1991 and 2016. Fifty-eight patients (39 females and 19 males, mean age: 50.1 years) were included. Imaging studies, pain and neurological evaluations, procedure-related data and complications were assessed. Descriptive statistics, expressed as means and proportions associated to 95 percent confidence interval and standard deviation were used to report the results.

Results: Thirty-eight out of 58 patients (65.5%) with back pain and no neurological symptoms had PVP as a single treatment for SAVHs limited to the vertebral body. Technical success was 100%. Clinical success was achieved in 35/38 patients (92.1%, 95% CI [78.6; 98.3]) with complete pain relief at last follow-up. Twenty out of 58 patients (34.5%) suffered from back pain and neurological symptoms related to SAVHs with extraosseous extension. Fifteen of them (25.9%) underwent sclerotherapy and additional PVP. Technical success was 93.3%. The 5 remaining patients (8.6%) received combined percutaneous and surgical treatments. Clinical success was achieved in 18/20 patients (90%) with full or almost full neurological recovery and total pain relief.

Conclusion: Image-guided percutaneous techniques, including PVP alone, or sclerotherapy followed by PVP, are safe and efficient providing excellent results in back pain and neurological symptoms resolution for the treatment of SAVHs.

B-0836 16:16

Does IV-tPA induce thrombus migration? A retrospective study comparing bridging therapy and thrombectomy alone

C. Cohen¹, K. Gaillot², K. Janot¹, J. Cottier¹, M. Dejobert¹, A.-P. Narata¹; ¹Tours/FR, ²La Rochelle/FR (clara.cohen.cc@gmail.com)

Purpose: Thrombus migration (ThrMi) before mechanical thrombectomy (MT) is an epiphenomenon in acute ischaemic stroke (AIS). The aim of this study is to evaluate ThrMi prior MT in a bridging protocol (tPA-MT-group) and stand-alone MT (MT-group).

Methods and Materials: 205 consecutive AIS patients treated by MT (tPA and no-tPA) were retrospectively analyzed. Distance between vessel origin and beginning of the thrombus on MRI (3D TOF and/or contrast-enhanced-MRA) and digital-subtracted-angiography (DSA) were measured in millimeters using a curve tool and the same anatomical parameters. DSA pixels were converted in millimetres by measuring 3 internal carotid diameters in MRI and determining the ratio from pixels to millimetres.

Results: In tPA-MT group (n=129), ThrMi occurred in 36.4%, and in 6.6% of MT group (n=76) (p<0.001, Student t-Test). In tPA-MT group, 27(20.9%) patients had a moderate migration (5-to-10 millimetres), 11(8.5%) patients had a distal migration (>10 millimetres or to another segment) and 9(7%) presented recanalization defined by spontaneous TIC1 score $\geq 2B$. In MT-group, 69 (90.8%) patients had no ThrMi, moderate ThrMi in 6.6%, thrombus' extension in 2.6%; no patient presented distal migration or recanalization. The two groups had the same clinical prognosis (bleeding at 48hours, discharge NIHSS, mRS/death at 3 months). Number of device passes to reach thrombectomy was 1.40 (± 1.39) in tPA-MT-group, 1.63 (± 1.09) in MT-group, p=0.061.

Conclusion: IV thrombolysis seems to promote thrombus migration, present in 36.4% of patients in tPA-MT-group compared to 6.6% of patients in MT-group. This study adds more data concerning IV thrombolysis effects on AIS treatment when MT is also involved.

B-0837 16:20

Focal prostate cancer ablation "out of the rectum and out of MRI": new tools for fusion-guidance and "super-active surveillance"

S. Xu, V. Anderson, M. Li, J. Peretti, C. Garcia, P.L. Choyke, P. Pinto, B. Turkbey, B.J. Wood; Bethesda, MD/US (xus2@cc.nih.gov)

Purpose: To describe novel approaches and tools for fusion guidance for focal prostate ablation outside of the MRI gantry.

Methods and Materials: Describe the approach, criteria, workflow, software, and hardware enabling MRI TRUS fusion guided prostate focal laser ablation outside of the MRI gantry, towards an office-based setting. A clinical trial is outlined for approaching focal laser ablation of prostate cancer without requiring MRI. Patients undergo diagnostic MRI only enabling fusion biopsy. Hardware and software tools to enable or facilitate focal laser thermal ablation of prostate cancer targets are identified. Hydrodissection, thermocouples, ultrasound monitoring, and composite ablation planning were implemented in patients. Other tools were deployed in phantoms prior to clinical trial deployment.

Results: Early clinical results demonstrate MRI-TRUS fusion system can guide ablation of focal prostate cancer outside of the MRI gantry. Custom software allows for composite laser ablation of targeted tumours via a transperineal approach with or without electromagnetism (EM) tracking. Treatment planning software successfully identifies tissue at risk for under-treatment. Future clinical tools were demonstrated in a custom pelvic phantom, such as augmented reality, an EM-tracked Foley bladder catheter for correction of mis-registration, and a transperineal ultrasound fusion enabling no transrectal imaging or interventions.

Conclusion: Novel tools and approaches are demonstrated for fusion guided focal ablation of prostate cancer out of the MRI gantry and out of the rectum. This includes fusion ablation in an ultrasound-guided office-like setting, augmented reality for transperineal interventions, EM-tracked Foley catheter, and transperineal prostate interventions fully outside of the rectum.

Safety and outcomes of transarterial chemoembolization using small-versus medium-sized drug-eluting beads for unresectable hepatocellular carcinoma

A.M.K. Abdel Aal, K. Mahmoud, H. El Khudari, N. Aboueldahab, S. Saddekni, A. Gunn; Birmingham, AL/US (akamel@uabmc.edu)

Purpose: The purpose of this study is to compare the safety and efficacy of using very small size (75um) drug-eluting beads (VS-DEB) with medium-size (100-300um) drug-eluting beads (M-DEB) in transarterial chemoembolization (TACE) for the treatment of unresectable hepatocellular carcinoma (HCC).

Methods and Materials: We retrospectively reviewed the medical records of patients with HCC between September 2010 and June 2018 who underwent TACE using VS-DEB (n=109) versus M-DEB (n=82). Imaging follow-up was done 4-6 weeks after TACE. Tumour response was measured by m-RECIST criteria. Toxicity was measured according to CTCAE v4.0. Overall and progression-free survival were calculated using Kaplan-Meier curves.

Results: The study included 191 patients with mean age of 63.4 (SD=8.6) years. The most common aetiology of cirrhosis was hepatitis C virus (58.1%). There was no difference in the demographics or the BCLC stage between both groups. In BCLC A and B patients, complete response, objective response and disease control was higher in the VS-DEB group (26.8%, 71.8% and 91.6%, respectively) compared to the M-DEB group (3.9% [p=0.001], 45.1% [p=0.003] and 78.4% [p=0.039]). Overall survival in BCLC A and B patients was higher in the VS-DEB group compared to M-DEB (p=0.05). There was no difference in the progression-free survival between both groups. There was no significant difference in grade 3 and 4 toxicity between the two groups.

Conclusion: In BCLC A and B patients, the use of VS-DEB offers superior radiologic response and survival advantage compared to M-DEB, without significant increase in toxicity.

MRI-CT fusion imaging before high-selective lumbar sympathectomy

B. Reichardt¹, A. Örnek¹, V. Nicolas², C. Maier²; ¹Essen/DE, ²Bochum/DE (benjamin.reichardt@uk-essen.de)

Purpose: To reduce side effects and the amount of alcohol applied, highly selective sympathectomy of individual ganglia is desirable. The sympathetic trunk and individual ganglia are not always visible in CT imaging. We expected from an MRI/CT image fusion before intervention a possibility to identify single ganglia and to lyse them highly selectively.

Methods and Materials: 14 patients received a native lumbar MRI (DWIBS, Shinkei, T1, STIR and PDWs) before sympathectomy. After successful detection of a single ganglion from the side to be treated, one day later a pre-interventional CT spiral of the lumbar spine in prone position was performed. The CT and the STIR or PDW fs sequence from the MRI data set were transferred to fusion software prior to puncture. After successful matching, highly selective sympathectomy was performed with 1.5ml 95% alcohol.

Results: All interventions were successful and pain reduction was achieved. Apart from dysesthesia of the genitofemoral cutaneous nerve, no side effects occurred. The automated MRT/CT image fusion worked in 12/14 patients, 2 data sets had to be readjusted manually.

Conclusion: MRI/CT image fusion before sympathectomy allows a highly selective intervention at the single sympathetic ganglion sympathetic ganglion, thus reducing the amount of alcohol to be administered and avoiding unwanted side effects. The technique is equally useful for other interventional treatments in which a CT alone is not sufficient.

B-0840 16:32

Lumbar sympathetic trunk in MRI and CT: its visibility and distance to two anatomical landmarks for pre-interventional planning

B. Reichardt¹, A. Örnek¹, V. Nicolas², C. Maier²; ¹Essen/DE, ²Bochum/DE (benjamin.reichardt@uk-essen.de)

Purpose: The lumbar sympathetic trunk's (LST) distance to two anatomical landmarks, the costal process and medial margin of the psoas muscle, was assessed due to its use as landmarks for lumbar sympathectomy blocks: the costal process for fluoroscopic guided techniques and the psoas major for CT- and MRI-guided techniques. Based on the measurements, we evaluate the trunk's visibility in MR and CT images for accurate needle positioning.

Methods and Materials: Retrospective analysis of 42 CT and MRI dataset before sympathectomy. LST's distances to the psoas major's medial margin and to the base of the lumbar vertebrae's costal process were measured on the levels L2/3, L3/4 and L4/5. CT protocol: Th12 to S1 (100 kV, 60mAs, 1mm slice thickness). MRI protocol: T1, T2, PDW/STIR, 1mm 3D-DWIBS or 3D-Shinkei with MIP for neurography.

Results: LST's mean distance to the psoas major was 0.4 mm at L2/3, 3 mm at L3/4 and 4.6 mm at L4/5. The mean distance to the costal process was 32 mm at L2/3, 34 mm at L3/4 and 33 mm at L4/5. In MR and CT imaging, a structure could be determined as the LST correlating to the measurements with decreasing possible identification from cephalad to caudad levels.

Conclusion: The costal process is a usable landmark for fluoroscopic guidance and the psoas major for CT- and MRI-guided techniques. The LST is clearly visible in MR and CT images, which gives both techniques a decisive advantage over fluoroscopy concerning interventions at the LST, due to a visible target.

B-0841 16:36

Bilateral carotid stenting in the same sitting in high-risk patients: a single-centre study

L.S.P. Karanam, S.R. Baddam, A. Alurkar, V. Pamidimukkala, R. Polavarapu; Guntur/IN (drklsp@gmail.com)

Purpose: To determine the role of simultaneous carotid artery stenting in high-risk patients with triple-vessel coronary artery disease, and the safety and efficacy of the procedure in these cases.

Methods and Materials: The present study is a retrospective analysis of 56 patients, who underwent carotid artery stenting in the same sitting in our institution from 2009 to 2018. There were 39 males and 17 females with a mean age of 65 years (53-76 years). Inclusion criteria of the present study were patients with bilateral internal carotid artery stenosis >50% (50-99%) in the symptomatic side and >60% in the asymptomatic side as seen on digital subtraction angiography.

Results: Technical success was 100% in our series. Intra-procedural and post-procedural events in the form of hypotension and bradycardia were seen in 23 patients. This was treated with intra-procedural atropine and post-procedural dopamine (5-15 µg/kg/min) or noradrenaline (2-4 µg/min) infusion. One patient suffered from hyperperfusion bleed. 48 patients underwent cardiac bypass surgery after three weeks. No deaths or myocardial infarctions occurred either in the post-procedural period (up to 1 month) or on clinical follow-up of 3 and 6 months.

Conclusion: Bilateral carotid artery stenting in the same sitting is a safe treatment option even in patients with high-risk factors and can be considered as a safe treatment option in patients with significant bilateral carotid artery disease.

B-0842 16:40

Pneumothorax and pulmonary haemorrhage after CT-guided lung biopsy: incidence, clinical significance and correlation

V. Sabatino, U. Russo, F.V. d'Amuri, A. Bevilacqua, F. Pagnini, G. Milanese, R. Nizzoli, G. Pedrazzi, M. De Filippo; Parma/IT (vittorio.sabatino@gmail.com)

Purpose: To evaluate incidence and clinical significance of pneumothorax (PTX) and pulmonary haemorrhage (PH) after CT-guided lung biopsy (CT-LB). To test correlations of PTX and chest tube insertion (CTI) with PH and different imaging and procedural parameters.

Methods and Materials: Pre-procedural CT and CT-LB scans of 904 patients were retrieved. Incidence of PTX and of PH (location: type 1 along needle track or type 2 perilesional; severity according to its thickness: low grade <6mm or high grade >6mm) were recorded. CTI was assessed by reviewing medical charts. PTX was considered clinically significant if treated with CTI, PH if treated with endoscopic/endovascular procedure. Evaluated parameters included: nodule-to-pleura distance (mm), emphysema (subjectively quantified in ≤25%, 25-50%, ≥50%) and procedure time (minutes). Binary logistic regression analyses tested whether PH and imaging and procedure parameters were associated with development of PTX and CTI.

Results: PTX occurred in 306/904 cases (33.8%); CTI was requested in 18/306 (5.9%). PH occurred in 296/904 cases (32.7%), of which 165/296 (55.7%) type-1 high-graded; no case requested treatment. Type-1 high-graded PH showed a protective effect against PTX and CTI (OR_{PTX}=0.340; OR_{CTI}=0.177). Nodule-to-pleura distance (OR_{PTX}=1.046; OR_{CTI}=1.057), emphysema (OR_{PTX}=1.330; OR_{CTI}=2.074) and procedure time (OR_{PTX}=1.018; OR_{CTI}=1.037) were associated with an increased risk for PTX and CTI.

Conclusion: Pneumothorax and pulmonary haemorrhage have similar incidence after CT-guided lung biopsy. Treatment was required only for pneumothorax (<6% of cases) while pulmonary haemorrhage was not clinically significant. Pulmonary haemorrhage along needle track >6mm may represent a protective factor against development of pneumothorax and against pneumothorax requesting chest tube insertion.

B-0843 16:44

MR imaging-based response evaluation of two different transarterial chemoembolisation protocols using degradable starch microspheres in the therapy of hepatocellular carcinoma

M.C. Langenbach, M.H. Albrecht, R. Hammerstingl, T. Gruber-Rouh, T.J. Vogl; Frankfurt am Main/DE (marcel.langenbach@me.com)

Purpose: Therapy response evaluation of transarterial chemoembolisation [TACE] in hepatocellular carcinoma [HCC] comparing two different embolisation protocols, either with Lipiodol or with an additional use of degradable starch microspheres [DSM], based on ADC findings.

Methods and Materials: Sixty-one patients (44 men; 17 women; mean age 71 years; range 44-85) with HCC were evaluated in this prospective randomised trial. Treatment protocol included three TACE sessions in 4-week intervals with multiparametric MRI prior and 4 weeks after the last TACE (endpoint). In group 1 (n=30), TACE was performed using Lipiodol only. In group 2 (n=31), Lipiodol

was combined with DSM. Differences in tumour volume, diameter, RECIST 1.1 criteria, ADC and survival were analysed and compared using Mann-Whitney U test, Kruskal-Wallis H test and Spearman-Rho.

Results: Overall, a decrease in tumour volume and diameter was strongly significant correlated to an increase in ADC values (volume: $\rho = -0.397$, $p < 0.001$; diameter: $\rho = -0.585$, $p < 0.001$) with no differences between the embolisation protocols ($p = 0.489$). Average tumour volume and diameter reduction were comparable between both groups (volume $p = 0.653$, diameter $p = 0.678$). Further, response evaluation according RECIST 1.1 showed no differences ($p = 0.112$). Estimated overall survival was in mean 32.5 months (95% CI: 26.6-38.4), in group 1 29.4 months (95% CI: 21.7-37.1) and in group 2 33.4 months (95% CI: 25.5-41.4) ($p = 0.844$), respectively.

Conclusion: An increase of ADC values during TACE is strongly correlates with the local tumour response and thus, may be used as a therapy monitoring factor. Furthermore, additional DSM application showed no significant differences in diameter and volume reduction compared to standard TACE.

B-0844 16:48

The anatomic options of vessels and haemodynamic redistribution of the blood flow at selective intra-arterial chemotherapy (SIAC) in children with an intraocular retinoblastoma

I. Pogrebnyakov, I. Trofimov, A.V. Kukushkin, E. Virshke, B. Dolgushin;
Moscow/RU (i.pogr@mail.ru)

Purpose: Describing the methodology of a SOAI in organ-preserving treatment of children with an intraocular retinoblastoma and demonstrating the various ways of alkylating agent delivery to a tumour.

Methods and Materials: 316 SIAC procedures to 110 children (129 eyes) have been performed from 2011 to 2017. 2 methods of SOAI were applied: 1) the microcatheter technique - superselective catheterization of an eye artery or collateral branches of an ECA at blood flow haemodynamic redistribution; 2) the micro-balloon technique.

Results: Technical success was 95.8% (303 procedures). 245 procedures with the use of a microcatheter infusion was carried out in: a. ophthalmica - 196 (80%), a. meningea media - 27 (11%), a. infraorbitalis - 20 (8.2%), a. temp. superficialis - 1 (0.4%), and a. facialis - 1 (0.4%). From 61 procedures with using of micro-balloon 58 were successful. We did not manage to put a balloon more distally than the place of an entry of an eye artery in 3 cases. Unsuccessful attempts - 13 cases: failure of catheterization of a femoral artery - in 3, a kinking/coiling of the ICA - in 3, a vascular collapse as a result of reaction to contrast agent and/or mechanical impact on ICA - in 3, lack of contrasting of a retina - in 3, an occlusion of an ICA - in 1.

Conclusion: Use of various techniques for drug delivery to an eye tumour allows to achieve the maximum effect and does not depend on anatomy options and blood flow haemodynamic redistribution in the main vessels of an eye.

B-0845 16:52

The role of selective intraarterial and intravitreal chemotherapy in organ-preserving treatment of the children with an intraocular retinoblastoma

I. Pogrebnyakov, B. Dolgushin, I. Trofimov, A.V. Kukushkin, E. Virshke;
Moscow/RU (i.pogr@mail.ru)

Purpose: Improving of organ-preserving treatment results of the children with an intraocular retinoblastoma (IRB) with local selective intraarterial (IAC) and intravitreal (IViC) chemotherapy methods.

Methods and Materials: 110 children (129 eyes) with a one - and bilateral retinoblastoma were included in the study. All patients/eyes were divided into 2 groups. The 1st group included 99 children/116 eyes who received SIAC as a combined treatment if their previous treatment was not effective enough. The 2nd group included treatment-naïve 11 children/13 eyes with unilateral and bilateral IRBs who received SIAC as the first means of treatment.

Results: In the first group, 95 of 116 eyes were saved. The globe salvage by Kaplan-Meier was reached in 94.5% in 1 year, 88.5% in 2 years, 86.5% in 3 years, 82.9% in 4 years and 75.0% from 4th to 6th years. Patients were followed up to 30.3±16.81 month, and 23.74 ±12.45 months was the relapse-free period. In the second group, 12 of 13 eyes were retained. The globe salvage by Kaplan-Meier was reached in 92.3% in 1 and 2 years. Patients were followed up to 13.5±5.3 months, and 23.74 ±12.45 months was the relapse-free period.

Conclusion: Local chemotherapy is an effective and perspective organ-preserving method. It can be used as a complex therapy part of advanced and refractory IRB forms and as a monotherapy of the primary identified IRB.

B-0846 16:56

Intermediate-stage HCC, SIRT and balloon-occlusive micro-catheter: the right way?

A. Paladini¹, G.E. Vallati², G. Pizzi², F. Cappelli², D. Beomonte Zobel², E.M. Amodeo², A. Borzelli³; ¹Novara/IT, ²Rome/IT, ³Naples/IT
(andreapaladini1988@gmail.com)

Purpose: The use of selective internal radiation therapy (SIRT) with 90-Yttrium resin microspheres (Y⁹⁰-ms) for hepatocellular carcinoma (HCC) is increasing. The use of Occlusafe microcatheter (Terumo, Japan) as new balloon antireflux microcatheter for Y⁹⁰-ms infusion is a promising innovative technique potentially improving dose distribution within tumour while sparing normal liver. We evaluated the benefits of using Occlusafe microcatheter in terms of dose distribution as predictor of patients' outcome.

Methods and Materials: A prospective enrollment of 10 patients with unresectable HCC who underwent planning pre-SIRT phase was performed. Volumes of the normal liver and tumour were contoured using a software based on pre- and post-treatment CT and SPECT/CT images. Two radiologists performed a qualitative volumetric evaluation in a blinded and randomized fashion using mRECIST parameters. Quantitative analysis of activity distribution based on pre- and post-treatment imaging and dose gradient was performed using a home-made tool for tumour/non-tumour (T/NT) evaluation.

Results: Higher T/NT ratio was observed on pre- and post-SIRT images thanks to the use of Occlusafe microcatheter compared with our historical cohort. In particular, the agreement of dose-distribution pre- and post-SIRT was observed in 100% patients, higher than 80% previously reported by our group. The evaluation of the two radiologists, using mRECIST parameters, showed a high dose-outcome relationship.

Conclusion: Volumetric and activity distribution measurements of superselective angiography during pre- and post-treatment confirm Occlusafe microcatheter as an improved strategy for increase T-NT ratio and dose distribution prediction in SIRT procedure thus increasing the predictive capability of treatment planning.

B-0847 17:00

Robot-assisted percutaneous placement of K-Wires during minimal-invasive interventions of the spine

M.H. Albrecht¹, Y. Croissant¹, C. Czerny¹, T.J. Vogl¹, S. Zangos²;
¹Frankfurt a. Main/DE, ²Göppingen/DE (MoritzAlbrecht@gmx.net)

Purpose: To assess the accuracy and time requirements of image-guided percutaneous K-wire insertion in the spine using an advanced robot assistance device for needle guidance and to demonstrate a radiation-free workflow for the physician.

Methods and Materials: A planning CT-scan was acquired of a cadaver specimen and analyzed using a 3D-interventional software integrated in the robotic device. The optimal needle path was simulated and the needle holder of the robot was used for guidance during K-wire insertion. Twenty-four K-wires were inserted percutaneously in a transpedicular approach in the following vertebrae: thoracic (T) 2, 7-12 and lumbar (L) 1-5. A post-procedural CT scan was performed to analyse the accuracy of the K-wire insertion.

Results: All procedures were carried out without any perforation of the pedicle wall. The mean duration of planning the intervention path was 2:54±2:22min, mean positioning time was 2:04±0:42min and the mean time for K-wire insertion was 2:13±0:54min. In total, the average intervention time was 7:10±3:06min per pedicle. Compared to the planning, the K-wire position showed a mean deviation of 0.5mm in the vertical-axis and 1.2mm in the horizontal-axis. The average intervention path length was 8.1cm.

Conclusion: Our findings show a high accuracy in robot-assisted K-wire insertion during spinal interventions without any exposure of the operator to radiation.

Predictive ^{99m}Tc MAA-SPECT/CT dosimetry in patients with locally advanced inoperable hepatocellular carcinoma treated by selective internal radiotherapy with ⁹⁰Y resin microspheres

A.-L. Hermann¹, A. Dieudonné², M. Ronot², M. Sanchez², H. Pereira¹, G. Chatellier¹, E. Garin³, R. Lebtahi², V. Vilgrain²; ¹Paris/FR, ²Clichy/FR, ³Rennes/FR (Annelaure.hermann@gmail.com)

Purpose: To predict survival and tumour response in patients with locally advanced and inoperable hepatocellular carcinoma (HCC) treated by SIRT (yttrium-90 [⁹⁰Y] resin microspheres) using tumour-absorbed-dose calculated prior to therapy.

Methods and Materials: Among 184 patients from the SARAH trial who received SIRT, 121 and 109 were included in dose/survival and dose/tumour response analyses, respectively; CT, ^{99m}Tc-MAA-SPECT/CT and ⁹⁰Y SPECT/PET were centralized. Tumour-absorbed-dose was computed using

^{99m}Tc-MAA-SPECT/CT. Visual agreement between CT-MAA-⁹⁰Y (optimal, suboptimal, not optimal), overall survival (OS) and tumour response on 6-months follow-up CT (RECIST 1.1) were assessed.

Results: In the dose/survival population, median OS was 9.3 months (95%CI, 6.7 to 10.7) and median tumour-absorbed-dose was 112Gy (IQR, 67.8 to 220). Patients who received ≥ 100 Gy (n=67) had significantly longer survival than patients who received < 100 Gy (median 14.1 months; 95%CI, 9.6 to 18.6 v 6.1 months 95%CI, 4.9 to 6.8, respectively; $P < .0001$). Among them, those with optimal agreement (n=24) had the longest median OS (24.9 months; 95%CI, 9.6 to 33.9). In the dose/tumour response population, tumour-absorbed-dose was significantly higher in treatments leading to DC v no-DC (median 121Gy; IQR, 86.0 to 190 v 85.1Gy; IQR, 58.4 to 164, respectively, $P = .0204$), while it was not significant with OR v no-OR ($P = .20$). The highest DC rate (77.5%) was observed with tumour-absorbed-dose ≥ 100 Gy and optimal agreement (m=40).

Conclusion: Tumour-absorbed-dose computed on ^{99m}Tc-MAA-SPECT/CT is significantly associated with OS and DC; the most benefit is observed with both tumour-absorbed-dose ≥ 100 Gy and optimal visual CT-MAA-⁹⁰Y agreement.

B-0849 17:08

Trans arterial embolization of non-variceal upper gastrointestinal bleeding: is the use of ethylene-vinyl alcohol Copolymer as safe as Coils?

M. Tiplaldi¹, M. Krokidis², G. Orgera¹, A. Rebonato³, C. Ambrogi¹, M. Rossi¹; ¹Rome/IT, ²Cambridge/UK, ³Perugia/IT (tiplaldi.andrea@gmail.com)

Purpose: The safety of liquid embolics over the conventional coils for the treatment of non-variceal upper gastrointestinal bleeding (UGIB) approach is still unclear. Purpose of this study is to assess the safety of ethylene-vinyl alcohol copolymer (EVOH 6%) over coils in the treatment of UGIB.

Methods and Materials: All the upper gastrointestinal tract embolization procedures performed in a single center in a 6-year period were reviewed. Patients embolised with coils (Group A) versus those embolised with EVOH 6% (Group B) were compared. Technical/clinical success, bleeding recurrence, complication and mortality rates were analyzed.

Results: A total 71 patients were included in the study (41 Group A and 30 Group B). Coagulopathy was present in 21% of Group A and 46% of Group B patients ($p < 0.05$). Technical and clinical success was 97.6 and 92.7% for Group A, and 100 and 93.3% for Group B respectively, ($p > 0.05$). Ten patients (17% Group A; 10% Group B) rebled within the first 72h and all of them were re-treated successfully with a second embolization. In Group A one major complication (bowel ischaemia) occurred. No complication occurred in Group B. The survival rate in the first 30 days was 90.3% for group A and 90% for group B ($p > 0.05$).

Conclusion: This study demonstrated EVOH 6% appears to be as safe and effective as coils in the treatment of non variceal UGIB.

B-0850 17:12

Prospective monocentre pilot study of intrahepatic mitomycin C infusion after radioembolisation with Y-90 in chemo refractory liver dominant metastatic breast cancer patients

B.M. Aarts¹, E.G. Klompenhouwer¹, R.C. Dresen², C. Deroose², A. Laenen², R.G.H. Beets-Tan¹, P. Neven², H. Wildiers², G. Maleux²; ¹Amsterdam/NL, ²Leuven/BE (b.aarts@nki.nl)

Purpose: In this pilot study we evaluated the safety of intrahepatic Mitomycin C (MMC) infusion after radioembolization with Yttrium (Y90)-labelled microspheres in chemo resistant LMBC patients.

Methods and Materials: Sixteen LMBC patients were included in this pilot study from 2012-2018 and first received Y90. The response after Y90 was evaluated with MRI, PET and laboratory tests. After assessment of no progression of disease, Mitomycin C infusion was administered in different dose cohorts; A: 6mg in 1 cycle, B: 12 mg in 2 cycles, C: 24 mg in 2 cycles and D: max 72 mg in 6 cycles. In cohort D the response was again evaluated after every 2 cycles and continued after assessment of no progression of disease. Toxicities were measured according to common toxicity criteria adverse events (CTCae) version 5.0.

Results: Sixteen patients received Y90 treatment. Three patients showed disease progression and 1 patient had serious side effects of Y90, and consequently, were excluded for further intra-arterial therapy. The intended dose of MMC was adjusted in 5 out of the 12 patients due to progressive disease (n=3) and biochemical toxicity (n=2). No grade 3 toxicity levels or higher were reported after MMC infusion. Three grade 2 toxicities were reported consisting of thrombocytopenia (n=1), leukopenia (n=1) and increase in bilirubin levels (n=1).

Conclusion: The combined treatment of intrahepatic infusion of MMC after Y90 therapy is safe with a low toxicity profile when MMC is administered in different escalating dose cohorts and adjusted based on clinical, radiological and biochemical parameters.

B-0851 17:16

In the ablation of colorectal cancer liver metastases with a new generation MW system nodule size > 2 cm independently predicts worse local tumour progression free survival

P. Marra¹, A. Della Corte², F. Ratti¹, F. Cipriani¹, S. Gusmini¹, M. Salvioni³, M. Venturini¹, L. Aldrighetti¹, F. De Cobelli¹; ¹Milan/IT, ²Vimodrone/IT, ³Bergamo/IT (dellacorte.angelo@hsr.it)

Purpose: In the ablation of colorectal cancer liver metastases (CRLM) high-power microwave generators present theoretical advantages in terms of local tumor control. We aimed to evaluate the outcome of CRLM microwave ablation (MWA) with a new generation system, assessing potential predictors of local tumour progression free survival (LTPFS).

Methods and Materials: From November 2014 to June 2018, 31 patients underwent 34 percutaneous, laparoscopic or open MWA procedures for the treatment of 51 CRLM with a 2450MHz/100W generator. Contrast-enhanced CT/MRI were used to assess 1-month complete ablation and LTP at follow up.

Results: Technical success and complication rates were respectively 96% and 4.9%. At the time of the analysis 11/51(21.6%) CRLM had locally progressed and overall estimated 1- and 2-year LTPFS rates for all 51 ablated CRLM were 84% and 63%, respectively. At univariable analysis CRLM diameter ≥ 2 cm was the strongest predictor of worse LTPFS with 1-year LTPFS 64% vs 85% (of < 2 cm nodules), $p = 0$. In a multivariable Cox regression model with CRLM number, RAS mutation, timing of CRLM development, history of post-MWA chemotherapy, number of pre-MWA chemotherapy cycles and time of chemotherapy discontinuation before ablation, nodule proximity to large vessels, energy administration, and side of primary colon cancer, CRLM diameter ≥ 2 cm independently predicted worse LTPFS (HR:28.9, $p = 0.009$).

Conclusion: Our preliminary data show that the outcomes of MWA for CRLM with a new generation system are comparable with those reported in the literature and nodule size, with a threshold of 2 cm, represents the strongest predictor of worse LTPFS.

Perivertebral muscle as index of sarcopenia: comparison with previous muscle imaging and functional indexes

H.S. Seo; Ansan/KR (seohs@korea.ac.kr)

Purpose: The area of perivertebral muscle can be easily achieved on abdominal and visceral fat CT scans. The purpose of this study is whether perivertebral muscle can be an index of sarcopenia by comparison with widely used muscle imaging and functional indexes.

Methods and Materials: Total 1270 seniors (mean age=63.57±6.94 years (range: 53-83), M:F=69:661) were included. The area of perivertebral muscle was the area of psoas and erector spinae muscles measured at the level of L3-4 on visceral fat CT between -30 and 150 HU. The area of thigh muscle in both sides was measured on CT. Appendicular muscle mass(ASM) was achieved in the mass of the extremities without the bone on DEXA. Right and left hand powers, standard and rapid walking speeds were also measured. The Pearson's correlation was used in statistics.

Results: The area of perivertebral muscle was well correlated with the area of thigh muscle($r=0.83$, $p<.001$) and ASM($r=0.83$, $p<.001$), and modified ASM, such as ASM/Ht²($r=0.729$, $p<.001$) and ASM/BMI($r=0.729$, $p<.001$). The area of perivertebral muscle was well correlated with right and left hand powers($r=0.738$ and 0.749 , $p<.001$, respectively) and standard and rapid walking speeds($r=0.268$ and 0.280 , $p<.001$, respectively).

Conclusion: The area of perivertebral muscle on visceral fat CT was well correlated with widely used sarcopenia indexes from muscle imaging and functions. The perivertebral muscle can be a new sarcopenia index and visceral fat CT can supply the information about sarcopenia as well as visceral fat as the risk factor of metabolic syndrome.

B-0853 08:34

T2* value analysis of achilles tendons disease with ultra-short echotime (UTE) MRI

J.-G. Zhang, Z. Li, C. Xia; Chengdu/CN (zjgscuhx@126.com)

Purpose: To compare T2* value of healthy subjects and patients with achilles tendons (AT) disease by using ultra-short echotime (UTE) MRI, and to analyze the correlation between T2* value and clinical scores.

Methods and Materials: 23 patients with AT disease (patients group) and 18 healthy subjects (control group) were enrolled and underwent MR scan with UTE sequence. The T2* values of 3 ROIs in AT were measured on each patient. Independent sample t-test was used to compare the difference of T2* values between the two groups. The correlation of T2* values with the American Orthopaedic Foot and Ankle Society ankle hindfoot scale (AO-FAS) and achilles tendon total rupture score (ATRS) were analyzed.

Results: The T2* values were significantly higher in patients group than those in control group (all $P<0.05$). And there was strong negative correlation between T2* values and AO-FAS or ATRS scores ($r=-0.88$, $P<0.01$ and $r=-0.91$, $P<0.01$).

Conclusion: The T2* values can reflect the degree of oedema in AT, and have strong negative correlation with clinical scores. As an emerging imaging technique, UTE-MRI can not only provide anatomical morphology of AT but also assess AT disease quantitatively, which is helpful to improve the diagnosis of AT disease in early stage.

Terahertz time-domain spectroscopy of collagen I and tendon

J. Yuan¹, L. Yang², M. Wang¹, Z. Feng¹, S. Zhang¹; ¹Shanghai/CN, ²Zhengzhou/CN (happyuanjie@163.com)

Purpose: This research studied the spectral characteristic of collagen I and tendon in terahertz (THz) range by the terahertz time-domain (THz-TDS) spectroscopy (THz-TDS).

Methods and Materials: Collagen I powder from bovine flexor tendon was obtained from Sigma-Aldrich with purity $\geq 99\%$. About 250mg of powder was compressed into a tablet 13mm in diameter. And then we mix collagen with polyethylene (PE) which is transparent in THz frequency region with a vortex mixer. The mixing ratios are 1:4, 2:3, 3:2, and 4:1. The absorption spectra of collagen pellets are measured in the frequency range of 10-100 cm⁻¹ using the THz-TDS setup. Bovine tendon was fresh and cut approximately to 1 mm. The

tendon dried at room temperature.

Results: The vibrational absorption spectrum was calculated based on the semi-empirical theory in the range of 0.1-10THz. The calculated spectrum of collagen I exhibits one absorption peak. The absorption band is 1.16 THz. The absorption bands of tendon are 1.16 THz and 1.43 THz.

Conclusion: We demonstrated the use of THz-TDS for measuring absorption spectrum in collagen I and tissues rich in collagen I.

B-0855 08:42

Investigating the appropriateness of radiological investigation of lumbar spine and determining relationship between appropriateness and imaging findings in a tertiary hospital

S. Suganchand Rikabchand; Jodhpur/IN (Sunilmed@gmail.com)

Purpose: The utilization of radiological investigations is increasing with increase in evidence based medicine and recording of pathology. Investigations though important are sometimes not required as they don't change clinical outcome of disease and thus unnecessary but are still ordered inappropriately. This study aims at studying the appropriateness of radiological investigations ordered in a tertiary hospital.

Methods and Materials: We studied all the radiological investigations (Plain radiography, CT and MRI) of lumbar spine during the period January to June 2017. A total of 2416 investigations were ordered, of these 854 were inpatient and 1562 were outpatient. To assess the appropriateness of the investigations ACR Appropriateness Criteria was used.

Results: Of 2416 radiological investigations ordered, 1509 were plain radiograph, 749 were MRI and 158 were CT scans. Based on the ACR appropriateness criteria 76% of the radiographs, 54% of MRI and 72% of CT were appropriate. The most common indication for radiograph and MRI was chronic low back pain with radiculopathy. Of the appropriate radiographs (n=1147) ordered 88% had a pathological finding, MRI's (n=405) ordered 78% had a pathological finding and CT's (n=114) ordered 85% had a pathological finding. The most common indication for CT was spine trauma. A Chi Square test correlation of ACR appropriateness criteria and positive finding in a radiological investigation was found to be significant ($p<0.03$).

Conclusion: Based on the results most of the plain radiograph and CT scans ordered were appropriate but the MRI study of the spine was the most misused modality of the all.

B-0856 08:46

Identification of Scheuermann's disease with different radiological scoring methods for osteoporotic vertebral fractures: the Rotterdam study

L. Oei, F. Koromani, S. Breda, S. El Saddy, A. Makurthou, F. Rivadeneira, E. Oei; Rotterdam/NL

Purpose: Osteoporotic vertebral fractures are a major health issue and should be diagnosed accurately. An important differential diagnosis is Scheuermann's disease. Our aim was to evaluate how different radiological assessment methods perform on independently ascertained cases of radiological Scheuermann's disease.

Methods and Materials: Two independent groups of trained research assistants applied the algorithm-based qualitative (ABQ) or software-assisted quantitative morphometry (QM using SpineAnalyzer® software to measure vertebral height ratios, shape and severity of vertebral deformities classified according to Genant). These methods for osteoporotic vertebral deformities were compared on cases of radiological Scheuermann's disease, which were diagnosed by a third group applying the radiological criteria by Sorensen and Sachs. In addition, thoracic spine indexes according to Masharawi were calculated from the raw QM data. Complete data were available for 2,656 lateral spine radiographs from the population-based Rotterdam Study (43% men, age 45-89), an ongoing Dutch prospective cohort study.

Results: Radiographic Scheuermann's disease was present in 4.1% (95% CI: 3.3%-4.9%; N=109) of the sample. Of these participants identified with radiographic Scheuermann's disease, QM scored 65.1% (95% CI: 56.2%-74.1%; N=71) as having an osteoporotic vertebral deformity, while ABQ classified only 7.3% (95% CI: 2.4%-12.2%; N=8) of the participants with radiographic Scheuermann's disease as having osteoporotic vertebral fractures. The QM-based Masharawi method was unable to discern between osteoporotic vertebral fractures, Scheuermann's disease and controls.

Conclusion: The inability of QM to rule out non-fracture deformities explains in part the higher number of osteoporotic vertebral deformities misclassified when applying QM as scoring method compared to ABQ.

B-0857 08:50

Feasibility study of reducing artifacts of spine metal implants for patients at 3.0T magnetic resonance imaging

G. Feifei¹, Y. Ge¹, Y. Wei²; ¹Zhengzhou/CN, ²Chengdu/CN
(gaofei150@163.com)

Purpose: To investigate the feasibility of reducing artefacts of spine with removal metal artefacts sequence (WARP) at 3.0T MRI.

Methods and Materials: 29 patients after spine surgery with metal implants which including 15 cervical and 14 lumbar spine cases were prospectively included. The image quality of WARP sequences and conventional sequences were compared (5 score evaluation scale) as well as the signal to noise ratio (SNR) and contrast noise ratio (CNR) of the image artefacts. The scanning time was recorded. Paired-t test and Mann-Whitney test were used respectively to compare the SNR and CNR, and qualitative scoring between the two sequences. $P < 0.05$ was considered to indicate a significant difference.

Results: The image distortion and blur of the WARP sequences were obviously reduced compared with the conventional sequences. The SNR and CNR of the WARP sequences' artefacts were lower than that of the conventional sequences (All $P < 0.05$). The image quality scores of WARP sequences in cervical and lumbar spines[4(3 ~ 5) and 4(3 ~ 5)]were higher than that of conventional sequences[3(2 ~ 4) and 3(2 ~ 4)] ($P < 0.05$). The scanning time of cervical spines in WARP sequence(14 min 9 s)was increased by 64 s(8.2%),and the time of lumbar spines(13 min 41 s)decreased by 9 s(1.1%).

Conclusion: The WARP sequences at 3.0 T could effectively reduce the artefacts of metallic prosthesis without prolonging the scanning time at 3.0T MRI.

B-0858 08:54

Noise-optimised virtual monoenergetic imaging of dual-energy CT: effect on metal artefact reduction in patients with lumbar internal fixation

Y. Zeng¹, K. Deng², H. Yang², Y. Tan², J. Liu², D. Geng¹, J. Zhang¹;
¹Shanghai/CN, ²Changsha/CN (18211220088@fudan.edu.cn)

Purpose: The purpose of this study was to evaluate the effects of noise-optimised virtual monoenergetic imaging (VMI+) reconstructions on reducing metal artefacts compared to traditional virtual monoenergetic imaging (VMI) and linearly blended (M_0.6) reconstructions in patients with lumbar metal internal fixation in dual-energy CT (DECT).

Methods and Materials: Forty patients who underwent DECT were evaluated in this retrospective study. Images were reconstructed with M_0.6 as well as VMI+ and VMI at 10keV intervals from 40keV to 190keV. Attenuation and noise were measured in the hyperdense artefacts, the hypodense artefacts, the spinal canal, the abdominal aorta (AA), and the inferior vena cava (IVC). An artefact index (AI) was calculated. A subjective evaluation was conducted of the metal-bone interface, the surrounding soft tissue, the spinal canal, the AA, and the IVC.

Results: The AI values for the hypodense artefacts, the spinal canal, and the IVC were lowest in the 130keV VMI+ series, for the hyperdense artefacts in the 120keV VMI+ series, and for the AA in the 190keV VMI+ series. With the exception of the hypodense artefacts, AI values were lower compared to the M_0.6 images and all of the VMI series. The subjective image quality was greatest at 130keV VMI+ for the metal-bone interface, the surrounding soft tissue, the AA, and the IVC, as well as at 120keV VMI+ for the spinal canal. With the exception of the AA, these rating scores were higher compared to the M_0.6 images and the entire VMI series.

Conclusion: DECT with high-keV VMI+ efficiently reduce metal artefacts and show superior image quality in patients with lumbar internal fixation.

B-0859 08:58

Increased lateral meniscal slope is associated with greater risk of lateral bone contusion in noncontact ACL injury

J. Li, K. Li; Chongqing/CN (tianwei19900911@163.com)

Purpose: To investigate the effect of an increased lateral meniscal slope (LMS) as measured on magnetic resonance imaging (MRI) on the likelihood of bone contusions in noncontact ACL injury.

Methods and Materials: From January 2013 to March 2018, a retrospective review of all ACL reconstruction surgeries was performed. 56 patients were included as study group (ACL+bone contusion group), who were matched to 56 control participants (isolated ACL group). Presence of bone contusion was determined from preoperative magnetic resonance images (MRIs). The LMS, LPTS, MMS and MPTS were measured on the MRI in a blinded fashion. The predictors of lateral bone contusions (LFC, LTP or both) including age, sex, BMI, LMS, LPTS, MMS and MPTS were examined by multivariable logistic regression. Associated findings including concomitant meniscal lesions and intra-articular cartilage damages were also calculated by multivariable logistic regression.

Results: The mean LMS in the study group was 6.51 ± 3.52 , which was significantly larger than that in the control group (3.82 ± 2.70 ; $P < 0.01$). In addition, increased LMS was significantly ($P < 0.01$) associated with lateral bone contusions (lateral femoral condyle and lateral tibial plateau) in noncontact ACL injury. However, LPTS, MPTS and MMS were not significantly associated with bone contusions. Moreover, the presence of lateral contusions are associated with concomitant lateral meniscal tears and cartilage damages ($P < 0.01$).

Conclusion: An increased LMS is associated with increased risk of lateral bone contusions in noncontact ACL injury. LMS could be considered by orthopaedic surgeons as part of the preoperative evaluation of ACL injury.

Knee MR using a body coil is equivalent to CT in measuring the TTTG distance: removing the systematic bias

L.U. Aivazoglou, M.K. Toma, P.H.C. Arruda, O.A. Ezzeddine, A. Ormond, M. Nico, F. Silva; Sao Paulo/BR (lais.epm@gmail.com)

Purpose: To compare measurements related to patellar instability between MR and CT in asymptomatic volunteers, and to evaluate interobserver agreement between MR measurements.

Methods and Materials: 17 asymptomatic volunteers were enrolled. A low-dose CT and an MR T1w axial sequence of both knees were performed in full extension, the latter using a body coil. After a training session, two musculoskeletal radiologists evaluated the CT and MR images separately and chose the specific slices to assess the following landmarks: cartilaginous trochlear groove (CTG), bony trochlear groove (TG), center of insertional patellar tendon (PT) and centre of tibial tuberosity (TT). The chosen slices were compared and disagreements were solved in consensus. Then, the chosen slices were superimposed and the following measurements were assessed independently: PT-CTG and TT-TG. Statistical analysis (SPSS 20.0) consisted of intraclass correlation coefficient (ICC) to compare MR and CT measurements and interobserver agreement between MR measurements.

Results: Good agreement was observed between CT and MR measurements ($p < 0.0001$). The mean PT-CTG distance on CT and MR were 17.3 ± 4.2 mm and 16.5 ± 4.1 mm, respectively. When considering TT-TG distance (bony parameters), the mean values were respectively 17.1 ± 4.2 mm and 16.2 ± 3.7 mm. Interrater reliability was excellent for all measurements and for all slice choices on both imaging methods.

Conclusion: TTTG measures in MR using a body coil showed excellent reproducibility when compared to CT using both soft-tissue and bony parameters, removing the bias of knee flexion when using the dedicated knee coil.

B-0861 09:06

Quantitative magnetic resonance imaging in patellar tendon-lateral femoral condyle friction syndrome: relationship with subtle patellofemoral instability

J. Li, H.-T. Yang; Chongqing/CN (tianwei19900911@163.com)

Purpose: To investigate the correlation of patellar tendon-lateral femoral condyle friction syndrome (PTLFCFS) with subtle patellofemoral instability to explore its pathogenesis.

Methods and Materials: One hundred knees of 80 patients with PTLFCFS were analysed retrospectively by retrieving magnetic resonance (MR) imaging data over a 3-year period from our database. Seven quantitative parameters for evaluating patellofemoral stability were measured on MR images, including the Insall-Salvati ratio, tibial tuberosity-trochlear groove (TT-TG) distance, trochlear groove depth, medial trochlear/lateral trochlear length (MT/LT) ratio, medial trochlear/lateral trochlear height (MH/LH) ratio, lateral patellofemoral angle (LPA) & lateral trochlear inclination (LTI) angle. These patellofemoral parameters were compared between the PTLFCFS group & the normal control group ($n = 88$), & receiving operator characteristic (ROC) curve analysis was conducted to determine the specificity & sensitivity of these parameters.

Results: The trochlear depth, MT/LT, LPA, & LTI angle were significantly lower ($P < 0.001$) & the Insall-Salvati ratio was significantly higher ($P < 0.001$) in the PTLFCFS group. However, the TT-TG distance & MH/LH ratio had no significant difference ($P = 0.231$ & 0.073 , respectively). The area under ROC curve of the Insall-Salvati ratio, trochlear depth, MT/LT, LPA, & LTI angle were 0.925, 0.784, 0.8, 0.731, & 0.675, respectively. The efficiency of the Insall-Salvati ratio was the highest among those 5 parameters.

Conclusion: This study verified the presence of subtle patellofemoral instability by measuring various patellofemoral parameters in patients with PTLFCFS. It confirmed that PTLFCFS is associated with subtle patellofemoral instability & could substantially explain the pathogenesis of PTLFCFS.

Clinical utility of fat suppressed 3-dimensional CAIPIRINHA SPACE MRI of the knee in adults

S. Lee, G.Y. Lee, S. Kim; *Seoul/KR (lish1220@gmail.com)*

Purpose: This study was purposed to evaluate the clinical utility of 3-dimensional CAIPIRINHA SPACE MRI of knee compared to 2D conventional method in the symptomatic patients.

Methods and Materials: Following internal review board approval and informed consent, in 3 months we enrolled 93 symptomatic patients (37 males and 56 females) who underwent knee MRI with both 2D conventional and 3D CAIPIRINHA methods. Among them, 17 patients had arthroscopic surgery after MRI study. Two radiologists evaluated pathologic MRI findings by scoring systems in each anatomic region. We measured signal to noise ratio (SNR) in 3D CAIPIRINHA MRI. Using intraclass correlation coefficient (ICC), inter-reader agreement, intra-reader agreement and inter-method agreement were applied. In 17 patients who underwent arthroscopy, we evaluated diagnostic performance of both two methods.

Results: The 3D CAIPIRINHA MRI had good to excellent inter-reader agreement (ICC, 0.73 - 0.96) and intra-reader agreement (ICC, 0.88-1.0). Inter-method agreement between the 2D conventional and 3D CAIPIRINHA images was also good to excellent (ICC, 0.8-1.0). The diagnostic performance of 3D CAIPIRINHA MRI was equal or better to the one of 2D conventional MRI. The SNR of 3D CAIPIRINHA MRI showed mean, 14.51 and standard deviation, 5.17. Mean scan time of 3D CAIPIRINHA MRI was 4 minutes 43 seconds and the one of 2D conventional method was 17 minutes 27 seconds.

Conclusion: In the real practice, the 3D CAIPIRINHA MRI could have equal or better performance compared to 2D conventional MRI, to evaluate pathologic findings of symptomatic patients with faster scan time.

B-0863 09:14

The most accurate measurement of TT-TG distance is through the 2/5 point of femoral trochlear notch

Y. Qi, Z. Wang; *Tianjin/CN (qiywjdyt@126.com)*

Purpose: To find a point at femoral trochlear notch to accurately measure tibial tuberosity-trochlear groove distance (TT-TG), and correlate TT-TG with the ratio of lengths of patella ligament and patellar (PLL/PL) and lengths of medial and lateral patellar retinacula (MPR and LPR), using CT scan and image fusion.

Methods and Materials: 60 volunteers (average age, 31.87±7.28y; range,18-40y; men:women, 42:18) underwent CT (GE Discovery CT750) of knee joints, 30 left and 30 right knees, respectively, voltage: 100-120kV, current: 180-230mAs. 5 points were divided equally at femoral trochlear notch on reformatted median sagittal plane. TT-TG was measured on corresponding axial fused images, the distances between the vertical lines of prominent tibial tuberosity and each of the five points at femoral trochlear notch. ANOVA and Mann-Whitney U tests were used to analyse data. PLL/PL was measured on median sagittal image which was the ratio of length of patellar ligament and maximum distance of patella. The lengths of MPR and LPR were measured on axial images of the maximum patella transverse diameters. The correlation between each of 5 TT-TG and PLL/PL and the lengths of MPR and LPR were calculated using Spearman rank correlation tests.

Results: The most accurate measurement of TT-TG was the vertical line through 2/5 point of femoral trochlear notch (F=0.668, p=0.615). TT-TG between gender and sides showed no difference (P=0.116, 0.456). There was no correlation of five TT-TG with PLL/PL and the lengths of MPR and LPR (p=0.541-0.909, p=0.068-0.770).

Conclusion: The most accurate measurement of TT-TG is the vertical line through 2/5 point of femoral trochlear notch on axial CT fused images, and the distance is irrelevant to PLL/PL and the lengths of MPR and LPR.

B-0864 09:18

Coll-Ha versus bone marrow stimulation for chondral and osteochondral lesion: a 2-year randomized controlled trial

C. Tamburrano¹, M. Busacca²; ¹Bologna/IT, ²Bologna/IT (chiara.tamburrano@libero.it)

Purpose: To assess the benefit provided by a collagen-hydroxyapatite (coll-HA) multilayer scaffold for the treatment of chondral and osteochondral knee lesions.

Methods and Materials: The coll-HA scaffold was compared to bone marrow stimulation (BMS) in a multicenter randomized controlled trial: 100 patients affected by symptomatic grade III-IV lesions were evaluated for up to 2 years (51 study group, 49 control group). Primary efficacy measurement was IKDCsubj score at 2 years; secondary were: KOOS, IKDC, Tegner and VASpain scores at 6, 12 and 24 months. Tissue regeneration was evaluated with MRI Mocart score at 6, 12 and 24 months. An external independent agency ensured data correctness and objectiveness.

Results: A significant improvement of all clinical scores was obtained in both groups, although no overall significant differences were detected between

treatments. The subgroup of patients affected by deep osteochondral lesions (i.e. Outerbridge IV and OCD) showed a significantly better IKDCsubj outcome (p=0.036) in the coll-HA group. Severe adverse events were documented in 3 patients in the coll-HA group and in 1 in the BMS group. The Mocart score showed no statistical difference between groups.

Conclusion: This biomimetic implant showed no benefit compared to BMS for chondral lesions, but this procedure can be considered safe and a suitable option for the treatment of osteochondral lesions.

B-0865 09:22

Application of simultaneous multi-slice TSE in high-resolution hand and foot imaging

G. Feifei¹, Y. Ge¹, Y. Wei²; ¹Zhengzhou/CN, ²Chengdu/CN (gaofei150@163.com)

Purpose: To investigate the feasibility of simultaneous multi-slice (SMS) technique in hand and foot imaging by comparing it with the routine TSE sequence and iPAT in regards to imaging time and images quality

Methods and Materials: 40 patients underwent MR exams on a MAGNETOM Prisma 3T MR scanner. A sixteen-channel foot/ankle coil and a sixteen-channel hand/wrist coil were used. The MR exam included routine TSE, TSE with iPAT (iPAT-TSE), and a prototype SMS-TSE sequence. The apparent signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. Image quality was rated by radiologist blindly based on a five-point evaluation. The SNR and CNR were statistically analyzed using LSD-t test. Image quality scores were tested for statistical significance by using Games-Howell test.

Results: Compared with the Routine-TSE and iPAT-TSE sequences, the SMS-TSE sequence could greatly shorten the scan time to 55% of the standard TSE. For hand and foot MR imaging, the SNR,CNR of the SMS-TSE sequence are close to the Routine-TSE and slightly higher than the iPAT sequence(p<0.05). No significant difference was observed between the SMS-TSE and Routine-TSE sequence for the SNR. For the hand MR imaging, the image quality scores of the SMS-TSE and Routine-TSE sequences were significantly higher than that of the iPAT sequence(Hand: p=0.005, SMS vs iPAT; p=0.001, Routine vs iPAT; p=0.536, Routine vs SMS).

Conclusion: The SMS-TSE sequence can be used to obtain high quality images for the hand and foot at 3T with 45% less acquisition time than the standard TSE sequence.

B-0866 09:26

Cinematic MRI of the wrist: initial study for instability of the wrist in correlation to fluoroscopy and x-ray findings

B. Reichardt¹, A. Örnek¹, V. Nicolas²; ¹Essen/DE, ²Bochum/DE (benjamin.reichardt@uk-essen.de)

Purpose: Initial study on scapholunate ligamentary instability and ulnar impaction syndromes in MRI compared to radiography and fluoroscopy. The aim of this study was to develop an MRI protocol for the evaluation of the wrist during continuous active movement to show that dynamic imaging of the wrist is feasible and to show that the resulting anatomical images allow the measurement of metrics commonly used for the dynamic instability of the wrist.

Methods and Materials: 10 probands and 10 patients with wrist-pain over the SL-slit or ulna-impaction signs received an initial x-ray in 2 planes as well as instability images with ulnardeviation and "clenched-fist" of both wrists. Additionally fluoroscopy at 7.5f/s with same movements were done. MR-Protocol: 32Chh head coil, standard static MRI were done. Additionally adapted cardiac cine Sequences: single and multislice bSSFP for active MRI with radial/ulnar deviation and "clenched-fist" maneuvers. Evaluation of distal radioulnar joint (DRUJ) congruity, the scapholunate (SL) interval.

Results: SL-Slit widening was 4mm (healthy), 9 mm (patients) in ulnar-deviation, 4mm in clenched-fist, 8 mm in patients; correlating to findings in fluoroscopy. DRUJ subluxation ratio were 0.04 (supination), 0.10 (neutral), and 0.14 (pronation) and 0.15, 0.25 and 0.16 in patients. SL interval were 1.43mm (healthy) and 2 (patients) for neutral, ulnar deviation, radial deviation positions, and increased to 1.64 mm (healthy) during the clenched-fist maneuver and 3.1mm in patients.

Conclusion: This study demonstrates the initial performance of active-MRI of scapho-lunate instability and ulnar-impaction-syndrome which may be useful in the investigation of dynamic wrist instability.

B-0867 09:30

Comparison of patient satisfaction for wrist examinations in cone beam-computed tomography and multidetector-computed tomography

J. Neubauer¹, C. Reidelbach¹, E. Kotter¹, S.M. Goerke²; ¹Freiburg/DE, ²Offenburg/DE (jakob.neubauer@uniklinik-freiburg.de)

Purpose: To evaluate and compare patient satisfaction for wrist examinations in cone beam-computed tomography (CBCT) and multidetector-computed tomography (MDCT). Our hypothesis is that patient satisfaction is higher in the CBCT.

Friday

Methods and Materials: This IRB approved prospective study included patients who were scheduled for a computed tomography examination of the wrist in our institution over a period of 1 year. Patients were randomly assigned to either dedicated musculoskeletal CBCT or MDCT. After the examination, patients were asked to complete a questionnaire that included several questions regarding their satisfaction with the examination. Patients were asked to evaluate on a 6-point Likert scale whether the positioning was comfortable, whether they found the duration of the exam adequate, whether they were able to keep their hands steady during the exam, whether they were in more pain during the exam, and if they were getting intimidated through the scanner. Ratings for the CBCT and MDCT were compared with Mann-Whitney U test. P values <0.05 were considered to denote statistical significance.

Results: 108 patients returned the questionnaire, composed of 53 CBCT and 55 MDCT examinations. The patients rated positioning in the CBCT as more comfortable than in the MDCT (<0.001). For the ratings on all other questions, there was no difference between the two modalities.

Conclusion: Positioning in the CBCT was perceived as more comfortable than in the MDCT. All other measures of patient satisfaction were rated similarly for both devices.

B-0868 09:34

Diagnostic performance of high-resolution ultrasound in the evaluation of intrinsic and extrinsic ligaments of the wrist in patients with previous trauma or carpal instability

S. Gitto¹, D. Albano², C. Messina¹, V. Chianca¹, S. Rapisarda¹, A. Corazza³, L.M. Sconfienza¹; ¹Milan/IT, ²Palermo/IT, ³Genoa/IT (sal.gitto@gmail.com)

Purpose: To investigate the role of ultrasound (US) in the evaluation of intrinsic and extrinsic carpal ligaments having magnetic resonance arthrography (MRA) as reference standard.

Methods and Materials: This prospective study included 19 patients (12M, 7F; mean age 44±19 SD years) referred for wrist MRA and having history of trauma or carpal instability. US examination was performed just before MRA using a 14-6 MHz linear transducer. On both the dorsal and volar sides of the wrist, the intrinsic interosseus and midcarpal, collateral and extrinsic ligaments were evaluated. Ligament thickness was measured and tears were detected. Thereafter, ligament thickness and integrity were blindly assessed on the MRA images obtained with a 1.5-T unit. Ligament detection rate and thickness reproducibility between US and MRA were calculated.

Results: On the dorsal side, US detected more ligaments (108/114, 94.7%) than MRA (96/114, 84.2%; P=0.016), while on the volar side the difference was not significant (149/171, 87.1% vs. 156/171, 91.2%, respectively; P=0.296). Ligament thickness reproducibility ranged between 44% (COR=0.9, bias=-0.8, P<0.001) of the volar ulnocapitate ligament and 71% (COR=0.05, bias=-0.1, P<0.001) of the volar scaphotriquetral ligament. Diagnostic performance of US for ligaments where a tear was found was 100% sensitivity, 100% specificity, 100% positive predictive value, 100% negative predictive value, 100% accuracy for the volar and dorsal scapholunate ligaments, and the ulnar collateral ligament; it was 100%, 94%, 50%, 100%, 94%, respectively, for the volar ulnolunate ligament.

Conclusion: US has similar diagnostic performance to MRA in the assessment of intrinsic and extrinsic carpal ligaments and ligamentous tears.

B-0869 09:38

Submarine sign of epidermoid cysts: a diagnostic model based on ultrasound feature

D.H. Lee, S. Kim, A.L. Choi, C. Yoon; Seoul/KR (edahyunle@gmail.com)

Purpose: To develop a diagnostic model for superficial soft tissue mass with differentiation of epidermoid cyst (EC) based on ultrasound (US) features including a 'submarine sign'.

Methods and Materials: In this retrospective study, patients (n=210) who undertook US for superficial soft tissue mass and surgical excision were included from January 2008 to October 2017. Included patients were split into a derivation (n=114) and validation cohort (n=96) by date of imaging (November 1, 2016). Following US features were analyzed: more than half depth involvement of dermal layer; 'submarine sign' (focal protrusion toward the epidermis); posterior acoustic enhancement; posterior wall enhancement; shape, margin, echogenicity, morphological types, vascularity and perilesional fat change. Multiple logistic regression was performed to develop a diagnostic model and constructed it as a nomogram. Then, we assessed the performance of this diagnostic model by discriminatory ability (AUC) and calibration through derivation cohort and validation cohort.

Results: More than half depth involvement of dermal layer (OR=2.092; 95% CI: p-value=0.047), submarine sign (OR=7.077; 95% CI: p-value<0.001) and posterior acoustic enhancement (OR=4.251; 95% CI: p-value=0.013) were significantly associated with ECs. The diagnostic model statistically constructed with these features showed good discrimination and calibration ability on both derivation (AUC = 0.831, 95% CI: 0.758-0.904 and Hosmer-Leme show goodness-of fit test, p-value=0.8153) and validation cohort (AUC = 0.865, 95% CI: 0.795-0.933 and Hosmer-Leme show goodness-of fit test, p-value=0.1816).

Conclusion: Our diagnostic model and nomogram can be utilized to predict the probability of EC. Also, submarine sign may be helpful image marker for EC.

B-0870 09:42

Machine learning classification of low-grade and high-grade chondrosarcomas based on magnetic resonance imaging-based texture analysis

S. Gitto¹, D. Albano², V. Chianca¹, R. Cuocolo³, L. Ugga⁴, C. Messina¹, L.M. Sconfienza¹; ¹Milan/IT, ²Palermo/IT, ³Naples/IT, ⁴Scafati/IT (sal.gitto@gmail.com)

Purpose: Reliable grading of bony chondrosarcomas is crucial for the clinical outcome, because treatment ranges from intralesional curettage for low-grade neoplasms (G1) to resection or amputation for high-grade tumours (G2-G3). We aim to evaluate the diagnostic accuracy of machine learning (ML) algorithms for discrimination between low-grade and high-grade chondrosarcomas based on texture analysis (TA) parameters extracted from unenhanced Magnetic Resonance Imaging (MRI).

Methods and Materials: We retrospectively enrolled 58 patients with histologically proven chondrosarcoma (26 low-grade and 32 high-grade tumours). Patients were randomly divided into training (n=42) and test (n=16) groups for classification model development and testing, respectively. All tumours were manually segmented on T1-weighted and T2-weighted images by drawing a bidimensional polygonal region of interest (ROI). ROIs were used for first order and texture feature extraction on dedicated software, Pyradiomics. For each tumour, different data subsets were obtained by six feature selection methods (C4.5 learner-based, gain ratio evaluator, information gain evaluator, Principal Component Analysis and subset evaluator) and analyzed using 9 ML classification algorithms, evaluating their accuracy for differentiation of low-grade from high-grade chondrosarcoma.

Results: A Support Vector Machine correctly classified 75% of chondrosarcomas as low or high grade based on the datasets obtained by the subset evaluator feature selection mode. Specifically, true positive rate was 80% and 67% for identification of high-grade and low-grade tumours, respectively.

Conclusion: ML algorithms showed good accuracy for low-grade and high-grade tumour classification based on unenhanced MRI examinations and could prove a valuable aid in preoperative characterization of chondrosarcomas.

Use of MRI for age verification of U-17 footballers: the Ghana study

B.D. Sarkodie; Accra/GH (ghana_neo@yahoo.com)

Purpose: A fair playground is absolutely necessary in any age limited sports. Age determination in countries where birth registration is not compulsory can often be difficult making it a challenge to determine ages of people born in such countries. The purpose of this study was to determine the correlation between the chronological ages of under 17 Ghanaian footballers and the FIFA MRI grading.

Methods and Materials: The degree of radial epiphyseal fusion was evaluated in 486 male Ghanaian footballers aged 13-16 years over a 4 year period (June 2012-July 2018) using 1.5 T Magnetic Resonance Imaging. The ages of the participants used in the study were those provided by the football players and confirmed with their national passports.

Results: Over 49% of these Ghanaian players below the age of 17 years had completely fused radial epiphysis. No significant correlation between the given chronological ages and the degree of fusion was found. The Spearmans correlation was given as (r = 0.068; p = 0.542).

Conclusion: There was no correlation between chronological age and degree of radial fusion among Ghanaian players. Normative study among Ghanaian/black African players is long overdue to ensure the U-17 players from these countries are not unfairly disadvantaged.

Detection of prostate cancer: comparison between robotic-assisted "in-bore" MRI-guided biopsies and cognitive transrectal ultrasound-guided biopsies

E. Demozzi¹, F. Cavicchioni¹, M. Hoogenboom², M. Catania³, G. Foti¹, E. Munari¹, S. Cavalleri¹, G. Carbognin¹; ¹Negrar/IT, ²Arnhem/NL, ³Verona/IT (e.demozzi@gmail.com)

Purpose: To compare prostate cancer detection rate (PCaDR) and clinically significant prostate cancer detection rate (csPCaDR) between magnetic resonance imaging-guided biopsies (MRI-PB) and cognitive transrectal ultrasound-guided prostate biopsies (TRUS-PB).

Methods and Materials: For this prospective study, approved by our IRB, between November 2017 and September 2018, 167 men with clinical suspicion for PCa underwent mpMRI and, when suspicious lesion were found (PI-RADS 4 or 5, according to the PIRADSV2 scoring system), MRI-PB (arm A, 86 Patients, 67.6 y, PSA 9.1 ng/mL, PSA_d 0.19) or TRUS-PB (arm B, 82 patients, 69.4 y, PSA 11.6 ng/mL, PSA_d 0.23) was performed. Clinically significant prostate cancer (csPCa) is defined as Gleason score \geq 3+4.

Results: Prostate cancer was diagnosed among 70 patients in arm A (PCaDR 81.4%) and 51 patients in arm B (PCaDR 62.9%; $p=0.006$). csPCa was diagnosed among 46 patients in arm A (csPCaDR 53.4%) and 15 patients in arm B (csPCaDR 18.5%; $p<0.001$). Among PI-RADS 4, PcaDR and csPCa was 76.2 (46/59) and 38.9% (23/59) in arm A and 60.0 (36/60) and 16.7% (10/60) in arm B (respectively, $p=0.034$ and $p=0.006$). Among PI-RADS 5, PcaDR and csPCa was 92.5 (25/27) and 85.1% (23/27) in arm A and 71.4 (15/21) and 23.8% (5/21) in arm B (respectively, $p=0.051$ and $p=0.001$).

Conclusion: Robotic-assisted MRI-targeted biopsy can easily be implemented in a general clinical practice and could play a crucial role in the detection of PCa with the goals of reducing the detection of clinically insignificant PCa and maximizing the detection of csPCa.

B-0873 10:47

Is it today acceptable to perform only targeted fusion MR/US prostate biopsy in naïve patients?

S.R.M. De Martino, B. Corcioni, C. Gaudio, F. Ciccarese, V. Vagnoni, R. Schiavina, R. Golfieri; Bologna/IT (sara_demartino@live.it)

Purpose: The recent literature proposes the use of only targeted MR/US fusion biopsy of suspicious lesions (PI-RADS $>$ 3) in patients without a prior random mapping prostate biopsy. We evaluate our experience in naïve patients who underwent to mpMRI and MR/US fusion prostate biopsy.

Methods and Materials: We retrospectively evaluate 56 patients who underwent prostate mpMRI in our Institute, followed by a MR/US fusion biopsy of suspicious lesions completed with random biopsy. 70 lesions were identified and classified according to PIRADSV2 [31 PIRADS 3 (44%); 35 PIRADS 4 (50%); 4 PIRADS 5 (6%)].

Results: Of 70 lesions, we found 41 lesions (59%) positive for csPCa (GS \geq 7) and 29 negative lesions (41%). Among negative lesions (GS \leq 6), 5 of the 29 (17.2%) showed foci of csPCa in the random samples, in particular, 4 of the 20 negative PIRADS 3 (20%) and 1 of 9 negative PIRADS 4-PIRADS 5 group (11.1%).

Conclusion: In our experience, we cannot recommend performing only MR/US fusion biopsy in naïve patients due to the significant risk of missing csPCa in the rest of the gland (17.2% of our patients), especially for PIRADS 3 GS 6 lesions of the posterior zone, in which the probability of missing csPCa rises to 20%.

B-0874 10:55

Accuracy of mpMRI/US fusion prostate biopsy in diagnosis of clinically significant carcinomas with histopathological verification

M. Zagrodzka, M. Lichtarski, A. Lewicki, S. Niezgodna, E. Stachura, J. Brzezinski; Warsaw/PL (brzezinski.j@gmail.com)

Purpose: The purpose of the study was to establish the success rate of mpMRI/US fusion prostate biopsy in patients with histological confirmation of its result, performed in MR diagnostic centre with fusion biopsies performed on site.

Methods and Materials: 86 consecutive patients (aged 42-78 mean 64) with PSA level mean 10.01 (0.96-53.1 ng/ml), mean prostate volume 61.7 ml (13-273 ml), median PSAD 0,13 had mpMRI/US fusion prostate biopsy (with up to 4 target lesions per patient, total 193 lesions assessed) performed after a positive (PI-RADS v.2.0 score 3,4,5) mpMRI. Multiparametric MRI examination and the biopsies were done in MR department (on 1,5T GE HDxt system according to PI-RADS v.2.0 guidelines) specializing in urology and were assessed with regard to the results of the histological examination.

Results: Overall 60/193 lesions (31%) had confirmation of clinically significant cancer in the biopsy. In groups with PIRADS score of 5,4,3 the results were respectively 10/12 (83%), 31/60 (52%) and 19/118 (16%). With regard to histopathological findings they were all adenocarcinoma. The remaining findings in all groups were: 8 prostatitis, 88 BPH, 34 prostatitis with BPH, 1 HGPIN, 1 HG with prostatitis, 1 ASAP with prostatitis.

Conclusion: Multiparametric MRI/US fusion biopsy is a highly useful diagnostic tool, with marked impact on the success rate of the prostate biopsy in diagnosis of clinically significant cancer. High success rate of cancer detection (83%) can be attributed to precise targeting thanks to biopsy being performed at the same site as the mpMRI examination. There is markedly higher prevalence of prostatitis in lower PI-RADS groups.

B-0875 11:03

Technique and first results: targeted MRI and [⁶⁸Ga]-PSMA PET/MRI ultrasound fusion-guided transperineal prostate biopsies

N. Guberina¹, L. Püllen¹, T. Stephan¹, J. Grueneisen¹, M. Forsting¹, L. Umutlu¹, H. Reis¹, B. Hadaschik², A. Wetter¹; ¹Essen/DE, ²Heidelberg/DE

Purpose: The aim of this study was to examine whether patients with elevated PSA-levels benefit from targeted MRI and [⁶⁸Ga]-PSMA PET/MRI ultrasound fusion-guided biopsies, compared to systematic saturation biopsy.

Methods and Materials: This retrospective study evaluated 219 patients with increased PSA-level (median PSA 8.3ng/ml) examined according to a multiparametric prostate protocol on a 3T-MR-scanner (PI-RADSVs2). Additionally, 23 patients were examined on an integrated 3T-PET/MRI-scanner. [⁶⁸Ga]-PSMA-11-PET/MR was assessed for functional (SUV_{max}) and for morphological variables. All patients underwent systematic transperineal prostate biopsy and targeted-MRI-biopsy using rigid image-fusion (MiM-software, USA) in case of PI-RADS3-5 lesions (median 26 systematic cores and 9 targeted cores). Detection rates for prostate cancer of targeted ultrasound fusion-guided biopsies were compared to systematic prostatic biopsy.

Results: Altogether 5979 systematic cores, 1407 MRI-targeted cores and 217 PET/MRI-targeted cores were obtained. Per core targeted MRI ultrasound fusion-guided biopsy (35%, positive target lesions 247/716) and [⁶⁸Ga]-PSMA-PET/MRI ultrasound fusion-guided biopsy (48.5%, positive target lesions 49/101) showed a significantly higher detection rate of prostate cancer than non-targeted systematic biopsies (17.5%, positive systematic cores 492/2800). In the saturation prostatic biopsy histological grading was distributed as follows: grade groups (1) 15.7%; (2) 32.7%; (3) 14.3%; (4) 5.8% and (5) 2.5%. MRI- and PET/MRI-targeted biopsies identified clinically significant prostate cancer with following histological distribution: grade groups (1) 19.7%; (2) 30.1%; (3) 14.8%; (4) 6.6% and (5) 9.5%.

Conclusion: The [⁶⁸Ga]-PSMA-PET/MRI ultrasound fusion-guided biopsy is a promising technique for histological tissue verification. It contributes to accurate prostatic biopsies at a considerably lower level of biopsy tissue cores.

B-0876 11:11

A quantitative approach to pinpoint prostate targets in order to reduce the number of TRUS-MRI fusion biopsy cores per patient without affecting the detection rate

M. Pecoraro, R. Campa, G. Barchetti, V. Salvo, C. Catalano, V. Panebianco; Rome/IT (pecoraro.martina1@gmail.com)

Purpose: The purpose is to further investigate how many and how larger cores are needed to properly localise and correctly identify the grade of PCa.

Methods and Materials: We prospectively analysed 54 patients who underwent radical prostatectomy following TRUS-MRI fusion biopsy, from 2016 to 2018. Two Uro-genital Radiologists used the standard procedure to identify biopsy targets (RADt) and delineated an "ADC-guided phantom target" falling into the standard one (ADCt). They also countered the area of the lesion with the lower normalised ADC value (nADC), minimum 6mm in diameter. So a

correlation of the biopsy and the radical prostatectomy results was made.

Results: Index lesion was correctly detected in 78% of cases for both RADt and ADCt. The latter showed a better estimation of the final ISUP classification with a 70% concordance vs 67% of RADt. Both ADCt and RADt overestimated the final ISUP category in 4 cases, RADt caused an underestimation in two. PCa index lesions showed a 0,950cc mean volume and 12,2mm mean diameter, these were found to be 0,435cc and 9,4mm for RADt and 0,268cc and 8mm for ADCt. Mean nADC was 0,61 for PCa, 0,59 for RADt and 0,52 for ADCt.

Conclusion: ADC value and dimensional characteristics of PCa were more similar to those of RADt, however there was not a significant difference between ADCt and RADt PCa detection rate. Finally, ADCt showed a finer ISUP category correlation with RP results, allowing the operator to reduce the number of core per lesion, lowering the chances of complications.

B-0877 11:19

Cognitive-MR-US fusion prostate biopsy: which one is worthier to perform?

R. Turkay, E. Inci; *Istanbul/TR (rustuturkay@hotmail.com)*

Purpose: The goal of our study is to compare two prostate fusion biopsy modalities in a selected patient population.

Methods and Materials: 100 patients whose psa levels were between 3-10 and had no prior biopsy were enrolled for the study. They were divided randomly into 2 groups. Each group included 50 patients. All patients had PIRADS 3 or 4 or 5 category lesions in their multiparametric prostate magnetic resonance imaging (mp-MRI). Patients with lesion smaller than 5 mm were excluded. Group 1 patients were biopsied with cognitive fusion method and patients in group 2 were biopsied with Toshiba Aplio 500 MR-US fusion biopsy device. Results of histopathologic examinations along with demographic and psa levels were analyzed.

Results: We calculated no significant difference between 2 groups in terms of age, psa level and lesion diameter ($p=0.025$, $p=0.031$, $p=0.040$ respectively). In group 1 we detected 38 prostate cancer cases in cognitive fusion biopsy (Gleason scores were 3+3 in 23 patients, 3+4 in 10 and 4+3 in 4 and 4+5 in 1 patient). In group 2 we found 42 prostate cancer cases (Gleason scores were 3+3 in 25 patients, 3+4 in 13 patients, 4+3 in 3 and 4+5 in 1 patient). There was no significant difference between 2 prostate biopsy methods in terms of catching targeted lesions ($p=0.032$).

Conclusion: Our study reveals that in a selected group of patient cognitive biopsy can be alternative for MR-US fusion biopsy method.

B-0878 11:27

Focal cryoablation for recurrent prostate cancer following radiation therapy: assessment of iceball margin and signal intensity of tumour by 3D registration of MRI

I.I. Oz¹, J.G. Bomers¹, C.G. Overduin¹, S.F. Jenniskens¹, J.P.M. Sedelaar¹, T. Paetz², C. Rieder², C. Schumann², J.J. Futterer¹; ¹Nijmegen/NL, ²Bremen/DE (ilkeroz@yahoo.com)

Purpose: To evaluate the effects of iceball margin and T2 signal intensity (SI) of tumour on local outcome of prostate cancer after cryoablation by 3-dimensional (3D) registration of intraprocedural magnetic resonance (MR) images.

Methods and Materials: Sixty-one percutaneous MR-guided focal cryoablation procedures were retrospectively reviewed. Intraprocedural MR images were analysed and registered using Software Assistant for Interventional Radiology (SAFIR) software to achieve the assessment of the 3D ablation margin. Local tumour recurrence was defined as evident tumour recurrence on follow-up MR images, positive MR-guided biopsy or biochemical failure without radiological evidence of metastatic disease.

Results: The median minimum iceball margin was 2.27 mm (-4.73 to 6.32). The cut-off value for the minimum iceball margin to discriminate local tumour recurrence was 1 mm ($p<0.001$, $AUC = 0.839$ (0.722-0.921)). Median tumour volume was 1.22 ml (0.21-11.80) and a significant difference was found in tumour volumes between local control group ($n=45$) and local tumour recurrence group ($n=16$) ($p=0.049$). A significant difference was determined in prior history of androgen deprivation therapy (ADT) administration between local control group and local tumour recurrence group (20% and 50%, respectively; $p=0.048$). On multivariable analysis, minimum iceball margin ($p=0.001$) and prior ADT use ($p=0.015$) remained independent predictors of local tumour progression. Additionally, standard T2-SI value of tumours did not correlate with Gleason score ($n=54$, $p=0.365$) and local tumour recurrence ($p=0.977$).

Conclusion: Although 5-10mm iceball margin is preferred to guarantee adequate coverage and treatment, prostate cancer may be effectively treated if iceball margin extends at least 1mm along tumour.

B-0879 11:35

Suspected lesions categorised as PIRADS 3 at multiparametric magnetic resonance (mp-MRI) for prostate cancer (PCa): should we biopsy?

V. Giasotto, L. Basso, A. Casaleggio, V. Prono, C. Terrone, C.E. Neumaier; *Genoa/IT (Veronicagiasotto@gmail.com)*

Purpose: The aim of this retrospective study is to investigate the diagnostic performance of Targeted Biopsy+Standard Biopsy (TB+SB) of lesions categorised as PIRADS 3 at multiparametric Magnetic Resonance (mp-MRI).

Methods and Materials: Between March 2017 and August 2018, we enrolled a total of 68 patients suspected to have Prostate Cancer (PCa) on the basis of clinical and laboratory data underwent mp-MRI on 1.5T with Endorectal Coil. All images were evaluated according to PIRADSV2, expressing location of suspected foci based on zonal prostate anatomy. Prostate Volume (PV) and Prostate Specific Antigen density (PSAD) were calculated. All patients underwent TB+SB. All histological results were matched with radiological findings.

Results: A total of 79 lesions were identified: 28 PIRADS-3, 37 PIRADS-4 and 14 PIRADS-5. The Detection Rate (DR) of TB+SB was 21,9% for all suspected lesions, 11,8% for PIRADS-3 and 22% for PIRADS-4/5. The DR of SB was 18,7% for all suspected lesions, 10,2% for PIRADS-3 and 16,7% for PIRADS-4/5. The DR of TB was 33,8% for all suspected lesions, 24,3% for PIRADS 3 and 37,8% for PIRADS-4/5. The mean PSAD was 0,08 for PIRADS-3 and 0,2 for PIRADS-4/5.

Conclusion: The DR of TB was significantly higher than SB for all lesions sampled, especially for PIRADS-3. The use of PSAD, with clinical and laboratory data, could represent an important adjuvant tool to suggest which lesions scored as PIRADS-3 should be biopsied. Due to the low PPV of PSAD <0,15 reported in literature, biopsy of lesions scored as PIRADS-3 is a cautious approach.

B-0880 11:43

Feasibility of target dependent systematic core biopsy distribution models for transperineal MR/US fusion biopsy

N.L. Hansen¹, T. Lloyd², A. Macchi³, A. Warren², T. Barrett², C. Kastner²; ¹Cologne/DE, ²Cambridge/UK, ³Milan/IT

Purpose: To retrospectively model prostate biopsy core distribution with reduced biopsy core numbers and focal distribution using transperineal MR/US fusion guided biopsies.

Methods and Materials: Analysis was performed using data from a prospectively completed database of transperineal MR/US fusion guided biopsies between 2012 and 2016. Targeted Biopsy (TB) with 2 cores was taken from each mpMRI lesion followed by 18-24 Systematic Biopsies (SB) from sectors using the Ginsburg protocol. In a data based modelling exercise overall and GS 7-10 prostate cancer detection rate were compared between 2-core TB, 4-core background target biopsy (TB+BSB), 10-20 core saturation target biopsy (Sat TB), and combined TB+SB.

Results: 487 men had a single target lesion in MRI followed by combined transperineal targeted and systematic biopsy. TB alone, TB+BSB, and Sat TB detected 71% (246), 78% (269), and 91% (314) of 345 PCa, respectively, and 67% (149), 76% (169), and 91% (202) of 221 GS 7-10PCa, respectively. The best detection rates were found for outer location, Likert 5 tumour probability, prostate volume ≤ 45 cc, and lesion volume >0.5 cc, leading to detection rates of 98% (44/45) PCa and 94% (34/36) csPCa with 4-core TB+BSB.

Conclusion: MRI can give valuable information for which patients a target-dependent systematic core biopsy distribution is possible. A 4-core TB+BSB biopsy model with detection rates of 98% PCa and 94% csPCa may be feasible for large, highly suspicious lesions of those in the outer sectors of small prostates (10% of our study population).

MRI/US fusion transperineal prostate biopsy versus systematic biopsy for clinically significant prostate cancer detection in patients with negative ultrasound findings

Y. Chen, Y. Zhu, W. Guan, Y. Qu; *Shanghai/CN (joychen1266@hotmail.com)*

Purpose: To assess MRI/US fusion transperineal prostate biopsy versus standard systematic biopsy for clinically significant prostate cancer (PCa) detection in patients with negative US findings.

Methods and Materials: A total of 97 men with suspicious multiparametric prostate MRI (PI-RADS category 3 or above) and negative US scheduled for MRI/US transperineal fusion biopsy were enrolled in this prospective study. Transperineal fusion biopsy was performed using Real-time Virtual Sonography system with 2-3 cores sampled from each suspicious lesion. After fusion biopsy, standard 12-core systematic biopsy was performed by another group of physicians who were blinded to MRI results. The diagnostic performance for clinical significant PCa of fusion biopsy was evaluated in comparison with systematic biopsy.

Results: The overall cancer detection rate was 49.5% (48/97). PCa was detected by fusion biopsy in 45 patients (46.4%, 45/97) and systematic biopsy in 36 patients (37.1%, 36/97, $P=0.035$). Among 48 patients with PCa, 44 (91.7%, 44/48) were diagnosed with clinically significant PCa. In comparison with systematic biopsy, the significant PCa detection rate for fusion biopsy was statistically higher (44.3%, 43/97 versus 30.9%, 30/97, $P=0.001$). MRI / US transperineal fusion biopsy resulted in an additional diagnosis of 14 patients with clinically significant PCa, including 10 patients missed by systematic biopsy and 4 patients undergraded by systematic biopsy. If fusion biopsy was omitted, only one patient with clinically significant PCa would be missed.

Conclusion: MRI/US transperineal fusion biopsy can improve clinically significant PCa detection in patients with negative baseline TRUS findings compared with standard systematic biopsy.

Predictive value of 18F-FDG PET/CT information in the modern 3D-based radiotherapy treatment of head and neck cancer patients

A. Kedves¹, Z. Dr. Tóth¹, M. Emri², D. Sipos¹, V. Koczka¹, I. Repa¹, Á. Kovács¹,
¹Kaposvár/HU, ²Debrecen/HU (kedvesandras94@gmail.com)

Purpose: The aim of the study was to evaluate the potential predictive value of the maximum standard uptake value (SUV_{max}), lean body mass corrected SUV (SUL_{peak}), metabolic tumour volume (MTV) and total lesion glycolysis (TLG) values of the primary tumour in the clinical outcome.

Methods and Materials: Retrospective evaluation was performed using PET/CT image datasets of 52 histologically proven head and neck cancer patients, receiving definitive 3D PET/CT fused chemo-radiotherapy (CRT). PET/CT was performed before the start of the CRT and repeated after the completion of the therapy clinical for response evaluation. SUV_{max} , SUL_{peak} , MTV and TLG values of the primary tumour have been assessed before and after the therapy. Two patient groups were created in relation to the presence or absence of viable primary tumour tissue. Group related metabolic parameter evaluation was performed, using the Kruskal-Wallis test.

Results: In 28/52 (54%) cases viable residual tumour tissue was detected on the restaging PET/CT image datasets, and in 24/52 (46%) cases complete remissions were found. For therapeutic success prediction assessment, we were unable to find any statistically significant correlation with pre-treatment SUV_{max} and SUL_{peak} values ($p=0.44$, $p=0.33$). TLG provided nearly statistically significant differences ($p=0.052$), and MTV have shown significant differences ($p=0.001$) between patient groups.

Conclusion: According to our results simple metabolic data provided by FDG PET/CT were unable to predict therapeutic response, while complex PET/CT volume information containing parameters proved to be more useful. Survey is planned to be followed with more subject and parameter inclusions.

B-0883 10:38

Comparative evaluation of in-house-prepared 99mTc-ethylene-dicysteine-deoxyglucose and 18F-fluorodeoxyglucose in breast cancer

J. Horn-Lodewyk¹, J. Zeevaart², J. Wagener², G. Engelbrecht¹;
¹Bloemfontein/ZA, ²Pretoria/ZA (jeninehorn@gmail.com)

Purpose: To compare the uptake pattern of in-house-prepared (IHP) 99mTc-ethylene-dicysteine-deoxyglucose (99mTc-EC-DG) with 18F-fluorodeoxyglucose (18F-FDG) in histologically proven breast carcinoma patients.

Methods and Materials: Serial whole-body scans were acquired at different time intervals in five breast cancer patients (Stages II-IV). SPECT/CT was performed at 2 hours (h) post-99mTc-EC-DG administration. An average blood time-activity curve was calculated from the pooled blood sample data of five patients at 0-, 1-, 2- and 4 h after 99mTc-EC-DG injection. One-hour post-administration 18F-FDG-PET scans were also acquired. All the scans were qualitatively evaluated by one board-certified nuclear medicine physician. Quantitative comparisons were also made by drawing three-dimensional regions of interest and calculating tumour-to-background (T:B) ratios.

Results: The primary breast tumour uptake was visualised with 99mTc-EC-DG and 18F-FDG in five patients. 99mTc-EC-DG tumour uptake in $n=3$ patients was similar to the 18F-FDG uptake. Lower 99mTc-EC-DG was found in $n=2$ compared to 18F-FDG. The blood time-activity curve indicated rapid 99mTc-EC-DG clearance. The T:B ratios of 18F-FDG indicated a mean \pm SD of 7.29 ± 3.26 and for 99mTc-EC-DG 2.49 ± 1.1 for the five patients. A $p=0.124$ indicated non-statistical significant difference between two paired samples.

Conclusion: IHP 99mTc-EC-DG SPECT/CT scan has similar diagnostic accuracy compared to 18F-FDG PET/CT for the primary breast tumour. Yet, advantages of 99mTc-EC-DG would be lower cost (no special equipment) as well as lower radiation dose patient and staff. IHP 99mTc-EC-DG has promising uptake properties as a diagnostic tumour-imaging agent and could play a future role in the diagnostic workup and monitoring of these patients.

B-0884 10:46

SPECT/CT artefacts: nuclear medicine point of view

A. Geão¹, E. Pereira²; ¹Lisbon/PT, ²Almada/PT (ana.r.geao@gmail.com)

Purpose: The association of SPECT and CT images can have a synergic effect in Nuclear Medicine imaging. Although, the use of SPECT and CT combined images must be carefully done, due to the several artefacts that may occur and that can diminish the accuracy of this technique.

Methods and Materials: The acquisition and processing protocols must be carefully followed, and the acquired images must be reviewed for technical and diagnostic quality before the patient leaves the department.

Results: The identification of the artefact and its source (if related to the equipment or to patient characteristics) is very useful in order to prevent or correct the artefact or minimise its effect on image quality.

Conclusion: Nuclear Medicine Technologists and Radiographers have an important role on the implementation of strategies to avoid artefacts to occur or to minimise its impact if they are not avoidable. Images must be interpreted by skilled readers who are well aware of the patients' clinical history, using workstations that allow integrated viewing of the functional and na atomic data. In this way, a high quality study will provide useful diagnostic information for further clinical management and patient care. Knowledge and training is very important to enhance image quality and as the quality of SPECT/CT device improves, it is expected that new applications will emerge.

B-0885 10:54

Impact of cardiac CT on the use of invasive diagnostic catheterisation in paediatric patients

C. Griffiths, A.R. Rafferty, R. Allen, P. Noonan; Glasgow/UK
(c.griffiths2@nhs.net)

Purpose: Diagnostic cardiac catheterisation is an invasive procedure used in paediatric patients with congenital heart disease. The investigation requires general anaesthesia (GA), which is associated with neurodevelopmental risks (1). However, non-invasive CT angiography with a cardiac package can also be used and provides detailed information on intra- and extra-cardiac anatomy, coronary arteries, and vascular structures. We investigated whether the introduction of a non-invasive CT scanner with a cardiac imaging package reduced the number of patients undergoing invasive diagnostic cardiac catheterisation procedures.

Methods and Materials: A retrospective analysis of patients undergoing diagnostic cardiac catheterisation and CT angiography was conducted for 2 years prior to (2013/14) and after (2016/17) introduction of a cardiac CT scanner at the Royal Hospital for Children, Glasgow. Statistical comparison of the data was undertaken using chi-squared tests.

Results: There was a significant difference in the number of diagnostic cardiac catheterisation and CT angiography procedures being conducted pre- and post-introduction of the CT scanner ($X^2 = 118.09$, $P < 0.01$). Diagnostic CT imaging increased from 85 to 345 cases in 2013/14 vs. 2016/17, whereas cardiac catheterisation procedures decreased from 143 to 88 cases, respectively.

Conclusion: Introduction of a CT scanner with a cardiac package resulted in a significant decrease in invasive cardiac catheterization procedures and an associated increase in non-invasive CT imaging. The shift from invasive to non-invasive investigations reduces patient and parental distress, as well as the risks associated with GAs in the paediatric population (2).

B-0886 11:02

Comparison of radiation dose and image quality between an image intensifier and flat panel detector system in ERCP

E. Saukko¹, H. Niiniviita¹, A. Henner², M.T. Nieminen²; ¹Turku/FI, ²Oulu/FI
(ekaterina.saukko@tyks.fi)

Purpose: In recent years, many conventional image-intensifier (II) fluoroscopy systems have been replaced by flat panel detector (FPD) technology. The aim of this study was to assess the patient radiation dose and image quality in endoscopic retrograde cholangiopancreatography (ERCP) with both types of fluoroscopy systems. ERCP is a gastrointestinal procedure used as a gold standard in the treatment of pancreatobiliary disorders.

Methods and Materials: Data related to patient demographics and radiation exposure in ERCP from an II system (n=91) and FPD system (n=101) was retrospectively collected at the same institution. Image quality was evaluated by measuring image noise from regions of interest (ROIs) on ERCP images acquired on each type of fluoroscopy system (n=30 and n=30). These measurements were further used in the signal-to-noise ratio (SNR) and figure of merit (FOM) calculations

Results: The median dose area product (DAP), fluoroscopy time (FT) and number of acquired images from II system were 1.55 Gy^{cm}², 1.4 min and 3 images. With FPD system, the median DAP, FT and number of acquired images were 1.72 Gy^{cm}², 1.7 min and 3, respectively. There was no difference in SNR (mean±SD) between systems (II 16.5±5.0 vs. FPD 17.1±7.9). However, the FOM was lower with II system compared to FPD system (1.5±1.1 I/Gy^{cm}² vs. 3.6±6.3 I/Gy^{cm}²).

Conclusion: The results underline the necessary measures towards the optimisation of patient dose and image quality in ERCP procedures. Slight increase in DAP and FT needs to be further investigated in clinical practice.

B-0887 11:10

Patient radiation dose during coronary angiography and intervention: a multi-centre, retrospective study

S. Kaartinen, A. Henner, T. Mäkelä; Oulu/FI (anja.henner@oamk.fi)

Purpose: Radiation dose to patient undergoing coronary angiography procedures is high. In Finland there are diagnostic reference levels for coronary angiographic procedures. This study sought to examine if the reference levels were met in the five hospitals in Northern Finland during the study period and are there differences between different hospitals.

Methods and Materials: Data related to radiation exposure, patient demographics and procedural characteristics in coronary angiographic procedures (n=2 901) performed in 2016 in five different hospitals was retrospectively reviewed and analyzed. Patient doses were compared between hospitals, between procedures and to diagnostic reference levels given by STUK.

Results: Results of this study indicate that patient radiation doses vary not only between different interventional cardiology procedures but also between the hospitals. Doses given as DAP (Gy*cm²) ranged between 0,00 and 989,69 in all the coronary angiography procedures in all five hospitals and averages (+/-SD) were 39,61 (41,08) for hospital 1, 20,13 (11,44) for hospital 2, 24,74 (19,62) for hospital 3, 15,31 (14,51) for hospital 4 and 38,56 (61,72) for hospital 5. Doses were mostly dependent on the fluoroscopy equipment, patient demographics, procedure and performing physician.

Conclusion: There is need to make effort to further minimize the patient doses during coronary angiography and measures should be made to meet the guidelines given by diagnostic reference levels.

B-0888 11:18

Infection control: developing aseptic methods and creating a guideline for interventional radiology unit

S. Simelius-Nieminen, H. Malmivirta, V. Seiko-Vänttinen, E. Saukko; Turku/FI
(suvi.simeliusnieminen@gmail.com)

Purpose: Aseptic conscience is the base for aseptic procedures. Healthcare-associated infection (HAI) can occur because of microbes in patient, personnel, surfaces or contaminated instruments. WHO estimates that there are 4.5 million HAIs yearly in Europe. Infection control depends on very simple things as good hand hygiene and good aseptic methods in invasive interventions. The aim of this development project was to assess aseptic technique and to create a written guideline for aseptic methods for Interventional Radiology Unit of Turku University Hospital.

Methods and Materials: The action research study was carried out with electronic questionnaire and observation of aseptic methods. Electronic questionnaire was sent in September of 2017 to the personnel (n=27) of Interventional Radiology Unit and response rate of 81.5% was achieved. Observation was done from October to November of 2017. In total, 40 interventional procedures were observed and personnel's participation was 100%. The electronic questionnaire and observation material were analysed and similarities with differences were searched using content analysis.

Results: Five main themes were highlighted: improving hand disinfection, usage of surgical masks, usage of sterile indicator gloves, usage of chlorine dioxide-based disinfectants and improving antibiotic prophylaxis on bile duct procedures and on nephrostomy patients. Chlorine dioxide-based disinfectant was reclaimed and four other themes were discussed on learning café with personnel. Based on the literature and results, a guideline was created in Interventional Radiology Unit for fluoroscopy-guided procedures.

Conclusion: Improvements were done on these themes, but it takes time and effort to successfully implement new ways in practice.

B-0889 11:26

Inoperable patients with chronic thromboembolic pulmonary hypertension: initiation a balloon pulmonary angioplasty programme

T. Loupa, L. Brites, C.M.D.S. Almeida; Lisbon/PT (cristindr@gmail.com)

Purpose: Balloon pulmonary angioplasty (BPA) is an emerging treatment for patients with inoperable chronic thromboembolic pulmonary hypertension (CTEPH), however there is a lack of studies in safety and efficacy of BPA for chronic thromboembolic pulmonary disease (CTED) patients.

Methods and Materials: Data from all CTEPH patients were collected retrospectively in the centre records. The mean pulmonary artery pressure, the cardiac index and home oxygen therapy were analysed in order to compare patient's progress.

Results: BPA sessions were performed in 11 patients (n=14). All patients underwent a comprehensive diagnostic work-up including right heart catheterism at baseline and 24 weeks after intervention. BPA resulted in improvements in World Health Organization (WHO) functional class (3.5 to 2.1). Home oxygen therapy was used (57% to 20%) and a reduction of mean pulmonary artery pressure (59±11 to 46±8 mmHg) and cardiac index (2.3±1.1 to 2.5±1.4 L/min/m², P = 0.92) was verified. Procedure-related adverse events occurred in 20% of the interventions.

Conclusion: BPA was an effective therapeutic approach for non-operable CTEPH patients. BPA can be a new treatment option for carefully selected CTED patients.

B-0890 11:34

Dose distribution for vascular procedures at a tertiary training hospital in South Africa

H. Muller¹, W.I.D. Rae², H. Friedrich-Nel¹; Bloemfontein/ZA, ²Sydney/AU
(henramuller@cut.ac.za)

Purpose: Radiation exposure during interventional radiology can deliver skin doses, which can approach the lower limit for biological effects (2Gy). It is thus important that referring clinicians, radiologists, radiographers and patients are aware of these potentially high doses. Interventional procedures are often complicated, requiring long fluoroscopy times. It is, therefore, important to identify specific procedures with an increased risk of radiation injury. The aim of this study was to determine which procedures contribute the highest radiation dose to individual patients and the population in a tertiary training hospital in South Africa.

Methods and Materials: The study included 3310 patients undergoing diagnostic and interventional vascular procedures, which involved fluoroscopic x-ray exposure, for a three-year period. Procedural data were entered into a database, which included dose-area products (DAP) and screening times.

Results: The maximum dose delivered to an individual patient was 4.16Gy during a renal arteriogram. Doses delivered during transfemoral outflow and endovascular aneurysm repair procedures approached or exceeded the threshold for deterministic effects. Transfemoral outflows and four-vessel angiograms delivered the highest population dose.

Conclusion: Specific high-dose procedures were identified which may require patient follow-up to monitor skin effects. Measures to decrease radiation doses and limit radiation effects must be taken especially for the identified procedures. From the study, it is seen that diagnostic procedures are performed more often resulting in a high population dose. Interventional procedures are performed less often but can deliver a high dose to the individual patient due to the complex nature of these procedures.

B-0891 11:42

The establishment of a triage tool for patient stratifications undergoing myocardial perfusion scintigraphy stress tests in Malta

K. Borg Grima¹, P. Bezzina¹, L.A. Rainford²; ¹Malta/MT, ²Dublin/IE
(karen.borg-grima@um.edu.mt)

Purpose: Normal myocardial perfusion stress (MPS) scans are associated with less than 1% chance of cardiac events, annually. Within clinical practice it is difficult to identify patients who will not reach 85% or more of the target heart rate during the MPS stress test, potentially undermining the diagnostic capability of the test. A triage tool may provide an alternative way to assess the functional status of a patient before the stress test, aiding to standardise practice across Nuclear Medicine (NM) departments.

Friday

Methods and Materials: This study consisted of a multi phased approach using several data collection methods, including: an international online survey; 252 retrospective patient file analysis; 6 qualitative interviews with physicians and 300 patient questionnaires. Ethical permission was obtained for each phase.

Results: Online survey results highlighted the need for a patient triage tool. In 17 NM centres (n = 43) practitioners were unsure of the presence of stress testing protocols. The final phase linked population identified risk criteria: diabetes (p = 0.012), smoking (p = 0.003) and previous myocardial infarction (p < 0.001), with the results of the interviews, in order to establish through the use of a triage tool, each patient's ability to successfully finish the exercise stress test.

Conclusion: Initial findings indicate the proposed triage tool may be an effective method for referring physicians in Malta, to direct patients to the type of diagnostic test suited for their clinical scenario and to the stress test (exercise or pharmacological) that may correctly determine the extent of ischaemia.

B-0892 11:50

Dose reduction in hybrid imaging techniques in nuclear medicine

A. Geao¹, E. Pereira²; ¹Lisbon/PT, ²Almada/PT (ana.r.geao@gmail.com)

Purpose: Vogel and Wainwright (1969) said "structure without function is a corpse and function without structure is a ghost". Nowadays, hybrid imaging is changing this paradigm. "Nuclear Medicine is evolving into nuclear radiology" and the same procedure is combining functional and structure evaluation. However, hybrid equipments are as challenging as interesting areas of radiation safety for both professionals and patients.

Methods and Materials: The frequency of hybrid imaging modalities, like PET/CT and SPECT/CT is increasing because the use of CT in nuclear medicine imaging improves diagnostic accuracy. Hybrid imaging is also increasing patient doses. Huang et al. (2009) points that CT may contribute up to 76% on the total effective dose of a PET/CT, raising special concerns on dose reduction.

Results: The first and perhaps most important way to minimize dose comes from deep understanding the equipment. Protocol optimization may enable decreasing the administrated activity of emission image. CT dose can vary widely according to equipments and protocols, defining importance of the appropriate protocol for the scans purpose.

Conclusion: Technological improvements in nuclear medicine imaging can influence patient radiation burden significantly: available data on SPECT/PET and PET/CT innovations are mostly linked to improved image quality and/or reduced scanning times, however dose reductions are possible. Available data in CT innovations are often linked to patient dose reduction while maintaining image quality. Nevertheless, a trade-off should be made with respect to image quality improvement, scan time reduction and patient dose reduction.

Measurement of femoral antetorsion with CT and MR: why trigonometry should be added

F. König¹, E. Rutz², J.A. Jacobson³, A.L. Falkowski², O. Magerkurth¹;
¹Baden/CH, ²Basle/CH, ³Ann Arbor, MI/US (fabian.koenig@ksb.ch)

Purpose: To describe a mathematical model allowing transfer of measurements of femoral antetorsion (AT) acquired from axial-oblique-images to the „axial method" combining advantages of better visibility of the collum and ability to use the established normal values for assessment of femoral AT.

Methods and Materials: Measurement of AT on axial imaging omits the true CCD angle by assuming 90°. Hence, AT is a result of a projection. On oblique-axial-imaging the CCD angle is fully appreciated and anteversion of the collum represents a projection other than that of 90°, inevitably resulting in smaller AT angles. To transfer measurements of oblique-axial-images (OAI), the CCD on true coronal images is assessed (cCCD). Then the angle (oblique-alpha) of the long axis of the collum to the horizontal on OAI is measured. Finally length of the collum (c) from the center of the femoral head to the center of the diaphysis is assessed. By using different right triangles and basic geometry the AT of the

femur can be calculated stepwise. Final formula of AT = arctan ((sin(oblique-alpha) x collum length) / (cos(cCCD-90°) x √(collum length²-(sin(oblique-alpha) x collum length²)))

Results: This formula provides AT angles equal to those measured on axial images. For example: cCCD=122°; alpha oblique=9°; Collum length: 57mm; Calculated AT=28.457°, Measured AT=28.

Conclusion: It is possible to calculate the classic AT angle from measurements on one coronal and one oblique-axial-image with better visibility of the collum. This may increase inter- and intrareader reliability and still allows the use of normal values provided by earlier studies with axial Images.

B-0894 10:38

Failure patterns in femoral head osteonecrosis: a micro-CT study with histological correlation

C. Mourad¹, C. Galani², F. Libert³, B. Vande Berg²; ¹Beyrouth/LB, ²Brussels/BE, ³Tournai/BE (charbel.j.mourad@hotmail.com)

Purpose: To describe failure patterns of bone and cartilage in osteonecrotic femoral heads using micro-CT with histological correlation.

Methods and Materials: Seven resected osteonecrotic femoral heads (6 men and 1 woman) were scanned by using micro-CT (Skyscan 1173, Bruker, Kontich-Belgium; 12 µm isotropic resolution) before histological processing. Fifteen micro-CT images were reformatted to match with fifteen histological slices (9 necrotic and 6 non-necrotic areas). Micro-CT images were analyzed by a musculoskeletal radiologist blinded to histology, to detect cartilage or bone interruption within the non-necrotic specimens and the different layers of the necrotic lesions (hyaline cartilage, the subchondral lamellar bone plate, the subchondral, deep and peripheral trabecular bone of the lesion). The corresponding histological images were independently analyzed by a bone pathologist to assess cartilage and bone interruptions in a similar layer approach.

Results: No cartilage/bone interruption was detected in the non-necrotic areas of the specimens at micro-CT and at histology. Within the necrotic areas, bone interruptions were noted in the subchondral bone plate (9/9; 100%), subchondral trabecular bone (7/9; 78%), deep trabecular bone within the necrotic lesion (4/9; 44%) and peripheral trabecular bone near the reactive interface (1/9; 11%). All lesions were seen at microscopic analysis. Interruption of the cartilage was detected in 1 specimen at micro-CT and in 4 specimens at histology. A quantitative analysis after segmentation is undergoing.

Conclusion: At micro-CT imaging, bone interruptions are found exclusively in the necrotic areas. Superficial layers are more involved.

B-0895 10:46

Image quality of hip MR arthrography with intra-articular injection of hyaluronic acid

E.A. Nocerino¹, L. Nicosia², M. Ali³, C.B. Monti³, F. Sardaneli³, A. Aliprandi³;
¹Cassina de' Pecchi/IT, ²Gallarate/IT, ³Milan/IT
(elisabetta.nocerino85@gmail.com)

Purpose: To compare image quality of hip magnetic resonance arthrography (MRA) with intra-articular injection of high-viscosity hyaluronic acid (HA-MRA) to that of hip MRA with intra-articular injection of Gd-based contrast agent (Gd-MRA) in patients with femoral-acetabular impingement (FAI).

Methods and Materials: Design: single centre, observational, retrospective, inter-individual, cross-sectional. FAI patients with who underwent hip HA-MRA (3 mL of high-viscosity HA plus 17 mL of saline) were compared with 37 age- and possibly sex-matched FAI patients who underwent hip Gd-MRA (20 mL of 2-mmol/L solution of gadopentetate dimeglumine). Two independent blinded radiologists assessed image quality for all sequences (two-dimensional proton density, non-fat-sat axial, fat-sat coronal and sagittal; three-dimensional dual-echo steady state), using a 5-point Likert scale considering separately cartilage, labrum, as well as round and transverse ligaments. Pearson's χ^2 and Cohen's κ were used.

Results: The HA-MRA group was composed of 37 patients (23 males, 14 females; median age 38 years), the Gd-MRA group of 37 patients (21 males, 16 females; median age 38 years), without significant difference for age (p=0.937) and sex (p=0.636). For both readers, image quality for all the investigated hip structures never resulted significantly different on any of the sequences: labrum (p≥0.340), cartilage (p≥0.198), round ligament (p≥0.255), transverse ligament (p≥0.806), and capsule (p≥0.314). Inter-reader agreement ranged from κ = 0.785 to κ = 1.000.

Conclusion: Hip HA-MRA provided a performance not significantly different from that of hip Gd-MRA. A perspective for a one-shop-stop combination of MRA and viscosupplementation in FAI is open.

Traction MR arthrography of the hip for characterisation of femoral head necrosis and resulting femoral cartilage damage in patients eligible for joint-preserving surgery

F. Schmaranzer¹, T. Lerch¹, J.L. Cullmann¹, E. Schmaranzer², J.T. Heverhagen¹, K. Siebenrock¹, M. Tannast¹; ¹Berne/CH, ²St. Johann/AT (florian.schmaranzer@insel.ch)

Purpose: To assess (1) the location of necrosis, (2) location and pattern of femoral cartilage damage, and (3) diagnostic accuracy to detect femoral cartilage lesions using direct, traction MR arthrography (MRA).

Methods and Materials: This is an IRB-approved retrospective study. The institutional database (2016-2018, 360 hips) was reviewed for patients with AVN and complete radiographs and direct, traction MRA of the hip at 3T. Thirty patients were included (mean age 31 ± 9 years, 60% female; ARCO stages (I=30%, II=57%, III=13%). Fourteen (47%) hips underwent joint preserving surgery (10 open, 4 arthroscopic). Traction technique included weight-adapted traction (15-23 kg), a supporting plate to avoid pelvic tilt. Imaging protocol included coronal, axial, sagittal and radial 2D PD-w TSE sequences without fat saturation obtained under traction. Location of necrosis and lesions was described circumferentially and allocated to 4 joint quadrants. We assessed (1) location of necrosis, (2) location and pattern of femoral cartilage damage (normal/delamination/thinning/defect) on traction MRA, and (3) diagnostic accuracy of traction MRA to detect femoral cartilage lesions in the 14 patients (14 x 4 = 56 quadrants) undergoing surgery.

Results: (1) Necrosis was located most frequently in the antero-superior quadrant (93% of hips). (2) Most frequently femoral cartilage delamination was found in the antero-superior quadrant (87% of hips). (3) Sensitivity was 93% (25/27) and specificity was 100% (29/29) of traction MRA to detect femoral cartilage lesions.

Conclusion: AVN predominantly affects the antero-superior quadrant and leads to corresponding femoral cartilage delamination which can be detected accurately using traction MRA.

B-0897 11:02

Postoperative, traction MR arthrography in patients with persisting pain after arthroscopic FAI correction reveals high prevalence of osseous deformities and intra-articular lesions

F. Schmaranzer¹, T. Lerch¹, K. Siebenrock¹, M. Tannast¹, E. Schmaranzer²; ¹Berne/CH, ²St. Johann/AT (florian.schmaranzer@insel.ch)

Purpose: Patients management after failed arthroscopic FAI surgery is challenging. To assess prevalence of new/residual (1) osseous deformities, (2) intra-articular lesions and (3) progression of osteoarthritis in symptomatic patients undergoing pre- and postoperative MR imaging after hip arthroscopy.

Methods and Materials: This is an IRB-approved, retrospective study. From 2010 to 2017, 806 patients underwent arthroscopic FAI correction. Database was reviewed for symptomatic patients with traction MR arthrography (MRA) of the hip obtained before, after hip arthroscopy. 49 patients were included 29±10 years, 67% female. Traction was applied using a MR-compatible traction device. One reader assessed pre-/postoperative images. (1) Acetabular coverage (LCE<25°/39°=dysplasia/pincer) and Tönnis osteoarthritis (OA) grade were assessed on AP pelvic views. Cam deformity: radial images α>60°. Femoral torsion: low/high torsion: <5°/30°. (2) Residual tears, retears of the labrum, capsular adhesions/defects. (3) OA progression on MRI.

Results: Preoperatively 42 (86%) hips showed deformities: 2 (4%) dysplastic-, 11 (22%) pincer- and 39 (80%) cam deformities. Postoperatively 39 (80%) hips showed deformities: 9 (18%) dysplastic-, 8 (16%) pincer-, 20 (41%) cam deformity, 4 (8%) hips with torsion <5°, 10 (20%) hips with torsion >30°. Postoperatively 14 (29%) cases with residual and 12 (24%) cases with labrum retears were observed. 6 (12%) hips had capsular adhesions and 22 (45%) had capsular defects. Radiographic OA progression was observed in 5 (10%) hips, in 14 (30%) hips on traction MRA.

Conclusion: Prevalence of osseous deformities due to over- or undercorrection and intra-articular lesions is high after failed hip arthroscopy. Traction MRA was useful for detection of OA progression.

B-0898 11:10

The extension thickness damage (ETD) score: a pre-operative hip MR arthrography-based classification to predict type of labrum surgery

D. Albano¹, A. Aliprandi², M. Brioschi², S. Magnani², C. Messina², S. Sdao², F. Randelli², L.M. Sconfienza²; ¹Palermo/IT, ²Milan/IT, ³Lodi/IT (albanodomenco@me.com)

Purpose: To develop a new hip MR arthrography (MRA)-based scoring system of labral tears to predict before surgery the treatment option more suitable for labral tears.

Methods and Materials: Forty-seven patients (29 males) performed hip MRA for suspicious of femoroacetabular impingement and were afterwards

subjected to arthroscopic treatment. Two musculoskeletal radiologists reviewed preoperative examinations and provided the extension thickness damage score based on Extension of tear, Thickness of labrum and type of damage. Chondral lesions grading was based on the arthroscopic findings according to Konan classification. For statistical purposes, patients were divided into two groups, depending on the type of treatment: labral repair or debridement. U Mann Whitney, Chi-square, receiver operator curves, and Cohen kappa statistics were used.

Results: 35/47 underwent repair, while 12/47 were debrided. In both groups, the median chondral damage was grade III, with no significant differences (p=0.439). The median extension thickness damage score in the repair group (6) was significantly lower (p<0.001) than that in the debridement group (8). The highest diagnostic performance (Area Under the Curve) of extension thickness damage was 0.819. The inter-observer agreement was substantial in the evaluation of Extension (k=0.626) and Thickness (k=0.771), and almost perfect for damage (k=0.827). Higher scores of Extension and Thickness were more frequently associated with debridement (p<0.001;p=0.0016, respectively), with no significant differences on the basis of damage parameter (p=0.284).

Conclusion: The MRA-based extension thickness damage score could represent a helpful pre-operative tool, expressing the extent of the damage and its reparability before arthroscopy.

B-0899 11:18

Cam vs pincer femoroacetabular impingement: which type is associated with more hip structural damage? An exploratory cross-sectional study using MRI

Y. Ragab¹, Y. Emad¹, A. Anbar¹, M. Khalil², J. Rasker³; ¹Cairo/EG, ²Stokholm/SE, ³Amsterdam/NL (yragab61@hotmail.com)

Purpose: To investigate the pattern and magnitude of hip structural damage associated with each type of femoroacetabular impingement (FAI) before the development of established hip osteoarthritis (OA).

Methods and Materials: Forty-four patients (78 hips) diagnosed with either cam or pincer FAI were consecutively recruited in a prospective cohort study. None of our patients had evidence of osteoarthritis (OA) on the initial plain radiography. All patients had contrast-enhanced MRI and CT scans of the hips. All patients filled in a visual analogue scale (VAS) for pain.

Results: The frequency of bone marrow oedema (BME) was 37% in cam FAI and 20.8% in pincer FAI. In cam FAI, BME positively correlated with pain severity as measured by VAS (P<0.0001), cartilage degradation (P=0.001), pseudocysts (P<0.0001), hip effusion (P=0.013) and reactive synovitis (P<0.0001). However, in pincer FAI, BME only correlated with pain severity (P=0.004) and duration (P=0.011) and did not correlate with other MRI signs of structural hip damage.

Conclusion: In cam FAI, BME of the femoral head and neck on MRI positively correlated with chondral damage and synovitis, but not in pincer FAI. This correlation suggests that cam FAI might be associated with a worse long-term prognosis. This finding might have an impact on clinical practice and decision-making as it would encourage surgeons to intervene early in cases of cam FAI, thus preventing the possible development of irreversible established hip OA.

B-0900 11:26

MRI hip findings in asymptomatic professional Rugby players, ballet dancers and age-matched controls

T.N. Blankenstein¹, A. Grainger, B. Dube, R. Evans, P. Robinson; Leeds/UK (tomblankenstein@nhs.net)

Purpose: The objective of this study was to investigate the findings in MRI of the hips amongst asymptomatic professional male rugby players and male ballet dancers compared to age- and sex-matched controls.

Methods and Materials: After ethics committee approval, 11 professional rugby players, 10 professional ballet dancers and 10 controls completed activity and symptom questionnaires and underwent 3.0T MRI of their dominant hip. Each scan was independently scored by two musculoskeletal radiologists for multiple features, including joint morphology, acetabular labrum appearance, cartilage loss and capsular thickness.

Results: Hip questionnaire symptom scores (Hip disability and Osteoarthritis Outcome Score) were significantly higher in rugby players (5/100) and ballet dancers (10/100) compared to controls (0/100) (p<0.05). There was no significant difference in the other questionnaire subscales. The prevalence of labral tears was 87% with no significant difference between groups (p>0.05). The majority of labral tears were full thickness or complex, degenerative type tears. Rates of paralabral cysts were significantly higher in ballet dancers (50%), compared to rugby players (0%) and controls (10%) (p=0.01). Acetabular cartilage loss was present in 54% with no significant differences between groups. Superior capsular thickness was significantly greater in ballet dancers (5.3mm) compared to rugby players (3.8mm) and controls (3.8mm) (p=0.03).

Conclusion: Despite the difference in activity between groups, there were equally high rates of labral tears and acetabular cartilage loss, questioning the role which sport plays in the development of these findings and their relationship to symptoms. The focally increased superior capsular thickness in ballet dancers may be an adaptive response to extreme ranges of movement.

B-0901 11:34

3D T1 mapping of hip cartilage: a comparison of a new inversion-recovery-based method with conventional dual-flip angle acquisition

F. Schmaranzer, T. Lerch, J.L. Cullmann Bastian, K. Siebenrock, M. Tannast, J.T. Heverhagen, M. Ith, B. Jung; *Berne/CH (florian.schmaranzer@insel.ch)*

Purpose: Although commonly used for quantitative imaging of hip cartilage, 3D dual-flip angle (DFA) techniques are highly sensitive to flip angle variation (B1 inhomogeneities), even more at 3T. The purpose is to compare precontrast T1 values of hip cartilage using a new inversion-recovery (IR)-based method with conventional DFA acquisition in asymptomatic volunteers.

Methods and Materials: This is an IRB-approved study of 18 asymptomatic hips (9 volunteers; mean age 27±2 years, 60% female). Subjects underwent non-contrast, quantitative T1 imaging of hip cartilage at 3T: (1) 3D DFA GRE-based technique (0.9 mm³ isotropic T1 VIBE; acquisition time 8:30 min) including a prescan for B1 correction. (2) 3D dual-IR approach that has been recently introduced in brain imaging (0.9 mm³ isotropic T1 MP2RAGE; acquisition time 7:30 min) in which T1 values are calculated based on two different inversion pulses. Radial images were reformatted for both T1 techniques. Regions of interest were placed manually, based on anatomic landmarks within the cartilage at each hour position of the clock face.

Results: Mean T1 values and standard deviation of overall (1488±174ms vs 1036±41ms), anterior (1533±219ms vs 1026±45ms) and posterior (1444±157ms vs 1047±43ms) hip cartilage was higher for the DFA compared to the IR-based method (all p<0.001).

Conclusion: Despite the B1 prescan inter-individual differences (standard deviation), T1 values of cartilage were greater with the DFA method compared to the IR method due to the greater flip angle variations at 3 T. Thus, 3D MP2RAGE may provide a more robust alternative for T1 mapping of hip cartilage.

Hip arthroplasty and computed tomography of abdomen: a retroperitoneal indicator of post-arthroplasty hip flexor impingement

M. Alfaqih¹, S. Ali¹, J. Sana Ali¹, P. Chea¹, S. Flacke¹, R. French², D. Elentuck¹; ¹Burlington, MA/US, ²Durham, NC/US (sarah.m.ali@lahey.org)

Purpose: To evaluate if a tangible association exists between psoas muscle (PM) atrophy with acetabular component version.

Methods and Materials: 190 CT scans of abdomen/pelvis in patients with unilateral total hip arthroplasty (THA) were reviewed, culminating a total of 50 patients meeting inclusion and exclusion requirements. The length of the uncovered acetabular component (UAC) was measured. The acetabular version angle was measured on axial (AAV) and sagittal (SAV) reformats. The percentage difference between ipsilateral and contralateral PM in terms of Hounsfield unit (DHU) and area measurement (AM) was assessed. UAC, AAV, and SAV were measured blindly to DHU and AM. Additional analysis was performed by dividing the patients into two groups: group A patients had DHU over 50% and group B patients had DHU less than 50%. UAC, AAV, SAV were compared between groups A and B.

Results: Findings revealed a substantial positive correlation between DHU and UAC ($r^2=0.8$, $p<0.001$). A negative correlation was demonstrated between AAV, SAV and DHU ($r^2 = -0.4$, $p<0.005$) and a positive correlation between UAC and AM ($r^2=0.5$, $p<0.001$). No correlation was observed between AAV, SAV and AM ($r^2 = -0.1$, $p>0.005$). Groups A and B included 14 and 34 patients, respectively. Group A was found to have an increased UAC (8mm ±4, $p<0.001$), decreased SAV (22° ±10, $p<0.01$) and decreased ASV (24°±11, $p<0.0$) compared to Group B (0.08mm±0.5, 32°±11, 34°±10).

Conclusion: A strong association was found between ipsilateral psoas muscle atrophy in patients with THR who have an increased UAC and decreased AAV and SAV.

The value of the single energy metal artefact reduction algorithm in post-surgery follow-up of patients with hip tumour prostheses

L. Ding, L. Ma, F.-L. Zhang; *Guangzhou/CN (408021193@qq.com)*

Purpose: To evaluate the effect of the single energy metal artefact reduction (SEMAR) algorithm with a 320 Multidetector computed tomography (MDCT) volume scanner in post-surgery follow-up of patients with hip tumour prostheses.

Methods and Materials: From November 2015 to September 2018, 103 consecutive patients with a tumour prosthesis of hip joint underwent a 320-MDCT scan. The images were reconstructed using two different methods: iterative reconstruction (IR) alone and IR associated with SEMAR. Four radiologists visually graded the whole image quality at articular level on a 6-point scale from 0 (periprosthetic anatomic structures are completely obscured by metal artefacts) to 5 (periprosthetic structures are recognised with high confidence). Additionally, the readers assessed the presence of periprosthetic complication on a similar 6-point scale from 0 (extensive artefacts, prosthetic complications are unable to be recognised) to 5 (minimal artefacts, prosthetic complications are recognised with high confidence). Wilcoxon matched-pairs signed rank test and Intra-class correlation coefficients (ICCs) were used for the scores of image quality and prosthetic complications.

Results: Visualization of periprosthetic structures were significantly improved by the SEMAR algorithm (3.3~4.2 vs. 1.5~2.4, $P<0.05$). In 64 of 103 patients, prosthetic complications were confirmed by other imaging examination, clinical or pathology, and prosthetic complications. The new algorithm also increased diagnostic confidence of prosthetic complications (4.0~4.4 vs 2.4~3.1, $P<0.05$). The sensitivity of diagnostic confidence of prosthetic complications was increased (93.2% vs.54.3%, $P<0.05$).

Conclusion: The SEMAR visibly reduces the metal artefact and can increase diagnostic confidence of prosthetic complications in patients with hip tumour prostheses.

Generation of a curated dataset from unstructured reports using natural language processing, illustrated on CT reports regarding pulmonary embolism

T.J. Weikert, I. Nestic, J. Cyriac, M. Moor, J. Bremerich, A.W. Sauter, G. Sommer, B. Stieltjes; *Basle/CH (thomasjohannes.weikert@usb.ch)*

Purpose: Retrospective classification of exams in positive vs. negative findings is a frequent first step in the development of curated datasets for the training of artificial intelligence algorithms. Given that radiology reports offer this information mostly in a non-structured fashion, we wanted to test the performance of a self-developed NLP-based procedure.

Methods and Materials: We downloaded all reports of CT pulmonary angiograms (CTPAs) conducted at our institution in 2016/2017 (n = 2,917; language: German). We then extracted the impression sections. The status (pulmonary embolism: yes/no) was manually assessed by a radiologist. CTPAs with other clinical questions than pulmonary embolism or poor diagnostic quality were excluded. The labelled impression sections from 2017 (n = 1,436) served as ground truth to train a deep neural network for NLP (linear support vector machine classifier). The performance of this network was tested using the exams from 2016 (n = 1,367).

Results: Our NLP approach reached a sensitivity of 88.9% and specificity of 96.5%. The positive predictive value was 81.6 and the negative predictive value was 98.1%. In total, the status of 1,303 of 1,365 exams was correctly predicted (accuracy: 95.5%). The cases with wrong classifications had a higher mean word count (40.1) than those with correct predictions (33.5).

Conclusion: Our NLP-based approach allows for an automated and highly accurate retrospective classification of CTPA data solely using the unstructured impression section from radiology reports. A higher word count, likely related to a higher number of secondary diagnoses, may be a potential cause of misclassification.

B-0905 10:38

Scanner parameter induced variability of radiomics features in routine chest CT data

S. Röhrich, J. Hofmanner, J. Pan, F. Prayer, H. Prosch, G. Langs; *Vienna/AT (sebastian.roehrich@meduniwien.ac.at)*

Purpose: To assess the influence of heterogeneous acquisition and reconstruction parameters on radiomic features in pulmonary CT-scans in a large-scale clinical routine population processed by a fully automated unsupervised machine learning (ML) pipeline.

Methods and Materials: 4800 patients who received a chest CT-scan at our hospital were included without regard to pathology or indication. An unsupervised ML-approach was applied to identify clusters of patients depending exclusively on imaging features. Prior to processing, images were resampled to an isotropic voxel resolution of 0.7mm. Visual clusters were identified by extracting texture and 3D-SIFT-features within the lung followed by unsupervised dimensionality reduction techniques (deep-stacked-autoencoder) and k-means-clustering. The resulting clusters were compared with regard to different technical parameters (kVp, convolution kernel, slice thickness and scanner type). We performed fisher's exact cell-chi-squared-tests to assess association between cluster membership and technical parameters. In addition, we studied variability in follow-up studies after lung transplantation (LuTX), n=182.

Results: Cell-Chi-squared-tests yield $p < 0.0002$ for all 20 parameters after Benjamini-Hochberg-correction for multiple testing, indicating strong associations between visual variation identified by unsupervised ML and technical parameters. There is a smaller variation in the more homogeneous cohort of LuTX-follow-ups, however, we still observed significant associations between technical parameters and visual variation (i.e., kVp, slice thickness, reconstruction kernel and scanner type, all ps ranging from 4.4e-5 to 0.04).

Conclusion: The known dependence of radiomics features on technical parameters in CT-scans greatly influences the results of unsupervised ML-approaches, up to a degree where pathological differences in images may become obscured by technical variability.

B-0906 10:46

ePAD: A platform to enable machine learning and AI application development in medical imaging

D.L. Rubin, M.U. Akdogan, C. Altindag, E. Alkim; *Stanford, CA/US* (dlrubin@stanford.edu)

Purpose: To develop a user-friendly tool to enable collaborative, multi-site image annotation and to capture the annotation data in a standards-based format to facilitate radiomics analysis and building deep learning models.

Methods and Materials: The electronic Physician Annotation Device (ePAD; <http://epad.stanford.edu>) is an open source, web-based tool enabling distributed, large scale collection of radiology image annotations. ePAD provides a user friendly interface for image viewing and annotation similar to a PACS, but captures all annotations in the new DICOM-SR/AIM standard object, enabling interoperability of annotations across institutions. ePAD also collects clinical and descriptive information about patients (e.g., diagnoses, imaging observations, and anatomic locations) using AIM templates, and it provides collaboration features such as privileging of access/viewing of annotations and summaries of annotation efforts. ePAD includes tools that leverage the image annotations for creating machine learning models. ePAD is modular and extensible by the community.

Results: ePAD is being used by many institutions, currently with 423 users who have created over 50,000 image annotations in 504 projects (on servers that are online, local instances are not included). The platform is particularly well suited for supporting multi-institutional collaborative projects for collecting image annotations in large scale, and it has been recently used for collecting image annotations for The Cancer Genome Atlas (TCGA) project for brain and bladder cancer collaborative groups.

Conclusion: The ePAD platform is expected to catalyze image annotation data collection efforts, accelerate collaborations in such projects, and ultimately help lead to machine learning and AI applications to improve radiology.

B-0907 10:54

On the generalisability of deep learning across populations and abnormalities: a case study of the Stanford MURA and CheXNet algorithms

H. Wang¹, T. Zou¹, C. Xia¹, P. Borrego², P. Sousa², M. Zhang³; ¹Beijing/CN, ²Barcelona/ES, ³Zhejiang/CN (zhangminming@zju.edu.cn)

Purpose: To investigate the generalisability of deep learning across populations and abnormality locations.

Methods and Materials: We re-implemented Stanford ML Group's CheXNet (chest x-ray abnormality detection) and MURA (musculoskeletal abnormality detection) on their original datasets (mainly from American hospitals), and then tested the models on independently collected datasets. We tested three labels (effusion, nodule and pneumonia) of CheXNet on 769 China adults and 200 Spanish children, and tested the MURA model on a Chinese dataset consisting of both MURA's original 7 abnormalities locations (3019 studies: elbow, finger, hand, forearm, humerus, shoulder and wrist) and 5 additional locations (3475 studies: foot, thoracic spine, extremity, sacrum and pelvis).

Results: The AUCs of CheXNet on its original American adult test dataset, Chinese adults, and Spanish Children were 0.86 vs. 0.88 vs. 0.84 (effusion), 0.84 vs. 0.72 vs. 0.77 (nodule), 0.81 vs. 0.70 vs. 0.57 (pneumonia). Regarding the MURA model, when the original 7 locations were tested, algorithm's sensitivities on the original test dataset and the Chinese dataset were 80.3% vs. 43.9% (elbow), 74.7% vs. 50.0% (finger), 71.9% vs. 53.3% (forearm),

43.9% vs. 19.9% (hand), 86.6% vs. 69% (humerus), 86.3% vs. 69% (shoulder), 75.3% vs. 26.9% (wrist); on the other 5 labels, MURA algorithm's performance was: foot 59.4%, Thoracic-spine 33.9%, extremity 84.1%, Sacrum 70.6%, pelvis 74.0%.

Conclusion: Deep learning showed some satisfactory transferability (e.g., effusion and extremity abnormality). Yet, algorithms' overall performance compromised when generalised to different populations; disease complexity (i.e., musculoskeletal abnormalities) and demographic distance (i.e., adults vs. children) may exacerbate the problem.

Fully automatic construction of optimal radiomics workflows

M.P.A. Starmans, S.R. van der Voort, M. Vos, F. Incekara, J.J. Visser, M. Smits, M.G. Thomeer, W.J. Niessen, S. Klein; *Rotterdam/NL* (m.starmans@erasmusmc.nl)

Purpose: Radiomics uses medical image features to establish relationships between imaging and clinical data. Many radiomics methods have been described in the literature. However, there is no method that works for all applications. We present a workflow for optimal radiomics classification (WORC) to fully automatically construct an optimal workflow per application.

Methods and Materials: WORC states the complete radiomics workflow as a combined algorithm selection and hyperparameter optimisation problem. During training, WORC automatically adapts itself by testing thousands of pseudo-randomly defined radiomics workflows. The best workflows are combined into a single optimal signature. To evaluate WORC, three experiments on different clinical applications were performed: (1) classification of 119 patients with primary liver tumours in benign or malignant on T2-weighted MRIs, (2) prediction of 1p/19q co-deletion in 287 patients with presumed low-grade gliomas on T1- and T2-weighted MRIs and (3) distinguishing liposarcomas from lipomas in 88 patients on T1-weighted MRIs. Ground truth was obtained through pathology. Evaluation was implemented through a 100x random-split cross-validation, with 80% of the data used for training and 20% for independent testing. Performance is given in 95% confidence intervals (CIs).

Results: The CIs of the area under the curve, sensitivity and specificity were (0.86, 0.99), (0.58, 0.89) and (0.85, 0.98) for liver tumours (0.74, 0.85), (0.58, 0.76) and (0.72, 0.86) for brain tumours and (0.74, 0.93), (0.59, 0.86) and (0.67, 0.92) for lipomas/liposarcomas.

Conclusion: The good results in three different applications demonstrate that WORC is a promising approach for fully automatic construction of optimal radiomics workflows.

B-0909 11:10

Deep DSA (DDSA): learning mask-free digital subtraction angiography for static and dynamic acquisition protocols using a deep convolutional neural network

E. Eulig¹, J. Maier¹, M. Knaup¹, T. Koenig², K. Hörndler², M. Kachelrieß¹; ¹Heidelberg/DE, ²Nuremberg/DE (elias.eulig@dkfz-heidelberg.de)

Purpose: To provide DSA-like images in the absence of a mask (unenhanced image).

Methods and Materials: Conventional DSA selectively displays vessels by subtracting an unenhanced mask image from a contrast-enhanced fluoroscopic image. It thereby relies on the assumption that the static mask, which is typically acquired prior to contrast injection, accurately represents the background anatomy of the patient also during contrast injection. In case of patient, table or C-arm motion this assumption is not fulfilled, however. Therefore, we developed DDSA, a deep convolutional neural network similar to the U-net. DDSA predicts DSA-like images directly from their corresponding contrast-enhanced x-ray images. Supervised training was performed on patient data of different anatomical regions, acquired with a commercial mobile C-arm system. The ground truth was available through conventional DSA. Data were augmented to improve generalisation of the network. Due to its frame-wise applicability DDSA can predict angiograms for static and dynamic data in real-time without the need to acquire masks. DDSA was applied to several clinical test cases with and without patient and C-arm motion.

Results: The performance of DDSA was 7 ms for a 1024x1024 x-ray image on a GTX 1080ti GPU. In all test cases, the resulting images are visually similar to conventional DSA even for the challenging case of very thin vessels. Quantitative evaluation on static data showed very small (median absolute relative error: 5.4%) deviation from conventional DSA.

Conclusion: Deep DSA has the potential to replace conventional DSA by reducing patient dose and making it applicable to dynamic acquisitions.

Are radiologists bad teachers for AI algorithms: differences in the interobserver variability between consensus-defined labelling and free labelling of NIH chest x-ray14 dataset

H. Mahajan, P.K. Ganesan, A. Vaidya, G. Nanda, M. Murugavel, V. Venugopal, M. Barnwal, V. Mahajan; *New Delhi/IN (geetutomar@yahoo.co.in)*

Purpose: To assess differences in interobserver variability before and after a consensus-based definition of the NIH Chest x-ray14 dataset labels.

Methods and Materials: We randomly extracted 800 x-rays from the NIH chest x-ray14 dataset. They were read by three radiologists (25 years, 20 years and 15 years of experience) in two equally divided batches. Of the 14 NIH labels, atelectasis, consolidation and pneumonia were clubbed under 'opacity'. The other labels were used 'as is'. For batch-1, the radiologist assigned labels for 400 x-rays based on their prior understanding of nomenclature. For batch-2, the labels were defined by consensus and assigned on the remaining 400 x-rays. Interobserver variability was assessed (Fleiss bounds) via the Krippendorff's alpha coefficient corrected for chance.

Results: Interobserver variability between free and consensus labelling did not vary in general. Opacity, pneumothorax, effusion, nodule/mass and 'no finding' were in the 'fair to good' (0.41-0.75) range, while infiltration, emphysema, fibrosis and pleural thickening were in the 'poor' (<0.40) bound in both tests. Interestingly effusion and cardiomegaly labelling worsened to 'poor' post-consensus. Significantly, no label was in the 'very good' (>0.75) category.

Conclusion: Training of AI algorithms is advised only on labels with alpha close to 0.75 (example 'Normal' vs 'Abnormal' or 'pneumothorax') when employing a purely image-based interobserver metric as ground truth. More research into the reasons for interobserver variability, and its significance in clinical practice, is needed.

Supervised one-to-one style transfer to improve the quality of CT images

L. Li¹, B. Ren², S. Wang¹, C. Xia¹; ¹Beijing/CN, ²Amherst, MA/US (llanqing@infervision.com)

Purpose: The quality of CT is largely affected by attributes of the scan, such as radiation dose, convolution kernel and sharpness. CNN-based technique is susceptible to small perturbations for input. A standardisation is essential for improving the effectiveness and robustness.

Methods and Materials: We employed an unrolled proximal-dual optimisation scheme, where the operators were replaced with convolutional neural network. It iterates between source-target image pairs to learn the style difference such as noise level and convolution kernel of the commercial scanner. The model was trained on a collection of FDA phantom and data from collaborating hospital, and applied to reconstruct CT scans from our private database. The images were subsequently tested using Infervision AI-CT model with relatively low precision, whose latest version has been commercialised for early lung cancer screening.

Results: The reconstructed images achieved SSIM>97% (20-30% improvement), PSNR>39 on validation set, and SSIM>94% (7-12% improvement), PSNR>34 on human phantom test set. The detection result on reconstructed images exhibited significant increase in precision at cost of a modest decrease in recall. The total F1 score was improved by 32% on our private dataset. It was also observed that the lung-to-standard reconstruction was effective regardless of the sharpness attribute.

Conclusion: Standardisation of CT images is key to the success of an effective and specialised CNN-based methods. In our attempt to address the issue, results have shown a significant improvement of image quality and detection performance on the reconstructed images.

Opening the "Black Box": radiological insights into a deep neural network for lung nodule characterisation

V. Venugopal¹, K. Vaidhya¹, V. Mahajan¹, H. Mahajan¹, S. Vaidya², A.R. Devalla³; ¹New Delhi/IN, ²Mumbai/IN, ³Bengaluru/IN (vasanthdrv@gmail.com)

Purpose: To explain predictions of a deep residual convolutional network for characterization of lung nodule by analysing heat maps.

Methods and Materials: A 20-layer deep residual CNN was trained on 1245 chest CTs from NLST trial to predict the malignancy risk of a nodule. We used occlusion to systematically block regions of a nodule and map drops in malignancy risk score to generate clinical attribution heatmaps on 160 nodules from LIDC-IDRI dataset, which were analysed by a thoracic radiologist. The features were described as heat inside nodule (IH) - bright areas inside nodule, peripheral heat (PH) - continuous/interrupted bright areas along nodule contours, heat in adjacent plane(AH) - brightness in scan planes juxtaposed with the nodule, satellite heat (SH) - a smaller bright spot in proximity to nodule

in the same scan plane, heat map larger than nodule (LH) - bright areas corresponding to the shape of the nodule seen outside the nodule margins and heat in calcification (CH).

Results: These six features were assigned binary values. This feature vector was fed into a standard J48 decision tree with tenfold cross-validation, which gave an 85% weighted classification accuracy with a 77.8%TP rate, 8% FP rate for benign cases and 91.8% TP and 22.2%FP rates for malignant cases. IH was more frequently observed in nodules classified as malignant whereas PH, AH, and SH were more commonly seen in nodules classified as benign.

Conclusion: We discuss the potential ability of a radiologist to visually parse the deep learning algorithm-generated 'heat map' to identify features aiding classification.

Generating dual-energy images from monoenergetic 80 kV images using a conditional generative adversarial network

A. Demircioglu, J. Haubold, M. Forsting, K. Nassenstein, L. Umutlu, F. Nensa; *Essen/DE (aydin.demircioglu@uk-essen.de)*

Purpose: To reduce the image noise and beam hardening artifacts in computed tomography images a conditional generative adversarial network was trained and evaluated.

Methods and Materials: In dual-source techniques acquired dual-energy (80+140kV) computed tomography images were retrospectively used to train a conditional generative adversarial network (cGAN), which contains a generative and a discriminative neural network. 80 kV monoenergetic images and 0.5M dual energy images were obtained from 14 patients (4748 images in total) and were used as input data for the cGAN. The trained model was evaluated on another patient (571 images). The quality of the artifact reduction was measured by computing the median of the absolute difference in intensity per pixel relative to the 80kV image. Overall error is computed by average over all test images.

Results: The overall error of the cGAN was 0.24 (95 CI%: 0.22-0.27), indicating a very clear reduction of image noise and beam hardening artifacts. None of the test images showed a degradation relative to the 80 kV monoenergetic image. Additional inspection by an expert radiologist showed that the cGAN results were also visually of high quality.

Conclusion: Using 4748 training images from 14 patients a conditional generative adversarial network could be trained to generate virtual dual-energy images from 80kV monoenergetic images with an overall good similarity to ground truth 0.5M dual energy beam hardening and image noise reduced images.

B-0914 11:50

Machine learning-based prediction of haematocrit values from native MRI myocardial T1-maps to avoid blood sampling for extracellular volume fraction analysis

A. Varga-Szemes¹, M. Bauer², M. van Assen³, C.N. De Cecco¹, P. Suranyi¹, L. Griffith¹, U.J. Schoepf¹; ¹Charleston, SC/US, ²Munich/DE, ³Groningen/NL (vargaasz@muscu.edu)

Purpose: To evaluate a machine learning (ML) algorithm to estimate blood haematocrit levels (Hct) from native MRI myocardial T1-maps to avoid blood sampling prior to cardiac MRI studies involving extracellular volume fraction (ECV) analysis.

Methods and Materials: A total of 51 patients (56±13y) who underwent 1.5T cardiac MRI were included. MRI protocol consisted of native (MOLLI 5(3)3) and post-contrast (4(1)3(1)2) myocardial T1-mapping. Native blood T1 values were measured in the left ventricle for Hct estimation. A linear regression (LR) analysis was applied to model the relationship between the image-derived and laboratory Hct (Hct[lab]) values. For the ML approach, 31 additional features based on patient demographics, clinical history, and imaging parameters were extracted and used to train a linear Support Vector Machine.

Results: Hct derived by the LR and ML algorithms were 38.7±3.3% and 39.1±3.6%, respectively, and were in good agreement with Hct[lab] (38.7±4.8; P=0.446). The LR approach provided the following model for Hct calculation: Hct[%]=89.8×(R1[native,blood]-19.0). The ML-based Hct showed stronger relationship (r=0.78; p<0.001) to Hct[lab] values than the LR-based Hct (r=0.70; p<0.001). Analysis of the residuals demonstrated an increase in accuracy for the ML approach compared to LR (RMSE 3.07 vs. 3.47). ECV values derived from LR, ML, and lab techniques were in good agreement (38.1±16.9, 37.9±16.8, and 37.9±17.0%, respectively; P=0.475).

Conclusion: The ML-based algorithm provides accurate Hct estimation and reliable myocardial ECV calculation, highlighting its potential in clinical workflows to generate ECV without the need for same-day laboratory Hct measurement.

Impact of the use of a breast cancer risk assessment tool on the intensive screening of women clinically referred to as intermediate to high risk

S. Woussen¹, H. Westerlinck², M. Keupers³, R.M. Prevos⁴, T. Thywissen⁵, C. Van Ongeval³, ¹Harelbeke/BE, ²Heverlee/BE, ³Leuven/BE, ⁴Meerssen/NL, ⁵Diepenbeek/BE (sofie.woussen@gmail.com)

Purpose: Screening of women at intermediate risk of breast cancer (BC) requires yearly mammography and US; screening of high-risk women requires additional yearly MRI. Our goal is to verify the subjective interpretation of BC risks against a validated risk-estimation model (IBIS). Thus, to obtain more effective breast prevention strategies.

Methods and Materials: We retrospectively reviewed 471 clinically medium- to high-risk women who underwent screening mammography from August 2014 to August 2016. Because of presence of a BC gene mutation (33) or a lack of records (7), 40 women were excluded. Of the 431 remaining patients, 267 (62%) and 33 (14%) received additional screening US and MRI, respectively. Data from each included patient necessary to calculate the IBIS-BC-risk were inserted into the latest version (8.0b) of the risk- evaluation tool.

Results: The median age is 51 years and the median IBIS risk score is 23%. There were 6 (14%) breast cancer cases discovered through the screening. The personal lifetime risks are distributed as follows: <17% in 111, 17%-20% in 46, 20%-25% in 99, 25-30% in 71 and ≥30% in 104 women.

Conclusion: One fourth of the included patients showed a low IBIS-BC risk (<17%), lifetime risk of BC was clinically overestimated: they should not be screened more intensely. Considering an IBIS score of 25% as reference for breast MRI, 40% of our study group should receive breast MRI, instead of the 14% actually. More effective breast prevention strategies could be obtained by an objectification of the BC risk assessment.

B-0916 10:47

Defining a parsimonious breast cancer risk model to risk-stratify average-risk women for follow-up screening

M. Abdolell¹, J.I. Payne¹, P. Brown¹, P. Barnes¹, J. Caines¹, K. Tsuruda², P. Talbot¹, O. Tong¹, S.E. Iles¹; ¹Halifax, NS/CA, ²Oslo/NO (Sian.Iles@nshhealth.ca)

Purpose: This study evaluated the consistency and discriminatory power of short-term breast cancer risk models with and without biopsy history (BxHx) within a general screening population.

Methods and Materials: All screen-detected breast cancer cases among digitally screened women 40-75 years (2009-2015) within a population-based breast screening program and 3 age- and screen year-matched controls were sampled. Clinical risk factors, fully automated percent mammographic density (PMD), and breast volume assessments were obtained for 1,593 cases and 5,003 controls and used to derive patient-specific risk estimates from a series of logistic regression models. Predictive performance was assessed using area under receiver operator characteristic (AUROC), and agreement between models for assigning women to low (<90th percentile)- versus high (≥ 90th percentile)-risk groups was assessed using weighted kappa.

Results: Predictive performance of the multivariate models varied substantially (AUROC: 0.547-0.655). A reduced model with PMD, breast volume, age, family history, and BxHx performed equivalently to the full model that additionally included menopausal status and HRT use (AUROC=0.655 and 0.656, respectively); removing BxHx from the reduced model decreased performance (AUROC= 0.591). Agreement between predicted probabilities of the full versus reduced model classified into low versus high risk was almost perfect (kappa=0.982).

Conclusion: A short-term risk model incorporating PMD, breast volume, family history, BxHx, and age may provide a practical solution for risk stratification within a screening population without the need to collect other clinical risk factors that are prone to recall bias and are not always available.

Reproducibility and measurement error in automated breast density assessment

J.-L. Tham¹, E.F. Harkness¹, K. Stocking¹, A.R. Brentnall², J. Cuzick², D.G. Evans¹, S.M. Astley¹; ¹Manchester/UK, ²London/UK (Sue.Astley@manchester.ac.uk)

Purpose: To quantify the reproducibility and measurement error of volumetric breast density in mammograms.

Methods and Materials: We analysed data from the Predicting Risk of Cancer at Screening Study (PROCAS), a large cohort study to estimate risk of breast cancer in women attending routine breast screening. We used data from post-menopausal women who had a repeat mammographic view taken within 28 days of their screen on entry to PROCAS; all mammograms were taken on GE Senographe Essential systems. Volumetric percentage breast density for each mammographic view was assessed using Volpara V1.5.4 and log transformed. Measurement error was assessed by calculating the coefficient of variation and reproducibility assessed using the intraclass correlation coefficient (ICC).

Results: 519 repeat views from 419 women were eligible for analysis. The mean age of women was 60 years (range 46-73 years) and the median number of days between images was 18 days (interquartile range 14-21 days). The ICC (95% confidence interval [CI]) was 0.88 (0.84, 0.91), 0.89 (0.85, 0.92), 0.89 (0.84, 0.93) and 0.93 (0.90, 0.95) for the left and right craniocaudal (CC) and mediolateral oblique (MLO) views respectively. The coefficient of variation was 16.7% (15.1, 18.8), 16.4% (14.8, 18.5), 15.8% (13.9, 18.4) and 13.8% (95% CI: 12.1, 16.1) for LCC, RCC, LMLO and RMLO views, respectively.

Conclusion: This study found good to excellent reproducibility and a measurement error of 14-17% in assessing volumetric percentage breast density. This should be taken into account when interpreting changes in breast density between successive measurements.

Factors influencing the disagreement between the automated volumetric breast density and radiologist's visual assessment in assessment of breast density

H. Lee, J. Moon, J. Hwang, J.-Y. Woo; Seoul/KR (geenie-m@hanmail.net)

Purpose: To identify the various radiological and clinical factors associated with disagreement between automated volumetric breast density measurement (VBDM) and visual assessment by radiologists in assessment of breast density.

Methods and Materials: Three thousand and forty-three women who underwent screening and diagnostic mammography from August 2016 and February 2017 were included. The agreement in breast density between visual assessment by the radiologist based on 5th BI-RADS and VBDM (Volpara Version 3.1) were compared using a weighted kappa (k) value. The factors including patient age, the purpose of mammography, presence of mass, microcalcifications, macrocalcifications, asymmetry or architectural distortion, a difference in bilateral breast density and BI-RADS final assessment were evaluated using univariate and multivariate analyses.

Results: Among 3043 women, 873 (28.7%) showed disagreement. The agreements between visual assessment by radiologist and VBDM were substantial (weighted k value = 0.674). Univariate analysis showed patient age (p < 0.001), purpose of mammography (p = 0.026) and a difference in bilateral density (p < 0.001) as factors contributing to disagreement. In multivariate analysis, patient age (p = 0.003), presence of mass (p = 0.016) and a difference in bilateral density (p < 0.001) were contributing factors for disagreement.

Conclusion: There is substantial agreement in breast density evaluation between VBDM and visual assessment by radiologists. Disagreement between VBDM and visual assessment was related to patient age and a difference in bilateral breast density.

B-0919 11:11

The role of breast density in predicting interval detected breast cancer

M. Abdollell¹, J.I. Payne¹, P. Brown¹, P. Barnes¹, J. Caines¹, K. Tsuruda², P. Talbot¹, O. Tong¹, S.E. Iles¹; ¹Halifax, NS/CA, ²Oslo/NO
(Sian.Iles@nshhealth.ca)

Purpose: This study evaluated the predictive performance of short-term interval breast cancer risk models within a general screening population.

Methods and Materials: This case control study was performed among digitally screened women aged 40-75 (2009-2015) within a provincial breast screening program in Canada. The sample included all 132 interval breast cancer cases and 885 controls. Interval breast cancer was defined as breast cancer diagnosed after a negative screening examination or after an abnormal screening examination with negative work-up but before the next regularly scheduled screening examination. Data on clinical risk factors including age, breast volume (as a surrogate for BMI), first degree family history, history of breast biopsy, menopausal status, and HRT use were obtained for all subjects. Percent mammographic density (PMD) and breast volume assessments were obtained via automated software (Densitas Inc.). Logistic regression models were used to derive patient-specific risk estimates. Predictive performance was assessed using the area under receiver operator characteristic (AUROC).

Results: There was no difference in the average age of cases and controls at 55 and 56 years respectively. The model with PMD alone outperformed a model with all other clinical risk factors combined (AUROC=0.679 vs 0.614, respectively). Adding PMD to a model with all the other clinical risk factors increased the AUROC to 0.716.

Conclusion: Percent mammographic density was the most significant predictor of interval detected cancers and was a stronger predictor of interval detected cancers than all other clinical risk factors combined. Model performance needs to be validated using a separate dataset.

Mammographic parenchymal pattern: correlation with age, breast density and prediction of cancer detection and nodal status in a UK screening population

L.S. Wilkinson¹, L.M. Warren², E. Burnside³, K. Young², C. Patel⁴, N.J. Massat⁵, J. Myles⁵, S. Duffy⁵; ¹Oxford/UK, ²Guilford/UK, ³Madison, WI/US, ⁴Kingston/UK, ⁵London/UK (louise.wilkinson11@nhs.net)

Purpose: To investigate differences in parenchymal pattern (PP) of breast tissue on screening mammograms and evaluate association with screen-detected or interval cancer and node status.

Methods and Materials: This case-control study of 1204 women age 50-74 included 302 screen-detected and 297 interval cancers (239 node positive, 360 node negative) and 605 controls. Three readers classified PP grade on prior mammograms from smooth (PP1) to nodular (PP5). Volpara software calculated fibroglandular volume (FGV) and volumetric breast density (VBD) on unprocessed images. Intraclass correlation (ICC) compared readers' PP grades. Trend analysis was performed after one-way ANOVA to test for linear trends between increased PP and mean VBD, and mean FGV. Conditional logistic regression determined whether PP could predict mode of detection (screen detected or interval), and node status (positive or negative).

Results: There was good correlation between readers for PP grade (ICC 0.736, 95% CI 0.713, 0.757). Mean VBD did not differ significantly with increased PP grade. Mean FGV linearly increased with PP grade (p<0.0001). The relative risk (RR) of cancer in PP5 vs. PP1 was 2.2 (p<0.01) for screen detected cancer and 2.5 (p<0.01) for interval cancers. In PP5 vs. PP1, the odds ratio (OR) of node positive cancer vs. controls was 1.8 (non-significant, p=0.16) and for node negative cancer was 3.0 (p<0.01).

Conclusion: Visual assessment of PP is reproducible. PP grade increases with FGV and age. RR of screen-detected, interval, and node negative cancer significantly increases with PP grade, though the RR of node positive cancer does not.

Association between BMI and subsequent breast cancer among women with a prior false-positive without biopsy in BreastScreen Norway

M. Lilleborge, S. Hofvind; Oslo/NO (marie.lilleborge@krefregisteret.no)

Purpose: Evaluate the association between Body Mass Index (BMI) and a subsequent breast cancer, among women with a prior negative recall after additional imaging and ultrasound only (false-positive without biopsy) in BreastScreen Norway.

Methods and Materials: BreastScreen Norway is a population based screening program that invites all Norwegian women to biennial independently double-read two-view mammography in birth cohorts corresponding to age 50-69 years. 3,201,915 screens (97% negative and 3% resulting in a recall) were

performed among 763,470 women in the study period 1995-2016. We included 55,625 women who experienced a recall concluded negative after additional imaging and ultrasound only. We followed women for invasive breast cancer (ipsilateral and/or contralateral), from false-positive until end of follow-up (31.12.2016, date of death, emigration or diagnosis of breast cancer, whichever came first). Cox regression was used to study how BMI was associated with subsequent breast cancer among women with a prior false-positive without biopsy, adjusted for age.

Results: Compared to women of normal weight (BMI 18.5-25), underweight women (BMI <18.5) had a similar long-term risk of subsequent breast cancer (HR=1.07, 95% CI: 0.63-1.83) after a prior false-positive without biopsy. We observed a statistically significant increased long-term risk of subsequent breast cancer (HR=1.25, 95% CI: 1.09-1.43 and HR=1.43; 95% CI: 1.19-1.71) among overweight women (BMI 25-30) and obese women (BMI ≥30).

Conclusion: Among women with a prior false-positive without biopsy in BreastScreen Norway, overweight and obese women have a 25% and 43%, respectively, increased long-term risk of a subsequent breast cancer compared to women of normal weight.

B-0922 11:35

The value of automated breast ultrasound added to full-field digital mammography in women with dense breasts

I. Boca, A. Ciurea, C. Ciortea, A.-S. Berghe; Cluj-Napoca/RO (ioanaboca90@yahoo.com)

Purpose: The objective of our study was to assess the performance of the new imaging techniques: full-field digital mammography (FFDM), 3D mammography and automated breast ultrasound (ABUS) in the detection of breast cancer.

Methods and Materials: Two radiologists independently evaluated a total of 127 ABUS acquisitions, the FFDM and 3D mammograms of women with dense breast tissue. During the study no clinical information or patient history was provided to the readers. The results were compared to the gold standard: histopathology for biopsied lesions, HHUS-handheld ultrasound for typically benign lesions (cysts) and follow-up for benign appearing lesions unchanged for at least 2 years.

Results: Nineteen breast cancers were proved by biopsy. For FFDM alone the sensibility was 72.7%, the specificity and the positive predictive value was 100% and the negative predictive value was 92.3%. By completing the FFDM with ABUS the sensibility increased to 78.3%, the specificity was 91.8%, the positive predictive value was 69.2% and the negative predictive value was 94.7%. For 3D mammography the sensibility was 100%, the specificity 86.4%, the positive predictive value was 75% and the negative predictive value was 100%.

Conclusion: In screening, ABUS added to FFDM compared with FFDM alone, improved reader's detection of breast cancers in women with dense breast tissue, but did not exceed 3D mammography. As a diagnostic method, ABUS associated with FFDM outperformed 3D mammography.

B-0923 11:43

Automated breast ultrasound versus breast tomosynthesis in further evaluation of recalled dense breasts after screening mammograms

N.H. Saïd, L. Adel, N.A. Chalabi, R. El Sheikh, H. Aboelmagd; Cairo/EG (norrhanusseïn@yahoo.com)

Purpose: To compare the added value of automated breast ultrasound (ABUS) versus breast tomosynthesis (BT) as diagnostic tools in the work-up of screening detected positive findings in dense breasts recalled from the national screening program.

Methods and Materials: After ethics committee approval, and patients' consent, 242 women with dense breasts who underwent screening mammography, and were recalled for suspected positive findings were enrolled in the study. Positive findings included focal asymmetry, mass, distortion, or microcalcifications. All patients underwent both BT and ABUS by two independent breast radiologists and a BIRADS score was given for each modality. BT was performed in CC and MLO views. ABUS images were acquired in anteroposterior, lateral and medial views. Images were interpreted in the coronal 3D view using the survey mode, followed by the transverse and sagittal reconstructed images. Results were compared to pathology and follow-up of negative/typically benign findings

Results: Sensitivity, specificity, PPV, NPV, LR positive, LR negative and accuracy of ABUS were 92, 98, 92, 98, 44, 0.08 and 97, respectively, and in BT were 92, 92, 76, 98,12, 0.09 and 92. Agreement by Kappa was 0.896. ABUS and BT both agreed on TP in 43 cases out of 51 proved cancers. There were 4 FN cases in each modality. There were 4 FP by ABUS and 15 by BT. Biopsy was avoided by ABUS in 187 cases and by BT in 176 cases.

Conclusion: ABUS has shown a higher accuracy than BT. Its main limitations are microcalcifications and the retroareolar region.

B-0924 11:51

Mammographic screening in male patients at high risk for breast cancer: is it worth it?

M.A. Marino¹, A. Gucalp², B. Bernard-Davila², D.M. Keating², D. Martinez², E. Morris², M.S. Jochelson²; ¹Messina/IT, ²New York, NY/US (mariaadele.marino@gmail.com)

Purpose: There is currently no standard of care for screening asymptomatic men who are at increased risk for developing breast cancer. The purpose of this study is to investigate the utility of mammography for breast cancer screening in men at increased risk for breast cancer.

Methods and Materials: In this HIPAA compliant IRB-approved single-institution study, mammography, pathology and clinical records on 827 men who underwent mammography between 09/2011 and 07/2018 were analysed via the electronic medical record. 664 of these men presented with masses, pain or nipple discharge and were excluded. The remaining 163 asymptomatic men with family and/or personal history of breast cancer and/or known breast cancer mutation underwent screening mammography and are the subject of this analysis.

Results: 163 asymptomatic men 24-87 years (median 66 years) underwent 806 screening mammograms. 125/163 (76%) had a personal history and 72/163 (44%) had a family history of breast cancer. 24/163 (15%) had known mutations: 4/24 (17%) BRCA1 and 20/24 (83%) BRCA2. 792/806 (98%) of screening mammograms were negative (BI-RADS 1 or 2); 10/806 (1.2%) were BI-RADS 3, all of which were subsequently downgraded to BI-RADS 2. 4/806 (0.4%) mammograms were suspicious (BI-RADS 4/5) and all were malignant (mean size 6.25mm, range 4-7mm). There were three T1 and one T4 breast cancer. The estimated cancer detection rate was 4.9/1,000 examinations.

Conclusion: Screening mammography in high-risk men yielded a cancer detection rate of 4.9/1000 examinations.

Prediction of neurodevelopmental outcome in preterm neonates with cerebral MR spectroscopy and DWI using neural-network-based classifiers

T. Djurdjevic, S. Pereverzyev, L. Lamplmayr, V. Neubauer, U. Kiechl-Kohlendorfer, V. Wallner, A.E. Grams, E.R. Gizewski; Innsbruck/AT (tanja.djurdjevic@i-med.ac.at)

Purpose: We aimed to evaluate if magnetic resonance spectroscopy (MRS) and diffusion weighted images (DWI) performed in preterm neonates (PNs) at term equivalent age can predict their neurodevelopmental outcome at the corrected age of 12 months using neural-network-based classifiers (NNCs).

Methods and Materials: From 309 PNs born before 32 gestational weeks, 214 were excluded because of missing MRS or incomplete data sets. The data sets of 95 PNs were considered for motoric and cognitive development, of whom 8 and 5, respectively were categorized as underdeveloped. Seven potentially relevant metabolite ratios and 2 DWI characteristics were evaluated, each in 6 different areas of the brain. We performed a feature selection algorithm for receiving a subset of those characteristics that we could assume as significant. To reduce bias by unbalanced classes, only PNs that share values of those characteristics with ones that had shown underdevelopment were considered for further calculations. On those smaller sets of PNs, we finally constructed classifiers using NNCs. These classifiers were able to predict underdevelopment in PNs after considering the characteristics selected previously.

Results: The constructed NNCs give a 100% accuracy in the case of the motoric underdevelopment. In the case of cognition underdevelopment, we obtain a true positive rate of 100% and a positive predictive value of 83,3 %.

Conclusion: MRS and DWI obtained at term equivalent age in PNs allow prediction of their motoric and cognitive development at the corrected age of 12 months. The proposed approach using NNCs promise its use in the clinical practice.

Synthetic MRI detects delayed myelination in preterm neonates

V. Schmidbauer, G. Geisl, K. Goeral, K. Klebermaß-Schrehof, A. Berger, D. Prayer, G. Kasprjan; Vienna/AT (victor.schmidbauer@meduniwien.ac.at)

Purpose: "Synthetic MRI" generates different MR contrasts and characterises tissue properties based on one multi-dynamic multi-echo FLAIR sequence (MDME). The aim of this study is to assess the feasibility of "Synthetic MRI" in the assessment of myelination in term-born (TN) and preterm neonates (PN).

Methods and Materials: 30 PN and TN were examined at the approximate due date [gestational age+days to MRI=corrected gestational age (CGA)] using a standardised neonatal MRI protocol (1.5Tesla/T1SE/T2SE/DWI/DTI sequences). MDME sequence (FOV: 200x165x109mm/voxel: 0.9x1x4mm/matrix: 224x158x22slices/TE: 13ms/TR: 3309ms/acquisition time: 5min 22sec.)-based post-processing was performed using "Synthetic MRI" (Synthetic MR AB, Storgatan 11, Linköping, Sweden, version 8.0.4). Myelination was assessed by scoring seven brain regions on T1/T2 maps generated by "Synthetic MRI" and on standard T1/T2 images, acquired separately. Analysis of covariance (ANCOVA/covariate: CGA at MRI) was used for group comparison.

Results: In 25/30 (83.33%) cases [18 PN (mean gestational age: 178.17d/SD=12.56) and 7 TN (mean gestational age: 279.14d/SD=8.86)] myelination assessment could be performed. T1/T2 maps were generated by "Synthetic MRI": ANCOVA results showed significantly lower myelination scores in PN compared to TN [T1: F(1, 22)=7.420/p=0.012; T2: F(1, 22)=5.658/p=0.026]. The myelination score showed a positive correlation with the CGA at MRI (T1: r=0.662/n=25/p<0.001; T2: r=0.676/n=25/p<0.001). The myelination score based on standard T1/T2 images did not correlate with the CGA at MRI. No significant differences between PN and TN were detectable.

Conclusion: Substantial differences concerning the myelination in TN and PN are detectable on T1/T2 maps generated by "Synthetic MRI". The method allows to detect myelination differences more sensitively and rapidly than standard MR sequences.

Comparison of intracranial volumes of preterm-born infants and age-matched foetuses

V. Pfahler¹, G.M. Gruber², G. Kasprjan², A. Hilgendorff¹, K. Förster¹, A. Flemmer¹, B.B. Ertl-Wagner³, D. Prayer², S. Stöcklein¹; ¹Munich/DE, ²Vienna/AT, ³Toronto, ON/CA

Purpose: The aim of our study was to compare intracranial volume (ICV), brain volume (BV), and volumes of the inner and the outer cerebral fluid spaces (iCSF and oCSF) of preterm-born infants and age-matched foetuses.

Methods and Materials: Preterm born infants and foetuses were matched for gestational age (± 4 days). Gestational age ranged from 32 to 39 gestational weeks. 23 preterm born infants and 23 age-matched fetuses without reported brain pathology on structural MRI were included in the analysis. Manual segmentation and volumetry was conducted based on axial T2-weighted images of the brain (slice thickness 3 mm), using the itk-SNAP software. ICV, BV and volumes of iCSF and oCSF were compared applying a paired t test at a significance level of $\alpha=0.05$. Statistical analyses were conducted using MATLAB.

Results: ICV was significantly smaller in preterm born infants as compared to age-matched foetuses ($\alpha=0.003$, $ICV_{foetal}=382140 \text{ mm}^3+/-49713$, $ICV_{preterm}=320005 \text{ mm}^3+/-93416$). Likewise, preterm born infants displayed significantly reduced BV and oCSF volumes ($\alpha=0.005$ and $\alpha=0.035$, respectively, $BV_{foetal}=312254 \text{ mm}^3+/-42384$, $BV_{preterm}=259032 \text{ mm}^3+/-83413$, $oCSF_{foetal}=62903 \text{ mm}^3+/-13134$, $oCSF_{preterm}=53381 \text{ mm}^3+/-16732$). iCSF volumes did not show a significant difference. Notably, the relation of BV and oCSF volumes to ICV was constant in preterm-born infants and foetuses, meaning that the ratio BV/ICV and oCSF/ICV did not differ significantly in the two groups.

Conclusion: Preterm-born infants have significantly reduced ICV, BV and oCSF volumes as compared to age-matched foetuses in utero. The mechanisms underlying these differences and their potential impact on ex utero versus in utero brain development remain to be investigated.

B-0928 11:03

Dentate and basal ganglia T1 hyperintensity after multiple gadolinium administrations and brain microstructure: an in vivo diffusion-weighted MR study in paediatric patients

P. [Gulino](#)¹, E. Salvatore², A. Bianchi¹, M. Franzese², L. Sali¹, M. Aiello², C. Cavaliere², M. Salvatore², M. Mascali¹; ¹Florence/IT, ²Naples/IT (pietrogulino@yahoo.it)

Purpose: We explored if visually detectable T1-weighted hyperintensity (T1wH) in gray matter (GM) nuclei of paediatric patients is associated with evidence of local microstructural changes as revealed by diffusion-weighted imaging (DWI).

Methods and Materials: Retrospective study on data collected in a paediatric hospital between 2010 and 2017. We included 151 patients who had received 10 or more administrations of gadolinium-based contrast agents (GBCAs) for neuro-oncologic conditions (age <18 years at the time of the last administration) and 55 controls who had not received prior GBCAs. We visually assessed the signal intensity (SI) in T1-weighted images and measured the T1 SI ratio between dentate/pons and pallidus/parietal white matter, caudate/parietal white matter and thalamus/parietal white matter, and the apparent diffusion coefficient (ADC) in the dentate, pallidus, caudate and thalamus. We used non-parametric two-sample Wilcoxon test to evaluate differences of the T1 SI ratio and ADC and performed a multivariate analysis to evaluate the effect of age and of the number of prior GBCAs administrations.

Results: T1wH in the GM nuclei was visually detected in 23 of the 151 patients and in none of the controls. The 23 patients had a significantly higher T1 SI ratio in GM nuclei as compared to controls ($p<0.05$). ADC values in GM nuclei were not significantly different in patients with T1wH as compared to controls. Multivariate analysis showed that ADC is associated with age but not with number of GBCAs administrations.

Conclusion: T1wH is not associated to local microstructural changes in the mid-term as assessed with DWI.

B-0929 11:11

Gadoterate meglumine, a macrocyclic agent causes gadolinium retention in the brain of children: a case-control study

E.D. [Topcuoglu](#), O.M. Topcuoglu, A. Semiz Oysu, Y. Bukte; *Istanbul/TR* (elifdilartopcuoglu@gmail.com)

Purpose: To demonstrate whether there was intracranial macrocyclic gadolinium deposition after multiple contrast enhanced MRIs with gadoterate meglumine in paediatric population.

Methods and Materials: This retrospective case-control study included children who had at least 3 enhanced brain MRIs. Age- and sex-matched control group with unenhanced brain MRIs were selected for comparison. All patients received gadoterate meglumine intravenously (0.1 mmol/kg). Signal intensity (SI) measurements were made by drawing 6 region of interests (ROIs): dentate nuclei (DN), pons, globus pallidi (GP), frontal white matter (FWM), thalamus (T) and clivus for both groups on unenhanced T1 weighted images. The ratio of those to cerebro-spinal fluid (CSF) were also calculated for standardization. Student t-test was used for comparison of SI and SI ratios. Pearson correlation was calculated for the correlation between the SI and the number of gadolinium administrations.

Results: A total of 45 children (age range: 5-17 years; mean, 13.7±3.4 years) were included. A significant difference was detected between two groups for DN/CSF, pons/CSF, GP/CSF, talami/CSF and FWM/CSF ($P<0.001$, $P<0.001$, $P=0.002$, $P=0.002$, $P=0.024$, respectively). There was no significant difference between two groups for clivus and clivus/CSF ($P=0.41$ and $P=0.15$, respectively). A good correlation between the number of gadoterate meglumine administrations and the SI for DN/CSF, pons/CSF, GP/CSF and T/CSF ($r=0.80$, $r=0.73$, $r=0.91$ and $r=0.90$, respectively) was found.

Conclusion: A significant T1 SI increase reflecting gadolinium retention in the brain, was detected for children with at least three gadoterate meglumine administrations in this series.

B-0930 11:19

Cavernous sinus enlargement: a novel finding in Sturge-Weber syndrome L.

[Pasquini](#)¹, D. Tortora², M. Rossi Espagnet¹, L. Figà-Talamanca¹, F. Manunza², C. Occella², A. Rossi², M. Severino²; ¹Rome/IT, ²Genoa/IT

Purpose: The cerebral venous system is typically involved in Sturge-Weber syndrome and characterized by asymmetrical enlargement. Considering the anatomic centrality of the cavernous sinus and that it is intercalated in the venous network which is commonly affected by Sturge-Weber syndrome, we hypothesized its involvement in the disease and investigated possible clinical correlations.

Methods and Materials: Sixty patients with Sturge-Weber syndrome and 84 age-/sex-matched controls were included in this retrospective study. We measured on axial T2WI the left (A), right (B) and bilateral (LL) transverse diameters of the cavernous sinus. We calculated the difference |A-B|, and the "cavernous sinus asymmetry index" as the ratio |A-B|/LL. Finally, we performed

a visual analysis to identify patients with asymmetric cavernous sinus enlargement. Differences among groups were assessed by Mann-Whitney U and Jonckheere-Terpstra tests. Clinico-radiological associations were evaluated by Fisher's exact test.

Results: All the CS measures were significantly different between SWS patients and healthy controls. The SAI and the left-right difference were significantly higher in SWS patients ($p=0.36$, $p=0.12$). CS enlargement was significantly associated with intraosseous vascular malformations ($p=0.013$) and the presence of ectatic veins ($p=0.002$).

Conclusion: The cavernous sinus enlargement occurs not only at the same level of the facial and leptomeningeal capillary malformation, but may also present without other intracranial vascular anomalies and may be related to the blood overcharge or to the recently discovered GNAQ mutation. Further studies are needed to draw definite conclusions regarding this new feature, which should be carefully evaluated in MR scans of patients suspected for SWS.

B-0931 11:27

Pediatric brain: T1-weighted signal intensity of deep brain nuclei increases with age but not with a serial administration of gadoterate meglumine

P. [Pozeg](#), R. Meuli, J. Forget, P. Maeder; *Lausanne/CH* (polona.pozeg@chuv.ch)

Purpose: Current findings on gadolinium retention in the paediatric brain after repeated exposure to macrocyclic contrast agents are inconclusive and possibly confounded by brain maturation processes. We evaluated longitudinal effects of repeated Dotarem exposure (gadoterate meglumine) on the T1-weighted signal intensity (SI) changes in paediatric patients, and assessed the magnitude of age-related increase in T1-weighted SI in a control cohort without prior gadolinium exposure.

Methods and Materials: In this retrospective, double-cohort study, we measured SI (native T1-weighted GRE) of multiple deep brain nuclei, normalized by the pons (reference tissue). 24 patients (1-20 years, mean=5.74, SD=4.15), exposed to at least 10 consecutive administrations of exclusively Dotarem, were included in the longitudinal cohort. We analysed SI ratio changes over 10 successive administrations, accounting for age, using linear mixed effects modelling. Secondly, 190 patients, naive to any gadolinium-based contrast agents, were included in the control cohort (age range 1-20 years, 10 patients/bin, bin width: 1 year) to assess the age-dependent SI changes in the ROIs.

Results: The number of Dotarem administrations did not significantly affect the SI in any of the ROIs (all $p>.05$), whereas age significantly correlated with SI increase in the globus pallidus and caudate ($p<.05$). This was confirmed with the cross-sectional analyses of the control cohort showing a significant age-dependent SI increase in multiple ROIs, including the globus pallidus and caudate ($p<.05$).

Conclusion: Repeated exposure to Dotarem was not associated with brain hyperintensity in the paediatric patients, while age importantly contributed to the SI changes in several deep brain nuclei.

MRI findings in gene therapy-treated adrenoleukodystrophy

P.A. [Caruso](#), K. Buch, C. Corre, F. Eichler; *Boston, MA/US* (pcaruso@partners.org)

Purpose: X-linked cerebral adrenoleukodystrophy (ALD) is a genetic disorder caused by mutations in the ABCD1 gene with poor untreated prognosis. Starting in 2014, lentiviral-transfected autologous haematopoietic stem cell transfer (HSCT) was introduced for the treatment of ALD. The purpose of this study is to provide the first description of the time course of intracranial MRI findings in post-lentiviral HSCT treated ALD patients.

Methods and Materials: 17 ALD patients who underwent lentiviral gene therapy were included in our cohort. Patients received serial MRI scans at 1, 6, 12, 18, and 24 months s/p HSCT. The clinical neurology severity scale was calculated for each time point. The evolution of the T2 signal abnormality, enhancement, and the Loes score (the standard grading system for cerebral ALD) were evaluated.

Results: The clinical ALD severity score stabilised or improved for all patients. The high T2 signal component of the treated ALD increased in 100% of patients at one month and in 80% of patients at all subsequent time points. Enhancement resolved in 40% of patients at one month, and in 100% of patients by 6 months. The Loes score increased an average of 4 points over the 24 months.

Conclusion: All ALD patients treated with lentiviral HSCT stabilised clinically, while the T2 signal component of the treated disease extended over the 24-month follow-up period and the enhancement resolved by 6 months.

Polyp detection rate as a quality measure in CT colonography: analysis of the performance of a CT colonography service using a reduced bowel preparation without dietary restriction

S. Vicini¹, M. Rengo², F. Tiberia¹, D. Bellini¹, G. Trionfera³, I. Carbone², A. Laghi¹, L. Steri¹; ¹Latina/IT, ²Rome/IT, ³Valmontone/IT (simone.vicini@gmail.com)

Purpose: To evaluate the performances of a CT colonography (CTC) service using polyp detection rate (PDR) as quality measurement. To stratify results according to patient's age, gender and symptoms.

Methods and Materials: We retrospectively analysed 1446 consecutive patients who underwent CTC from July 2015 to September 2018. In all patients a reduce bowel preparation (100 g of Macrogol and 60 ml of hyperosmolar iodinated contrast media for fluid tagging) and no dietary restriction was administered the day before the examination. PDR was calculated, considering only polyps ≥ 6 mm, for the entire population and after the stratification in sub-groups according to age (< 65 vs ≥ 65 yy), gender (male vs female) and symptoms (asymptomatic Vs symptomatic). All positive patients at CTC were subjected to endoscopy to confirm the presence of polyps. Polyps were scored according to the location, dimension and quality of the bowel preparation. Differences between sub-groups were evaluated with Chi-square test.

Results: In total 1.446 patients (627/819 M/F, mean age 62.45 ± 14.22 years) were analysed. Bowel preparation was optimal in 1392 patients (96,3%). PDR of total population was 9.19% (133/1446). PDR was significantly higher in older (10.93% vs 7.54%, $P = 0.025$) and male patients (11.32% vs 7.57%, $P = 0.014$). PDR was not significantly different between symptomatic and asymptomatic patients (11.29% vs 8.16%, $P = 0.052$).

Conclusion: CTC without diet restriction for bowel preparation is effective in detecting colorectal polyps, with PDR comparable to those previously reported in literature.

B-0936 10:38

Quality of same-day CT colonography following failed optical colonoscopy

A. Foran, A. O'Shea, M. Morrin; Dublin/IE (foran@tcd.ie)

Purpose: To investigate the adequacy of bowel preparation and oral faecal tagging in same day CT colonography following incomplete same-day colonoscopy.

Methods and Materials: We conducted a retrospective review of all cases of same-day CTC (single centre) in a one-year period, between January 2017 and January 2018 ($n = 94$). The time interval between initial low-dose, non-contrast pre scan and CTC was then calculated. The colon was the subdivided into 12 sections on subsequent CT colonography; each section was evaluated in prone, supine and, where relevant, in decubitus positions for residual fluid and faeces, completeness of oral tagging and adequacy of distension. The data was the collated across all patients and the median score for each subsection calculated. Over 90% of patients were prepped using Moviprep.

Results: The median time to same day CT colonography following low dose non-contrast CT abdomen and pelvis was 4.5 hours (mean 4.4 hours). Overall, the average volume of residual fluid in any given section was just over 25% of the total luminal diameter of that section. Where present, residual fluid and feces was adequately labeled in nearly all patients. The median score for distension for all patients was 3.8 (range 0-5), meaning the entire segment of bowel was well distended and visualized.

Conclusion: Centres with capacity, ideally should aspire to same day CTC to avoid a second bowel prep for patients. We showed that same day CTC following failed colonoscopy is feasible with excellent image quality when combined with oral contrast labeling.

B-0937 10:46

Role of CT colonography in differentiating sigmoid cancer versus chronic diverticular disease

R. Valletta¹, N. Faccioli¹, M. Tagliamonte¹, M. Bonatti², G. Mansueto¹; ¹Verona/IT, ²Bolzano/IT (riccardo.valletta@studenti.univr.it)

Purpose: to retrospectively evaluate morphological findings of chronic diverticular disease and sigmoid cancer at computed tomography colonography (CTC) in order to differentiate them.

Methods and Materials: we included in our IRB-approved retrospective study 133 consecutive patients with histologically proven chronic diverticular disease ($n = 77$) or sigmoid carcinoma ($n = 56$). Two radiologists retrospectively analyzed CTC studies without awareness of the histological diagnosis. One reader scored each exam according to presence or absence of potential discriminators (length, wall thickness, shouldering phenomenon, thickening type, growth pattern, diverticula, fascia thickening, fat tissue edema, loco-regional lymph nodes, mucosal pattern).

Results: the findings that suggest carcinoma diagnosis were: absence of diverticula in the affected segment (sensitivity 87.9%; specificity 90.5%); straight growth pattern (sensitivity 71.4%; specificity 90.9%); shouldering phenomenon (sensitivity 90.5%; specificity 81.8%); complete distortion of mucosal folds (sensitivity 95.2%; specificity 75.8%). Considering mass-like lesions, growth pattern and mucosal folds distortion lose their diagnostic value. The only morphological finding with higher diagnostic value is absence of diverticula in the examined segment; its combination with shouldering phenomenon increases carcinoma diagnosis specificity.

Conclusion: carcinoma is best differentiated from chronic diverticular disease in CTC by the absence of diverticula in the affected segment and the presence of shoulder phenomenon.

B-0938 10:54

The diagnosis of internal haemorrhoids from CT colonography has a poor agreement with optical colonoscopy

L. Lambert, P. Hrabak, A. Novotny, J. Jahoda, A. Burgetova; Prague/CZ (lambert.lukas@gmail.com)

Purpose: The aim of this study was to assess the diagnostic performance of CT colonography (CTC) in the evaluation of internal hemorrhoids.

Methods and Materials: One-hundred-and-five patients who underwent CTC (balloonless rectal tube) for incomplete optical colonoscopy were included in the study. Three gastroenterologists were requested to make a note on the presence of internal hemorrhoids, should they consider requesting a subsequent CTC. For 45 patients, where internal hemorrhoids were reported, a 2:3 age- and a gender-matched cohort of 90 patients with normal findings in the rectum was selected, and images with the endoluminal and transaxial views (supine and prone) of the anal verge were created. Two radiologists and two gastroenterologists evaluated the images for the presence of internal hemorrhoids on a five-point Likert scale and the presence of anal verge prominence, asymmetry, and a cushion-like appearance.

Results: The sensitivity and specificity for the detection of hemorrhoids on CTC was 61% (95%CI 53%-68%) and 69% (95%CI 63%-75%). The specificity was better for the radiologists (81% vs. 63%) and the sensitivity was slightly better for the gastroenterologists (56% vs. 49%). The agreement between the raters in the assessment of the presence of hemorrhoids was 0.61 (95%CI 0.51 to 0.69). Logistic regression identified the prominence of anal verge in supine position (OR 2.7, 95%CI 2.0 to 3.5) as the best predictor of the absence of internal hemorrhoids.

Conclusion: Internal hemorrhoids on CTC cannot be distinguished with any certainty. Hemorrhoids should only be suggested as a differential diagnosis of rectal floor findings.

B-0940 11:10

Effectiveness of bowel preparation without diet restriction for optimal quality CT colonography: a validation study

F. Tiberia¹, M. Rengo², L. Steri¹, D. Bellini¹, G. Trionfera³, I. Carbone¹, A. Laghi¹; ¹Latina/IT, ²Rome/IT, ³Valmontone/IT (docfil@hotmail.it)

Purpose: The aim of our study was to investigate whether bowel preparation without diet restriction for CT colonography (CTC) is sufficient to reach the proposed minimum standard rate of adequate bowel preparation ($> 90\%$) and to identify any influencing factors in our population.

Methods and Materials: In our retrospective study we enrolled 1446 patients (mean age 62.45 ± 14.22 years, 627 men) who underwent CTC after bowel preparation with 100 g of macrogol 60 ml of sodium diatrizoate and meglumine diatrizoate solution, for fluid tagging, the day before the examination. No dietary restrictions were applied. Quality of bowel preparation was assessed with a previously validated 4-point Likert scale evaluating, on a per segment basis, the quantity of tagging and degree of distention. We performed a subgroup analysis to examine the impact of the following factors on bowel preparation: age (> 65 vs < 65 years) and diverticular disease.

Results: Optimal tagging and distention were rated in 1392 (96,26 %) and 1428 (98,75%) patients, respectively, resulting in optimal quality of preparation for 1409 (97,44%) patients. Diverticular disease was associated with lower incomplete distention rates (0.7% vs 1.98%, $p=0.03$) and lower quality of fluid tagging (4.6% vs 2.4%, $p=0,03$). Patient's age did not affect both tagging (3.5% vs 3.9%) and distention (0.8% vs 1.7%) ($p=0.63$ and $p=0.12$ respectively).

Conclusion: Our proposed preparation without dietary restriction is effective in providing optimal fluid tagging and bowel distention for optimal quality CTCs. Diverticula disease negatively affects the quality of fluid tagging and degree of bowel distension.

B-0942 11:26

Diagnostic performance of MRI- vs MDCT-categorised T3cd/T4 for identifying high-risk stage II or stage III colon cancers: a pilot study

S. Shin¹, S. Cho¹, W. Kim², H. Kim¹, G.-C. Kim¹, H.-K. Ryeom¹, S.M. Lee², K.M. Shin¹; ¹Daegu/KR, ²Seoul/KR (ssh-018@hanmail.net)

Purpose: To determine the diagnostic performance of magnetic resonance imaging (MRI)-categorised T3cd/T4 tumours for identifying high-risk stage II or stage III cancer in patients with curatively resectable colon cancer in comparison with that of multidetector computed tomography (MDCT).

Methods and Materials: Thirty-eight patients with histopathologically indicated adenocarcinomas prospectively underwent MRI of the colon. Two radiologists independently and retrospectively assessed for T-category, including T3 substage ($\leq T3ab$ vs. $\geq T3cd$). The diagnostic accuracy and inter-reader agreement between assessments using each modality were compared using a pairwise comparison of receiver-operating characteristic curves and a weighted κ statistic, respectively.

Results: Twenty-nine patients (76.3%) were histopathologically diagnosed with high-risk stage II or stage III colon cancer. The false-diagnostic-positive rate with MRI was lower than with MDCT (0% vs. 7.9% for reader 1, 2.6% vs. 10.6% for reader 2). The diagnostic performance of MRI was better than that of MDCT across both readers (AUC: 0.707 vs. 0.506 [$P = 0.032$] for reader 1, 0.651 vs. 0.485 [$P = 0.055$] for reader 2). Moreover, MRI inter-reader agreement for the assessment of T3cd/T4 was significantly better than that of MDCT ($\kappa=0.821$ vs. 0.391 [$p=0.017$]).

Conclusion: The diagnostic performance of MR imaging of the colon may be better than that of MDCT for identifying high-risk stage II or stage III cases. Given that colon MRI reduced the false-positive diagnosis rate, the usage of MRI-categorised T3cd/T4 diagnoses may prevent neoadjuvant chemotherapy overtreatment, though further studies with a larger sample size are required.

B-0943 11:34

Abdominal calcium score in the evaluation with computed tomography of the risk of leakage of the colon anastomoses

E. Santonocito, C. Trombatore, M. Travali, S.M. Santonocito, A. Di Cataldo, P.V. Foti, A. Basile, S. Palmucci; Catania/IT (enzo_san@hotmail.it)

Purpose: Surgery of the abdominal area is burdened by a 4% postoperative mortality, with non-fatal complications in 20-40% of cases. The leakage of surgical anastomosis is one of the complications with the highest rate of morbidity and mortality. The aim of this study is to analyze the correlation between development of complications and degree of atherosclerosis of the abdominal aorta by CT.

Methods and Materials: The study was conducted retrospectively, recruiting 57 patients: 30 with anastomotic leakage (cases) and 27 without any postoperative complications (controls). The atherosclerosis degree of the abdominal aorta was quantized in the preoperative CT images through the calculation of the Calcium Score (Agatston method), with identification of the value of AAC (Abdominal Aortic Calcification). The risk of leakage of the surgical anastomosis was analyzed by ROC (Receiver Operating Characteristic Curve) analysis. The AAC values were compared between the 2 groups by Mann-Whitney U-test.

Results: ROC analysis, with a threshold value of AAC ≥ 141 reported an AUC (Area Under Curve) of 0.707, with a 95% confidence interval equal to 0.572-0.820; the sensitivity and specificity values measured were 76.7% and 66.7%, respectively. By comparing the AAC values between cases and controls, the study demonstrated a statistically significant difference ($P = 0.003$)

Conclusion: Definition of the Calcium Score of the abdominal aorta, evaluated by CT, can be considered as one of the morphological predictors of surgical risk of anastomotic leakage; further studies are needed in order to validate the role of the abdominal calcium score in larger series.

B-0944 11:42

Does spectral CT help to predict the severity of ischaemic colitis?

E. Danse, N. Michoux, A. Kartheuser, O. Dewit, P. Baldin, A. Joret-Mourin, L. Jacquet, E. Coche; Brussels/BE (etienne.danse@uclouvain.be)

Purpose: To evaluate the ability of spectral CT to predict the severity of ischaemic colitis.

Methods and Materials: 19 patients with a final diagnosis of ischaemic colitis were evaluated with our spectral CT (IQON, Philips Healthcare). The maximal colon wall thickness (mm), UH density on virtual non contrast acquisition (HU^{VNC}), on portal phase (HU^{PORTAL}), HU^{PORTAL}/HU^{VNC} ratio, Iodine load (mg/ml), Z value were evaluated. CRP, blood lactate level, lactate dehydrogenase level (LDH), leukocyte count were analyzed. The search for differences between evolution (group 1 resolution without surgery, $n = 10$) and histologically proven necrosis (group 2, $n=9$) was performed using Mann-Whitney U-test. A multivariable logistic regression analysis followed by a ROC curve analysis was done to identify prognostic factors of necrosis.

Results: The HU^{PORTAL}/HU^{VNC} ratio was higher in group 1 (2.3 vs 1.3, $p = 0.008$). Z and Iodine load were higher in group 1 than in group 2 (Z: 7.97 vs 7.41, $p = 0.001$, Iodine load: 0.96 vs 0.22 mg/ml, $p = 0.001$). LDH was significantly higher in group 2 (421 vs 192 UI/L, $p = 0.004$). At multivariable analysis, the association of CRP and LDH count in predicting the severity of ischaemic colitis demonstrated the highest performance (AUC = 0.986 [0.781; 1.000], Se = 100% [63; 100], Sp = 89% [52; 100], NVP = 100% [63; 100], PPV = 89% [52; 100], $p < 0.001$).

Conclusion: The combination of blood tests and colic wall abnormalities observed with spectral CT can contribute to predict the outcome of ischaemic colitis.

B-0945 11:50

Whole-body MRI: prevalence and extent of asymptomatic diverticular disease and the association of dietary habits, cardiometabolic and constitutional risk factors

C. Storz¹, T. Rothenbacher¹, S. Rospleszcz², J. Linseisen¹, H. Messmann¹, C.N. De Cecco³, A. Peters⁴, C.L. Schlett⁵, F. Bamberg¹; ¹Tübingen/DE, ²Munich/DE, ³Charleston, SC/US, ⁴Neuherberg/DE, ⁵Heidelberg/DE (corinna.storz@med.uni-tuebingen.de)

Purpose: To assess the prevalence and extent of diverticular disease (DD) and the association of cardiometabolic risk factors, dietary habits and constitutional factors assessed by magnetic resonance imaging (MRI) in an asymptomatic general population.

Methods and Materials: Participants enrolled in a prospective case-control study underwent a 3 Tesla MRI, including an T1w-VIBE-Dixon sequence. Presence and extent of DD were categorized according to the number of diverticula in each colonic segment. The amount of visceral, subcutaneous and total adipose tissue and the degree of hepatic steatosis (PDFF) were quantified using a multi-echo T1w sequence. Traditional cardiometabolic risk factors were obtained and dietary intake habits were derived using a comprehensive food-intake questionnaire. Univariate and multivariate associations were calculated.

Results: Among 393 participants included in the analysis, 42% had DD, predominantly in the left-sided colon. Subjects with DD were older, had significantly higher body mass index as well as higher cholesterol levels and systolic blood pressure (all $p \leq 0.003$). In contrast, no significant correlation was found for physical activity, not for alcohol consumption (all $p > 0.31$). Furthermore, subjects with DD had higher amounts of adipose tissue and hepatic PDFF (all $p < 0.02$), and had significantly less intake of vegetables and fiber (OR: 0.73, 95%CI: [0.53, 1.00] and 0.65, 95%CI: [0.46, 0.92], all $p < 0.02$), which was independent of age, sex and mean caloric intake.

Conclusion: Assessing DD by whole-body MRI is feasible and demonstrates similar pathophysiological associations as previously reported. MRI as a non-invasive tool provides novel opportunities including identification of high-risk DD phenotypes.

Is there a clinical need for structured reporting or even more? Results from a clinical questionnaire in the context of head trauma CT

N. Schmidt, D. Zumofen, A. Jadcak, B. Stieltjes, K. Blackham; Basle/CH

Purpose: A challenge for the clinician is effective decision-making in the setting of information overload. A superimposed challenge is a radiologic report that is variable in format, length and linguistic style. Structured reporting helps enforce completeness and standardization. To improve the quality and usability

of our reports we assessed the referring clinician's needs for trauma head CT.

Methods and Materials: A literature search determined several evidenced-based parameters that should affect clinical decision-making. A questionnaire went by email to referring clinicians from emergency room, neurosurgery, otolaryngology, spinal and maxillofacial Surgery. The questionnaire contained calibration questions, opinion questions about the status of the current reports, questions regarding a proposed structured report and communication of findings.

Results: 41 respondents completed the questionnaire. 55% read the radiologic impression and 27% the findings on a regular basis. 80% prefer shorter reports and 76% prefer to get structured reports in a table form. 32% wished to receive results other ways than the telephone, for example, a signal on an electronic dashboard. When asked about possible improvements, respondents asked for a link to the images with critical findings, less description of normal findings and continued reporting of all secondary findings.

Conclusion: Clinicians prefer structured reports to the narrative style for trauma head CT. There is a clear need for more personalized reports depending on the clinical severity, the clinician's subspecialty and personal preferences. Further developments need to enable other ways to transmit information in a more rapid and personalized format.

B-0947 10:38

Computed tomographic pattern of intracranial injuries among patients with *okada* (motor cycle) road traffic accidents in Southwestern Nigeria

O.M. Atalabi, O. Akinwumi; Ibadan/NG_mojisola3t@hotmail.com

Purpose: To determine pattern and prevalence of intracranial injuries on cranial computed tomography scan in patients with head injury following motorcycle road traffic accident.

Methods and Materials: This study was a descriptive cross-sectional study conducted on 190 patients, who presented with head injury at the Accident and Emergency Unit of University College Hospital, Ibadan, following motorcycle road traffic accident in a five-month period and who underwent computerised tomography scan.

Results: More than half of the patients (n=59.8%) were within the ages of 20-39 years with a mean age of 33±14.37 years. A total of 183 patients did not wear the crash helmet at the time of injury with 155 patients (n=81.6%) sustaining intracranial injury (p=0.21). Cerebral contusion (n=62.6%), cerebral haematoma (n=31.7%) and cerebral oedema (n=86.8%) were noted in these patients. Intracranial bleed such as subdural, subarachnoid and epidural bleeds accounted for 28.5%, 22.2% and 21.5%, respectively. Only seven patients (3.8%) had intraventricular extension of these bleeds. One hundred and sixty-eight patients (n= 88.4%) had varying types of skull fractures. The significant relationship between the presence of intracranial injury and severity of head injury was demonstrated in this study as the increase in intracranial injuries correlated with severity of head injury from mild to severe (p<0.001).

Conclusion: The sharp increase in *okada* (motorcycle) accidents now account for life-threatening intracranial injuries and has become a major public health concern needing enforcement of traffic regulation and safety measures.

B-0948 10:46

CTA evaluation of cervical ICA occlusion vs pseudo-occlusion in major stroke

S. Molinaro, S. Veglia, O. Davini, C. Ruggieri; Turin/IT_ilmbialterego52@gmail.com

Purpose: To evaluate the PPV of CT angiography in distinguishing between thrombotic occlusion and pseudo-occlusion of cervical ICA, using density measures (ROI) in patients with major stroke eligible to endovascular treatment.

Methods and Materials: From 353 patients who received a diagnosis of major stroke between Jan 16 and Mar 18, we studied 19 of them with no enhancement of major intracranial vessel and ICA (tandem occlusion) in two-phase CTA scan. Both images and reports were reviewed and three ROI were placed, one in the proximal tract of ICA and two (I and II phase) in the distal one, to assess a correlation between ROI values, angiographic report and CTA.

Results: 14 out of 19 patients had a CT diagnosis of occlusion, which was confirmed after in 9 cases with angiography (PPV 64.3%, CI95% 35.1%-87.2%) and 5 of pseudo-occlusion (26%) with regular vessel opacification in angiography in 1 case (NPV 20%, CI95% 0.5%-1.6%). Using the ROI in the II phase allowed to increase the accuracy (AUROC 0.718, CI95% 0.430-1); more specifically, with a 65 HU ROI as cut-point (occlusion <65HU) the PPV was 85.7% (CI95% 42.1% 99.6%) and NPV was 41.7% (CI95% 5.2% 72%).

Conclusion: CTA in ischaemic stroke has the role of identifying the region of vascular occlusion. In case of suspect tandem obstruction, visual judgment cannot always distinguish between ICA true occlusion or pseudo-occlusion. The density measurement of the vessel by ROI increases both PPV and NPV and could be used as a new judgement criterion for correct reporting.

B-0949 10:54

Novel rapid imaging protocol of the bilateral MCA territories for thrombectomy in acute ischaemic stroke by old-model 320-row area detector CT

T. Morii, Y. Tanno, N. Nakai, K. Yoshioka; Kamakura/JP_morit-koc@umin.net

Purpose: The 320-row area detector CT (320ADCT) produces large volume data (VD) and image reconstruction of the old model is time consuming. Therefore, 4D-CT angiography (4D-CTA) is not always applicable to pre-thrombectomy. The aim was to design the practical protocol for pre-thrombectomy with any model.

Methods and Materials: To avoid subtraction of all images and to shorten image processing time, post-contrast volume scanning (VS) only was performed. VS used 1-s single rotation intermittent dataset scans. The mask was acquired at 1s and beginning 10 s after injection of contrast medium, 20 intermittent volume scans were acquired. Each volume consisted of 120 images, because of not 0.5-mm but 1-mm thickness with z-axis coverage of the not 160 mm but 120 mm (minimal width depending on the model), and total 2520 images were produced. After transferring VD to a workstation (WS), the 8-cm width VD along the middle cerebral artery (MCA) axis was cut out on the WS and 4D-CTA was generated. Examination time and image quality were evaluated.

Results: Small VD was transferred quickly to the WS and 4D-CTA of the MCA axis was generated soon and total time until viewing images on PACS was about 5 minutes. Image quality of 4D-CTA was useful in identifying candidates of thrombectomy. Compared to initial protocol of a 0.5-mm thickness with z-axis of the whole brain and subtraction of all images, total operation time became about a quarter.

Conclusion: Our protocol can provide practical 4D-CTA of the MCA axis in acute stroke setting.

B-0950 11:02

The Ottawa subarachnoid haemorrhage rule in the decision for acute CT head: external validation in a contemporary European cohort

R.W. Foley¹, S. Ramachandran², A. Akintimehin³, S. Williams³, P.A. Kelly³; ¹Bristol/UK, ²Leicester/UK, ³London/UK_rwjfoley@gmail.com

Purpose: The Ottawa subarachnoid haemorrhage (SAH) rule is a clinical decision tool to aid in the decision for CT Head in Emergency Department (ED) patients with acute non-traumatic headache. The objective of this study was to analyse the performance of the Ottawa rule in a UK cohort.

Methods and Materials: Patients undergoing CT Head for the investigation of non-traumatic SAH over a 6-month period at two tertiary centres were assessed. Each patient's Ottawa score was calculated and compared to their final diagnosis. The Ottawa score consists of 6 items, namely age ≥ 40, neck pain/stiffness, witnessed loss of consciousness, onset during exertion, thunderclap headache or limited neck flexion on examination. Analysis was undertaken using R version 3.1.1.

Results: The cohort consisted of 366 patients and there were 16 cases of SAH (based on CT findings or xanthochromia in cerebrospinal fluid). The Ottawa rule identified 288 patients requiring CT Head. The sensitivity of the Ottawa rule was 100% (95% CI; 71%-100%) and the specificity was 22% (95% CI; 18%-27%). The negative predictive value was 100% (95% CI; 93%-100%).

Conclusion: The Ottawa SAH Rule corrected identified all patients with SAH in this cohort. The use of this rule would allow for an objective triage of patients presenting with acute headache to ED and in 22% of patients CT head could have been avoided. The Ottawa Rule is a useful tool to aid in the decision for CT Head in ED patients under investigation for SAH and should be utilised in clinical practice.

B-0951 11:10

Value of spot sign (SS) on CT angiography (CTA) such indicator of early haematoma expansion in the spontaneous intracerebral haemorrhage (ICH) - some therapeutic considerations

E. Puqielli, M. Di Bartolomeo, M. Assetta, F. Navarra, M. Di Matteo, M. Galliano, G. Manente; Teramo/IT_edopug@hotmail.com

Purpose: Spot sign (SS) on CT-angiography (CTA) are a valid indicator of early haematoma expansion in spontaneous intracerebral haemorrhage (ICH). However, its contribution to outcome have not been well explored.

Methods and Materials: We evaluate 93 patients with spontaneous ICH, NCCT and CTA performed on admission within 6h after onset of symptoms, retrospectively from 20013 to 2018. We compare the Blend sign (BS) and black hole sign (BHS) on non-contrast computed tomography (NCCT). Discharge outcome was good (modified Rankin Scale [mRS] 0-3) and poor (mRS 4-6) outcomes. The impacts of SS on outcome were assessed in univariate logistic regression models and the relations with baseline haematoma volume and intraventricular haemorrhage or multivariate for the BS, BHS or SS.

Results: Of 93 patients with spontaneous ICH, 11 (11.8%) presented SS. There was a substantial correlation between SS and BS ($\kappa=0.631$) and a moderate correlation between SS and BHS ($\kappa=0.345$). In the univariate logistic regression the presence of BHS/BS/SS (all $P<0.001$) on admission CT scan were associated with poor outcome. The multivariate analysis identified intraventricular haemorrhage (odds ratio [OR] 2.32 per mL, $P=0.021$), baseline haematoma volume (OR 1.05 per mL, $P<0.001$) and SS on CTA (OR 12.16, $P<0.002$) as independent predictors of poor outcome.

Conclusion: Of the CT variables indicating early haematoma expansion, SS on CTA was the most reliable outcome predictor to address for a rapid endovascular treatment. However, some authors give a strong correlation with SS on CTA, BS and BHS on NCCT that can be used for predicting outcome.

B-0952 11:18

Non head-injured paediatrics in the emergency department: clinical predictors of abnormal head CT findings

J. Wu, H. Huang, M. He, Q. Fan, M. Ma, L. Lin; Fuzhou/CN (249961548@qq.com)

Purpose: To identify the clinical predictors of abnormal head CT findings of non head-injured paediatrics in emergency department.

Methods and Materials: Three years consecutive cases of non head-injured paediatrics (≤ 14 years old) with head CT acquisitions in emergency department of our hospital from 2015 to 2017 were reviewed retrospectively. Clinical predictors included age, gender, seizure, headache, dizziness or vertigo or ataxia, syncope, vomiting, fever, predisposing conditions (including history of hypoxic-ischaemic encephalopathy, bleeding disorders, malignancy, et al), abnormal physical examinations, altered mental status. Mono factor and multi factors logistic regression analysis were used to identify the independent clinical predictors of abnormal head CT findings of non head-injured paediatrics in emergency department.

Results: 22 cases with existed intracranial diseases (5), unclear medical history records (7) and a history of injury (10) were removed from total 396 cases, and final 374 cases were included. 230 males, 144 females, the average age was (6.9 ± 4.3) years, the medium age was 7.0 years. 29 (7.8%, 95%CI: 5%-10.5%) of 374 cases with abnormal head CT findings were found. headache (184/49.2%) and seizure (114/30.5%) were the main chief complains. None of abnormal head CT findings in patients with vertigo or dizziness, and syncope were detected. Three independent Clinical predictors of abnormal head CT findings were identified: predisposing conditions (OR=12.109, 95%CI:1.96-74.80), abnormal physical examinations (OR=3.704, 95%CI:1.17-11.72), altered mental status (OR=9.593, 95%CI: 2.80-32.83).

Conclusion: Predisposing conditions, abnormal physical examinations, altered mental status were the independent clinical predictors of abnormal head CT findings of non head-injured paediatrics in emergency department.

Contributions of the whole-body CT scan before multi-organ donation in brain dead patients

F. Leleu, C. De Margerie, C. de Bazelaire, F. Gaudez, C. Lefaucheur, E. De Kerviler; Paris/FR (florian.leleu.pro@gmail.com)

Purpose: To demonstrate the interest of whole-body CT before multi-organ donation in brain dead patients.

Methods and Materials: 240 consecutive patients were referred for CT angiography (CTA) diagnosis of brain death between June 2010 and December 2017. We tried to combine multiphase brain CTA and chest abdomen and pelvis CT in the same session to find contraindication to donation, evaluate the organ morphology and to detect anatomical variants. In addition to the brain evaluation, the CT protocol included an abdominal acquisition without injection, a chest, abdomen and pelvis acquisition at the arterial phase and abdomen pelvis acquisition at portal phase. CT scans were analysed according to a standardized report and compared to postoperative results.

Results: 43 out of 240 (17.7%) patients were excluded for organ donation. The first cause (20/43) was the results of the CT scan. In 12 patients (5%), CT revealed a malignant condition. Hepatosteatosis was found in 49 patients, 15 of whom were overweight. A hepatic arterial variant was detected in 51 patients (21%) and renal arterial variant in 86 patients (36%).

Conclusion: Whole-body CT performed in brain dead patients allows the detection of contraindications to organ donation. It also allows to analyse the morphology of all organs of interest and can constitute an aid to the surgical procedure by detecting anatomical variants. It is feasible at the same time of brain CTA in countries where this examination is validated for the diagnosis of brain death. Multi-organ donation should no longer be performed without prior whole-body scanning.

B-0954 11:34

Evaluation of a novel 3D-surface reconstruction technique in post-mortem CT after stab attacks: diagnostic accuracy and forensic impact compared to conventional CT and autopsy findings

J. Böven, J. Boos, R.S. Lanzman, Y. Klosterkemper, P. Kröpil, C. Thomas, G. Antoch, J. Aissa; Düsseldorf/DE (judith.boeven@med.uni-duesseldorf.de)

Purpose: Evaluation of diagnostic accuracy and forensic relevance of a novel 3D-reconstruction technique (cinematic rendering) used for stab wounds in post-mortem CT compared to conventional CT and autopsy findings.

Methods and Materials: Inclusion of six human cadavers undergoing whole body PMCT with blood loss as cause of death in all cases. Two radiologists counted the number of stab wounds in PMCT and the number of the wounds that were detectable in 3D-cinematic-rendering (CR) reconstructions. Afterwards assessment of the total number of stab wounds during autopsy by two forensic pathologists. One forensic pathologist evaluated the CR reconstructions regarding their relevance in forensic interpretation and demonstration on a five-point scale (1: very useful for forensic interpretation and demonstration; 5: not useful).

Results: 6 human cadavers had a total number of 99 stab wounds found in autopsy by pathologists. Both PMCT readers detected 59 stab wounds. 56/59 (94.9%) of the stab wounds were found on CR reconstructions. Both, CR and PMCT were significantly inferior compared to autopsy. CR reconstructions were significantly more useful than conventional PMCT ($p<0.005$) concerning forensic interpretation and demonstration aspects.

Conclusion: Photorealistic 3D-reconstructions are declared more useful for forensic interpretation and demonstration compared to conventional PMCT in the diagnosis of stab wounds. A significantly lower amount of stab wounds was found in autopsy performed by forensic pathologists than in PMCT and 3D-CR-reconstructions, however autopsy is still the method of choice in detection of stab wounds. 3D-reconstructions of stab wounds are more useful for demonstration aspects compared to conventional PMCT.

B-0955 11:42

Imaging of penetrating extremity injuries in a Scandinavian level-1 trauma centre: a 4-year analysis of the trauma registry data from the Karolinska trauma centre, Stockholm

P.M. Cewe Jönsson¹, S. Thorisdóttir², G.L. Óladóttir¹, S. Koskinen³, ¹Solna/SE, ²Stockholm/SE, ³Huddinge/SE (paulina.cewe-jonsson@sl.se)

Purpose: To analyse incidence, mechanism of injury, imaging approach and clinical outcome in penetrating extremity injuries at a level-1 trauma centre.

Methods and Materials: A retrospective cohort study of penetrating injuries between 2013 and 2016 (4 years) to the extremities retrieved from the Karolinska Trauma Registry. Imaging data were accessed through hospital RIS and PACS, and electronic medical records were analysed. Two radiologists collected and analysed imaging data while the third evaluated the subgroup of extremity injuries.

Results: Of 636 patients with penetrating injury, 443 had imaging data available. Of these, 36.8% (163/443) had penetrating extremity injuries. This cohort comprised 145 males (89.0%; age range 15-83, mean 31.4) and 18 females (11.0%; age range 18-93, mean 35.7). Main mechanisms of injury were stabbing (SW) 50.3% (82/163) and shooting (GSW) 43.0% (70/163). Half of the injuries were limited to the lower extremities (51.5%, 84/163). Imaging was performed in 85.3% (139/163) of patients. CT angiography (CTA) was the most common imaging modality (93/139; 67%). Arterial damage was present on 44 CTAs (47.3% 44/93). Compared to SW, GSW increased the odds for surgery significantly (OR 2.5 $p<0.02$). In general, GSW increased the odds for surgery by 7.7 times ($p<0.008$) compared to SW. 30-day morbidity rate was 11.7% (19/163). Overall mortality rate was 0%.

Conclusion: Penetrating extremity injuries are relatively common. In this study, imaging was performed in 85% of patients. CTA was the most common imaging modality. GSW significantly increased the overall odds of surgery compared to SW. No deaths occurred in our patient cohort.

Preoperative tibial artery run off score differences before endovascular or bypass surgery in patients with long popliteal artery lesions

A. Kratovska, S. Ponomarjova, P. Ivanova; Riga/LV

Purpose: Objective, quantitative preoperative tibial run-off score (TRS) calculation is not highlighted by guidelines of critical limb ischaemia (CLI) although it plays important role in revascularization treatment method selection (RTMS) for patients with long popliteal artery atherosclerotic lesion. The aim of this study was to analyse association of TRS with RTMS.

Methods and Materials: Single centre retrospective case-control study performed in 2016-2017 in tertiary care hospital. 47 patients with infrageniculate bypass surgery (IGBS) and 36 with endovascular therapy (EVT) of femoropopliteal segment (n=83) who met the inclusion criteria were selected. An authors adjusted TRS calculation system (total occlusion=0 point, intact=22) was used to analyse tibial artery status. Age, gender, Rutherford category, femoropopliteal lesion TASC II type, TRS and statistical association of variables with RTMS analysed by SPSS 22 program. $P < 0.05$ considered statistically significant.

Results: Mean TRS in IGBS group was statistically significantly higher than in EVT group- 9.074 ± 3.887 vs 5.7 ± 3.852 ($p < 0.001$). In univariate analysis from all the variables analysed age (t test, $p = 0.008$), gender (Exact Fisher test, $p = 0.032$), TASC II lesion type (Pearson Chi-Square test, $p = 0.006$) and TRS (t test, $p = 0.006$) were statistically significantly associated with RTMS. Multivariate analysis ruled out that only TASC II lesion type and TRS are significantly associated with RTMS ($p < 0.001$).

Conclusion: TRS is a strong predictor of revascularization modality choice in patients with CLI and long popliteal artery lesion and is significantly higher in IGBS group. Objective, quantitative preoperative TRS evaluation could be recommended in a routine practice.

B-0958 10:38

Long-term results of the aortoiliac kissing stents and risk factors of in-stent restenosis

M. Vértes, I.Z. Juhász, D.T. Nguyen, C. Csobay-Novák, B. Nemes, K. Hüttl, E. Dósa; Budapest/HU (vertesmiki@gmail.com)

Purpose: To determine the long-term patency of the aortoiliac kissing stents and to identify predisposing factors for the development of in-stent restenosis (ISR).

Methods and Materials: A retrospective analysis was conducted of 105 patients (median age 60.9 years; 64 women) with symptomatic aortoiliac occlusive disease who had kissing stents implanted between 2001 and 2015. Patient, vessel, lesion, and stent characteristics were examined. Lesions were TASC A in 52 (49.5%), B in 29 (27.6%), C in 4 (3.8%), and D in 20 (19%) patients. Twenty-five (23.8%) patients had heavily calcified lesions. In all, 210 stents [180 (85.7%) self-expanding and 30 (14.3%) balloon-expandable] were deployed. Follow-up included palpation of peripheral pulses, measurement of ankle-brachial index, and duplex ultrasonography. Mann-Whitney U , Fisher's exact, and log-rank tests, as well as Kaplan-Meier, Cox regression, and receiver operating characteristic analyses were used as statistical methods.

Results: The median follow-up was 45 months. Primary patency rates were 95%, 93%, 86%, and 77% at 6, 12, 24, and 60 months, respectively. Significant ISR developed in 23 (21.9%) patients. Multivariable analysis showed a longer aortic stent segment to be the only significant determinant of ISR (HR 1.44, 95% CI 1.02-2.01, $P = 0.035$). The primary patency was significantly worse ($P < 0.001$) in patients with longer (>20 mm) aortic stent segments.

Conclusion: The kissing stent technique can be performed with good long-term patency rates for the treatment of aortoiliac occlusive disease. Patients whose iliac stents protrude too far into the aorta need closer follow-up.

B-0959 10:46

Comparative assessment of occupational radiation exposure between transbasilic and transfemoral approach during percutaneous retrograde scleroembolisation of left varicocele

A. Conti, M.C. Calcagno, D. Meo, A. Modica, D. Rizzo, L. Mammino, P.V. Foti, S. Palmucci, A. Basile; Catania/IT (mc.calcagno@gmail.com)

Purpose: Aim of this study is to compare the occupational radiation exposure difference between transfemoral (TF) or transbasilic (TB) venous access, during percutaneous retrograde scleroembolisation of left spermatic vein.

Methods and Materials: In this randomized trial we evaluate 18 males patients (9 via TF and 9 via TB venous access - mean age 29.8 years old, range 18-43 years old), treated, between March and September 2018 (the study is still in progress), by retrograde scleroembolisation of left varicoceles. During the procedures, the occupational exposure is measured using a direct reading integral dosimeter calibrated in Hp(10) (personal dose equivalent at the depth of 10 mm). To maximize the statistical coherence and avoiding bias, the procedure has always been performed by the same operator, using the same angiography system, protocol and dosimeter. Data have been collected at the end of each procedure referring to fluoroscopy time, DAP (dose area product) and exposure measured in Hp(10). Statistical analysis has been performed using t-test.

Results: Operator occupational exposure in Hp(10) is higher using TF access (63.44 ± 47.24 vs 27.89 ± 17 μ Sv; $p = 0.0496$). Mean fluoroscopy time (8.311 ± 2.391 vs 5.489 ± 2.045 min; $p = 0.0161$), DAP (92.89 ± 62.69 vs 40.22 ± 22.7 Gy \cdot cm 2 ; $p = 0.037$), effective dose (E) and eye lens equivalent dose (HE) are higher as well using TF access.

Conclusion: TB venous access in the scleroembolisation of left varicocele offers an advantage in terms of better haemostasis, reduced complications, better patient compliance and moreover in terms of lower radiation exposure of the operator and the patient.

B-0960 10:54

Transcatheter arterial embolisation for traumatic thoracic bleeding: 4-years' experiences in a single trauma centre

C.M. Lee, C.H. Jeon, J.B. Park, C.W. Kim, H. Kwon, H.M. Cho; Busan/KR (changho.jeon@gmail.com)

Purpose: We aimed to assess the safety and efficacy of transcatheter arterial embolisation (TAE) for thoracic arterial haemorrhage following chest trauma.

Methods and Materials: From November 2013 to May 2017, 35 patients were referred to our interventional unit for thoracic arterial bleeding following chest trauma, based on clinical decisions and computed tomography (CT) images. We exclude seven patients expired within one week due to other medical problems. A total of 28 patients (male:female ratio, 21:7; median age, 54 years) who underwent selective TAE of thoracic haemorrhage-culprit arteries were included in this study. Technical and clinical success, complications, and 30-day mortality rate were analysed.

Results: In 28 patients who underwent TAE, the main bleeding arteries were in the intercostal artery (n=44), internal mammary artery (n=13), bronchial artery (n=3) and superior and/or lateral thoracic artery (n=2). Gelatin sponge particles (n=39), N-butyl-2-cyanoacrylate (NBCA) (n=15), combination of gelatin sponge particles and microcoils (n=4), polyvinyl alcohol (n=3) and microcoils (n=1) were used as embolic agents. Initial technical success was achieved in all 28 patients, with immediate cessation of bleeding. Four patients showed rebleeding 1-2 days later and underwent repeated TAE with successful result. Clinical success rate was 92.8% (26/28), and two patients underwent thoracotomy for controlling residual bleed. There were no TAE-related major complications infarction or quadriplegia. The 30-day mortality rate was 7.1% (2/28).

Conclusion: Our clinical experience suggests that TAE used to control thoracic arterial bleeding following chest trauma is safe and effective as a minimally invasive alternative to surgery.

B-0961 11:02

Vacuum-assisted aspiration thrombectomy for treatment of acute massive pulmonary embolism

A. Massmann¹, P.M. Lepper¹, P. Fries¹, H. Wilkens¹, A. Buecker¹, B. Huasen²; ¹Homburg/DE, ²Manchester/UK

Purpose: Prospective evaluation of feasibility and safety of vacuum-assisted aspiration thrombectomy (VAST) for percutaneous treatment of acute massive pulmonary embolism (PE).

Methods and Materials: In a multi-national cohort of 12 consecutive male patients (median age 54, range 35-80 years) acute massive PE was verified by contrast-enhanced computed tomography and transthoracic echocardiography. Endovascular vacuum-assisted aspiration thrombectomy (Penumbra Indigo XTORQ 8F) was performed during general anaesthesia in all patients after onset of cardiac shock. Two patients needed extracorporeal membrane oxygenation (ECMO) for cardiac assistance. Anticoagulation in ECMO patients included therapeutic heparinization, otherwise 5.000 I.U. of heparine before

and during VAST. Right heart strain, mean pulmonary-arterial pressure (mPAP), peripheral transcutaneous oxygenation, and survival were assessed.

Results: Technical success of VAST was achieved in all patients. Mean procedure time (puncture-to-haemostasis) was 112±/47 (range 55-180) minutes, contrast medium volume 130±/19 (100-150) ml, thrombectomy aspiration volume 213±/55 (150-300) ml. mPAP improved from 58±/7 (52-65) mmHg to 30±/3 (24-34) mmHg (p=0.0080) and peripheral oxygenation increased from admission 83±/4 (79-90)% to 96±/2 (96-99)% postinterventional (p=0.0222). Cardiac imaging studies 24 hours later showed improvement of right to left ventricular quotient from 1.5±/0.2 (1.24-1.7) to 1.0±/0.1 (0.86-1.2) (p=0.0031). Follow-up up to 2 years showed no procedure-associated bleeding complication or death.

Conclusion: In an international prospective registry of a limited number of patients vacuum-assisted aspiration thrombectomy proved to be a safe and effective option for percutaneous catheter-directed treatment of acute massive pulmonary embolism.

B-0962 11:10

Gemstone Spectral Imaging (GSI) in early CT-follow up after endovascular aortic repair (EVAR)

H. Muenzfeld, T. Schmidt, H. Posch, B. Gebauer, B. Hamm, G. Böning; Berlin/DE (hanna.muenzfeld@charite.de)

Purpose: Endovascular aortic repair (EVAR) is one of the most challenging procedures in interventional radiology related to several risks and complications. Next to contrast enhanced ultrasound, CT is used for follow up. We aimed to evaluate the diagnostic accuracy and dose reduction potential of Gemstone Spectral Imaging (GSI) for early CT-follow up after EVAR.

Methods and Materials: Preliminarily, 13 cases of GSI CT after EVAR were included. The dual phase protocol includes a dual energy (GSI) arterial phase and a monoenergetic venous phase at an equal scan length. Iodine suppressed images (ISI) and virtual monochromatic images (VMI) were reconstructed from GSI data. Radiation dose was compared intraindividually and to a low dose triple phase protocol, including a pre-contrast phase. Diagnostic confidence with special regard to endoleak detection was assessed.

Results: Preliminary results confirm the diagnostic usability of GSI-CT in early follow up after EVAR with diagnostic confidence levels equivalent to our standard. Intraindividually, GSI technique shows equal radiation exposure compared to monoenergetic images (mean CTDI 8,09±4,5 vs. 8,60±4,1). GSI did not significantly increase mean applied dose compared to the low dose triple phase protocol (mean DLP 1051±389 vs. 842±565 mGy*cm, p>0.2) by replacing the non-contrast phase by ISI.

Conclusion: Dual energy GSI CT with a dual phase protocol is feasible for early CT-follow up after EVAR without sacrificing diagnostic confidence and endoleak detection by utilization of ISI and VMIs. GSI does not significantly increase applied radiation dose compared to the monoenergetic phase and to a low dose triple phase protocol.

B-0963 11:18

Prospective single-centre registry of endovascular aortic repair (EVAR) using ultra-low profile altura endograft

A. Massmann¹, F. Frenzel¹, P. Fries¹, R. Kubale², R. Shayesteh-Kheslat¹, A. Buecker¹; ¹Homburg/DE, ²Pirmasens/DE

Purpose: To report preliminary prospective single-center experience of endovascular aortic repair (EVAR) using ultra-low profile (14F) Altura (Lombard Medical) stentgrafts.

Methods and Materials: During 2016-2018, 31 consecutive patients (3 females) (mean age 73±9; range 57-88 years) underwent elective or urgent (n=2) EVAR of abdominal aortic aneurysms (AAA) (mean diameter 55±4.5 (50-68)mm; angulation 31±24 (0-80°); infrarenal neck length 31±12 (14-55)mm; aorto-iliac aneurysms (n=2; common iliac artery aneurysm diameter 35 and 45mm) and one renal chimney (AAA 53mm) using Altura endografts. Prospective follow-up recording morbidity and mortality outcomes, endoleak and re-intervention included contrast-enhanced duplex-ultrasound and computed tomography.

Results: Technical success for device deployment was 100%. Mean procedure time (needle to hemostasis) was 59±13 (40-91)minutes; fluoroscopy time 10±4 (4-18)minutes; dose-area-product 4,131±2,030 (1,377-8,188) μGy*cm²; contrast medium volume 75±29 (40-150) ml. Compared to a per aneurysm characteristics matched patient cohort treated with Medtronic Endurant II, fluoroscopy (median 10 vs. 17minutes p=0.0001); dose-area-product (p=0.0063) and procedure-time (60 vs. 69 minutes; p=0.0477) were significantly lower for Altura. Overall hospitalisation was 6.6±5.2(3-26) days (Intensive care unit 1.4±0.8 (1-4) days). There was no relevant blood loss. Early (<30days) complications included endoleak type-2 in 30%; one patient experienced mild temporary post-implantation syndrome; 4 patients required additional surgery for symptomatic femoral artery dissection/pseudoaneurysm. During mean follow-up of 5±7(1-25) months freedom from device-related complications, aneurysm-related re-intervention or death was 100%. Aneurysm shrinkage (<5 mm) was seen in 20% of patients.

Conclusion: Preliminary experience showed promising short-term results with the low-profile easy-to-use Altura device. Long-term studies are required to assess durability and device-related complications.

B-0964 11:26

Fusion imaging to guide thoracic endovascular aortic repair (TEVAR): comparison of two methods: 2D/3D vs 3D/3D image fusion

P.-A. Barrai, A. Bartoli, P. Piquet, M. Demasi-Jacquier, M. Gaudry, A. Jacquier; Marseille/FR (pierre-antoine.barrai@ap-hm.fr)

Purpose: To compare two-dimensional (2D) versus three-dimensional (3D) image fusion for thoracic endovascular aortic repair (TEVAR) image guidance.

Methods and Materials: Between June 2014 and March 2018, all patients who underwent TEVAR were included. TEVAR was performed by a multidisciplinary team in a hybrid suite under image fusion guidance. Two different fusion procedures namely 2D/3D and 3D/3D were evaluated in terms of accuracy, X-ray exposure (dose-area product, DAP), volume of contrast medium injected, fluoroscopy time, and procedure time. All aortic and general complications were recorded at one-month follow-up.

Results: 42 patients were prospectively included, 26 were performed under 2D/3D, and 16 were performed under 3D/3D. The 3D/3D method allows a more accurate positioning of the aortic mask on the top of the fluoroscopic images (proximal landing zone error vector: 1.68mm±3.1) compared to the 2D/3D (6.6mm±5.8; p=0.008). The 3D/3D image fusion method was associated with significant DAP reduction compared to the 2D/3D method (51 Gy.cm² ± 29 for 3D/3D vs 91.9 Gy.cm² ± 76 for 2D/3D; p=0.01). The volume of contrast medium injected was statistically lower using 3D/3D method versus 2D/3D (47.4 ml±24 vs 113 ml±53; p<0.0001). At one month's follow-up, we recorded 4 complications for 2D/3D and one complication for 3D/3D with no significant differences between the two groups.

Conclusion: 3D/3D image fusion is feasible and safe and yields higher image fusion accuracy than 2D/3D image fusion during TEVAR. It helps to reduce contrast volume and irradiation, but does not demonstrate better clinical outcomes at one month.

B-0965 11:34

Distal transradial approach at the anatomical snuffbox for interventional procedures: a single-centre pilot study

S.-E. Park¹, S. Cho¹, C. Hocheol², S. Lee²; ¹Changwon/KR, ²Jinju/KR (uneyes@gnu.ac.kr)

Purpose: Distal radial artery (RA) access at the anatomical snuffbox is a new approach for endovascular procedure. We demonstrate in twenty-one cases the possibility of distal RA access to performed endovascular treatment without any additional equipment or cost. To evaluate the feasibility and safety in a single centre using distal transradial access (TRA) for endovascular treatment.

Methods and Materials: Distal TRA was attempted in 21 patients (16 men; mean age, 60.2 years) who underwent 21 consecutive procedures (chemoembolization [n=5], bronchial artery embolization [n=3], renal intervention [n=3], uterine artery embolization [n=1], arteriovenous fistula angioplasty [n=3], subclavian artery stenting [n=3], other embolization [n=3]) from January 2018 to September 2018. Exclusion criteria included procedures requiring sheath > 6 Fr, Barbeau D waveform and distal RA diameter < 2 mm on ultrasound. Patients were evaluated for complications during follow-up (range 14-60 days).

Results: Technical success was 95.2% (20/21). There was no major complication. Minor complication (4.8%) included distal RA segmental occlusion (n=1). The failed case required crossover to transfemoral access due to proximal subclavian artery occlusion. Mean haemostasis time is 151.8 minutes (range 120-360 minutes).

Conclusion: Distal TRA at the anatomical snuff box was feasible and safe in various diseases over a range of vascular interventions.

B-0966 11:42

Tunnelled central venous catheters (TCVC) in infants using adult peripheral inserted central catheters (PICC) devices: ten years experience

R. Nourzaie, H. Abbas H.M., L. Monzon, N. Karunanithy, S. Moser, P. Gkoutzios, I. Ahmed, S. Bookah, A. Diamantopoulos; London/UK (romman.nourzaie@nhs.net)

Purpose: Tunnelled Central Venous Catheters (TCVC) is a reliable venous access in infants (up to 12 months). We present our experience with tunnelled adult PICC line devices used in this age group.

Methods and Materials: We retrospectively searched our electronic hospital database for a 10 years period collecting data from consecutive pediatrics patients less than 1 year old, who underwent tunnelled central venous catheter insertion. The patient's demographics, site of access, and procedure details were recorded where outcomes included technical success and post procedure complications.

Results: From April 2008-April 2018 a total of 182 TCVC were inserted in 161 patients (49.7%, n=80 male). Mean age was 100 days (range 0-342) with average weight 4.20 Kg (range 1.80-9.40). The most common indication recorded for insertion was for antibiotics in 41% of cases (n=66) followed by TPN 34.7% (n=56) while other indications were recorded for the remaining cases. Technical success was 99% (n=180). Early complications were seen in 8.8% (n=14) including among others inadvertent line removal in 4.9%, line sepsis in 1.1%, line thrombosis in 1.6% (n=3), and others. Average line functional duration prior to removal was 26 days (range 0-180). The majority of the lines 76.9% lasted for the intended duration of treatment.

Conclusion: Tunneled Central Venous Catheters using adult PICC line devices in infants is a safe technique with excellent success rate and minimal complications rates.

B-0967 11:50

Efficacy of drug-eluting stents ELUVIA in treatment of high grade of femoropopliteal lesions

F. Rosella, T. Gorgatti, A. Vit, V. Gavrilovic, A. Pellegrin, M. Sponza; Udine/IT (francesco.rosella.md@gmail.com)

Purpose: Preliminary study of efficacy about Drug-Eluting Stents (DES) ELUVIA in 39 cases on 27 patients with high grade of symptoms and femoropopliteal lesions.

Methods and Materials: Patients were stratified according to clinical characteristics (age, sex, smoke, diabetes, CKD in HD, dyslipidemia). Lesions were stratified according to TASC II: 3A (7,6%), 2B (5,1%), 2C (69,2%), 7D (17,9%) (average length 95,25mm, DVstd 43,16mm). Primary Outcome was patency at 6, 12 and 18 months during follow up: absence of target lesion revascularization, no significant neointimal hyperplasia at B-Mode US and duplex ultrasound peak systolic velocity ratio of ≤ 2.5 , at clinical visit and EchoColorDoppler control.

Results: Success rate of procedures was 100%: any vascular complications, neither distal embolic events. The rate of primary patency was of 82% at 6 months, 74% at 12 - 18 months. During follow up occurred 9 restenosis/occlusion, 7 in the first 2 months, 6 TASC C and 1 TASC D, retreated with a success rate of 100%, and rate of secondary patency of 100% at 6 months, 91% at 12 months. Only 2 occurred after sixth month, in patients undergone major amputation (1knee, 1leg).

Conclusion: Patency rate was high despite the severity of lesions, and similar to results of studies performed on populations with lower grade of lesions. Study indicates that DES are safe and effective in treatment of high grade of femoropopliteal lesions.

Histogram analysis of CE-MRI for differential diagnosis of pleomorphic adenomas and malignant tumour of parotid gland

K. Xu, Y. Zhang; Zhengzhou/CN (109496417@qq.com)

Purpose: To assess the value of whole tumours volume based on enhancement MR histogram analysis in differentiating between pleomorphic adenomas and malignant tumour of parotid gland.

Methods and Materials: A retrospective analysis was conducted by brain MRI examination and pathology diagnosis of 64 cases of parotid tumour in our hospital. Among them, there were 41 cases of pleomorphic adenomas, 23 cases of malignant tumour of parotid gland. Respectively, to draw the region of interest (ROI) in the enhancement MR transaxial images of two groups on each layer of tumour level using Mazda software and analyse the whole tumour gray histogram, performing a statistical analysis on the two sets of parameters obtained from histograms to find out statistical significance of each parameter.

Results: Through histogram analysis of 12 parameters, these 3 parameters were statistically significant (all $P < 0.05$), including 50%, 90% and 99%, the remaining 9 parameters area, maxnorm, minnorm, mean, variance, skewness, kurtosis, 01%, 10% had no significant difference between the two groups (all $P > 0.05$). Among them, the sensitivity of 90% was 65.9%, the specificity was

73.9%, the area under the curve was 0.703, and the best cut-off value was 236.57, 90% had a high identification efficiency.

Conclusion: Histogram analysis of enhancement MR imaging can provide reliably objective basis for differentiating pleomorphic adenomas from malignant tumour of parotid gland. 90% had a high identification efficiency.

The value of high-resolution diffusion-weighted imaging in differentiating lingual squamous cell carcinoma and lingual lymphoma

B. Wen¹, J. Cheng¹, J. Zhu²; ¹Zhengzhou/CN, ²Beijing/CN (wenbaohong2012@163.com)

Purpose: To investigate the diagnostic value of readout segmentation of long variable echo-trains (RESOLVE) diffusion-weighted imaging (DWI) ($b=1000$ s/mm²) in the evaluation of lingual squamous cell carcinoma and lingual lymphoma.

Methods and Materials: 70 patients with lingual squamous cell carcinoma and 21 patients with lingual lymphoma confirmed by pathology were retrospectively analysed from February 2014 to January 2018; all patients underwent preoperative routine MRI and RESOLVE DWI. The ADC average values of the lesions were calculated; *t* test was used to compare the ADC values of lingual squamous cell carcinoma and lingual lymphoma. Diagnostic performance of ADC value was compared using receiver operating characteristic curves (ROC).

Results: The mean ADC value of lingual squamous cell carcinoma was $(1.09 \pm 0.16) \times 10^{-3}$ mm²/s and lingual lymphoma was $(0.64 \pm 0.11) \times 10^{-3}$ mm²/s, there were statistically significant differences between them ($t=12.40$, $P < 0.001$). The area under the ROC of ADC value differentiating lingual squamous cell carcinoma and lingual lymphoma was 0.999 ± 0.001 . Using ADC value $\leq 0.88 \times 10^{-3}$ mm²/s as the critical value for diagnosing lingual lymphoma and comparing with pathological results, the result obtained had a sensitivity of 100%, specificity of 98.57%, ADC value had high correlations compared with pathological results, and *Kappa* value was 0.970.

Conclusion: RESOLVE DWI is quite effective in differential diagnosis between lingual squamous cell carcinoma and lingual lymphoma.

B-0970 10:55

Staging tongue cancer with the 8th edition of TNM: can MR provide a surrogate of the pathologic DOI?

R. Campora, F.M. Piana Jacquot, I. Zorza, G.M. Agazzi, M. Ravanelli, D. Farina; Brescia/IT (camporic@hotmail.it)

Purpose: To assess the reproducibility of three surrogate methods of DOI measurements applicable to MR and their correlation with N stage at presentation and follow-up.

Methods and Materials: Retrospective analysis on 58 MR scans performed preoperatively in patients affected by SCC of the oral tongue. Two independent operators measured on axial and coronal plane: radiologic tumour thickness (RTT) drawing a line perpendicular to the mucosal surface and reaching the deepest part of the tumour; endophytic tumour (ET) drawing a line between the normal mucosal layers at the extremes of the lesion and from that measuring perpendicularly the tumour depth; reconstructed tumour thickness (TMR), measuring on the unaffected side the distance between normal mucosa and septum, subtracting then the distance between the deepest part of the tumour and the septum. Reproducibility was measured with ICC and Bland-Altman and clinical correlations were studied with Mann-Whitney test.

Results: Considering all techniques, ICC showed scored 0.9265 as worst value, Cohen's *k* scored 0.6463 as worst value. ET in the coronal plane was the only measurement significantly correlated to N stage (median in pN0 patients 6.7mm, in pN+ 10.6mm $p=0.0066$) and recurrences (median in R0 patients 5.9mm, in R1 13.9mm $p=0.0332$).

Conclusion: MR measurements showed acceptable reproducibility between two operators with very different experience. ET in the coronal plane appears a viable surrogate to the pathologic DOI.

B-0971 11:03

Parotid tumours differential diagnosis: MRI dynamic contrast-enhanced (DCE) and diffusion-weighted imaging (DWI) compared to fine needle aspiration cytology (FNAC)

G. Guazzarotti, E. Venturini, R. Mellone, A. De Gaspari, D. Di Santo, A. Del Maschio, F. De Cobelli; Milan/IT (guazzarotti.giorgia@hsr.it)

Purpose: To determine diagnostic accuracy of combined evaluation of DWI and DCE in the differential diagnosis of parotid tumors, compared to FNAC.

Methods and Materials: Patients with parotid lesion underwent preoperative multiparametric MRI (T2, T1, DWI [b:0-1000], DCE) and FNAC. Mean ADC was measured by ROI avoiding necrosis and compared to mean muscle ADC, obtaining ADCratio (rADC). 2 rADC thresholds (identified by ROC analysis) were used to obtain 3 groups: pleomorphic adenomas (PA)/cysts (Cy), lymphomas (L), indeterminate lesions. For indeterminate lesions, Time-Intensity Curves (TIC) were evaluated and classified as type A (time to peak [TTP] ≥ 150 s),

B(TTP<150s, washout ratio[WR]≥30%), C(TTP<150s, WR<30%), D(flat); type C were considered malignant. Sensitivity(SE), specificity(SP), positive and negative predictive values(VPP,VPN) were evaluated using histology as gold standard. Diagnostic accuracy of FNAC and MRI were compared.

Results: We evaluated 44 benign(19 PA, 2 basal cell adenomas[BA], 18 Warthin[W], 2 IgG4 disease[IG], 3 Cy), and 13 malignant lesions(7 carcinomas[K], 2 metastases[M], 4 L). 2 rADC thresholds were identified to distinguish PA/Cy(rADC>1.37; AUC=0.96) and L(rADC<0.57; AUC=0.96) to obtain 3 groups: rADC<0.57(3/4L), rADC>1.37(17/19PA, 3/3Cy, 1/18W, 1/7 K), 0.57<rADC<1.37(17/18W, 2/19AP, 2/2BA, 2/2IG, 6/7K, 2/2M, 1/4L). We analyzed TIC for 0.57<rADC<1.37 group, considering type C as malignant (6/6K, 1/2PA, 2/2BA). Combining DWI and DCE we correctly diagnosed 52/57 lesions (91.2%): 11 True Positives (TP), 2 False Negative (FN), 41 True Negatives (TN), 3 False Positives (FP) with 84.6%SE, 93.2%SP, 78.6%VPP and 95.3%VPN. T1&T2 signal and morphology did not allow a better characterization of FP&FN results. 54 patients underwent FNAC, with 8 non-diagnostic finding and 46 adequate specimens: 7 revealed malignant cells, 39 benign lesion, with 7TP, 1FP, 5FN, 33TN. FNAC correctly discriminated between benign and malignant lesions in 74% cases (40/54), fewer than MRI. **Conclusion:** DWI and DCE allow to confidently discriminate benign and malignant parotid tumors in preoperative work-out, representing a valid alternative to FNAC.

B-0972 11:11

The value of RESOLVE on 3.0 T MRI for predicting the early efficacy of concurrent radiochemotherapy of advanced stage nasopharyngeal carcinoma patients

C. Xu; Zhengzhou/CN (xcm-1977@163.com)

Purpose: To discuss the value of RESOLVE for predicting early therapeutic effect of concurrent radiochemotherapy in advanced stage nasopharyngeal carcinoma patients.

Methods and Materials: The ADC value and the area of the tumour was measured before treatment and 2 weeks after treatment independently performed by two radiologists with 5 years experiences and the agreement evaluation was performed using ANOVA analysis. The difference between pretreatment ADC value was compared in CR group and non-CR group by independent sample *t* test. ROC curve was drawn and the maximum Youden index value was the cutoff calculating the ADC value and predicting the sensitivity, specificity and area under the curve.

Results: (1) The agreement between 2 radiologist was excellent. The ICC values of the ADC and the area of the tumour before treatment and the area of the tumour after treatment were 0.89, 0.92 and 0.95, respectively. (2) The pretreatment ADC values of the CR group and the non-CR group were $(0.877 \pm 0.103 \times 10^{-3})$ and $(0.779 \pm 0.078 \times 10^{-3})$ mm²/s, respectively. There was statistical difference (*t* value=2.874, *P* value=0.005). (3) ROC curve showed that the sensitivity and specificity of the pretreatment ADC value in predicting CR was 85.2% and 71.0%, with the cut-off value of 0.792×10^{-3} mm²/s, and the area under curve was 0.778. (4) There was apparently correlation between the pretreatment ADC value and the tumour regression rate (*r*=0.333, *P*=0.006).

Conclusion: There was important value using the pretreatment ADC value measured by RESOLVE for predicting the early effect of concurrent radiochemotherapy in advanced stage nasopharyngeal carcinoma patients.

B-0973 11:19

Impact of radiologic imaging revision in the multidisciplinary management of head and neck cancer patient

D. Rossi¹, D. Alterio¹, S. Volpe¹, F.A.K. Pounou¹, C. Giannitto¹, M. Ansarin¹, M. Bellomi¹, B.A. Jereczek-Fossa¹, L. Preda²; ¹Milan/IT, ²Pavia/IT (duccio.rossi@ieo.it)

Purpose: To quantify impact of radiologic images revision performed by expert radiologists in the context of multidisciplinary team (MDT) discussion of head and neck cancers.

Methods and Materials: We retrospectively reviewed all cases discussed at MDT meetings from April 2014 to April 2017 and selected only those for whom a radiologic revision was required. Any changes of the radiologic description compared to the original chart was collected and classified as follow: 1) changes of radiological staging 2) changes in treatment strategy categorized as "major changes" and as "minor changes".

Results: 540 cases were analyzed. Imaging revision was required at the time of tumour diagnosis in 310 (57.4%) cases and most of patients (69%) had advanced stage (III and IV) tumour. In 262 (48%) cases no changes of the initial radiologic report was performed. In a total of 144 (27%) cases the available imaging was not considered sufficient for a final indication to treatment a further analysis were required. In the remaining 134 (25%) cases, the radiologic revision lead to a modification of either tumor staging (55%) or treatment strategy (45%). Specifically, major and minor modifications were applied in 44 (13%) and 17 (11%) of the considered cases, respectively.

Follow-up was available for 118 (86%) cases and showed that MDT decision was correct in 117/118 (99%) cases, with 43 patients having an histological confirmation.

Conclusion: Our data strongly confirm the paramount importance to include an expert head and neck radiologist in the core of each Institutional head and neck MDT.

B-0974 11:27

Quantification of heterogeneity to classify benign parotid tumours

F. Patella¹, M. Sansone², G. Franceschelli¹, R. Fusco², M. Pettrillo¹, F. Pesapane¹, S. Zannoni¹, P. Brambillasca¹, G. Carrafiello¹; ¹Milan/IT, ²Naples/IT (battellina@gmail.com)

Purpose: To measure heterogeneity to classify Warthin tumours (WT) and pleomorphic adenomas (PA) of parotid glands by correlating functional IVIM and DCE-MRI histogram parameters with pathology.

Methods and Materials: A total of 36 pathologically proven parotid tumours (18 WT and 18 PA) in 25 consecutive enrolled patients were included in this study. For both DCE-MRI and DW-MRI, model-free and model-based parameters were computed voxel-by-voxel on manually segmented VOIs. For each lesion, the following functional biomarkers were considered: Ktrans, kep, vp, MRE, TTP, WIS, WOS, WOR, MRE, f, D, D*. A histogram analysis was performed, identifying for each MRI biomarker central tendency features (mean, median) and heterogeneity parameters (standard deviation, kurtosis, skewness, mad, entropy and energy). The Wilcoxon signed-rank test was used to compare the histogram characteristics in WT and PA. Furthermore, ROC curves and multivariate analysis were employed to identify, respectively, the parameters and the pairs of parameters with the best accuracy.

Results: Univariate analysis findings showed that almost all biomarkers exhibit significant difference between PA and WT either for central tendency or heterogeneity parameters (*p* value <0.05 at Wilcoxon signed-rank test). As regards the ROC analysis, after cross-validation, the highest area under curve (AUC) was achieved using TTP median and skewness and by D* median and entropy. With respect to the multivariate analysis, it seems that no meaningful improvement of classification performance can be obtained using two features.

Conclusion: Differential diagnosis of WT and PA may benefit from the use of IVIM and DCE parameters and from the information provided by histogram descriptors.

B-0975 11:35

Lesion-parenchyma ratio of DCE-MRI pharmacokinetic parameters for characterization of salivary gland tumours

F. Mungai¹, G.B. Verrone¹, M. Pietragalla², L. Bonasera¹, M. Bartolucci¹, V. Miele²; ¹Florence/IT, ²Pistoia/IT, ³Rome/IT (f.mungai@gmail.com)

Purpose: Quantitative data derived from pharmacokinetic (PK) modeling of dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) are affected by high variability and their clinical use in characterizing tumours is controversial due to low reproducibility. This study introduces a clinically feasible method using DCE-MRI data for characterization of principal salivary gland tumours.

Methods and Materials: DCE-MR images were acquired from 60 patients with salivary gland tumours. For each patient, PK parameters of Ktrans, Kep, Ve, Vp, and iAUC (using modified Tofts model) were measured on both the lesion and the normal contralateral salivary gland parenchyma. Lesion-Parenchyma ratio (L/P) for each parameter was then calculated. ANOVA and ROC analysis were performed.

Results: Five groups of lesion were identified (reference standard: histopathology): pleomorphic adenomas (n=20), Warthin tumours (n=16), other benign entities (n=4), non-Hodgkin lymphomas (n=4) and malignancies (n=16). Among groups there were significantly different mean values of L/P-Ktrans (*p*=0.026), L/P-Kep (*p*=0.019), L/P-Ve (*p*=0.010), L/P-Vp (*p*=0.010) and L/P-iAUC (*p*=0.004). Ratio values higher than 1.0 were found for L/P-Ktrans in malignancies (mean value 1.966); L/P-Ve in adenomas (2.051), other benign entities (1.081) and malignancies (1.591); L/P-Vp in Warthin tumours (1.943) and malignancies (3.797); L/P-iAUC in malignancies (2.106). ROC analysis demonstrated the highest area under the curve (AUC=0.94) for L/P-iAUC, with sensibility and specificity for malignancy, respectively, of 88% and 100% (cut-off value=1.035).

Conclusion: The use of lesion-parenchyma ratio of DCE-MRI quantitative data can provide a robust and accurate method for characterization of salivary gland tumours and can be easily implemented in clinical routine.

Automatic segmentation for acute ischaemic stroke from DWI using deep convolutional neural networks

Q. Liu¹, G. Lu¹, X. Cheng¹, Q. Zhang¹, C. Zhou¹, S. Wang², K. Liang², X. Li²; ¹Nanjing/CN, ²Beijing/CN (349566651@qq.com)

Purpose: DWI hyperintensity region is one of the most important indicators of acute cerebral infarction. Our study is aimed at presenting a U-NET based Deep Convolutional neural network for acute ischaemic stroke lesion segmentation in DWI automatically and accurately. The model will lay the foundation for the follow-up research in AI, including lesion measurement, location and automatic recognition of responsible vessels.

Methods and Materials: Our study is validated on a dataset comprising clinical acquired DWI from 484 patients (2012-2017). All images are manually tagged. For each 3D slice, we combine the upper and lower slices as a 3-channel input to fuse the 3D information. The network has an analysis and a synthesis path. Each path contains three resolution steps. For the analysis path, each layer has two convolutions followed by ReLU activations. For the synthesis path, each layer consists of an upconvolution and two convolutions each followed by a ReLU activation. MRI equipment type distribution ('SIEMENS': 333, 'GE': 151). Training set included 434 samples, validation set includes 50 patients. The result is mainly evaluated by Dice coefficient.

Results: The experiment results show that the algorithm is both reasonable and effective compared with the results of manual annotation. The Dice coefficient is 0.823. (Sensitivity 0.916, Precision 0.850, Accuracy 0.850).

Conclusion: We present a deep convolutional neural network for acute ischaemic stroke lesion segmentation in DWI, which do preparations for the follow-up correlation studies. Automatic segmentation can save manpower and material resources for large data annotation. In addition, this model can help beginners to distinguish lesions and artefacts.

Can artificial intelligence improve physician sensitivity in detecting early ischaemic damage on computed tomography?

J. Chriashkova¹, C. Goncalves², M. Aslam², S. Perera², S. Walter³, J. Fisher², A. Podlasek², A.J. Schmitt⁴, I.Q. Grunwald¹; ¹Chelmsford/UK, ²Southend-on-Sea/UK, ³Homburg/DE, ⁴London/UK (julija.chriashkova@anglia.ac.uk)

Purpose: ASPECTS (Alberta Stroke Program Early CT Score) is a validated scoring system for assessment of early ischaemic change (EIC) on CT scans. This can be challenging particularly for less experienced clinicians. e-ASPECTS software uses machine learning algorithms to support physicians in detecting EIC using ASPECTS score.

Methods and Materials: 26 clinicians (11 radiologists, 6 junior and 7 consultant stroke physicians, 2 non-specialist physicians) independently scored 2560 ASPECTS regions from 64 patients for evidence of EIC on non-contrast CT brain acquired within 4.5 hours of stroke onset. A familiarization training set of 5 patients was used prior to scoring. Images were randomized to manual or software assistance. After two weeks images were rescored using the alternative method. Scorers were blinded to clinical symptoms. Reference standard scores were defined by an independent neuroradiologist with information on clinical symptoms, 24h follow-up, and CT perfusion / MRI scans when available.

Results: Mean NIHSS was 11. Mean time to score decreased by 34% (45s, 2:12 to 1:27, mm:ss) using e-ASPECTS assistance. Rater agreement with ground truth was greatest in the radiologist cohort, but performance improved across all clinician categories using e-ASPECTS assistance (radiology kappa: 0.26 to 0.38). Sensitivity to EIC improved by a factor of two across all clinician groups using e-ASPECTS assistance, particularly for less experienced physicians.

B-0976 11:43

Theatre radiology: making the inoperable operable with real time, intraoral ultrasound guided trans oral robotic surgery

A. Jaly, D. Ap Dafydd, V. Paleri, J. Hardman; London/UK

Purpose: Trans-oral robotic surgery is minimally invasive and has generated promising early results. We illustrate our experience using intra-oral ultrasound, intraoperatively to assess oropharyngeal tumours and guide trans-oral robotic surgery.

Methods and Materials: 12 month period: February 2018 to February 2019
Inclusion criteria: Cases suitable for TORS (T1/T2 tumours, recurrences, good mouth opening) Exclusion criteria: Limited mouth opening, high risk anatomy. All patients assessed whilst under general anaesthesia. A fine, linear intra-operative pencil probe (18 MHz) is applied to the lesion, prior to and/or after introduction of the robotic arms

Ultrasound findings cross-referenced with available pre-operative imaging and collaboratively mapped by the radiologist and surgeon.

Results: Good visual correlation of tumour morphology with CT/MR Greater access to the posterior tongue and oropharynx under general anaesthesia. Improved confidence of surgeon in orientating dissection planes. Where contact between the ultrasound probe and posterior oropharyngeal tumours is difficult due to curvature of the tongue, it would be feasible to flood the intubated pharynx with water enabling ultrasound conduction without direct probe contact. Ultrasound of the resected tumour tissue is performed to ensure adequate margins resected.

Conclusion: Oncological outcomes of TORS can be comparable to open surgery and transoral laser microsurgery. Added advantages are en bloc resection and inset of free flaps without mandibular split. Less blood loss, shorter patient hospital stay and overall lower complications are seen. The head and neck radiologist plays a vital role using intra-oral ultrasound to guide the surgeons orientation of excision planes with a view to optimising surgical margins.

Usefulness of CT perfusion generated time-density curves and perfusion parameters in the diagnosis and differentiation of parotid neoplasms

M. Swarup, L. Upreti; Delhi/IN (sarthak163@gmail.com)

Purpose: To evaluate role of Time-density curves (TDCs) and perfusion values generated from CT perfusion (CTP) in diagnosis and differentiation of parotid neoplasms.

Methods and Materials: CTP was performed in 32 patients on a 64 slice MDCT scanner. Data were analysed by deconvolution based software to obtain maps for blood flow (BF), blood volume (BV), mean transit time (MTT), and capillary permeability (PS). Regions of interest were placed through tumour to obtain perfusion values and tissue Time ~ Density curves. TDCs were classified into four types based on time to peak enhancement (TTE) and washout ratio (WR). Mann-Whitney U test was used for comparison of perfusion values. Final diagnosis was established by postsurgical histopathology examination.

Results: Study revealed 20 benign and 12 malignant lesions. Among pleomorphic adenomas 8 type A, 3 type C and one type B curve was seen. Two Warthin tumours showed type B curve. Two benign cysts showed type D curve. TDC type was variable in malignant tumours with 2 type A, one type B and 9 type C curves. The malignant tumours showed higher BF, BV and PS values and lower MTT value compared to benign tumours. The BF, BV and PS values (p < 0.001, p < 0.001, p < 0.001) were statistically significant in differentiating pleomorphic adenomas from malignant tumours.

Conclusion: TDCs obtained from dynamic CT perfusion of the parotid gland could considerably improve diagnostic accuracy and is helpful in differentiation of various parotid neoplasms complimentary to perfusion values and conventional contrast CT.

Conclusion: In acute ischaemic stroke e-ASPECTS assistance increased accuracy and reduced time for detection of EIC. Routine assistance in CT interpretation has the potential to reduce time to treatment and improve accuracy across clinicians and sites.

Automated detection and localisation of pneumocephalus in head CT scan

S. [Tanamala](#)¹, S. Chilamkurthy¹, M. Biviji², P. Rao¹, R. Ghosh¹; ¹Mumbai/IN, ²Nagpur/IN (swetha.tanamala@qure.ai)

Purpose: Pneumocephalus, accumulation of air in intracranial space, can lead to midline shift and compression of brain. In this work, we detail the development of deep learning algorithms for automated detection and localization of pneumocephalus in head-CT scans.

Methods and Materials: Firstly, to localize the intracranial space from a given head-CT scan, a skull-stripping algorithm was developed using a randomly sampled anonymized dataset of 78 head CT scans (1608 slices). We sampled another anonymized dataset containing 83 head-CT scans (3546 slices) having pneumocephalus and 310 normal head-CT scans which were randomly sampled to represent natural distribution. These 3546 slices (932 slices had pneumocephalus) were annotated for pneumocephalus regions. Then UNet based deep neural network algorithm was trained on these scans to accurately predict the pneumocephalus region. The predicted pneumocephalus region is refined by removing the regions outside the intracranial space identified by the skull stripping algorithm. The refined pneumocephalus region is then used to extract features. Using these features, a random forest was trained to classify the presence of pneumocephalus in a scan. Areas under receiver operating characteristics curves (AUC) were used to evaluate the algorithms.

Results: An independent dataset of 1891 head-CT scans (40 scans had pneumocephalus) was used for testing above algorithms. AUC for the scan level predictions was 0.89. Sensitivity and Specificity of 0.80 and 0.83 respectively were observed.

Conclusion: In this work, we showed the efficacy of deep learning algorithms in localizing and classifying the pneumocephalus accurately in a head-CT scan.

Automatic detection of intracranial calcifications in CT using deep learning

G. [Bortsova](#), F. Dubost, A. Van der Lugt, D. Bos, M. De Bruijne; *Rotterdam/NL* (gerdabortsova@gmail.com)

Purpose: Intracranial carotid artery calcification (ICAC) is a major risk factor for stroke, and might contribute to dementia and cognitive decline. Further research into the relationship between ICAC and neurological diseases is hampered by the time-consuming manual annotation of ICAC lesions. Therefore, we introduce a fully automatic ICAC detection method.

Methods and Materials: Non-contrast-enhanced CT scans were performed in 2319 participants of the Rotterdam Study, a population-based cohort study (mean age 69.6(6.8), 51.7% female). Two trained observers annotated the scans by indicating regions of interest (ROI) on the intracranial carotid artery (from the horizontal petrous segment to the circle of Willis) where calcifications were visible. ICAC lesion segmentations were obtained by thresholding these ROIs at 130 HU. We developed a deep learning based algorithm to automatically delineate ICAC lesions in CT scans. The performance was estimated by 10-fold cross-validation.

Results: Pearson correlation between ICAC volumes computed from manual and automatic ICAC segmentations was 98%. The interrater agreement was 96%. For patients with ICAC, median sensitivity was 87% (74, 95) and false positive volume (FPV) was 5.4mm³ (1, 19.5). Median FPV to ground truth volume ratio was 0.07 (0.02, 0.2). For ICAC-free patients, median FPV was 1.4mm³ (0.1, 5.5).

Conclusion: Our algorithm can be used to automate the time-consuming manual annotation of ICAC in large epidemiological studies, whilst maintaining a comparable level of accuracy. This can facilitate research into causes and consequences of ICAC, which might result in development of new treatments.

Automated age-specific regional brain atrophy estimation: an integrated workflow

J. [Caspers](#), B. Turowski, C. Rubbert; *Düsseldorf/DE* (Julian.Caspers@med.uni-duesseldorf.de)

Purpose: Estimating deviations of regional brain volume from a patient's normative age cohort is challenging and entails immense inter-reader variations. We propose an automated workflow for age-dependent estimation of brain volume changes relative to a standard population.

Methods and Materials: 3D T1w MRIs of 693 healthy subjects aged between 16 and 77 years from the publicly available enhanced Nathan Kline Institute Rockland Sample were preprocessed to generate age- and gender-specific grey-matter (GM) templates. Preprocessing is performed with CAT12 for SPM12 and comprises GM segmentation, normalization to MN152 and 8mm smoothing. For each age between 18 and 75, voxel-wise mean and standard deviation (SD) maps were generated across all subjects of the respective age ± 2 years. To estimate volume changes of an out-of-sample subject, a 3D T1w scan is preprocessed in the same way as for template generation. Then a voxel-wise z-value map is generated from the resulting normalized GM map using the age-dependent mean- and SD-templates. The z-map is transformed into subject space, colour coded and fused with the structural MRI.

Results: The proposed workflow can be implemented in a parallelized fashion on a state-of-the-art server to automatically generate individual atrophy maps and send them into the PACS. Processing of one subject is feasible in less than 10 minutes. The colour-coded maps fused with the structural MRI allow for direct semi-quantitative detection of regional brain volume deviations in individual patients.

Conclusion: Automated brain volume change estimation as implemented in the presented framework is feasible and could significantly facilitate radiologic workflows.

Radiological reading: man vs machine

W. [Van Hecke](#)¹, A. Ribbens¹, T. Billiet¹, T. Wang², L. Ly², H.N. Beadnall², M.H. Barnett²; ¹Leuven/BE, ²Sydney/AU (wim.vanhecke@icomatrix.com)

Purpose: MRI is of paramount importance in the diagnosis and monitoring of patients with multiple sclerosis (MS). Typically, MRI scans are obtained yearly and are crucial to assess disease activity, and therefore therapeutic decision-making, in MS patients. As MS is an inflammatory and neurodegenerative disease, both lesions T2/FLAIR and brain atrophy on T1 should be evaluated. The aim of this study was to assess the quality of clinical radiological reports in patients with MS and to compare these with a radiological structured reporting review and clinically cleared automated software.

Methods and Materials: Lesion burden and whole brain atrophy was assessed on baseline MRI scans of 50 MS patients (RRMS or SPMS) in 3 different ways: (1) a standard clinical radiological report, (2) a structured radiological report assessed by a neuroradiologist, (3) quantitative assessment using the CE/FDA cleared icobrain software. A statistical comparison between the three different reporting methods was performed evaluating T2/FLAIR lesion load and brain atrophy.

Results: A large discrepancy was found between the radiological report and the expert structured review (i.e. 50% vs 100% of the reports mentioned lesion burden at baseline and 24% vs. 48% mentioned brain atrophy). On the contrary, the expert assessment and the quantitative icobrain results showed a high similarity ($p < 0.001$, ANOVA comparing both assessments in terms of small vs. severe lesion load/atrophy).

Conclusion: These results demonstrate that automated and clinically cleared MRI software outperforms a standard radiological report in the assessment of disease status on MRI in patients with MS.

Predicting response to somatostatin analogues in acromegaly: machine learning-based high-dimensional quantitative MRI texture analysis

B. [Kocak](#), E. Memis Durmaz, P. Kadioglu, O. Polat Korkmaz, N. Comunoglu, N. Tanriver, N. Kocer, C. Islak, O. Kizilkilic; *Istanbul/TR* (drburakkocak@gmail.com)

Purpose: To investigate the potential value of machine learning (ML)-based high-dimensional quantitative texture analysis (qTA) against previously suggested relative signal intensity (rSI) evaluation on T2-weighted magnetic resonance imaging (MRI) in predicting response to somatostatin analogs (SAs) in acromegaly patients with pituitary macroadenomas.

Methods and Materials: Forty-seven patients (24 responsive, 23 resistant to SAs) were eligible for this retrospective study. Following image processing steps, 828 texture features were extracted from coronal T2-weighted images by manual segmentation of the whole tumour for each patient. Dimension reduction was first done with a reproducibility analysis by two radiologists and then with a wrapper-based algorithm using a nested cross-validation. The macroadenomas were also grouped according to their rSI (hypointense versus others) on T2-weighted MRI. The ML classifiers for qTA and rSI evaluation were k-nearest neighbours (k-NN) and J48, respectively. Reference standard for classifications was biochemical response and resistance. Main performance metric for comparison was area under the curve (AUC).

Results: Only 535 out of 828 texture features had excellent reproducibility. Among these, the wrapper-based algorithm yielded 4 textural features. Using qTA, the k-NN algorithm correctly classified 85.1% of the macroadenomas in terms of response to SAs with an AUC of 0.847. Using rSI, the J48 classifier correctly classified 53.1% of the macroadenomas with an AUC of 0.468. There was statistically significant difference between qTA-based classification and rSI-based classification performances ($P < 0.05$).

Conclusion: The machine learning-based qTA of T2-weighted MRI might be a potential non-invasive tool in predicting response to SAs in patients with acromegaly and pituitary macroadenomas.

Combining multiple magnetic resonance imaging sequences provides independent reproducible radiomics features

L. Duron, A. Lecler, D. Balvay, J. Savatovsky, O. Bergès, A. Bouhouicha, O. Galatoire, L. Fournier; Paris/FR (loic.cmprepa@gmail.com)

Purpose: To evaluate the relative contribution of different Magnetic Resonance Imaging (MRI) sequences for the extraction of radiomics features in a cohort of patients with lacrimal gland tumors.

Methods and Materials: This prospective study was approved by the Institutional Review Board and signed informed consent was obtained from all participants. From December 2015 to April 2017, 37 patients with lacrimal gland lesions underwent MRI before surgery, including axial T1-WI, axial Diffusion-WI, coronal DIXON-T2-WI and coronal post-contrast DIXON-T1-WI. Two readers manually delineated both lacrimal glands to assess inter-observer reproducibility and one reader performed two successive delineations to assess intra-observer reproducibility. Radiomics features were extracted using an in-house software to calculate 85 features per region-of-interest (510 features/patient). Reproducible features were defined as features presenting an intra-class correlation coefficient ≥ 0.8 and a concordance correlation coefficient ≥ 0.9 across combinations of the three delineations. Among these features, the ones yielding redundant information were identified as clusters using hierarchical clustering based on the Spearman correlation coefficient.

Results: All the MR sequences provided reproducible radiomics features (range 14(16%)-37(44%)) and non-redundant clusters (range 5-14). The highest number of features and clusters were provided by the water and in-phase DIXON T2-WI and water and in-phase post-contrast DIXON T1-WI (37, 26, 26 and 26 features and 14, 12, 9 and 11 clusters, respectively). A total of 145 reproducible features grouped in 51 independent clusters were provided by pooling all the MR sequences.

Conclusion: All MRI sequences provided reproducible radiomics features yielding independent information which could potentially serve as biomarkers.

B-0988 11:34

Glioblastoma survival prediction using residual tumour volumes detected and segmented by a deep learning model in post-operative MRI

M. Perkuhn, P. Stavrinou, R. Shahzad, F. Thiele, G. Shakirin, D. Garmpis, M. Schlamann, J. Borggrete; Cologne/DE (michael.perkuhn@uk-koeln.de)

Purpose: Cytoreductive surgery is the cornerstone of glioblastoma (GB) therapy and residual tumour volume is considered to be an important outcome measure. Contrast-enhancing residual tumour volume (CE-RTV) on MRI is known to predict survival. However, interpretation of MRI is challenging due to e.g. small tumour volumes and is associated with high inter-rater variability. Our objective was to evaluate survival prediction of three CE-RTVs, obtained from human readers and a deep learning model (DLM).

Methods and Materials: 80 GB patients were retrospectively included, with age=60±12y, Karnofsky performance score (KPS)=85±14. On post-operative MRI, acquired 24-48 hours after surgery, CE-RTV were manually delineated by two experts (radiologist, neurosurgeon). In addition, CE-RTV were segmented by a fully automatic DLM. Impact of CE-RTV on prediction of overall survival (OS) and progression free survival (PFS) was assessed using Cox proportional hazard modelling with censored data. Age and KPS were included as covariates.

Results: Median survival was 16.8 months (OS) and 8.8 months (PFS). CE-RTV correlations (R) were 0.73 (radiologist-neurosurgeon), 0.67 (radiologist-DLM). CE-RTV were found to be significant predictors of PFS: radiologist

(Hazard ratio (HR)=1.1, $p < 0.02$), neurosurgeon (HR=1.1, $p < 0.02$), DLM (HR=1.2, $p < 0.001$), age and KPS were not significant. For OS, only age was a significant predictor (HR=1.03 $p < 0.03$). KPS and CE-RTVs were not significant. **Conclusion:** Fully automatic quantification of CE-RTV by the DLM was found to be a significant predictor of PFS in post-operative GB, showing the potential of automatic CE-RTV segmentation. For the OS, additional covariates like treatment modalities and performance scores after progression need to be investigated.

4D-flow-based monitoring of pulmonary pressure in patients with pulmonary hypertension: a feasibility study

G. Reiter¹, G. Kovacs¹, C. Reiter¹, C. Kräuter¹, A. Greiser², H. Olschewski¹, M.H. Fuchsjäger¹, U. Reiter¹; ¹Graz/AT, ²Erlangen/DE (gert.reiter@siemens-healthineers.com)

Purpose: Longitudinal haemodynamic follow-up of patients with pulmonary hypertension (PH) is important for individual treatment response monitoring. The purpose of this study was to analyze the potential of magnetic resonance 4-dimensional (4D) flow-derived duration of vortical blood flow along the main pulmonary artery to predict alterations of mean pulmonary arterial pressure (mPAP).

Methods and Materials: 29 patients with borderline mPAP or PH repeatedly (2.5±2.3 years) underwent right-heart catheterization (RHC) and near-term, time-resolved, 3-directional phase-contrast imaging at 1.5T or 3T covering the main pulmonary artery. Duration of vortical blood flow along the main pulmonary artery (t_{vortex}) were evaluated from velocity vector-fields using prototype software (4DFlow, Siemens Healthcare). The relationship between RHC-derived mPAP differences (ΔmPAP) and differences of t_{vortex} (Δt_{vortex}) at baseline and follow-up assessment were analyzed by means of correlation and regression analysis. The diagnostic performance of Δt_{vortex} to predict ΔmPAP increases ($\Delta\text{mPAP} > 0$ mmHg) or decreases ($\Delta\text{mPAP} < 0$ mmHg) was investigated by receiver operating characteristic curve analysis.

Results: Mean mPAP at baseline was 44±11 mmHg and 44±14 mmHg at follow-up; ΔmPAP ranged from -20 to +37 mmHg. Δt_{vortex} correlated strongly with ΔmPAP ($r=0.92$), and root mean square error of the regression of ΔmPAP on Δt_{vortex} was 5 mmHg. Areas under the curve for predicting increases/decreases of mPAP were 0.95/0.94. The cut-off $\Delta t_{\text{vortex}}=8\%$ resulted in sensitivity/specificity=0.90/0.95 for the prediction of mPAP increases, the cut-off $\Delta t_{\text{vortex}}=0\%$ in sensitivity/specificity=0.94/0.83 for the prediction of mPAP decreases.

Conclusion: 4D-flow-derived duration of vortical blood flow along the main pulmonary artery allows accurate mPAP monitoring in patients with PH.

Towards virtual MR imaging: predicting diffusion-weighted brain MR images from T2-weighted images using convolutional neural networks

V. Mahajan, A. Upadhyaya, A. Venkatraman, V. Venugopal; New Delhi/IN (vidur@mahajanimaging.com)

Purpose: In a quest for standardisation and speeding up of MR imaging, there is a move towards having a 'universal' MRI sequence from which all MR contrasts can be obtained. We propose first-of-its-kind virtual MR imaging where we predict "virtual" diffusion-weighted (DW) images of the brain from axial T2W images using convolutional neural networks (CNN).

Methods and Materials: 100 whole-brain MRI scans of patients with no abnormality and 30 with acute infarcts, comprising 25 T2W and DWI ($b=1000$) slices each, acquired retrospectively, were fed into a 15-layered CNN model with a 75-25 training-validation split. T2W images were assigned as the input to predict DW Images. Binary cross entropy was used as the loss function and

training took 48 hours on an Nvidia 1080ti GPU. For testing T2W, images from 5 independent cases, having 7 T2 hyperintensities with corresponding diffusion restriction (group 1) and 16 with no diffusion restriction (group 2), were also analysed.

Results: Binary cross entropy of 0.15 for normal and of 0.11 for infarct cases was obtained. The model took 750ms to produce each image. In the test cases, 6 out of 7 T2 hyperintensities in group 1 showed diffusion restriction and all 16 T2 hyperintensities in group 2 did not show restriction. The one 'missed' lesion in group 1 was 2.5mm in diameter. Blurring of virtual DW images was observed, which did not impede clinical judgement.

Conclusion: We demonstrate a novel use-case for deep learning in reducing the MRI exam time and potentially creating a single universal MRI sequence.

B-0991 10:46

An inter and intra patient radiomic study to select the most promising features aiming to precision medicine feasibility

C. De Mattia, R. Ronza, M. Grassi, M. Pecorilla, P.E. Colombo, S. Siena, A. Vanzulli, A. Torresin; Milan/IT (cristina.demattia@ospedaleniguarda.it)

Purpose: To characterize with radiomics techniques the pulmonary metastases of 176 patients, distributed in two cohorts, according to primitive cancer. To identify the features (RFs) variability due to image acquisition, reconstruction, contouring, and to lesions morphology.

Methods and Materials: First, a standard of CT acquisition and image reconstruction was defined. 357 lesions were contoured using Multi-Modality Tumour Tracking (IntelliSpace Portal 9.0, Philips). For each lesion, 865 RFs were extracted using IBEX platform, v1.0 β . For each RF, we evaluated Student t test and relative discrepancy between the two cohorts. For each exam, in all lesions we calculated the relative discrepancy changing scan phase, reconstruction filter, layer thickness and segmentation parameters. Ibox can analyze only the layer where the lesion appears larger (2D) or the entire lesion volume (3D). We compared the two methods.

Results: We identified 12 promising RFs (p-value<0.01). Intra-cohort ANOVA test showed no scanner and voltage dependence, excluding images reconstructed with iterative filters. All RFs strongly depend on phase and reconstruction filter, with relative discrepancies over 1000%. Autocorrelation, sum average, sum variance, HGLRE, LRRGLE and SRHGLE are the less dependent on these parameters (relative discrepancy <50%). Segmentation seems to be the less relevant factor on the RFs variability. Generally, RFs more sensitive to lesion morphology are also those more affected by modifications of the above-mentioned parameters. From 3D analysis to 2D, discrepancy can be more than 1000%.

Conclusion: A lesion by lesion radiomic characterization is possible, provided that it is obtained with a standardization process of the radiomic workflow.

B-0992 10:54

A novel machine learning approach for assessing osteoporotic fracture risk by texture analysis of femoral neck radiographs

T. Yeshua, S. Rebibo, K. Sfez, O. Safran, M. Liebergall, I. Leichter; Jerusalem/IL (Izhak@hadassah.org.il)

Purpose: Bone strength is determined not only by its mineral density but also by the spatial structure of bone trabeculae. Our aim was to assess osteoporotic fracture risk by texture analysis of the proximal femur in routine radiographs, using machine-learning tools.

Methods and Materials: 17 radiographs of in-vitro femurs and routine proximal femur radiographs of 44 subjects (15 with osteoporotic fractures and 29 without a fracture) were analyzed. The critical force required to fracture the in-vitro femurs was measured. The gray-levels of all images were automatically balanced to yield equal brightness and contrast. Two regions-of-interest (ROI) for texture analysis were defined, one in the femoral neck, and the other, distal to the lesser trochanter. Five parameters describing the distribution of the gray-levels in the ROIs and 6 Gray-Level Co-occurrence Matrix (GLCM) parameters, describing the spatial allocation of the gray-levels in the ROIs were defined. Support Vector Machine (SVM) with cross-validation was used to train the algorithm and test its results, based on a combination of both ROIs.

Results: The algorithm characterized the in-vitro weak and strong bones with an accuracy of 88%. The radiographs of the patients were characterized as osteoporotic or non-osteoporotic with an accuracy of 86%. The most prominent features for estimating fracture risk were the mean gray-level, which is related to bone density, as-well-as smoothness, uniformity and entropy, which are related to the spatial distribution of the trabeculae.

Conclusion: Machine-learning tools may be used to analyze routine femoral radiographs and assess fracture risk with high accuracy.

B-0993 11:02

Implementation of channelised hotelling observer (CHO) to assess image quality of GE discovery IGS 740 angiography system

M. Bertolini¹, V. Trojani², A. Nitrosi¹, M. Iori¹, R. Sassatelli¹, O. Ortenzia³, C. Ghetti²; Reggio Emilia/IT, ²Bologna/IT, ³Parma/IT (marco.bertolini@ausl.re.it)

Purpose: To use the well-known CHO to characterize a novel angiography system (GE Discovery IGS 740) using a contrast-detail phantom simulation in a clinical scatter condition.

Methods and Materials: A Leeds TO10 phantom was used. The phantom has 108 details: 12 diameters (size range: 0.25 mm - 11 mm), each with 9 contrasts (declared range: 0.012 - 0.930 at 70 kVp 1.00 with mm Cu filtration). TO10 has been imaged between two 10 cm thick homogeneous solid water slabs. Two FOVs (32 and 20 cm side) were used. Fluoroscopy images were taken using an abdominal protocol at 2 different frame rates (15 fps and 7.5 fps) and at 2 dose levels (low and normal); fluorography images were acquired using an abdominal protocol at 15 fps at 2 dose levels (low and normal). A CHO with 40 Gabor channels was used. An eye-internal noise was added. The model response was compared with human observers for validation. Contrast-detail curves were obtained from the CHO output using a visibility threshold of 75%. Wilcoxon signed rank tests were performed.

Results: The CHO model distinguishes between the 2 dose levels (p<0.002). FOVs and frame rates were not statistically significant (p=0.10 and p=0.18). It's worth noting that fluoroscopy with FOV=20 normal dose level (17.6 mGy/min) was not statistically different (p=0.50) respect to fluorography with FOV=32 low dose level (42.1 mGy/min).

Conclusion: A model observer is an effective tool to evaluate image quality even in clinical protocols optimization thanks to higher results reproducibility compared with human one.

Effective atomic number image produced with energy-resolved photon counting detector toward the development of next-generation plain X-ray diagnosis

N. Kimoto¹, H. Hayashi¹, T. Asakawa¹, T. Asahara², A. Katsumata³, Y. Kanazawa², S. Yamamoto⁴, M. Okada⁴; ¹Kanazawa/JP, ²Tokushima/JP, ³Gifu/JP, ⁴Yokohama/JP (natsumi.kimoto.0717@gmail.com)

Purpose: Analysis of X-ray attenuation is fundamental for developing a material identification method. We have developed a procedure to derive an effective atomic number (Z_{eff}) image using a prototype energy-resolving photon counting detector. In this study, we aim to verify our procedure for the application to diagnosis using plain X-ray.

Methods and Materials: Our method can determine Z_{eff} pixel by pixel. First, the intensity of X-rays before and after penetrating the samples in three energy bins was measured, and the products of linear attenuation coefficient (μ) and material thickness were calculated. Next, beam hardening was properly corrected; the response of a multi-pixel-type CZT detector, energy resolution and charge sharing were also taken into consideration. Then we calculated Z_{eff} by means of our method in which the relationship between μ and Z_{eff} was used. To verify our method, we measured samples of which Z_{eff} was known: acrylic ($Z_{\text{eff}}=6.5$) and aluminium ($Z_{\text{eff}}=13$) having mass thicknesses of 1, 5, and 10 g/cm², and dental samples. Finally, we compared the difference between calculated and reference Z_{eff} .

Results: Our present method can obtain Z_{eff} images with accuracies of $Z_{\text{eff}} \pm 0.5$ regardless of material thickness. Furthermore, we can analyse the fine structure of dental enamel and dentine quantitatively. These results show our method works properly for human body structure material ($Z_{\text{eff}} < 20$).

Conclusion: Using a prototype photon counting detector, we demonstrated the procedure of generating Z_{eff} image. We expected that it has carry-over effect to establishment of new quantitative diagnosis and utilization of plain X-ray to various diseases.

K-edge subtraction imaging at the Munich compact light source

S. Kulpe¹, E. Braig¹, M. Dierolf¹, B. Günther¹, K. Acherhold¹, J. Herzen¹, E.J. Rummeny², F. Pfeiffer¹, D. Pfeiffer²; ¹Garching/DE, ²Munich/DE (stephanie.kulpe@tum.de)

Purpose: About one-third of all deaths worldwide can be traced back to cardiovascular diseases. An important interventional radiology procedure for their diagnosis is digital subtraction angiography (DSA). An alternative to DSA is K-edge subtraction (KES) imaging, which has been shown to be advantageous for moving organs and to eliminate image artefacts caused by

patient movement. As highly brilliant, monochromatic X-rays are required for this method, it has been limited to synchrotron facilities so far, limiting the feasibility in clinical routine.

Methods and Materials: In this study, a filter-based KES method was applied at the Munich compact light source (MuCLS), a compact synchrotron X-ray source based on inverse-Compton scattering, which provides a tunable, quasi-monochromatic X-ray beam. A series of experiments of an excised porcine heart was performed to demonstrate the feasibility of the proposed KES technique. To simulate the situation in a realistic setting, namely ribs of the chest overlying the coronary arteries, a porcine costal arch fixated in formalin was set in front of the heart in the experimental setup.

Results: It is shown experimentally that the technique of KES increases the visibility of small blood vessels overlaid by bone structures. Thereby, the contrast-to-noise ratio (CNR) of the KES images was significantly higher than the CNR of the conventional X-ray image.

Conclusion: The results show that the quasi-monochromatic spectrum of the MuCLS enables filter-based K-edge subtraction imaging. We believe that KES at a compact synchrotron source can become an important tool in pre-clinical research and possible future clinical diagnostics.

Areal bone mineral density estimation using photon-counting energy-discriminating computed tomography topograms

T. Nowak¹, B. Schmidt¹, A. Euler², N. Salybaeva², T. Flohr¹, H. Alkadhi²;
¹Forchheim/DE, ²Zurich/CH (Tristan.Nowak@gmx.net)

Purpose: Dual-energy X-ray absorptiometry (DXA) is a well-established standard for the diagnosis and monitoring of osteoporosis. DXA provides areal bone mineral density (aBMD) maps which are estimated from two spectrally separate planar x-ray images. With the advent of photon-counting energy-discriminating detectors, perfectly aligned multi-energy topograms with good spectral separation can be acquired in a single scan. We investigated the potential of these topograms for a DXA-like aBMD evaluation.

Methods and Materials: A series of topograms of a BMD calibration spine phantom (European Spine Phantom, QRM GmbH, Möhrendorf, Germany) was acquired on a research photon-counting CT scanner (Siemens Healthcare GmbH, Forchheim, Germany). A tube voltage of 140 kV and two energy thresholds of 20 keV and 75 keV were selected. The phantom consists of water-equivalent plastic with diameters of 260 mm (lateral) and 180 mm (anterior-posterior) and holds three anthropomorphic vertebrae, L1-L3, of varying hydroxyapatite content. Collimation and mAs-product were set to 3 mm and 6 mAs. A custom tool was developed to subtract soft tissue and create aBMD density maps from the input topograms. Deviations from the known aBMD values of 0.5, 1.0 and 1.5 g/cm² of the anterior-posterior projections of vertebrae L1-L3 were evaluated.

Results: From the generated aBMD maps, mean values for vertebrae L1-L3 were extracted and averaged across scans. The resulting values of 0.53 ± 0.10 g/cm², 0.99 ± 0.09 g/cm² and 1.45 ± 0.09 g/cm² for L1-L3 were in good agreement with the ground truth.

Conclusion: Our evaluation shows a promising new application for single-scan multi-energy topograms, which might provide an alternative to using dedicated DXA.

Spectral photon-counting for gout diagnosis in plain radiography: a feasibility study

F.A. Huber¹, S. Gkoumas², T. Thuerling², F. Becce³, R. Guggenberger¹;
¹Zurich/CH, ²Baden-Dättwil/CH, ³Lausanne/CH (florian.huber@usz.ch)

Purpose: To distinguish crystal suspensions of monosodium urate (MSU) from calcium hydroxyapatite (HA) deposits in plain radiography.

Methods and Materials: Three suspensions of either MSU (200mg/ml) or HA (150 and 200mg/ml) synthetic crystals in agar were produced at clinical concentrations, each sealed in industry-standard polystyrene and supported on a thick polymethylmethacrylate (PMMA) plate with equal attenuation to cortical bone. Samples were scanned with both conventional radiography using a vendor microfocus X-ray tube (50kV/300uA) and a spectral photon-counting (PC) detector prototype with four energy thresholds per acquisition set at 15, 25, 30 and 35 keV. Images were then reconstructed for the following energy bins: 15-25, 25-30, 30-35 and 35-50 keV. Material decomposition calibration was performed with chemically pure PMMA and polyvinylchloride slabs of multiple different thicknesses, respectively. Using a custom Python-based post-processing software, effective atomic numbers (Z_{eff}) of the respective samples were calculated. All samples were additionally scanned with dual-energy CT (80kV and tin-filtered 150kV) and analysed with a vendor workflow for gout (syngo.via CT DE Gout).

Results: Despite equal concentrations, MSU was significantly less attenuating than both HA-samples. MSU and HA suspensions had significantly different Z_{eff} (mean±/SD: 7.76±/-.26 vs. 9.67±/-.39, p<.001). Z_{eff} of HA was significantly higher than of similar attenuating PMMA plate. Z_{eff} numbers from PC were comparable to dual-energy CT reference values.

Conclusion: This feasibility study demonstrates discrimination of MSU from HA crystal suspensions in PC radiography based on Z_{eff} differences. Further studies have to investigate whether this novel technique could replace DECT in vivo.

Automatic analysis and result presentation workflow for diagnostic X-ray quality assurance

V.-M. Sundell, E. Hippeläinen, J.I. Peltonen; Helsinki/FI (juha.peltonen@hus.fi)

Purpose: The quality assurance (QA) of diagnostic X-ray systems is regulated with international and national guidelines. The measurement of different radiation and image quality parameters is required in constant intervals. The follow-up of the results requires substantial manual labor in multi-unit radiological department. We have developed an automatic QA analysis and result presentation workflow to enable efficient monitoring of the X-ray equipment performance.

Methods and Materials: Monthly DIGRAD phantom images from 63 diagnostic X-ray machines were analysed with the developed workflow. The workflow included the follow-up of exposure (mAs), dose area product (DAP), exposure index (EI), modulation transfer function (MTF), noise-power spectrum (NPS) and contrast-to-noise ratio (CNR). Of the measures, mAs, DAP and EI are extracted from the image header and MTF, NPS and CNR calculated from the image. The images are sent to an image-processing server for analysis and results available in a web based-interface within a few minutes. Additionally, if the results are exceeding predefined error borders, e-mail is automatically sent to QA experts.

Results: The developed centralized QA workflow enables an effective follow-up of the diagnostic X-ray equipment performance. The produced data can be utilized to detect possible drifts in the imaging hardware before substantial change in image quality or radiation dose. The results are immediately available for radiographers and QA experts.

Conclusion: The presented workflow is providing an effective tool for QA experts to follow the performance of diagnostic X-ray equipment in large radiological department.

B-0999 11:50

Quality controls in ultrasound: a trial to evaluate the obsolescence of ultrasound probes with a low-cost agar gel phantom

A. Collocola¹, M. Ortino², S. Durante²; Bologna/IT, ²Taranto/IT (alessio.collocola@studio.unibo.it)

Purpose: Nowadays ultrasounds are the most installed equipment within the medical operative realities, but that does not fall into precise quality control programs like all other imaging equipment. Considering (Considering the elevated number of exams performed every day, it is essential to set up intuitive programmed quality controls using simple and low-cost accessories.

Methods and Materials: Only linear probes with different crystal technology are underwent quality check. In order to do this, a 5% agar gel phantom was created with a set of two modules specifically designed to certify in an effective way, the uniformity, sensitivity, mechanical, electrical and global hygiene of the device.

Results: The studied probes tend to lose uniformity and sensitivity even after 3 years with an average of 40 daily examinations and about 8 hours of non-stop operation. The phantom used was homogeneous and isoecogenous in 95% of uses according to the professionals. The equipment was found to be dirty and with mishandled power and network cables in the 70% of cases.

Conclusion: Unlike the experts and installers declarations the probes begin to lose uniformity and sensitivity after 3 years from the first date of installation. The absence of a programmed quality control discourages the professionals and it could damage patients over time. However, the use of a low-cost phantom and pre-filled forms could improve the obsolescence of the probes.

Are the referrals being made for the investigation of pulmonary nodules appropriate according to the BTS guidelines?

W. Weston; London/UK (williamweston@gmail.com)

Purpose: The British Thoracic Society (BTS) provide guidelines for the investigation and management of pulmonary nodules (PNs). The Imperial healthcare trust runs a PN multi-disciplinary team (MDT) meeting weekly. The service aims to save time in outpatient appointments and lung cancer MDTs, reduce the number of CT examinations requested, and provide a systematic approach to ensure BTS guidelines are complied with. We aimed to assess if referrals to the PN MDT and their recommendations were in accordance with BTS guidelines.

Methods and Materials: We carried out a retrospective study of the referrals and follow-up for patients discussed in the PN MDT between 9/2017 and 4/2018.

Results: 154 nodules were referred to PN MDT. 16% of PNs referred to the MDT were discharged without any follow-up. 38% were discharged after CT surveillance or further investigations i.e. PET-CT. 44% of nodules had volumetric analysis performed.

Conclusion: The Imperial College Healthcare Trust runs a comprehensive service for the investigation of PNs. Although there is scarcity of published data on this topic, our finding that only 16% of referrals were immediately discharged from the PN MDT shows a good awareness of what requires further investigation. We provided a summary of the BTS management algorithms locally to raise awareness amongst general radiologists of features of benign nodules that do not require referral. We also emphasised the importance of seeking out previous imaging studies for comparison and performing volumetric analysis where possible.

Accuracy of model-based iterative reconstruction for CT volumetry of part-solid nodule and pure solid nodule at various dose settings: an anthropomorphic chest phantom study

S.-K. Kim, C. Kim, K.Y. Lee, J. Cha; Ansan/KR

Purpose: To investigate the accuracy of model-based iterative reconstruction for volume measurement of part-solid nodule (PSN) and pure solid nodule (SN) compared with filtered back projection (FBP) and hybrid iterative reconstruction (HIR).

Methods and Materials: Four different SNs (diameters: 3 mm, 5 mm, 7 mm, and 9 mm) and 4 PSNs (3 mm, 5 mm, 7 mm, and 9 mm, inner solid portion diameters; 20 mm, outer ground-glass portion diameters) and chest phantom was used for study. The scanning was repeated 4 times at five radiation dose levels (120 kVp at 100 mAs, 50 mAs, 20 mAs, and 10 mAs, and 80 kVp at 10 mAs). Each CT scan was reconstructed using FBP, HIR (iDose⁴), and MIR (IMR-R1, IMR-ST1, IMR-SP1). The volume of SNs, and solid/GGO portion of PSNs were measured semi-automatically.

Results: The lowest absolute percentage measurement error (APE) of GGO part of PSN were demonstrated in IMR-R1 among the algorithms in all dose level setting (all $P < 0.05$), and the APE of solid portion of PSN in all dose level setting without 80 kVp/10 mAs also showed the significantly lowest value in IMR-R1 among the algorithms (all $P < 0.05$). For SNs, the APEs at 120 kVp/50 mAs, 20 mAs, and 10 mAs were the lowest in IMR-ST1 among the algorithms (all $P < 0.05$, except 120 kVp/20 mAs), and the others were the lowest in IMR-SP1 (all $P \leq 0.01$).

Conclusion: MIR showed higher accuracy of SN and PSN volume measurements compared with FBP and HIR in most dose settings in this phantom study.

B-1002 10:55

Assessment of predictors for pulmonary subsolid nodule detection in non-lung apex in ultralow dose CT reconstructed with ASiR-V

Y. Kai, Y. Hui Shu; Beijing/CN (yekaibysy@bjmu.edu.cn)

Purpose: The purpose of this study was to assess independent predictors for sensitivity of pulmonary subsolid nodule detection in non-lung apex by using ultralow dose CT (ULDCT) reconstructed with ASiR-V.

Methods and Materials: 37 patients who underwent chest LDCT with Revolution CT (GE Healthcare, USA) and found subsolid nodule in non-lung apex were additionally scanned with a chest ULDCT. Reference tube voltage and current were set to be 120 kV and smart mAs for LDCT and 120 kV/2.8 mAs for ULDCT. After scanning, LDCT were reconstructed with 50% ASiR-V and 90% ASiR-V for ULDCT. A standard of reference (SOR) was established about the presence, types and size of lung nodules on LDCT. Sensitivity of the ULDCT was compared against the SOR. Then, logistic regression was used to test independent predictors for performance of pulmonary nodule detection.

Results: The mean effective radiation dose of ULDCT was 0.096 ± 0.005 mSv compared with 0.83 ± 0.32 mSv for LDCT, which was 88% lower. A total of 46 nodules were identified by LDCT and overall sensitivity was 63.04% for ULDCT (29/46). The sensitivity for nodules with diameter greater than 5mm and 6mm, it was 81.8%(27/33) and 92%(23/25), respectively. In multivariate analysis, size and patients' BMI were independent predictors for sensitivity ($P < 0.05$). But when it came to BMI ≤ 30 , size was the definitive factor for nodule detection and BMI had little influence on it.

Conclusion: For people with BMI ≤ 30 , ultralow dose CT reconstructed with ASiR-V enables a high sensitivity for the detection of pulmonary subsolid nodules longer than 6 mm in an extremely low dose.

B-1003 11:03

Comparison of the capability of nodule component measurement and management on follow-up CT examinations between 3D CADv systems with and without CNN

Y. Ohno¹, A. Yaguchi², K. Aoyagi³, Y. Kishida¹, S. Seki¹, Y. Ueno¹, T. Yoshikawa¹, T. Murakami¹; ¹Kobe/JP, ²Kawasaki/JP, ³Otawara/JP (yosirad@kobe-u.ac.jp)

Purpose: To evaluate the utility of 3D computer-aided volumetry (CADv) with convolutional neural network (CNN) for pulmonary nodule management on follow-up CT examinations.

Methods and Materials: 139 pulmonary nodules (70 malignant and 69 benign nodules) underwent repeated CT, pathological, and follow-up examinations as well as surgical resections. In this study, CADvs with and without CNN automatically assessed solid, GGO and total nodule (TN) volumes. Then doubling time (DT) was determined from TN volume change by each CADv system. To evaluate the accuracy of volume measurement on each CADv method, solid, GGO and TN volumes within each nodule were measured by 3 different radiologists. Then gold standards were determined by simultaneous truth and performance level estimation method. To determine the utility of CNN, each volume assessed by CADvs with and without CNN was statistically correlated with those of gold standard. Then each volume measurement error was also compared between CADvs with and without CNN by t test. ROC analysis was performed and diagnostic performance of DT was compared with each other by McNemar's test.

Results: CADv with CNN ($0.82 < r < 0.92$, $p < 0.0001$) showed better correlations with gold standard than that without CNN ($0.57 < r < 0.75$, $p < 0.0001$). Measurement errors of GGO and TN by CADv with CNN were significantly smaller than those without CNN ($p < 0.05$). When applied each feasible threshold value, sensitivity of CADv with CNN (92.2%) was significantly higher than that without CNN (83.3%, $p = 0.004$).

Conclusion: 3D CADv with CNN is more useful than that without CNN for management of pulmonary nodule on routine follow-up CT examinations.

Comparing volume doubling time and SUV_{max} for benign and malignant lung nodules

D.D. Yang, B. Riley, A.N. Tavaré, S. Hare, A. Parthipun; London/UK (ddyang21@gmail.com)

Purpose: To assess the ability of volume doubling time (VDT) and PET/CT avidity to distinguish between benign and malignant lung nodules.

Methods and Materials: All patients with lung nodules ≤ 3 cm who underwent lung biopsy at a single centre between May 2016 and May 2017 were identified retrospectively. Patients with CT and ¹⁸F-FDG-PET/CT scans performed ≥ 28 days but < 2 years apart, both demonstrating the biopsied nodule, were

included. VDT was calculated from interval change in longest axial diameter and compared with SUV_{max} . Statistical comparisons were performed using t test and chi-squared test.

Results: 49 lung nodules were included. 12 nodules were benign, 6 squamous cell lung cancer (SCC), 27 lung adenocarcinoma, 1 small cell lung cancer, and 3 metastatic disease from extrapulmonary primaries. Median VDT was 488 days for benign and 317 days for malignant nodules. Median SUV_{max} was 2.7 for benign and 4.0 for malignant nodules. Comparing benign and malignant nodules, difference in VDT was statistically significant ($p=0.04$), while difference in SUV_{max} was not ($p=0.16$). There was no statistically significant association between VDT (categorised as ≤ 400 days and >400 days) and SUV_{max} (categorised as $>$ mediastinal blood pool (MBP) and \leq MBP) ($p=0.72$). Comparing adenocarcinoma and SCC, median VDT was 332 and 92 days, respectively, and median SUV_{max} was 3.2 and 9.2, respectively.

Conclusion: VDT demonstrated significant difference between benign and malignant nodules, while SUV_{max} did not. Future work will determine an optimal VDT cut-off for predicting malignancy and assess whether a combination of VDT and SUV_{max} can improve accuracy of prediction.

B-1005 11:19

Quantitative analysis of diffusion weighted magnetic resonance imaging in lung nodules characterisation

A. Sudarkina, A. Dergilev, N. Gorbunov, V. Kozlov; *Novosibirsk/RU* (a.sudarkina@mail.ru)

Purpose: To evaluate the contribution of diffusion weighted imaging (DWI) with different types of data acquisition for differentiation of malignant and benign lung nodules.

Methods and Materials: 63 patients (mean age of 57.5 ± 15.7 years) with 76 lung nodules (33 benign, 43 malignant; mean size of 2.1 ± 1.1 cm) were undergone chest MRI on 1.5T scanner. Two series of DWI (acquired during free breathing and synchronized with breathing) were obtained for all patients. 72 solid lung nodules were included in the study with assessment of Lesion-to-Spinal cord Ratio (LSR) on DWI with high b-factor and apparent diffusion coefficient (ADC) for each nodule in both series of DWI.

Results: In benign nodules the mean ADC values obtained from synchronized and non-synchronized sequences were $1.52 \pm 0.46 \times 10^{-3}$ mm^2/s and $1.42 \pm 0.49 \times 10^{-3}$ mm^2/s respectively, LSR - 0.52 ± 0.49 and 0.39 ± 0.45 respectively. In malignant nodules the mean ADC values obtained from synchronized and non-synchronized sequences were $1.18 \pm 0.23 \times 10^{-3}$ mm^2/s and $1.13 \pm 0.26 \times 10^{-3}$ mm^2/s respectively, LSR - 1.28 ± 0.64 and 0.9 ± 0.5 respectively. The differences of the mean ADC and LSR in both malignant and benign nodules were significant ($p < 0.05$) in both types of data acquisition. The best area under the curve of 0.826 was obtained for LSR values from synchronized diffusion series (the cut-off value of 0.8 can be used for differentiation malignant and benign nodules with a sensitivity of 80% and a specificity of 72%).

Conclusion: Quantitative analysis of DWI is a promising tool which can be used in combination with CT and conventional MRI for noninvasive differentiation of malignant and benign lung nodules.

B-1006 11:27

A feasible method to set coherent image quality between different CT scanners with a general phantom for low dose lung cancer CT screening

W. Qi, R. Shanshan, Z. Miao, S. Ye, C. Lei, H. Nan; *Beijing/CN* (qiweiwei@pkuph.edu.cn)

Purpose: To develop a feasible method to generate adequate image quality for lung cancer CT screening at low radiation dose between different CT scanners with general image quality control phantoms.

Methods and Materials: First, the Lungman N1 phantom simulating normal size chest with 4 nodules and the Catphan 500 phantom were scanned with low dose on scanner1 (Philips iCT). The image quality of the simulated nodules with FBP reconstruction were evaluated by two radiologists to select the lowest reference mAs (mAs0) for detecting nodules. Second, the physical parameters were also assessed using the Catphan 500 at the lowest mAs. Third, CT scanner2 (GE Revolution) scanned the Catphan 500 phantom to find the right NI (NI0) for getting the above mentioned physical parameters. Finally, 100 volunteers assigned to two scanners randomly underwent lung cancer screening with either the NI0 or mAs0 setting.

Results: 1. The Reference mAs0 was 23mAs@100kV on CT scanner1 and NI=27HU@100kV on CT scanner2. The physical parameters for lung cancer screening with the determined scan techniques were 7 line pairs/cm for the spatial resolution and 15.0mm@1.0% for the low contrast resolution. 3. The image quality of the two groups had similar scores ($p > 0.05$) but with similar radiation doses ($P > 0.05$). All positive nodules (Group 1: 9 solid and 3 ground glass opacity (GGO) nodules, and Group 2: 11 solid and 9 GGO nodules) were detected.

Conclusion: Using general quality control phantoms to set coherent image quality between different CT scanners for low dose lung cancer CT screening is feasible.

B-1007 11:35

Understanding temporal enhancement of pulmonary nodule with dynamic contrast enhancement CT and utility of each acquisition

C. Jakerst¹, M. Gotway¹, D. Panse², K. Cummings¹, E. Jensen¹, P. Panse¹; ¹Phoenix, AZ/US, ²Albany, NY/US (panse.prasad@mayo.edu)

Purpose: Dynamic contrast enhancement for pulmonary nodule entails image acquisition precontrast, 1, 2, 3 and 4 minutes post-contrast and predicts aggressiveness if the nodule enhances >15 HU over baseline (Swensen et. al, Radiology 2000; 214: 73-80). However, the temporal enhancement of the pulmonary nodule over this time frame is not well validated especially the necessity of the 3- and 4-minute acquisitions. An IRB-approved retrospective study was conducted to evaluate these temporal characteristics.

Methods and Materials: All SPN enhancement CT studies (n=610) successfully completed from 2004 to 2017 were included. The average nodule attenuation (HU) from unenhanced and dynamic contrast-enhanced images at 1, 2, 3 and 4 minutes were recorded. An attenuation difference greater than 15 HU between the unenhanced and any of the enhanced 1, 2, 3 or 4 minutes was considered a positive study. The number of nodules showing >15 HU enhancement only at 3 or 4 minutes but did not enhance at 1 and 2 minutes was also calculated.

Results: 61 nodules demonstrated maximal positive enhancement at 1, 86 at 2, 66 at 3, and 69 at 4 minutes. 16 and 18 nodules showed more than 15 HU enhancement only at 3 and 4 minutes, respectively.

Conclusion: Nodule enhancement exceeding 15 HU using a dynamic enhancement protocol may occur at any of the 4 time points dictated by the study protocol. Although a large number of nodules demonstrate maximal enhancement at 1 and 2 minutes, maximal nodule enhancement occurring at 3 and 4 minutes is seen in a substantial proportion of patients.

B-1008 11:43

Effect of iterative reconstruction and artificial neural network denoising techniques on lung nodule volumetry in ultra-low dose computed tomography: a phantom study

D. Han, M.A. Heuvelmans, G. Pelgrim, G. Sidorenkov, P.M.A. van Ooijen, M. Oudkerk, R. Vliegthart; *Groningen/NL*

Purpose: To compare lung nodule volumetry for iterative reconstruction (IR) and non-iterative technique artificial neural network (NiTANN) in ultra-low dose CT (ULD-CT), using low-dose CT (LDCT) with filtered back projection (FBP) as reference.

Methods and Materials: Five artificial round solid nodules (volume, 40-85 mm^3) placed in a thoracic phantom, were scanned with third generation dual-source CT (Force, Siemens, Germany) with three repositions. A LDCT protocol (120 kVp, 20 ref mAs), and ULD-CT protocol with tin filter (Sn100 kVp, 46 ref mAs) were used, with dose-length product of 33.7 mGycm and 4.9 mGycm, respectively. ULD-CT images were reconstructed with FBP and IR (ADMIRE) level 3 and 5, with a sharp reconstruction kernel without edge enhancement. ULD-CT FBP images were further processed using NiTANN (PixelShine, Algomedica, USA). Semi-automated volumetry (MMOncology, Siemens, Germany) was performed on 120 nodule datasets. Accuracy and variability of nodule volumetry in ULD-CT were compared to LDCT using Wilcoxon signed-rank test with Bonferroni correction and Bland-Altman's analysis, respectively.

Results: Nodule volumes for ULD-CT were significantly lower than for LDCT (median difference for ULD-CT/IR3: -2.5 mm^3 IQR [7.3], ULD-CT/IR5: -3 mm^3 IQR [4.5], ULD-CT/NiTANN: -8 mm^3 IQR [6.0]). The relative 95%-limits of agreement were $\pm 20\%$, $\pm 19\%$ and $\pm 15\%$ for IR3, IR5 and NiTANN, respectively. No significant difference was found when measured volumes were compared to physical volume.

Conclusion: An artificial neural network denoising technique showed slightly larger underestimation of nodule volumes than IR in ULD-CT, but tended to have less variability.

B-1009 11:51

Detectability of non-solid pulmonary nodules by deep learning: results from a phantom study

Q. Li¹, L. Li², K. Liu¹, C. Xia², Y. Xiao¹, S. Liu¹; ¹Shanghai/CN, ²Beijing/CN (925454346@qq.com)

Purpose: To investigate how different nodule size, nodule density, effective dose and reconstruction kernels affect the performance of a deep learning algorithm for the detection of non-solid pulmonary nodules in phantom CT scans.

Methods and Materials: CT scans were performed on a chest phantom containing non-solid nodules (diameters of 5, 8, 10, and 12 mm; -630 and -800 HU for each diameter) at two different radiation dose settings (4.1mGy and 0.3mGy). A total of 64 scans were obtained. A deep learning model was developed based on real-patient data (without any phantom data). Evaluation of deep learning model focused on sensitivity [TPs/(TPs + FNs)] and precision [TPs/(TPs + FPs)].

Results: Higher nodule density [-800HU: 67.4%; -630HU: 91.2%] and larger nodule size [5, 8, 10, 12mm: 57.8%, 89.1%, 98.6%, 82.0%] were significantly associated with higher detection sensitivity of non-solid nodules. Dose significantly affected both detection sensitivity [low dose vs. ultra-low dose: 90.3% vs. 62.0%] and precision [low dose vs. ultra-low dose: 77.4% vs. 55.9%]. Additionally, dose effect strongly interacted with nodule density; it was more challenging for deep learning algorithm to detect lower density nodules in ultra-low dose scans [-800HU vs. -630HU: 38.7% vs. 84.7%] than in low dose scans [-800HU vs. -630HU: 84.9% vs. 95.7%].

Conclusion: Phantom studies can be applied to systematically evaluate the performance of deep learning algorithms in computer-aided detection tasks.

Acute chest pain evaluated with coronary CT: validation of new atherosclerotic markers

M. Fusaro¹, M. Rattazzi², C. Nardin¹, M. Tiepolo¹, A. Dorigo¹, G. Tessarin², G. Stamati³, C. Agostini¹, G. Morana¹; ¹Treviso/IT, ²Padua/IT, ³Corigliano Calabro/IT

Purpose: The aim of this study is analysing the association between circulating new atherosclerotic markers and the presence of coronary artery disease (CAD).

Methods and Materials: Patients with acute chest pain (ACP) and low risk of ACS (normal TnT and ECG) arriving to ED from March 2016 to October 2017 were evaluated with a triple rule-out CT. We measured circulating levels of polymorphonuclear elastase (PMN), lactoferrin, proteinase 3 (PR3) and neutrophil gelatinase-associated lipocalin (NGAL). Patients have been then divided according to the presence/absence of CAD and biochemical/clinic parameters and correlated to CT scan. Statistical analysis was performed with SPSS 24.0.

Results: 200 consecutive patients, 86 with CAD (A) and 114 without CAD (B). The two groups showed significant difference in terms of age (A: 57.6±8.0, B: 50.5±9.3, p<0.001) and gender (males: A 79.1%, B 57%, p=0.001). No difference was observed for systolic and diastolic blood pressure, lipid profile and smoke. Circulating levels of PR3, NGAL and PMN appear superimposable in both groups while a significative increase of lactoferrin levels has been observed in group A (A: 128.7±78.0 U/ml, B: 105.5±42.6 U/ml, p=0.014), which remained significative even after adjustment for age, gender, waist circumference, presence of hypertension, presence of diabetes, lipid profile and smoke habit (p=0.015). After exclusion of patients with CAD >50%, the difference remained significant (p=0.033).

Conclusion: Circulating levels of lactoferrin are associated with the presence of CAD, independent of traditional cardiovascular risk factors, leading to a more precise stratification of patients with acute chest pain.

HTA of patient management with and without triple rule out CT protocol

G. Tessarin¹, M. Fusaro², C. Bortolanza², G. Morana², E. Quaià¹; ¹Padua/IT, ²Treviso/IT (tessarin.giovanni@gmail.com)

Purpose: Health technology assessment (HTA) of Triple Rule Out (TRO) CT protocol vs standard of care for the management of Patients with acute chest pain, in the the clinical setting of a tertiary referral hospital.

Methods and Materials: We evaluated 8 parameters derived from the HTA hospital-based model: general relevance, safety, effectiveness in literature and real life, economic impact, equity, social and ethical impact, management impact. The study consists of 3 phases: parameter prioritization, analysis and conclusions.

Results: We identified 1420 expected cases/year for NSTEMI, 426 for pulmonary embolism, 9676 for aortic aneurysm. Both safety and social impact fostered TRO protocol (Likert scale 1 vs 0). Effectiveness, quoted in terms of length of stay in the hospital, was 23.22 hours for TRO vs 30.8 hours for standard of care. Estimated costs were 349.23 € for TRO and 336.65 € for standard of care per Patient. Cost-effectiveness analysis showed a Incremental cost-effectiveness Ratio of -1.66 for the TRO. Both protocols had same equity, legal and organisational impact. Final score was of 0.89 for CT vs 0.74 for standard of care, showing superiority of TRO.

Conclusion: HTA analysis showed a better score for TRO, thanks to his safety, effectiveness and good social impact.

B-1012 10:55

Second generation of dual source computed tomography for evaluating coronary artery lesions in Vietnamese paediatric patients with Kawasaki disease

H. Nguyen, T. Nguyen, P.M. Thong, H.S. Ha, N.K. Viet, L.T.T. Lien, P.B. Ngoc, H.V. Hoa; Hanoi/VN (thanhuong.nguyenrad82@gmail.com)

Purpose: To evaluate coronary artery lesions (CAL) in paediatric patients with Kawasaki disease by DSCT 256 detectors then comparing with the measurements of 2D echocardiography (2DE).

Methods and Materials: 24 children (21 boys) from with Kawasaki disease underwent DSCT 256 detectors at Bach Mai hospital from December 2015 to July 2018. The average effective dose of DSCT and 4-point subjective imaging quality was collected. The location, number and size of coronary aneurysm were independently evaluated by DSCT and 2DE. Bland - Altman analysis was used to evaluate the agreement of aneurysms measurements between DSCT and 2DE.

Results: 96.7% (232/240) coronary artery segments had good imaging quality (score ≤ 3). Average effective dose of DSCT was 1.58 ± 0.56 mSv (0.77-3.20). Coronary aneurysm in 1 segment, 2 segments and 3 segments was 80.5%, 16.7% and 2.8%, respectively. The mean ± SD aneurysm diameter measured by DSCT and 2DE was 7.18 ± 2.72mm and 7.16 ± 2.55mm, respectively. The mean ± SD aneurysm length measured by DSCT and 2DE was 13.49 ± 8.65mm and 13.28 ± 8.58mm, respectively. Bland - Altman plot showed a good agreement between DSCT and 2DE.

Conclusion: DSCT is a feasible modality with excellent imaging quality and low effective dose exposure for rapid and accurate assessment of CAL in infants and children due to Kawasaki disease.

B-1013 11:03

Randomised trial comparing transdermal with lingual and sublingual nitroglycerin administration for coronary vasodilation in coronary CT-angiography

J.-E. Scholtz¹, V. Baliyan², S. Hedgire², N.D. Mercaldo², R.A. Takx³, U. Hoffmann MD MPH², T.J. Vogl⁴, B. Ghoshhajra²; ¹Frankfurt a. Main/DE, ²Boston, MA/US, ³Utrecht/NL, ⁴Frankfurt/DE (janerikscholtz@gmail.com)

Purpose: Nitroglycerin increases coronary artery diameter and improves coronary artery evaluation in coronary CT-angiography (CCTA). This study aimed to compare the safety and efficacy of lingual, sublingual and transdermal administration of nitroglycerin in coronary vasodilation.

Methods and Materials: This prospective, randomized controlled study included 198 subjects who underwent scheduled CCTA between 6/2017-9/2017. Subjects were randomized to one of three routes of nitroglycerin (0.8mg) administration: tablet(sublingual), spray(lingual), or patch(transdermal). After acquiring ECG-gated non-contrast CT, nitroglycerin was given at least 5 minutes (lingual/sublingual) or 45 minutes (transdermal) before ECG-gated CCTA. Linear quantile mixed-effects models were constructed to quantify relationship between coronary diameter and nitroglycerin administration method. Side effects and vital sign changes were documented. When headaches were present, intensity was scored using a 10-point Likert scale (1-minimal to 10-worst imaginable headache).

Results: The studied population had a mean age of 58.1±12.6 years of which 91/198 [46.0%] were female. On average, coronary diameters in CCTA were 1.14 (95% confidence interval: 1.13-1.15) times larger compared to coronary diameters prior to nitroglycerin treatment. Differences between spray (1.15[1.14-1.16], difference: 0.00[-0.02, 0.01], p=0.815) or patch (1.16[1.15-1.17], difference: 0.01[-0.01, 0.03], p=0.201) compared to tablet (1.15[1.14-1.16]) as reference were unable to be detected. Thirty (15.2%) patients reported transient headache with a median intensity of 3 (Q25-Q75: 2-5), 2(2-5), and 2(2-5) for tablet, spray, and patch, respectively (tablet vs. patch, p=0.004).

Conclusion: Lingual, sublingual and transdermal nitroglycerin administration had no statistically significant differences in the vasodilatory effect on coronary arteries, with transdermal route being a safe alternative for CCTA.

Comparison of coronary lumen diameter in CT angiography: spray nitroglycerin vs sublingual nitroglycerin tablet administration

B. Choi¹, K.Y. Lee¹, C. Kim¹, S. Lee¹, B.-K. Je¹, J. Cha¹, H. Yong², E.-Y. Kang², Y.-W. Oh²; ¹Ansan/KR, ²Seoul/KR (chlqurruudk@gmail.com)

Purpose: To compare the coronary vasodilation effects of spray nitroglycerin (NTG) with those induced by sublingual NTG administration in coronary CT angiography (CTA) and to investigate the effects of spray NTG in elderly patients.

Methods and Materials: From June 2016 to March 2018, a total of 1169 CTA using spray NTG (spray group) and 828 CTA using sublingual NTG (sublingual group) were analysed. Our institution used only sublingual NTG tablet for coronary CTA prior to March 2017 and subsequently only used spray NTG according to the hospital policy. Among these, 93 patients underwent CTA twice using both spray NTG and sublingual NTG. Diameters of all measurable segments were measured and compared between spray group and sublingual group. Also, comparison of vessel diameters between spray group and sublingual group in the elderly patients were performed. The intra-individual analysis was also performed in 93 patients.

Results: No statistically significant differences were evident between these 2 groups in baseline characteristics. Spray group tends to have more measurable vessels than sublingual group. All coronary segments in spray group were significantly larger than those in sublingual group (all $P < 0.01$). This tendency was also found in the elderly. In the intra-individual analysis, all coronary segments in spray group were significantly larger than those in sublingual group (all $P < 0.001$).

Conclusion: Spray NTG is more effective in evaluating coronary arteries in CTAs even in the elderly, resulting in vasodilatation more effectively than sublingual NTG. We recommend spray NTG to be preferred mode of administration at CTA.

B-1015 11:19

Systolic high-pitch coronary CT angiography for evaluation of the coronary arteries in heart transplant recipients

M. Calvo Imirizaldu, A. Ezponda Casajús, A. García Baizán, J.C. Pueyo Villoslada, G. Rabago, G. Bastarrica Alemañ; Pamplona/ES (mcalvoi@unav.es)

Purpose: This study aimed to evaluate the feasibility, image quality, and radiation dose of high-pitch coronary CT angiography (CCTA) in orthotopic heart transplant recipients (OHT).

Methods and Materials: 22 consecutive OHT (16 men, mean age 62.5 ± 11.8 years, mean BMI 26.4 ± 4.3 kg/m², mean heart rate 88.2 ± 13.6 bpm) underwent CCTA to rule out coronary allograft vasculopathy in a high-pitch mode using a third-generation dual-source CT scanner. Data acquisition was triggered at 35% of the R-R interval. Two independent observers blindly assessed image quality on per-segment, per-vessel, and per-patient basis using a 4-point scale (4-excellent, 1-not evaluative). Scores 2-4 were considered of diagnostic quality. Interobserver agreement on the image quality was assessed with kappa statistics. Radiation dose was recorded for each patient.

Results: 322 coronary segments were evaluated. Diagnostic image quality was observed in 98.1% of the segments. Interobserver agreement for image quality assessment was very good on a per-patient ($\kappa = 0.82$), per-vessel ($\kappa = 0.83$), and per-segment basis ($\kappa = 0.89$). Mean image quality score was 3.5 ± 0.74 for the entire coronary tree, 2.7 ± 1.03 for the RCA, 3 ± 0.76 for the LCA, and 2.5 ± 0.8 for the Cx. Per-patient mean image quality score was 2.2 ± 0.79 . Estimated mean radiation dose was 0.49 ± 0.32 mSv.

Conclusion: High-pitch coronary CCTA in a systolic phase of the cardiac cycle allows achieving diagnostic image quality coronary angiograms in OHT at very low radiation dose.

Automated coronary artery segmentation using a U-net deep learning architecture on cardiac CT

C. Wald, N. Aldoj, S. Feger, N.-A. Hartmann, S. Lukas, S. Zargaran Tavakoli, M. Dewey; Berlin/DE (christian.wald@charite.de)

Purpose: Exact segmentation of coronary arteries on cardiac computed tomography (CT) is crucial for accurate evaluation of the presence of coronary artery disease. In an automatic approach we propose a convolutional neural network in order to segment the coronary arteries on cardiac CT.

Methods and Materials: We used a total of 22 patients who underwent 320 row coronary CT. For each we obtained a 3D CT volume with $512 \times 512 \times 560$ voxels where coronary arteries were manually annotated slice-wise. We developed a neural network of 3D U-net architecture for automated segmentation. Nine of the manually segmented volumes were used for training, three for validation and nine for testing. For computational reasons we used patches with $48 \times 48 \times 48$ voxels and included 20,000 for training. We evaluated the model patch-wise on test cardiac CT volumes and reconstructed the coronary arteries of the whole volumes by merging patches.

Results: We evaluated the performance of the network by computing the dice score between the manual segmentations and the network output on test volumes. We achieved an average dice score of 0.75 ± 0.04 . The test volumes were manually annotated twice and the average inter-reader dice score was 0.77 ± 0.05 which was not significantly different from the network performance ($p = 0.27$). Evaluating the network on the right coronary artery only resulted in an average dice score of 0.75 ± 0.1 which did not differ significantly from the entire network output ($p = 0.87$).

Conclusion: The proposed method of automatically extracting coronary arteries using a 3D U-net is comparable to a human reader.

The optimal monochromatic image level of coronary CT angiography on a dual-layer detector spectral CT with half-dose contrast agent

X. Huang, Y. Hou, Y. Ma, S. Gao, Z. Jia, X. Lu; Shenyang/CN (632136789@qq.com)

Purpose: To investigate the optimal monochromatic level of reconstruction images of coronary CT angiography (CCTA) on a dual-layer detector spectral CT (DLCT) with half-dose contrast agent.

Methods and Materials: A prospective collection of 200 patients (116 males, 84 females, age 55 ± 11 years) were randomly divided into the routine dose contrast group and half-dose contrast group (both $n = 100$). CCTA was performed on a DLCT with prospective ECG-gated mode and 120 kV. For the routine dose group, polychromatic images with iterative model reconstruction (IMR) (group A) were reconstructed. For the half-dose group, three monochromatic levels of images were reconstructed (group B, 45 keV; group C, 50 keV; group D, 55 keV). Iodixanol 270mg/ml was used with a dose of 0.8ml/kg and 0.4ml/kg, respectively, for the routine group and half-dose group. Objective indicators (CT values, SD, SNR, CNR), subjective indicators (contrast, sharpness, subjective noise, acceptability) in each group were compared.

Results: The CT value, SNR, CNR in group C were higher than those in group A ($P < 0.001$). The SD in group B was larger than that in group A ($P < 0.001$). There was no significant difference between objective scores of group D and group A ($P > 0.05$). There were no significant differences in sharpness, subjective noise, and acceptability between group C and group A ($P > 0.05$), and the contrast was superior to that of group A ($P < 0.001$). The contrast in group B was better than that of group A ($P < 0.001$), but the subjective noise was worse than that of group A ($P < 0.001$). The contrast, sharpness and acceptability of group D were all worse than that of group A ($P < 0.001$).

Conclusion: 50 keV monochromatic images of DLCT provide compatible coronary image quality with half-dose contrast agent.

B-1019 11:43

Predictive role of lipid panel and DLCN score in the assessment of coronary artery disease with coronary CT in patients with familial hypercholesterolemia

A. Ascione, G. De Rubeis, N. Galea, M. Francone, C. Catalano; Rome/IT (andrea121.ascione@gmail.com)

Purpose: To assess the possibility of predicting presence and severity of coronary artery disease as observed with cardiac CT through lipid panel and Dutch Lipid Clinic Network (DLCN) score.

Methods and Materials: Between January 2014 and March 2018, 86 patients (50 males [58%]; mean age 48) affected by Familial Hypercholesterolemia were analyzed through coronary CT. Lipid panels and DLCN scores were completed for all patients. The degree of stenosis for all 17 coronary segments was assessed according to CAD-RADs; total calcium burden was also computed. The predictive model was implemented using linear and logistic regression.

Results: Mean values (mg/dL) of the lipid panels were: Total cholesterol 340 ± 88 , HDL 60 ± 16 , TG 120 ± 56 , LDL 257 ± 79 ; mean DLCN score was 7 before genotyping and 13 after genotyping. Prevalence of significant Coronary Artery Disease (CAD-RADs ≥ 4) was 12.8% (11 out of 86). The average number of lesions detected at pre-contrast CT was 2 ± 5.2 , Agatston score 73 ± 257.5 . LDL cholesterol, TG and total cholesterol levels were able to predict the Agatston score ($r = 0.26$ [$p = 0.03$]; $r = 0.4$ [$p = 0.006$]; $r = 0.24$ [$p = 0.4$]). Only the TG value was able to predict the level of CAD-RADs ($r = 0.4$ [$p < 0.05$]); neither DLCN score nor any lipid panel value can predict significant coronary artery disease (CAD-RADs > 4).

Conclusion: Lipid panel and DLCN score cannot predict the degree of significant Coronary Artery Disease at cardiac CT.

Comparison of RECIST, iRECIST, and PERCIST for the evaluation of response to PD1/PD-L1-blockade therapy in patients with non-small cell lung cancer

L. Beer, M. Hochmair, A. Haug, D. Kijak, B. Schwabel, M.E. Mayerhöfer, H. Prosch; Vienna/AT (lucian.beer@meduniwien.ac.at)

Purpose: The aim of this study was to compare the Response Evaluation Criteria in Solid Tumors (RECIST) 1.1, the immune RECIST (iRECIST) criteria, and the Positron Emission Tomography Response Criteria in Solid Tumors (PERCIST) 1.0 for the assessment of response evaluation in patients with advanced non-small cell lung cancer (NSCLC) treated with PD-1 / PD-L1 inhibitors.

Methods and Materials: This prospective study of 42 patients treated with a PD-1 / PD-L1 inhibitor was approved by our Institutional Review Board, and all patients gave written, informed consent. Tumor burden dynamics were assessed on [18F]FDG PET/CT before and after treatment initiation. Immunotherapeutic responses were evaluated according to the RECIST 1.1, iRECIST, and PERCIST 1.0 for the dichotomous groups, responder vs. non-responders. Cohen's κ coefficient, and Wilcoxon's signed-rank test were used to evaluate concordance among these criteria. We assessed progression-free survival (PFS) and overall survival (OS) using the Kaplan-Meier test.

Results: RECIST 1.1 and PERCIST 1.0 response classification were discordant in six patients (14.2%); $\kappa = 0.581$. RECIST 1.1 and iRECIST were discordant in two patients, who evidenced pseudoprogression after treatment initiation. Median PFS, as well as OS, was significantly longer for responders compared to non-responders for all criteria ($p < 0.001$) without any significant difference between the three criteria ($p > 0.05$).

Conclusion: RECIST 1.1 and PERCIST 1.0 show only a moderate agreement, but both can predict treatment response to PD-1 / PD-L1 inhibitor therapy. In cases of pseudoprogression, metabolic tumor activity may help to correctly classify treatment response.

Imaging programmed cell death ligand-1 (PD-L1) expression in non-small cell lung cancer with ^{99m}Tc-anti PDL1 sdAb SPECT

G. Chand¹, Y. Xing¹, C. Liu¹, N. Wong¹, L. Meszaros¹, J. O'Doherty², H. Ting¹, J. Zhao¹, G. Cook³; ¹Shanghai/CN, ²Doha/QA, ³London/UK

Purpose: This early phase 1 study aimed to evaluate safety, dosimetry, biodistribution and imaging characteristics of ^{99m}Tc-anti PDL1 sdAb with single-photon emission computed tomography-computed tomography (SPECT-CT).

Methods and Materials: 10 patients with advanced untreated non-small cell lung cancer underwent whole body planar and thoracic SPECT/CT imaging at 1 and 2h post injection after injection of 5.3-11.1 MBq/Kg. 3 patients underwent further imaging at different timepoints for dosimetry calculations. Patients were monitored for adverse events. All patients had immunohistochemistry analysis of %PD-L1 on biopsies of the primary tumours.

Results: No adverse events related to ^{99m}Tc-anti PDL1 sdAb were recorded. Effective dose was 0.009±0.001 mSv/MBq. All scans showed an expected biodistribution of PD-L1 including kidneys, spleen, liver, bone marrow and low-level lung activity. SPECT primary tumour to blood pool ratios (T:BP) varied from 1.24 to 2.23 (mean 1.71) at 1h and 1.24-3.12 (mean 2.13) at 2h. Nodal T:BP ratio varied from 1.04 to 2.36 (mean 1.78) at 1h and 1.18-3.4 (mean 2.21) at 2h. Pleural and bone metastases also showed tracer uptake. Heterogeneity between primary tumour and metastatic PD-L1 expression (>25% difference) was present in 4 of 7 patients with nodal metastases.

Conclusion: ^{99m}Tc-anti PDL1 sdAb is safe and is associated with acceptable dosimetry similar to other diagnostic SPECT agents. Biodistribution is as expected for tissues that express PD-L1. Tumour PD-L1 expression and heterogeneity is measurable with better contrast at 2h and correlates with IHC measurements in the primary tumour.

Non-small-cell lung cancer treated with pembrolizumab: correlation between texture analysis and iRECIST

M. Zerunian¹, D. De Santis¹, D. Caruso¹, T. Biondi², G. Funicelli¹, E. Rosati¹, A. Zucchelli¹, C. De Dominicis¹, A. Laghi¹; ¹Rome/IT, ²Belvedere Marittimo/IT (marta.zerunian@gmail.com)

Purpose: To correlate CT-derived texture parameters and iRECIST in patients with advanced non-small-cell lung cancer (NSCLC) treated with pembrolizumab as a first line.

Methods and Materials: Twenty patients with advanced NSCLC were prospectively enrolled. All participants underwent contrast enhanced CT at baseline and after pembrolizumab. Response to therapy was assessed with iRECIST. An expert radiologist, blind to response to therapy results, manually drew a volume of interest (VOI) of the whole tumour at baseline and after immunotherapy on venous phase by a dedicated software (TexRad). Texture parameters (Mean, Entropy, Kurtosis, Skewness, and MPP) were extrapolated and reported. Results were correlated with iRECIST and P values < 0.05 were considered significant.

Results: Twelve (60%) patients showed partial response (iPR) while 8 (40%) patients had confirmed progressive disease (iCPD). Entropy and Mean decreased in patients with PR (Entropy: 5.2 ±0.3 vs 4.3 ±0.4, $P = 0.03$; Mean: 14.7 ±24.9 vs 8.0 ±25.8, $P = 0.01$) and increased in patients with DP (Entropy: 4.9 ±0.3 vs 5.1 ±0.3, $P = 0.04$; Mean: 6.3 ±15.8 vs 12.0 ±23.1, $P = 0.01$). The others texture parameters analyzed did not show significant differences before and after immunotherapy (all $P > 0.05$).

Conclusion: Entropy and Mean could be used as imaging biomarkers to predict response to immunotherapy in patients with NSCLC. Texture parameters may play a role in the radiologic assessment of advanced NSCLC treated with pembrolizumab.

B-1023 10:54

RECIST 1.1 evaluations in a phase II clinical trial: does reader expertise represent a risk factor for measure reliability?

H. Beaumont¹, T.L. Evans², C. Klifa¹, S.R. Hong³, M. Chadjaa⁴, Z. Monostor⁵, A. Iannesi⁶; ¹Valbonne/FR, ²Philadelphia, PA/US, ³Seoul/KR, ⁴Vitry-sur-Seine/FR, ⁵Budapest/HU, ⁶Nice/FR (hubert.beaumont@mediantechnologies.com)

Purpose: In imaging-based clinical trials, double reads of imaging data are common practice; therefore, discrepant interpretations can result from these two evaluations. This study analysed discrepancies that occurred between local investigators (LI) and blinded independent central review (BICR). We tested if the LI reader expertise was a potential risk factor in RECIST 1.1 evaluations of progressive disease (PD).

Methods and Materials: We retrospectively analysed imaging data from a RECIST 1.1, multi-site, phase II clinical trial of 147 patients with adult small cell lung cancer. All LI and BICR readers were similarly trained prior to the trial. Qualifications of LI readers were radiologist, oncologist, clinical research associate (CRA) and sub-investigator. We compared the proportions of adjudication rate triggered by radiologists versus non-radiologists in using R CRAN test for equality of proportions. Reasons for discrepancies were analysed by a third-party reader.

Results: A total of 36.7% patient data required adjudication. The reasons for adjudication included differences in 1) reporting new lesions (53.7%), 2) measures of tumour burden change (18.5%), and 3) progression status of non-target lesions (11.2%). The proportion of patient data evaluated by LI readers were radiologist: 79.6% (117/147), oncologist: 13.6% (30/147), CRA 2% (3/147), sub-investigators: 2% (3/147), miscellaneous: 2.7% (4/147). The adjudication rate was not different between radiologists and non-radiologists ($p = 0.28$), neither the adjudication rate due to the appearance of new lesions ($p = 0.52$).

Conclusion: In this trial, we did not find that different reader qualifications were associated with significant risk factors.

Everolimus-related pneumonitis in advanced neuroendocrine tumours: correlation of radiologic findings and clinical symptoms
 U. Fehrenbach¹, V. Rodriguez Laval², M. Pavel³, I. Steffen¹, A. Enriquez Puga², H. Jann¹, T. Denecke¹; ¹Berlin/DE, ²Madrid/ES, ³Erlangen/DE (uli.fehrenbach@charite.de)

Purpose: Everolimus, an mTOR inhibitor, is approved for the treatment of advanced pancreatic neuroendocrine tumours (NET). Drug-induced pneumonitis is a major adverse event in everolimus treatment and can lead to determination of the treatment. To evaluate the correlation between clinical symptoms and radiological findings in everolimus-induced pneumonitis in patients with advanced neuroendocrine tumours.

Methods and Materials: 90 patients with advanced NET treated with everolimus were included in this retrospective study. All patients received chest CT scans prior to the initiation of everolimus and at a regular interval during the treatment. At the day of the scan, every patient was clinically examined. Cough and dyspnea as the most common symptoms of pneumonitis were scored according to the "Common Terminology Criteria for Adverse Events 3.0"(symptomatic score). Chest CT scans were scored based on the severity of interstitial lung disease (ILD score) and the overall pulmonary extent (pneumonitis extent). Pattern analyses of the pulmonary disease was performed independently by 2 radiologists.

Results: Pneumonitis was diagnosed in 18(20%) of the patients. There was no significant correlation between symptomatic score and ILD score or pneumonitis extent. Pattern analyses showed significant results when divided in cryptogenic organizing pneumonia(COP)(n=14) and non-COP(n=4) pattern. Patients with non-COP pattern showed significantly higher ILD scores than with COP pattern(p=0.035).

Conclusion: We could show that the severity of CT findings in everolimus-induced pneumonitis does not correlate with the patients' clinical symptoms. That's why asymptomatic patients should not ultimately quit therapy in advanced neuroendocrine tumours. CT pattern analysis could help in the prediction of clinical impact.

Differentiation of benign lung nodules and metastases: a machine-learning approach using texture features from spectral detector CT-derived iodine maps and conventional images

S. Lennartz¹, A. Mager¹, N. Grosse Hokamp¹, S. Schäfer², D. Maintz¹, T. Persigehl¹; ¹Cologne/DE, ²Heidelberg/DE (simon.lennartz@uk-koeln.de)

Purpose: The diagnostic value of iodine quantification for assessing pulmonary malignancies has previously been investigated mostly with ROI-based iodine quantification. The purpose of this study was to analyze if benign lung nodules (BLN) and pulmonary metastases (PM) can be differentiated with a machine-learning-based classification approach using texture analysis of spectral detector CT (SDCT)-derived iodine maps and the referring conventional images.

Methods and Materials: For this IRB-approved study, we retrospectively identified 66 patients who underwent SDCT (IQon, Philips) of the chest: 29 patients with 54 BLN confirmed by prior/follow-up CT (constant in size for ≥6 months) or histopathology and 37 patients with 180 PM verified by histopathology, ¹⁸F-FDG-PET-CT or unequivocal change during treatment (maximum lesion number: 6 per patient). Semi-automatic 3D segmentation of all lesions was performed (mint lesion, Mint Medical). Volumetric attenuation (from conventional images) and iodine concentration (from iodine maps) were acquired. Entropy, kurtosis, mean of the positive pixels (MPP), skewness and uniformity of the positive pixels (UPP) within the volumes of interest were calculated for conventional images and iodine maps. All acquired parameters were transferred to an available machine-learning framework (Matlab, MathWorks).

Results: K-nearest neighbour classification method (KNN) with 10 neighbours and Euclidean distance metric yielded the best performance in differentiating BLN from PM with a diagnostic accuracy of 84.2% using cross-validation with a prediction speed of approx. 1200 obs/sec.

Conclusion: Based on first-order texture features derived from quantitative iodine maps and conventional images obtained with SDCT, KNN facilitates accurate differentiation of benign lung nodules and pulmonary metastases.

Lung cancer screening with low dose computed tomography: the republic of Kazakhstan experience

Z. Zholdybay, G. Akhmetova, G. Akhmetova, A. Panina, A. Ainakulova; Almaty/KZ (doctorpanina@gmail.com)

Purpose: To evaluate the initial results of a pilot project of a lung screening program with low dose computed tomography (LDCT) in the Republic of Kazakhstan, discuss the challenges of program implementation.

Methods and Materials: 569 patients were screened from July to October 2018. 230 men (40.5%) and 339 women (59.5%), ≥30 years old (smokers, non-smokers, former smokers with no previous history of cancer and healthy individuals). A helical LDCT of the chest was performed (120 kVp, 10mA with images reconstruction at 1-1.25mm overlapping slices). Baseline LDCT data were considered positive if at least one non-calcified nodule 6mm or larger in size, or non-solid nodule 8mm or larger in size was identified. Follow-up monitoring for persons with positive baseline LDCT data were carried out according to Fleischner guidelines.

Results: The median age at baseline was 58.5 years (range 35-82). A total of 38 pathological findings were revealed in the lungs. Of these, 22 (57.9%) with obvious malignant signs, 10 (26.3%) ground glass opacity areas and 6 (15.8%) were assessed as probably benign. All nodules were pathologically verified. Thus, from the 32 suspicious nodules in 21 (65.6%) cases - non-small cell lung cancer was identified, in 5 (15.7%) cases - adenocarcinoma, in 6 (18.7%) cases no tumour cells were detected.

Conclusion: LDCT lung cancer screening program showed rather high specificity 98,0% with lower sensitivity 81,3%. The average frequency of lung cancer in randomized patient population was 4,6%.

One-year results from the South Wales Rapid Diagnostic Clinic for patients with serious but non-specific symptoms of cancer

I.A. Siddiqui¹, K.G. Foley¹, B. Palaniappan¹, A. Gibson², T. Pearce², G.J. Davies²; ¹Cardiff/UK, ²Ynysmaerdy/UK (imran.a.siddiqui@gmail.com)

Purpose: Cancer is a leading cause of death in the UK. Initiatives such as the 2-week wait (2-WW) have been implemented to expedite investigations for patients with red-flag symptoms. However, only 50% of patients diagnosed with cancer have such symptoms. Approximately 20% of patients have serious but non-specific symptoms, such as nausea and weight loss. These patients often experience diagnostic delays. Here, we present results from the first 12 months of a rapid diagnostic clinic (RDC) aiming to investigate patients with serious but non-specific symptoms of cancer.

Methods and Materials: This is an ongoing prospective population-based interventional study. Forty-two GP practices covering a population of approximately 301,000 patients were invited to participate. Consultant review was performed in the RDC and appropriate radiological investigations were requested. The CT was performed and reported by a consultant radiologist on the same day. The primary outcome was the conversion rate.

Results: In 12 months, 259 patients (median age 69.2 years) were recruited. Twenty-five cancers were diagnosed, a conversion rate of 9.7%. Lung cancer was the most frequent malignancy (n=6). Overall, 76% of patients were stage 4. The most common presenting symptom was weight loss (77%). 138 patients (53.3%) were seen within 1 week of referral.

Conclusion: These results highlight the potential benefit of a RDC investigating patients with serious but non-specific signs of cancer. This rate was higher than the USC conversion rate in our health board (3-8%). Such diagnostic interventions should be considered to improve conversion rates in this specific patient group.

B-1028 11:34

Polmonary metastases from pancreatic cancer: morphologic and quantitative differences compared to lung metastases from colorectal cancer

I. Vicentin¹, R. Ronza, M. Pecorilla, C. De Mattia, C. Sgrazutti, P.E. Colombo, A. Torresin, S. Siena, A. Vanzulli; Milan/IT (ilaria.vicentin@unimi.it)

Purpose: To find out the morphological and quantitative differences between lung metastases from pancreatic cancer (PC) and colorectal cancer (CRC).

Methods and Materials: 326 lung metastases derived from PC (160) and from CRC (166) were retrospectively reviewed at CT by 2 radiologists, categorizing them in 3 groups according to their morphology: solid nodule, solid excavated nodule, air space pattern (ground glass lesions and nodules with a halo sign). The quantitative analysis consisted in radiomics workflow: 10 categories of radiomics features were considered, clustered in 5 families (Shape, First Order Statistics, Gray Level Co-occurrence Matrix, Gray Level Run Length Matrix, Neighbour Intensity Difference). A statistical univariate analysis was conducted.

Results: Among the 160 PC lung metastases, 43 presented the air space pattern (26.9%), 87 were solid nodules (54.3%) and 32 were solid excavated nodules (18.8%). Among the 166 CRC lung metastases, 140 were solid nodules (84.3%), 20 were solid excavated nodules (12.1%) and 6 nodules presented an air space pattern (3.6%). The statistical univariate analysis showed that radiomics families of First Order Statistics, Gray Level Co-occurrence Matrix, Gray Level Run Length Matrix and Neighbour Intensity Difference were valid predictors for the discrimination between the two cohorts. **Conclusion:** The difference between the metastatic pattern of PC and CRC is significant since among our cohort, 25 patients with PC presented lung metastases with an air space pattern, whereas only 2 patients with CRC presented the same occurrence. This difference can also be assessed from the quantitative point of view through specific radiomics features.

B-1029 11:42

Difference between measurement of T size at computed tomography and at resected specimen; is it relevant for NSCLC stage?

D. Colombi¹, S. Chiesa¹, F. Bodini¹, N. Morelli¹, M. Silva², N. Sverzellati², C. Franco¹, E. Michieletti¹; ¹Piacenza/IT, ²Parma/IT (colombidavide@gmail.com)

Purpose: To evaluate the impact of the differences between presurgical contrast enhanced computed tomography (CECT) and gross pathology measurements on the non-small-cell-lung-cancer (NSCLC) T-staging.

Methods and Materials: Thirty-eight tumours were evaluated in 34 consecutive patients (8 females; median age: 69 years-old; interquartile range: 66-76) with NSCLC surgically treated. The maximum diameter of the tumour was measured with digital caliper at CECT, using multiplanar reconstruction if necessary. The largest diameter from the pathology report was used. Tumour stage was defined by the 8th edition lung cancer TNM stage classification, for radiological stage (rStage) and pathological stage (pStage). The Wilcoxon test examined the difference between tumour size obtained by CECT and pathology. The concordance correlation coefficient (CCC) was used to explore the agreement between the measurements.

Results: The median largest diameter of the tumour on CECT (median size: 30 mm; interquartile range: 19-43) was significantly ($p=0.02$) higher than the median pathology measurement (median size: 25 mm; interquartile range: 15-41). The CCC between the two diameters was poor (CCC: 0.781; 95%CI: 0.624-0.878). Upstaging at rStage was observed in 15/38 (39%) tumours, due to larger T size on CECT in 93% of the cases. Most frequent upstaging occurred from IA1 pStage to IA2 rStage and from IA2 pStage to IA3 rStage (respectively 4/15, 27%).

Conclusion: In resected NSCLC, tumour T size as assessed by CECT is significantly larger than the corresponding gross pathology specimen. These differences would imply radiological upstaging in 39% of the cases, especially within subclassification of stage I.

B-1030 11:50

Assessing the precision of an AI-powered algorithm for automatic detection and 3D segmentation of primary tumours in NSCLC

T.J. Weikert¹, M. Pradella¹, F. Durlak², J.I. Sperl², B. Stieltjes¹, J. Cyriac¹, J. Bremerich¹, G. Sommer¹, A.W. Sauter¹; ¹Basel/CH, ²Forchheim/DE (thomasjohannes.weikert@usb.ch)

Purpose: Manual tumour segmentation is time consuming and cost intensive, but mandatory when it comes to radiation treatment planning, therapy response monitoring or radiomics. The purpose of this study was to assess the performance of an AI-based radiology assistant to automate this task.

Methods and Materials: We preselected 75 FDG-PET/CTs for non-small-cell lung cancer (NSCLC) staging from our RIS/PACS archive (all confirmed by histology, solid and peripheral T1/T2 stages). First, all main masses were fully segmented and annotated manually by a radiologist on the CT component. Lesion volumes were calculated. In parallel, the same series were fed into interlinked AI-algorithms applying deep convolutional neural networks for automated detection and segmentation. The time required for both procedures was recorded. The intraclass correlation coefficient (ICC) for the detected volumes as measure of interrater reliability between manual and automatic analyses was calculated based on a single-rater, absolute agreement, 2-way random-effects model.

Results: The algorithm correctly detected 75 of 75 main lesions and attributed them to the respective lung lobe. Mean tumour volumes were: 6,810.52±8,353.53 mm³ for manual segmentation versus 7,105.45±8,989.48 mm³ for automated analysis. ICC was 0.956 (95% confidence interval 0.931 - 0.972; $p<0.001$). Mean processing time of the algorithm was 64±23 seconds compared to a mean of 342±382 seconds for manual tumour segmentation.

Conclusion: The algorithm facilitates a fast and reliable detection and 3D segmentation of solid peripheral pulmonary T1 and T2 tumours. Further evaluation regarding the performance on advanced and more challenging tumours (T3/T4, central, subsolid) is warranted.

Functional MRI study of language organisation in left-handed and right-handed trilingual subjects

S. Yazbek, C. Atat, J. Abdel Hay, R. Moussa; Beirut/LB (chirine.atat@gmail.com)

Purpose: fMRI has replaced WADA testing for preoperative assessment of language lateralization and localization. In Lebanon, most people are trilingual. Selecting the appropriate language to test is, therefore, intricate. Our objective is to compare fMRI maps for all 3 languages in left-handed and right-handed trilingual subjects.

Methods and Materials: We included 15 right-handed and 15 left-handed healthy adult volunteers, fluent in Arabic, French and English. We performed fMRI for each volunteer with a visual responsive naming task paradigm repeated for every language and we compared the areas of activation.

Results: Language lateralization was identical for the 3 languages in 87% of volunteers. The 4 subjects who demonstrated different lateralization were all left-handed. Broca and Wernicke areas demonstrated a bilateral activation in 88% of the cases, and presented the same anatomical localization for all 3 languages whereas the number and localization of the accessory language areas were different. There was a strong correlation between the global activation index and the chronology of language acquisition in right-handed subjects ($r_s = .275, p = .0068$) with the last language learned inducing a higher degree of activation.

Conclusion: In right-handed trilingual patients, fMRI performed for a single language can accurately determine language lateralization, whereas in left-handed all languages need to be tested. To determine the anatomical localization of accessory language areas, it is preferable to study all 3 languages. If the duration of the fMRI study was to be shortened, a study of the last language learned in right-handed patients could be considered.

Functional network analysis of human language: a novel approach using task-based fMRI

L. Pasquini, Q. Li, G. Del Ferraro, K. Peck, A.I. Holodny, H. Makse; New York, NY/US

Purpose: Task-based functional MRI (tb-fMRI) is a powerful method to identify brain areas involved in cognitive performances, such as language production. Pre-surgical planning of brain tumour is routinely accompanied by fMRI investigation to guide the neurosurgeon's understanding of the eloquent brain areas. Although tb-fMRI sheds light on brain areas involved in cognitive processes, it does not elucidate how these areas functionally interact with each other and integrate to form a comprehensive network. Resting-state fMRI on the other hand, has provided information on brain connectivity, but it is less implemented in clinical practice.

Methods and Materials: In this work, we employ statistical inference techniques to reconstruct brain networks from tb-fMRI unearthing the functional connectivity among brain areas involved in language performances. We tested this new method on 9 healthy right-handed subjects who performed a language production task.

Results: Our results show a robust common functional language network across healthy individuals which entangles the Broca's area, Wernicke's area, supplementary motor area, and pre-motor cortex in the left hemisphere of right-handed subjects. Furthermore, we investigated the functional connectivity of the anatomical sub-parts of the Broca's areas, such as pars opercularis and pars triangularis.

Conclusion: This new approach allows to gather valuable information about brain connectivity from the tb-fMRI examination routinely performed in clinical practice. This post-processing technique is general and not limited to language tasks, in addition to healthy controls it can be applied to patients and help understanding critical clinical questions, such as brain functional connectivity for pre-surgical planning.

B-1033 10:46

Altered resting-state functional connectivity of the anterior cingulate cortex in anxious rats post-acoustic trauma

X.-M. Xu, G.-J. Teng; Nanjing/CN (xmxu15@163.com)

Purpose: Acoustic trauma (AT) often leads to aberrant neural activity in a distributed brain network that not only includes the central auditory pathway, but also extra-auditory brain regions. Exactly where and how AT-induced cochlear hearing loss affects the central nervous system during the acute and sub-acute periods are poorly understood. We aimed to identify the neural substrate for aberrant patterns that mediate AT-related anxiety.

Methods and Materials: Forty-five male Sprague-Dawley (SD) rats were exposed to broadband noise of 122 dB for 2 hours and randomly divided into three groups: 0-day post-noise (N0D-acute period), 10-day post-noise (N10D-subacute period) and controls. Each group had 15 rats. All of them underwent emotion-related behavioural measurements (including open-field test and light/dark box) and resting state blood oxygenation level-dependent fMRI.

Results: Behavioural tests revealed that rats were much more anxious in the acute period and sustained little till 10 days later. Using an anterior cingulate cortex (ACC) seed, rats undergoing acoustic trauma demonstrated a large-scale network that had a spatial distribution beyond auditory network during both periods (N0D and N10D). Between-group analysis revealed that N0D rats displayed widespread reductions in functional connectivity, spanning primary somatosensory cortex, medial geniculate body, inferior colliculus, cingulate cortex, area 2, cerebellar lobule comparing with N10D rats and a similar pattern had also occurred in comparison with control group, while the FC increased during the sub-acute period.

Conclusion: Taken together, an "acoustic-causing" network accounting for distress, pain and gating of anxiety was proposed.

B-1034 10:54

Reward-related system fMRI activation as a monitoring tool for alcohol abuse rehabilitation

O. Omelchenko, M. Makarchuk, O. Podkovka, L. Myronyak, V. Rogozhyn; Kiev/UA (Ol.Omelchenko@gmail.com)

Purpose: Early response evaluation is necessary in patients with alcohol abuse rehabilitation. We propose reward-related system activation analysis with fMRI as the rehabilitation monitoring tool in alcohol abuse patients.

Methods and Materials: Two groups of subjects were studied using 1.5T CANON Titan. Group 1 consisted of 8 patients (4F, 4M, aged 28-43) with alcohol abuse, undertaking non-pharmaceutical rehabilitation and alcohol drinking refusal for 8 weeks. Group 2 consisted of 10 healthy volunteers (5F, 5M, aged 22-50) without alcohol abuse and normally drinking small amounts of alcohol. Event-related fMRI was used. Visual stimuli of alcohol-related items contrasting with non-alcohol related bottles were used for stimulation. For fMRI we used EPI pulse sequence: TR/TE=3000/60ms. Analysis was made with FSL (Oxford, GB).

Results: No alcohol craving was reported by Group 1 patients. No strong emotions were reported by Group 1 patients during observation of alcohol-related stimuli. Activation of the uncus of left hemisphere was shown for Group 1 and 2. Activation of right insula, right dorsolateral prefrontal cortex and left striatum was shown for Group 1. Pronounced activation of right insula, dorsolateral prefrontal cortex and left uncus was found in Group 2. Activation of right nucleus accumbens, left anterior cingulate cortex and motor cortex was shown for Group 2. Thus, absence of activation of reward-related system (nucleus accumbens, anterior cingulate) may be the correlate of successful alcohol abuse rehabilitation.

Conclusion: Reward-related system fMRI activation may reward-related as a tool for alcohol abuse patients rehabilitation monitoring.

B-1035 11:02

Brain resting state connectivity in the development of secondary hyperalgesia in healthy men

M.S. Hansen¹, L. Becerra², J.B. Dahl¹, D. Borsook³, J. Mårtensson⁴, A.F. Christensen¹, J.D. Nybing¹, I. Havsteen¹, M. Boesen¹, M.S. Asghar¹; ¹Copenhagen/DK, ²Boston, MA/US, ³Charlestown, MA/US, ⁴Lund/SE (morten.sejer.hansen@regionh.dk)

Purpose: Central sensitisation is a condition in which there is an abnormal responsiveness to nociceptive stimuli. As such, the process may contribute to the development and maintenance of pain. Factors influencing the propensity for development of central sensitisation have been a subject of intense debate and remain elusive. Injury-induced secondary hyperalgesia can be elicited by experimental pain models and is believed to be a result of central sensitisation, potentially reflecting individual levels of central sensitisation. The objective of this study was to investigate possible associations between the size of secondary hyperalgesia area and brain connectivity in known resting state networks.

Methods and Materials: We recruited 121 healthy, male participants (age 22, (SD 3.35)) who underwent resting state fMRI. Prior to the scan, areas of secondary hyperalgesia following brief thermal sensitisation (3 min. 45°C heat stimulation on the right thigh) were evaluated in all participants. Data were processed using FSL-Melodic software and analysed using dual regression.

Results: 115 participants were included in the final analysis. We found a positive correlation (increasing connectivity) with increasing area of secondary hyperalgesia in the sensorimotor- and default mode networks. We also observed a negative correlation (decreasing connectivity) with increasing secondary hyperalgesia area in the sensorimotor-, fronto-parietal-, and default mode networks.

Conclusion: Our findings indicate that increasing area of secondary hyperalgesia is associated with increasing and decreasing connectivity in multiple networks, suggesting that differences in propensities for central sensitisation, assessed as secondary hyperalgesia areas, may be expressed as differences in the resting state central neuronal activity.

B-1036 11:10

Altered cortical morphology of visual cortex in children with intermittent exotropia

L. Lu, S. Tang, X. Wang, Q. Gong, X. Huang; Chengdu/CN (1575389273@qq.com)

Purpose: To investigate cortical differences and age-related cortical differences between children with intermittent exotropia (IXT) and normal developmental children (NDC).

Methods and Materials: 16 IXT and 16 age-, gender-, handedness-, education- matched NDC were recruited. All participants completed ocular examinations, including visual acuity, cycloplegic refraction, angle of deviation measured by prism and alternate cover test, stereoacuity, and exotropia control using the Newcastle Control Score. All participants underwent high-resolution anatomical magnetic resonance imaging (MRI) using a 3-T MR scanner. FreeSurfer software was used to obtain measures of cortical volume, thickness, and surface area. Statistical differences of MRI measures between IXT and NDC were identified using a least general linear model with the intracranial volume, gender and age as covariates.

Results: Compared to NDC, children with IXT showed reduced surface area in primary visual cortex, increased surface area in inferior temporal cortex, increased cortical thickness in left orbitofrontal cortex, right middle temporal and inferior frontal cortex ($p < .05$; Monte Carlo corrected). We also observed significant age-related differences of cortical measures between two groups. Specifically, normal age-related decreases of surface area and cortical volume of superior parietal cortex were disrupted in children with IXT.

Conclusion: Quantitative characterization of independent aspect of cortical anatomy in IXT patients, we identified neuroanatomic deficits in visual cortex and association cortices highlighting the widespread impact of altered input to the visual system in IXT.

B-1037 11:18

Preoperative brain mapping: task-based and resting-state fMRI matching

A. Smirnov, M. Sharaev, T. Melnikova-Pitskhelauri, E. Pogosebkyan, L. Fadeeva, D. Pitskhelauri, I. Pronin; Moscow/RU (alex.smirnov@gmail.com)

Purpose: In the current work, we propose a three-step approach to automatic and efficient functional brain areas mapping as well demonstrate in case studies on three patients with gliomas the potential applicability of constrained source separation technique (semiblind independent component analysis, ICA) to brain networks discovery and the similarity of task-based fMRI (t-fMRI) and resting-state fMRI (rs-fMRI) results.

Methods and Materials: Three patients with brain glioma were examined with MRI 3T with t-fMRI and rs-fMRI protocols. Here we used tapping and language tests for t-fMRI, blind and semiblind ICA for both methods t-fMRI and rs-fMRI. Pre-processed fMRI data were passed to GIFT software to create both blind and semiblind spatially constrained ICA for both task-based and rs-fMRI. To measure similarity between spatial maps, we use Dice coefficient, which shows the ratio of overlapping voxels and all active voxels in two compared maps for each patient.

Results: RSNs of interest (motor and language) discovered by rs-fMRI highly correlate with t-fMRI reference and are located in anticipated anatomical regions. In general, in comparisons of the functional brain areas obtained with t-fMRI and rs-fMRI, there is a greater specificity of semiblind ICA compared to blind ICA.

Conclusion: Our preliminary stage in the study of functional changes in neuronal activity caused by brain tumours showed the degree of concordance between t-fMRI and rs-fMRI as well as produced by blind and semiblind ICA. We hope that further our research will allow predicting the activity of neural network architectures and non-invasive mapping of functional areas for preoperative planning.

The effect of visual stimulation on the aspartate concentration in activated cortex at 3T

A. [Manzhurtsev](#), P. Menshchikov, M. Ublinskiy, I. Melnikov, T. Akhadov, N. Semenova; *Moscow/RU (andrey.man.93@gmail.com)*

Purpose: Aspartate (Asp) is a neurotransmitter whose levels are reported to be decreased in activated brain zones at 7 Tesla. Previously we demonstrated that Asp can be measured more accurately using MEGA-PRESS pulse sequence at 3T. The fMRS of Asp is performed at 3T for the first time.

Methods and Materials: Eleven healthy subjects (19-34 y.o.), Philips Achieva dStream 3T and Head-Neck SENSE coil. Video stimulation: monitor, mirror, 8-Hz flashing checkerboard. The spectroscopy voxel (20x40x30 mm) was located in visual cortex. Asp signal was obtained with Asp_{MEGA-PRESS} sequence: TE=90 ms, TR=2000 ms, NSA=288, 27 ms editing pulses applied at $\delta_{OH}=3.89$ ppm and $\delta_{OH}=5.21$ ppm (9.5 min). Spectrum in rest was obtained and then spectrum during visual stimulation. Asp peak was processed in jMRUI (AMARES) and Asp intensity (I_{Asp}) was found. PRESS spectra from OFF-series were compiled; creatine (I_{Cr}) was found in LCModel. Asp was normalized on Cr: $I_{Asp}/I_{Cr} = Asp_{Cr}$. For each participant, the relative effect of stimulation on Asp_{Cr} was calculated: $rel.Asp_{Cr} = Asp_{Cr}(stimulus)/Asp_{Cr}(rest)$. $rel.Asp_{Cr}$ was compared with 1 with Mann-Whitney (MW) criterion.

Results: The Asp peak at 2.71 ppm has high SNR and is easily approximated by a single peak in AMARES (jMRUI). The statistically significant (p value<0.05) decrease of $rel.Asp_{Cr}$ by 4% was revealed.

Conclusion: The SNR of Asp peak in Asp_{MEGA-PRESS} 24 mL spectrum is much greater than at 7T without spectral editing and is sufficient enough for the confident quantitative analysis. The decrease of Asp in response to neuronal activation is in good accordance with previous findings at 7 Tesla.

B-1039 11:34

Advanced MR imaging with cognitive and vestibular stimulation in vestibular migraine

H.S. [Qubuk](#), K. Bicakci, S. Bicakci; *Adana/TR (hazal_selvi@hotmail.com)*

Purpose: The aim of the study was to evaluate the changes in cortical activation during 5 different tasks after stimulation of vestibular pathways at patients with vestibular and episodic migraine and to identify metabolic changes possibly be seen in thalamus, that is a key role in vestibular and pain pathways.

Methods and Materials: Fifteen patients with vestibular migraine and 15 patients with episodic migraine that had diagnosed at Çukurova University Neurology Department were included into this prospective study. Functional MRI was applied before and after the caloric test. BOLD fMRI data were registered during conjunctive eye movements, cognitive task, visual stimuli with 3 Tesla MR 32-channel head coil. SPSS v20 and SPM software was used for the statistical analysis.

Results: Functional MR imaging demonstrated increased cerebellar and insular activation in patients with vestibular migraine following caloric testing during finger-nose testing. During object naming task to activate linguistic-associated cortical areas increased thalamic activation was determined in vestibular migraine patients after caloric testing. In migraine patients, loss of activation in the occipital lobe was observed during visual stimulation after caloric testing.

Conclusion: Activation changes in brain regions during vestibular pathway activation and during performing cognitive, different tasks in vestibular and episodic migraine patients provide information about the pathophysiology of disease and functional changes that may occur during an attack in patients.

B-1040 11:42

Long-term reactions to pulsatile tinnitus are featured by weakened short-range functional connectivity within a brain network on the right-sided temporal lobe

H. [Lv](#), Z. Wang, P. Zhao, Z. Wang; *Beijing/CN (chrislvhan@126.com)*

Purpose: Recently, efforts that characterize the brain functional activity features in patients with pulsatile tinnitus (PT) are getting increasing concern. Accumulating evidence indicated aberrant functional connectivity (FC) of right middle temporal gyrus (MTG) in PT patient group with prolonged disease duration. Possible predictive effect of those functional connections may exist.

Methods and Materials: To test this hypothesis, resting-state functional magnetic resonance imaging (fMRI) were obtained from 34 patients with recent onset PT (RPTIN), 24 patients with long-term PT (LPTIN) and age-, gender-, education-matched 35 healthy controls were enrolled in this study. Right MTG was set as seed region to investigate the intrinsic FC within the whole brain. Results were further correlated with pulsatile tinnitus characteristics, especially disease duration.

Results: Functionally connected with hubs belonging to executive control network, default mode network (DMN) and limbic network, the strength of FC was mainly decreased in patient groups compared with normal controls. Relative to RPTIN and normal controls, LPTIN patients were further characterized by significant decreased FC among several short-range brain regions adjacent to the seed. Lastly, the disease duration showed negatively correlated with decreased FC between the seed and right fusiform gyrus/parahippocampal gyrus, right inferior frontal gyrus as well as right MTG (brain area adjacent to seed region) significantly, indicating a possible predictive effect of those functional connections.

Conclusion: Long-term reactions to pulsatile tinnitus mainly involved weakened short-range functional connectivity, especially within a functional network in the temporal lobe on the right hemisphere of the brain.

Functional network-based statistics reveal abnormal resting-state functional connectivity in minimal hepatic encephalopathy

H.-J. [Chen](#), T.-X. Zou; *Fuzhou/CN (chj0075@126.com)*

Purpose: Whole-brain functional network analysis is an emerging methodology for exploring the mechanisms underlying hepatic encephalopathy (HE). This study aimed to identify the brain subnetwork that is significantly altered within the functional connectome in minimal HE (MHE), the earliest stage of HE.

Methods and Materials: The study enrolled 19 cirrhotic patients with MHE and 19 controls who underwent the resting-state fMRI and cognitive assessment based on the psychometric hepatic encephalopathy score (PHES). A whole-brain functional connectivity (FC) matrix was calculated for each subject. Then network-based statistical analyses of the functional connectome were used to perform group comparisons, and correlation analyses were conducted to identify the relationships between FC alterations and cognitive performance.

Results: MHE patients showed significant reduction of positive FC within a subnetwork that predominantly involved the regions of the default-mode network, such as bilateral posterior cingulate gyrus, bilateral medial prefrontal cortex, bilateral hippocampus and parahippocampal gyrus, bilateral angular gyrus, and left lateral temporal cortex. Meanwhile, MHE patients showed significant reduction of negative FC between default-mode network regions (such as bilateral posterior cingulate gyrus, medial prefrontal cortex, and angular gyrus) and the regions involved in the somatosensory network (i.e., bilateral precentral and postcentral gyri) and the language network (i.e., the bilateral Rolandic operculum). The correlations of FC within the default-mode subnetwork and PHES results were noted.

Conclusion: Default-mode network dysfunction may be one of the core issues in the pathophysiology of MHE. Our findings support the notion that HE is a neurological disease related to intrinsic brain network disruption.

Lung cancer risk after baseline round of screening: only 20% of NLSST eligibles require annual round

M. [Silva](#)¹, F. [Sabia](#)², G. [Milanese](#)¹, S. [Sestini](#)², C. [Jacobs](#)³, B. [van Ginneken](#)³, M. [Prokop](#)³, C.M. [Schaefer-Prokop](#)⁴, N. [Sverzellati](#)¹, A.V. [Marchianò](#)², U. [Pastorino](#)²; ¹Parma/IT, ²Milan/IT, ³Nijmegen/NL, ⁴Amersfoort/NL (mariosilvamed@gmail.com)

Purpose: To calculate the risk of lung cancer (LC) in 1 year and 3 years after baseline low-dose computed tomography (LDCT) in high-risk subjects selected by the National Lung Cancer Screening Trial (NLSST) criteria.

Ethics committee approval: IRB: ProtINT05/53

Methods and materials: Subjects from the Multicentric Italian Lung Detection (MILD) trial were selected according to NLSST criteria: age≥55 years and pack-years≥30. Baseline characteristics were: smoking status (former/current), gender, percent of predicted forced expiratory volume in first second (FEV1%pred,90%threshold), Tiffeneau ratio (70%threshold), nodules at

baseline LDCT. The risk of LC in 1 and 3 years was calculated by multivariate models.

Results: In 1,248 NLST eligible screenees, LC frequency was 1.2% at 1 year, 2.6% at 3 years. At 1 year, nodule volume on LDCT was the only predictor of LC risk (volume>250mm³, odds ratio (OR) 34.25, p=0.0009). At 3 years, the risk of LC was predicted by: nodule volume 113-250 mm³(OR9.52 p=0.01), nodule volume >250 mm³(OR29.07, p<0.001), Tiffeneau≤70% (OR2.08 p=0.0195). A simulation of triennial screening rounds, with selective annual round only for nodule volume ≥113 mm³(19.9% in our population) showed 40% reduction of LDCT through 3 years, and 80% LDCT saving at each annual round.

Limitations: Administrative difficulties and lack of funding limited the recruitment (4,099 recruited as compared to 10,000 of original design).

Conclusion: Annual round is worthwhile for nodule ≥113mm³ (about 20% in our population). Screening every 3 years can safely reduce the LDCT burden for nodule <113mm³(about 80% in our population).

Clinical trials in Radiology and data sharing: results from a survey by the European Society of Radiology research committee

M. [Bosserd](mailto:bosserd@charite.de), B. Hamm, M. Dewey; Berlin/DE (maria.bosserd@charite.de)

Purpose: To determine the current situation and future directions of trials and data sharing in radiology.

Ethics committee approval: not necessary

Methods and materials: This survey was conducted between July and September 2018 among European heads of imaging departments and speakers at the Clinical Trials in Radiology sessions at ECR 2015-2018. The survey was approved by the ESR research committee and administered online.

Results: The response rate was lower among department heads (27%, 114/428) than among Clinical Trials in Radiology speakers (56%, 18/32; p<0.001). These institutions reported having conducted 429 trials, leading to 332 publications, of which 43% were first and 44% last authorships by those institutions. For future trials, 98% of respondents (93/95) said they would be interested in sharing data, although only 34% had shared data already (23/68, p<0.001). The major barriers to data sharing were data protection (78%, 74/95), ethical issues (49%, 47/95), and the lack of a data sharing platform (49%, 47/95). Of the respondents, 89% believed a platform would facilitate data sharing (85/95 vs. 10/95, p<0.001) and should offer easy data uploading (74%, 70/95), data safety (66%, 63/95), easy communication between providers and re-users (62%, 59/95), and data access policies (56%, 53/95).

Limitations: Low response rate.

Conclusion: A considerable number of imaging trials are being performed and published by radiologists in Europe while data sharing is hardly taking place, despite great interest: most likely because of data protection and ethical issues, as well as the absence of a data sharing platform.

Funding for this study: none

Carotid stenting with antithrombotic agents and intracranial thrombectomy leads to the highest recanalisation rate in acute stroke patients with tandem lesions

P. [Papanagiotou](#)¹, D. Haussen², M. Boutchakova-Meyer¹, F. Turjman³, J. Labreuche⁴, M. Piotin⁵, A. Kastrup¹, B. Gory²; ¹Bremen/DE, ²Atlanta, GA/US, ³Bron/FR, ⁴Lille/FR, ⁵Paris/FR

Purpose: The aim of this study was to identify the optimal endovascular approach in acute stroke patients with tandem lesions.

Ethics committee approval: The study was approved by the local institutional review board.

Methods and materials: This is an international, multicentre registry with a total of 482 patients with AIS and tandem lesions. Patients were treated by intracranial thrombectomy as well as one of the following four strategies: 1) acute carotid artery stenting of extracranial ICA with antithrombotic agents; 2) acute carotid artery stenting of extracranial ICA without antithrombotic agents; 3) balloon angioplasty of extracranial ICA; 4) intracranial thrombectomy alone. The main outcome endpoints of the study were the degree of recanalisation and the 90-day clinical outcome. The safety endpoints were symptomatic intracerebral haemorrhage (sICH) and all causes of mortality at 90 days.

Results: Using univariate analysis, the rates of successful reperfusion (modified thrombolysis in cerebral infarction 2b-3) and favourable clinical outcome after 90 days were significantly higher after acute carotid stenting with antithrombotic therapy and thrombectomy compared to the group with thrombectomy alone. After adjusting for confounding variables, acute stenting with antithrombotic therapy was independently associated with successful recanalisation (OR 2.4, 95%CI 1.25-4.59; P=0.008). The rates of sICH and 90-day mortality were comparable between all four treatment groups.

Limitations: This is a retrospective study with noncontrolled design.

Conclusion: Acute stenting of the extracranial ICA with antithrombotic therapy in combination with intracranial thrombectomy is associated with higher recanalisation rates in treatment of acute stroke patients with tandem lesions.

Funding for this study: This work was supported by Stryker.

Additional MRI screening in women with extremely dense breasts: primary outcome of the first round of the randomised DENSE trial

M.F. Bakker¹, S. Lange¹, R.M. Pijnappel¹, R.M. Mann², C. Loo³, B. Bisschops⁴, M.B.I. Lobbes⁵, M.D.-J.F. de Jong⁶, K.M. Duvivier², J. Veltman⁷, W.B. Veldhuis¹, C. van Gils¹. On behalf of the DENSE Trial Study Group; ¹Utrecht/NL, ²Nijmegen/NL, ³Amsterdam/NL, ⁴Dordrecht/NL, ⁵Maastricht/NL, ⁶s Hertogenbosch/NL, ⁷Almelo/NL

Purpose: To evaluate the effect of supplemental MRI for women with extremely dense breasts within a population-based screening programme.

Ethics committee approval: Approved by Dutch Minister of Health, Welfare and Sport (2011/19); participants gave written Informed Consent.

Methods and materials: Between 2011-2015, we randomised 40,373 screening participants (aged 50-75) with a negative screening mammography and extremely dense breasts (ACR category 4 by Volpara software) to (an invitation for) supplemental 3.0-T MRI at 8 sites (intervention arm; n=8,061) or mammography screening only (control arm; n=32,312). The difference in interval cancers, during the two-year screening interval, was investigated by intention-to-treat (ITT) analysis, and by complier-average causal effect (CACE) analysis to account for noncompliance.

Limitations: The study was not powered for mortality as outcome; interval cancer rate was used as the best proxy.

Detection rate for advanced neoplasia of single round of CT colonography vs three rounds of faecal immunochemical test in population screening for colorectal cancer: the SAVE randomised trial

L. [Sali](mailto:lapo.sali@unifi.it), L. Ventura, M. Mascalchi, P. Mantellini, M. Zappa, G. Grazzini; Florence/IT (lapo.sali@unifi.it)

Purpose: To compare a single round of CT colonography (CTC) vs three biennial rounds of faecal immunochemical test (FIT) for colorectal cancer (CRC) screening.

Ethics committee approval: Trial was approved by the Ethical Committee of the Local Health Unit of Florence (432/2010) and written informed consent was obtained in all participants.

Methods and materials: In this pragmatic randomised trial, 14981 subjects aged 54 to 65 years, living in a district of Florence, Italy, were randomised (1:2) and invited by mail to one of two screening interventions: 1) single round CT colonography; 2) three biennial rounds of FIT. Main outcome was detection rate for advanced neoplasia, defined as the proportion of invitees to screening intervention with screen-detected cancer or advanced adenoma. Secondary outcome was positive predictive value (PPV) for advanced neoplasia.

Results: Participants to single CTC were 1286/4825(26.7%) subjects, whereas participants to first, second and third FIT rounds were 4677/9288(50.4%), 4709/8676(54.3%) and 4215/7914(53.3%) subjects. The cumulative detection rate per-invitee for a single CTC round (1.39%; 67/4825) was lower than that for three FIT rounds (1.98%; 184/9288) (p=0.012). However, PPV of single

CTC (53.2%) was higher than that of three FIT rounds (32.4%) ($p < 0.0001$).

Limitations: Lack of a screening colonoscopy group as comparator for detection rate.

Conclusion: For population screening of CRC, a strategy based on single CTC yields a lower detection rate per-invitee than three biennial FIT rounds but is associated with less unnecessary diagnostic colonoscopies.

Funding for this study: This trial was funded by Tuscany Region and by Cassa di Risparmio di Firenze Foundation.

Cost-effectiveness analysis of computed tomography vs invasive coronary angiography in a randomised controlled trial

G. [Abdala Gehling](#)¹, I. Perez¹, A. Hollingsworth², T. Reinhold¹, M. Dewey¹; ¹Berlin/DE, ²Oklahoma City, OK/US

Purpose: To conduct a cost-effectiveness analysis of computed tomography (CT) coronary angiography and invasive coronary angiography (ICA) from the perspective of insurance providers.

Ethics committee approval: Institutional review board approval was obtained and all patients provided written informed consent.

Methods and materials: 329 patients with stable chest pain and suspected coronary artery disease were randomly assigned to either CT or ICA at a single centre. We gathered cost information from hospital billing information and from follow-up questionnaires. Quality of life was assessed with the EuroQoL-5D-3L questionnaire.

Results: 273 patients could be included in the cost-effectiveness analysis. There was no significant difference in quality of life before CT and ICA (0.86 vs 0.87 QALY/year; $p = 0.45$) and after a median of 4.43 years of follow-up in the CT and ICA group (0.85 vs 0.86 QALY/year; $p = 0.97$). Average insurance cost per patient for the initial management was 758.45±184.01€ in the CT and 1970.42±133.38€ in the ICA group ($p < 0.001$). Outpatient CT was significantly less costly than inpatient CT (394.85 vs 1501.42, $p < 0.001$). The incremental cost per follow-up year was similar in the CT (1805.76±511.99.€) and the ICA group (1997.31±742.92€; $p = 0.57$).

Limitations: Incomplete follow-up questionnaires and limited outpatient procedure cost information.

Conclusion: Initial management of patients with stable chest pain using CT is more cost-effective than using ICA while follow-up cost are similar.

Funding for this study: German Research Foundation was not involved in any stage of the study design, data acquisition, data analysis, or manuscript preparation.

Gadoxetic acid (GA)-enhanced liver MRI and hepatic haemangiomas (HH): diagnostic performance and impact of dynamic phase on lesion characterisation

F. [Castagnoli](#)¹, M. Grazioli¹, M. Puglia², B. Frittoli¹, M. Morone¹, L. Romanini¹, F. Donato¹, R. Ambrosini¹, L. Grazioli¹; ¹Brescia/IT, ²Naples/IT (francy-cast@hotmail.it)

Purpose: To evaluate diagnostic accuracy of MRI using GA for characterisation of HH, comparing the dynamic phase alone with respect to the whole study. Diagnostic confidence of different experienced radiologists was also tested.

Methods and Materials: We prospectively enrolled 124 patients with suspected lesions at CECT/US, excluding hepatopathic patients. Histology/biopsy or lesion stability at follow-up imaging were the standard of reference. A 1.5T scanner was used, with acquisitions of baseline, dynamic and hepatobiliary phase images before and during automatic i.v. injection of GA. Three sets of imaging were reviewed by 3 differently experienced radiologists in 3 sessions (1: baseline; 2: dynamic phase and 3: unenhanced+dynamic phase images). Pearson's Chi-square analysis was used to assess sensitivity, specificity and diagnostic accuracy for the whole examination, for the dynamic study and for each reader and session. Inter-reader agreement was evaluated using Cohen's Kappa.

Results: 332 lesions were analysed: 165 HH (49.7%), 91 metastases (27.4%), 3 CC (0.9%) and 76 benign lesions (22%). Sensitivity, specificity and diagnostic accuracy were, for the whole-study evaluation, 99.6%, 99.6% and 99.6% and, for the dynamic study alone, 98.2%, 99.6% and 98.8%, without a statistically significant difference between them ($p < 0.0001$). Excellent interobserver agreement (99% concordance, $k = 0.98$) was observed both for the whole study and for the dynamic phase evaluation (98.8%, $k = 0.97$).

Conclusion: The dynamic study alone using GA demonstrated high sensitivity and specificity values. Combined evaluation (baseline+dynamic images) slightly improves diagnostic performance in less experienced readers and in small, non-typical HH.

B-1043 10:38

Gadoxetic acid-enhanced magnetic resonance imaging for prediction of the postoperative prognosis of intrahepatic mass-forming cholangiocarcinoma

M.-J. Kim, S. Kim, C. An, K. Han, S. [Lee](#); Seoul/KR (sjlee37@yuhs.ac)

Purpose: To identify imaging markers that independently predict the postoperative outcome of intrahepatic mass-forming cholangiocarcinoma (IMCC) using gadoxetate disodium-enhanced magnetic resonance imaging (MRI).

Methods and Materials: Data from 54 patients who underwent preoperative gadoxetate disodium-enhanced MRI and curative surgery for IMCC were retrospectively evaluated. The prognostic power of various imaging and pathological features reportedly associated with recurrence-free survival (RFS) and overall survival (OS) were analysed using Cox regression models. A model combining imaging and pathological features was developed and its performance was evaluated using the Harrell C index and Akaike information criterion.

Results: Capsule penetration ($P = 0.016$) and tumour size ($P = 0.015$) were independent markers for RFS, while capsule penetration ($P = 0.012$) and hepatic vein obstruction (HVO, $P = 0.016$) were independent markers for OS, respectively, in the imaging-based model. Capsule penetration was the only imaging marker identified in the combined prediction model of RFS, and the combined model showed a higher C index and lower AIC value compared with the model based on pathological features alone.

Conclusion: The evaluation of capsule penetration and HVO using MRI may improve prediction of the postoperative prognosis of intrahepatic IMCC by incorporating imaging markers with a surgical staging system.

B-1044 10:46

Peritumoural radiomics features from gadoxetic acid-enhanced MR imaging predicting early recurrence of hepatocellular carcinoma

Z. [Zhang](#), J. Chen, H. Jiang, L. Cao, Z. Ye, B. Song, T. Duan; Chengdu/CN (zhangzhen950708@163.com)

Purpose: To investigate the ability of peritumoural radiomics features from gadoxetic acid-enhanced MR images for preoperative prediction of early recurrence (<1 year) in hepatocellular carcinoma (HCC).

Methods and Materials: 39 patients with surgically confirmed HCC were enrolled in this IRB-approved prospective study. A total of 1925 radiomics features within peritumoural region (a 5-pixel-wide radius surrounding the tumour boundary) were obtained from multiple phases (T2-weighted, non-enhanced T1-weighted, arterial phase, portal venous phase and hepatobiliary phase). The most predictive features were selected to build a radiomics signature using the least absolute shrinkage and selection operator (LASSO) algorithm with a 10-fold cross validation applied. Then, a prediction model comprising radiomics signature and predictive clinical variables was constructed using multivariable logistic regression analysis. Receiver operation characteristic (ROC) analysis and decision curve analysis were performed to evaluate the accuracies of the predictive models.

Results: Nineteen early recurrences (48.7%) were confirmed by imaging follow-up. A radiomics signature with four radiomics features, including Correlation, InverseDifferenceMoment (IDM) from T2-weighted images and Histogram MinIntensity, IDM from arterial phase images, demonstrated good performance with the sensitivity, specificity and area under the ROC curve of 85%, 92% and 0.926, respectively. Multivariate logistic regression analysis identified the radiomics signature (odds ratio [OR] = 1.761; $p < 0.001$), microvascular invasion (OR = 5.859; $p = 0.046$) and Edmonson-Steiner histologic

grade (OR=1.158;p=0.042) as independent predictive factors for early recurrence. The integrated prediction model comprising all predictive factors showed an improved predictive performance than the radiomics signature (AUC=0.975 vs.0.926, p<0.05).

Conclusion: Peritumoural radiomics features along with clinical variables had the potential of predicting early recurrence in patients with HCC after resection.

B-1045 10:54

Abbreviated gadoxetic acid-enhanced MRI (AGAM) including second shot arterial phase (SSAP) for hepatocellular carcinoma surveillance

J. Kim, C. Lee; *Seoul/KR (pridebio@naver.com)*

Purpose: To evaluate the feasibility of an abbreviated gadoxetic acid-enhanced MRI (AGAM) including second shot arterial phase(SSAP) for hepatocellular carcinoma (HCC) surveillance.

Methods and Materials: A total of 132 patients underwent gadoxetic acid-enhanced MRI using a modified injection protocol for HCC surveillance between July and December 2017. 82 HCCs in 68 patients were initially diagnosed based on the histopathologic result or typical imaging features. Modified injection protocol included routine dynamic imaging after a first injection of 6-mL and SSAP after a second injection of 4-mL. Image set 1 was full original protocol. Image set 2 consisted of T2WI, DWI, hepatobiliary phase, and SSAP (simulated abbreviated protocol). Acquisition time was measured in each image set. The per-patient sensitivity, specificity, PPV, and NPV, and per-lesion sensitivity and PPV were compared between two image sets. Image quality evaluation and visual assessment of vascularity were performed on the original AP, SSAP, and their subtraction images.

Results: The acquisition time was significantly shorter in image set 2 than in image set 1 (6.2 vs. 24.4 minutes, p<0.0001). The diagnostic performances were not significantly different between image sets 1 and 2 in two readers (p=0.277-0.814). The mean motion artefact score was significantly lower on the SSAP than on the original AP (1.77±0.74 vs. 2.07±0.84, p<0.001). 75/77 (97.4%) hypervascular HCCs showed hyperintensity on the SSAP and/or second subtraction images.

Conclusion: An AGAM including SSAP showed comparable diagnostic performance to a full dynamic MRI with faster image acquisition, fewer motion artefact, and preserved visual arterial hypervascularity for detecting HCC.

B-1046 11:02

Assessment of abbreviated MRI of liver for initial follow-up of patients with liver metastases from colorectal cancer

M.R. Torkzad¹, A. Riddell², D.-M. Koh¹; ¹Sutton/UK, ²Surrey/UK (michael.torkzad@gmail.com)

Purpose: To compare abbreviated MRI (ABB) of liver to standard MRI of liver (STD) for follow-up of patients treated for colorectal cancer liver metastases.

Methods and Materials: A retrospective analysis of all consecutive patients with colorectal metastases treated at our centre from 2011 until 2017 was done by two senior radiologists blinded to the results of each other. Each radiologist evaluated initially only HBP (hepatobiliary phase images with gadoxetate) and DWI (diffusion-weighted imaging) images up to b value of 800 (henceforth ABB). Later, the same radiologists assessed STD which included all pre- and postcontrast images, two sets of T2-weighted images with low TE (80-110 ms) and high TE (> 200 ms), double-echo images, as well as ABB sequences. One radiologist also compared surgical planning based on each of the two imaging sets.

Results: 114 patients could be included. A high degree of correlation was found between STD and ABB for both radiologists (R = 0.95; Spearman Rho) for the determination of type of response based on RECIST. The number of metastases found by both sets showed a high degree of correlation (R = 0.98; Pearson). Bland-Altman analysis revealed no bias (0.02) for number of metastases. No difference in surgical planning was found between the two sets of images.

Conclusion: Abbreviated MRI protocol for initial follow-up with only DWI and HBP provides almost the same results as a standard complete imaging set, and can, therefore, potentially reduce imaging and interpretation time and cost.

B-1047 11:10

Preoperative detection of colorectal liver metastases: DWI alone or combined with MDCT is no substitute for Gd-EOB-DTPA-enhanced MRI

A. Schulz, E.S. Joelsen-Hatlehol, K.W. Brudvik, B. Hanekamp, K.K. Aasand, E. Viktil, C.K. Johansen, J. Dormagen; *Oslo/NO (anselm.schulz@gmail.com)*

Purpose: To evaluate if preoperative detection of colorectal-liver-metastases (CRLM) with less resource-consuming DWI alone or in combination with MDCT can compete with gadolinium-ethoxybenzyl-diethylenetriaminepentaacetic acid (Gd-EOB-DTPA)-enhanced MRI.

Methods and Materials: Forty-four patients received MDCT and Gd-EOB-DTPA-enhanced MRI including DWI prior to liver resection for CRLM. Two radiologists evaluated five image sets each. The DWI-set consisted of diffusion-weighted sequences (b-values 0, 50 and 800s/mm²), ADC-map,

coronal, axial T2-weighted single-shot sequences. The DWI-T2F-set contained additionally respiratory-triggered T2-weighted TSE-SPiR sequences. The MDCT-set consisted of precontrast, arterial, portal-venous and late phase, the MDCT-DWI-set additionally of DWI. The CE-MRI-set contained all MRI-sequences. The diagnostic performance of the imaging-sets was based on 299 lesions including 123 CRLM. Histopathology and follow-up were reference standards.

Results: CE-MRI-set had highest sensitivity (p<0.013) with 95.1% compared to 72.4%, 73.2%, 73.2% and 87.0% for DWI-set, DWI-T2F-set, MDCT-set and MDCT-DWI-set. CE-MRI-set had highest sensitivity (p<0.012) for CRLM <10mm with 87.1% compared to 54.8%, 51.6%, 22.6% and 58.1% for DWI-set, DWI-T2F-set, MDCT-set and MDCT-DWI-set. The MDCT-DWI-set improved sensitivity overall and in size-dependent subgroup analyses compared to MDCT-set (p<0.031). MDCT-DWI-set showed highest specificity (98.3%) followed by 97.7%, 97.7%, 94.9%, 87.6% for the DWI-set, DWI-T2F-set, MDCT-set and CE-MRI-set (p<0.001).

Conclusion: Combination of DWI with MDCT improved sensitivity and specificity compared to each modality alone. DWI might be sufficient as follow-up or screening for primary staging of colorectal cancer in case of negative MDCT. MRI with DWI and Gd-EOB-DTPA showed highest sensitivity for CRLM and should be the preferred preoperative modality when meticulous lesion identification is essential.

B-1049 11:18

Findings of sinusoidal obstruction syndrome on gadoxetic-acid-enhanced MRI in patients with chemotherapy for colorectal liver metastases are poorly reproducible between radiologists

F. Staal¹, J.B. Houwers², B. Heeres¹, M. de Boer¹, D.M. Lambregts¹, M. Maas¹, R.G.H. Beets-Tan¹; ¹Amsterdam/NL, ²Maastricht/NL (f.staal@nki.nl)

Purpose: To assess the reproducibility of gadoxetic acid-enhanced MRI (EOB-MRI) to determine the presence and severity of sinusoidal obstruction syndrome (SOS) in patients treated with chemotherapy for colorectal liver metastases (CRLM).

Methods and Materials: 32 patients treated with chemotherapy for CRLM (either oxaliplatin based, oxaliplatin based in combination with bevacizumab, or non-oxaliplatin-based treatment), with available EOB-MRI scans in the hepatobiliary phase, were retrospectively included. The presence and severity of SOS were independently scored by three radiologists with varying experience (10-20 years of experience in EOB-MRI), who were blinded to the clinical data, using a 5-point scale (SOS score 0=definitely not present to 4=definitely present). The inter-observer agreement between readers was assessed with a quadratic-weighted kappa.

Results: The mean time between chemotherapy completion and EOB-MRI scan was 1.1 (+/-1.4) months. Inter-observer agreement was poor with kappas ranging from 0.25 (95%CI 0.01-0.48) to 0.33 (95%CI 0.08-0.58). More equivocal scores (SOS score = 2) were chosen by less experienced radiologists (6.3% and 43.8% equivocal scores) compared to a more experienced radiologist (3.1% equivocal scores).

Conclusion: The assessment of SOS on hepatobiliary phase EOB-MRI in patients treated with chemotherapy for CRLM shows a poor inter-observer agreement for the diagnosis of SOS. This questions the value of hepatobiliary phase EOB-MRI for this purpose.

B-1050 11:26

Enhancement features, blood-based bio-markers and immunohistochemical expression of hepatocyte transporters in patients with non-alcoholic fatty liver disease (NAFLD)

D.S. Feier¹, N. Bastati-Huber², A. Beer², S. Pötter-Lang², R.M. Fragner², A. Ba-Ssalamah²; ¹Cluj-Napoca/RO, ²Vienna/AT (diana.feier@gmail.com)

Purpose: To quantify enhancement features of gadoxetic acid enhanced-MRI and blood-based biomarkers parameters in patients with non-alcoholic fatty liver disease (NAFLD), and correlate them with the immunohistochemical expression of the hepatocyte transporters (OATP2/8, MRP2, MRP3).

Methods and Materials: The local institutional review committee approved this study and waived written informed consent. This was a retrospective study of gadoxetic acid-enhanced 3T MR imaging performed in 46 consecutive patients with NAFLD (mean age (SD), 49.46 (15.52) years). The MR images were analyzed by using the relative enhancement (RLE). NAFLD fibrosis score (NFS) and FIB-4 were used as blood-based biomarkers parameters. Regression analyses were applied to identify variables associated with OATP2/8, MRP2, MRP3 expression.

Results: A statistically significant higher number of patients with NASH had increased lobular inflammation (p<0.0001), ballooning (p<0.0001), liver steatosis (p=0.003) and liver fibrosis (p=0.002) compared to those with simple steatosis. RLE, NFS and FIB-4 were independent predictors of NASH patients with a generated model able to differentiate NASH from simple steatosis patients with a probability of 87% [AUROC=0.87 (95%CI 0.74-0.94)], a sensitivity of 85% (95%CI 70.2-94.3), and a specificity of 75% (95%CI 42.8-94.2). Relative enhancement was positively correlated with the expression of

OATP2/8 expression ($r=0.41$, $p=0.002$) and NFS and FIB-4 positively correlated with the expression of MRP2 ($r=-0.37$, $p=0.007$).

Conclusion: Imaging and blood-based biomarkers parameters used together may discriminate between patients with NASH and simple steatosis.

B-1051 11:34

Postoperative complications after living donor liver transplantation: risk assessment on Gd-EOB-DTPA-enhanced 3-T MR imaging using quantitative-qualitative parameters

A. Kahraman¹, M. Kolu², B. Kahraman¹, Z. Ozdemir¹, L. Karaca¹, S. Yilmaz¹;
¹Malatya/TR, ²Sanliurfa/TR (mdasagir2003@hotmail.com)

Purpose: To investigate if Gd-EOB-DTPA-enhanced magnetic resonance imaging (MRI) with measurements of quantitative and qualitative parameters on hepatobiliary phase images can predict the risk of postoperative complications after living donor liver transplantation (LDLT).

Methods and Materials: This prospective study included 60 subjects (30 living donor candidates and 30 their recipients). We obtained Gd-EOB-DTPA-enhanced 3T MRI before LDLT in donors and after LDLT in their recipients. MRI parameters including relative liver enhancement (RLE) value, biliary signal value and visual evaluation of liver and biliary enhancement on hepatobiliary phase images were recorded. The patients were followed for postoperative biliary and vascular complications and then grouped according to the presence and absence of complications. The relations between MRI parameters and postoperative complications were analysed statistically. In addition to MRI parameters, the latter also included postoperative laboratory variables.

Results: The recipients with postoperative complications had significantly lower mean RLE values and biliary signal values than those without and than donors ($p<0.001$). Qualitative MRI parameters involving visual assessments of liver enhancement and biliary signal were also significantly different in recipients with postoperative complications compared to donors and patients without postoperative complications ($p<0.001$). RLE values and biliary signal values were inversely related to the postoperative bilirubin values in recipients ($p=0.005$, $r=-0.496$; $p<0.001$, $r=-0.624$). There were no correlation between INR values and MRI parameters ($p=0.837$, $p=0.813$).

Conclusion: The quantitative and qualitative MRI parameters obtained by Gd-EOB-DTPA-enhanced MRI on hepatobiliary phase images can help with the assessment of the risk for postoperative complications after LDLT.

B-1052 11:42

What is the effect of steatosis, iron overload and renal function on the uptake and excretion of gadoxetic acid-enhanced MRI?

L. Beer, N. Bastati, S. Pötter-Lang, D. Stoyanova, E. Michael, Y. Bican, H. Einspieler, A. Ba-Ssalamah; Vienna/AT (lucian.beer@meduniwien.ac.at)

Purpose: To explore the effect of steatosis, hepatic iron overload, and renal function on gadoxetic-acid (GA) uptake in hepatobiliary phase (HBP) images in patients with diffuse chronic liver disease (CLD).

Methods and Materials: This retrospective IRB-approved study included 265 patients (164 men, 101 female, mean age 54 ± 16 years) with CLD who had undergone GA-enhanced MRI of the liver between 2010-2015. Demographic and clinical data were obtained from our patients' medical history and included age, sex, body mass index, creatinine, and estimated glomerular filtration rate (eGFR). Relative liver enhancement (RLE), was calculated by two radiologists using unenhanced and GA-enhanced HBP images, 20 minutes after administration of the GA. Hepatic fat fraction (%) was measured on dual-echo gradient-recalled echo. Hepatic siderosis was semi-quantitatively assessed on T2-weighted, fat-suppressed images (Grade 1-3). Spearman's correlation coefficients were used to assess the correlation between RLE and laboratory parameters. ANOVA with Bonferroni-post-hoc-test was used to compare different groups.

Results: There was a significant correlation between RLE and eGFR ($R=0.225$, $p<0.001$) and siderosis grade ($R=-0.210$, $p=0.001$), while hepatic fat fraction did not correlate with RLE ($R=0.098$, $P=0.116$). RLE in patients with highly impaired renal function ($eGFR<30$ ml/min/1.73 m²) was significantly lower than in patients with slightly impaired ($eGFR$ 30-90) or normal kidney function ($eGFR >90$) (RLE:46%vs.82%vs.89%, $p<0.001$). In addition, RLE was significantly lower in patients with severe siderosis compared to those with no siderosis (RLE:46%vs.86%; $p=0.011$).

Conclusion: Gadoxetic-acid relative enhancement significantly correlates with renal function; however, it is independent of hepatic fat fraction in patients with diffuse CLD.

Making measurements on coronal ultrasound images of infant hips during Barlow manoeuvre: a new and rapid screening method for developmental dysplasia of the hip

Ü.Y. Ayaz, M.E. Döğen; Mersin/TR (umityasarayaz@yahoo.com)

Purpose: In order to shorten the examination time for sonographic screening of developmental dysplasia of the hip (DDH), we aimed to obtain the femoral head coverage (FHC) as well as *alpha* and *beta* angles of the normal infant hips during Barlow maneuver using only the coronal ultrasound (US) images.

Methods and Materials: In this prospective study, a total of 150 hips of 75 healthy infants were included. The infants were initially evaluated by US and then clinically followed-up till their hips were proved to demonstrate normal orthopaedic development at physical examination. Median clinical follow-up time was 276 days. US examination of the hip in coronal plane was performed during Barlow maneuver in supine position using a linear-array transducer.

Results: The positions of the femoral heads in their acetabuli and the development of hip components (bony acetabulum, cartilaginous labrum) were normal in all the infants. All the hips were stable and classified as Graf type 1 with *alpha* angles $\geq 60^\circ$. Mean FHC with range values for the right and left hips were, $65.9\pm 7.3\%$ (range, 47.8%-80.8%) and $64.4\pm 6.9\%$ (range, 46%-77%), respectively. The difference between the mean FHC of right and left hips was not significant ($P>0.05$).

Conclusion: Our up-to-date FHC values were considered to be more clinically relevant, since the measurements were made during Barlow maneuver. Our newer technique can be used for obtaining FHC, as well as *alpha* and *beta* angles using the same single coronal US image for each hip which significantly shortens the examination time.

B-1054 10:47

Use of magnetic resonance imaging to predict progression of juvenile idiopathic arthritis in paediatric patients in clinical remission

F. Sertorio, M. De Cesari, M. Mazzoni, A. Pistorio, A. Urru, F. Magnaguagno, C. Malattia, G.M. Magnano; Genova/IT (fiammetta.sertorio@gmail.com)

Purpose: To assess the prevalence of subclinical synovitis as detected by MRI in a cohort of patients with juvenile idiopathic arthritis (JIA) in clinical remission and to evaluate its association with disease flare and structural damage progression.

Methods and Materials: All contrast-enhanced MR performed from 2007 to 2015 on patients with JIA in clinical remission were analysed by two independent readers. Joint damage progression was assessed by conventional radiography (CR). Statistical analyses were performed.

Results: Ninety patients were included: 14/90 (15.6%) in remission off medication, while 76/90 (84.4%) in remission on medication. 45 patients were assessed by MRI in the wrist, 30 in the hips, 13 in the ankle and 2 in the knee. 57 patients (63.3%) had evidence of subclinical synovitis on MRI. The interobserver agreement for presence/absence of synovitis was good ($k=0.74$). 43/57 patients (75.4%) with subclinical synovitis experienced a disease flare versus 11/33 patients (33.3%) who had not any synovial inflammation. Radiographic damage progression was assessed by CR in 54/90 patients and was detected in 19/54 patients (35.2%). A significant association between systemic JIA subtype and deterioration of joint damage was found; MRI-detected bone marrow oedema (BMO) score and the baseline radiographic damage score were also significantly related to structural progression.

Conclusion: Subclinical synovitis detected by MRI was significantly associated with disease flare, while BMO showed remarkable promise in predicting joint destruction. These findings support the MRI utility for the assessment of JIA patients in clinical remission and may have important clinical implications for their management.

Secondary fractures in paediatric radial head and neck fractures: common association, commonly missed

A.J. [Degnan](#), V.M. Ho-Fung, J.C. Nguyen, J.T.R. Lawrence, S.L. Kaplan; Philadelphia, PA/US (degnan.andrew@gmail.com)

Purpose: Radial head and neck fractures are typically viewed as adult-type fractures uncommon in children. The nature and frequency of associated additional fractures are poorly understood.

Methods and Materials: Elbow radiographs in 500 consecutive children (<18 years) during a five-year period (January 1, 2013-December 31, 2017) with reports containing terms related to radial head or neck fracture were re-reviewed for fracture identification. Pathologic fractures and fractures sustained prior to the study period were excluded. Review of cases yielded 270 unique patients with radial head and/or neck fractures.

Results: Approximately two-thirds (65.6%) of radial head and/or neck fractures occurred in isolation whereas 34.4% of patients had an additional elbow fracture with concomitant olecranon fractures being most common (23.0%), followed by medial epicondyle fractures (4.1%), coronoid fractures (3.3%) and other types of additional fractures. Complete radius fractures were more likely to have an additional fracture than incomplete fractures (OR: 3.30, CI: 1.88-5.78, $p<0.001$). Significant joint effusion was also associated with the presence of an additional fracture (OR: 2.18, CI: 1.06-4.45, $p=0.03$). Combined radial head/neck and olecranon fractures occurred in a younger age group (7.32 years, SD: 3.19) than isolated radial head/neck fractures (9.89 years, SD: 3.85), $p<0.001$. Approximately one-third (32.6%) of additional fractures were not identified on initial radiographs, 39% of which were not visible on initial radiographs.

Conclusion: Radial head and neck fractures are underappreciated in the paediatric population. These radius fractures have a substantial association with additional fractures, and secondary fractures are often missed or occult on initial radiographs.

B-1056 11:03

The applicability of the Greulich and Pyle atlas to a modern Irish population

L.L. [McCarthy](#)¹, C. Brenner¹, J. Sammon², L.D. Spence², J. O'Connor¹; ¹Dublin/IE, ²Cork/IE (lauraghmccarthy1@hotmail.com)

Purpose: The Greulich and Pyle Radiographic Atlas of the Hand and Wrist is the gold standard in clinical practice for assessment of skeletal development of children from birth to maturity. The literature however suggests that the atlas is not universally applicable to all populations. Given the clinical importance of the Greulich and Pyle atlas and the need to ensure that methods used for age assessment are tested it is imperative that a study be undertaken to determine its appropriateness for use in a modern Irish population.

Methods and Materials: A retrospective cross-sectional analysis was performed of hand/wrist radiographs from children presenting to the Accident and Emergency Department of Cork University Hospital between 2008-2013. Radiographs of 444 children (Male: Female 257:187) with an age range of 0-19 years were examined. Observers were blinded to chronological age at the time of assessment of skeletal age. Each radiograph was assessed using the Greulich and Pyle Atlas and a skeletal age assigned. Chronological age was subtracted from skeletal age to obtain the residual difference.

Results: Skeletal and chronological age were highly correlated in both males (0.968) and females (0.968) ($p<0.01$). The mean difference between skeletal age and chronological age was positive in value, indicating that in the current sample skeletal age was advanced compared to chronological age. For males mean skeletal age was advanced by 1.14 (± 15.12) months and for females mean skeletal age was advanced by 2.58 (± 12.78) months.

Conclusion: The Atlas appears to still be applicable to a modern Irish population.

B-1057 11:11

The value of MR spectroscopic bone marrow fat fractions in the assessment of treatment response in patients with Gaucher disease

A.J. [Degnan](#), V.M. Ho-Fung, D.-J. Wang, C. Barrera, R. Ahrens-Nicklas, C. Cicioglu; Philadelphia, PA/US (degnan.andrew@gmail.com)

Purpose: Gaucher disease involves deficiency of β -glucocerebrosidase that results in the accumulation of abnormal macrophages in the spleen, liver and bone marrow. Liver and spleen volumes are currently used alongside laboratory markers for disease severity. It is unclear if these markers are sufficient in assessing overall severity and risk for bone-related complications including impaired growth and osteonecrosis. Magnetic resonance spectroscopy (MRS) measures bone marrow quantitatively with lower fat fractions corresponding to more severe disease.

Methods and Materials: Patients with Type I Gaucher disease were imaged using MRI and MRS for liver and spleen volumes as well as fat fraction calculations within the lumbar spine and femoral neck prior to and during enzyme replacement therapy. Healthy control MRS data were included for

comparison. Statistical analysis included Mann-Whitney U tests and Pearson correlation.

Results: This IRB-approved retrospective study included 6 Gaucher patients (2 female, 4 male; 9.8 years, SD: 5.8) and 6 healthy controls (3 female, 3 male; 11.7 years, SD: 3.7). Fat fractions were significantly lower in patients (femoral neck: 31.9% vs. 62.6%, $p=0.020$; lumbar spine: 18.5% vs. 35.8%, $p=0.019$). Organ volumes decreased and fat fractions increased significantly with treatment. Treatment duration correlated with femoral neck fat fraction (Pearson: 0.912, $p<0.001$), age (Pearson: 0.892, $p<0.001$) and lumbar spine fat fraction (Pearson 0.689; $p=0.007$); inverse correlations with organ volumes were not significant.

Conclusion: Bone marrow fat fractions in Gaucher disease may better correspond with treatment duration than traditionally monitored organ volumes. Larger prospective study is needed to assess if bone marrow imaging provides additional information in guiding therapy in Gaucher disease.

B-1058 11:19

Non-breath hold dynamic contrast enhanced abdominal and thoracic MRI in paediatric oncologic patients using a GRASP-sequence at 3T

T. Woerner, P. Raczek, A. Buecker, G. [Schneider](#); Homburg/DE (dr.guenther.schneider@uks.eu)

Purpose: One of the few advantages of modern CT scanning over MRI in paediatric imaging is the possibility to perform dynamic CE studies without the need of a breath-hold. However, new MRI techniques like Golden-Angel Radial Sparse Parallel MRI (GRASP) allow for free-breathing dynamic contrast enhanced volumetric imaging. The aim of our study was to evaluate GRASP sequences in evaluation of abdominal and thoracic malignancies in paediatric patients.

Methods and Materials: In 32 paediatric patients MRI was performed on a 3T scanner (Siemens,VIDA). Patients below 10 years of age were sedated for imaging studies. MR protocol included non breath-hold unenhanced radial T2w images, radial T1w and T1w fs VIBE sequences and DWI. During contrast administration (0.05 mmol/kg MultiHance,Bracco) a GRASP Sequence with a temporal resolution of 4 - 6 sec and reconstruction of 16 - 26 phases was performed. After CM radial VIBE sequences were repeated. In patients with liver lesions another set of radial VIBE sequences was performed in the biliary phase of CM excretion to further characterise lesions.

Results: Dynamic non-breath-hold imaging of the abdomen was successful in all cases and even excellent in thoracic imaging depiction of perfusion characteristics of tumours. Characterisation of liver lesions based on the typical enhancement characteristics was feasible in all cases and in a similar manner renal and adrenal tumours could be evaluated.

Conclusion: Non-breath-hold dynamic contrast enhanced imaging is feasible in paediatric patients using GRASP sequence and gives detailed information about perfusion characteristics of abdominal and thoracic tumours without radiation exposure.

Is TI-RADS useful as an adult ultrasonographic malignancy risk stratification method in pediatric thyroid nodules?

Y. Durum, V. [Ozturk](#), N. Ersöz, A. Anik, C. Karaman; Aydin/TR (md.suhaozturk@gmail.com)

Purpose: Data on TI-RADS generally belong to studies performed in adults. Therefore we aimed to evaluate the performance and utility of TI-RADS in the paediatric groups.

Methods and Materials: From January 2015 to 2018, 108 nodules were evaluated in 1028 thyroid ultrasound examinations. Images were retrospectively evaluated by two radiologists with 3 and 7 years of paediatric radiology experience, according to TI-RADS classification. Morphological findings of the detected nodules and their histopathological results were recorded. Histopathological findings and at least 6 months of follow-up imaging were taken as reference.

Results: 73 patients were female (67.6%). The mean age was 11.4 and the mean nodule size was 7.5 ± 8.3 mm. According to TI-RADS, 41 (38%) were hypoechoic and 5 (4.6%) were very hypoechoic. When margin features evaluated, 85 (78.7%) lesions were smooth, 8 (7.4%) were irregular. According to the histopathologic assessment 100 (95.2%) of the nodules were benign and 5 (4.8%) were malign. 2 nodules were evaluated as non-diagnostic cytology and 1 nodule as suspicious for malignancy. All malign nodules were in the TI-RADS 5 category. The majority of benign nodules (79%) were found in TI-RADS 1, TI-RADS 2 and TI-RADS 3 categories. 80% of the malign nodules were very hypoechoic and taller than wide in shape, also all malign nodules had microcalcifications ($p=0.000$). The sensitivity of TI-RADS was 100%, specificity was 78.8%, PPD was 19.2%, NPD was 100%.

Conclusion: According to our study, TI-RADS system can be used to evaluate thyroid nodules in paediatric patients similar to adults.

B-1060 11:35

Paediatric rhabdomyosarcomas: which type of radiological assessment after induction chemotherapy better predicts the survival?

G. Orsatti¹, A. Varotto¹, M. Bonzini², M. Minotti², C. Morosi², F. Crimi¹, C. Giraud¹, E. Quaia¹, R. Stramare¹; ¹Padua/IT, ²Milan/IT
(giovanna.orsatti@gmail.com)

Purpose: To investigate the prognostic value of radiological response assessment after induction therapy in paediatric rhabdomyosarcomas (pRMS), comparing three different methods.

Methods and Materials: This retrospective, bicentric study included 62 non-metastatic pRMS. Two radiologists measured tumour size on pre- and post-treatment MR images using three methods: the maximal diameter, in accordance with the Response Evaluation Criteria in Solid Tumours (1D), the multiplication of the two maximal axial diameters, respecting the World Health Organization criteria (2D) and the multiplication of the three maximal diameters and $\pi/6$, following the European paediatric soft tissue sarcoma study group guidelines (3D). Regarding tumour response, each patient was classified as a responder (complete or partial response) or a non-responder (stable or progressive disease) according to each method and its respective therapeutic thresholds. The event-free survival (EFS) and the overall survival (OS) were assessed (Kaplan-Meier plots and log-rank test, $p < 0.001$). The inter-observer agreement (concordance correlation coefficient (CCC)) and the inter-method agreement for the therapeutic responses (weighted κ -coefficient) were calculated.

Results: As regards the five-year EFS, the 3D assessment showed significantly higher values for responders than non-responders (80.4% vs 22.2%, $p < 0.0001$); no significant differences emerged for 1D and 2D methods. The 3D measurements were significantly better predictors of five-year OS (84.1% vs 44.4%, $p = 0.0003$). The inter-observer agreement was higher for 3D than 1D and 2D measurements (CCC=0.93, 0.86 and 0.75, respectively); the inter-method agreement for the therapeutic responses was poor (highest value, $\kappa_{1Dvs2D} = 0.57$; $p < 0.0001$).

Conclusion: The 3D assessment of therapeutic response in pRMS seems to provide a better correlation with the clinical outcome than other radiological methods.

B-1061 11:43

Diffusion-weighted magnetic resonance imaging for the evaluation of Wilms tumours: radiological-pathological correlation

E. Nazarova, N. Merkulov, A. Mitrofanova, G. Tereshenko; Moscow/RU
(evelina.nazarova@fcho-moscow.ru)

Purpose: Wilms tumour (WT), or nephroblastoma is one of the most common extracranial tumours in pediatric population. Different histological types of nephroblastoma impact staging, treatment options and outcome. The aim of the study was to analyze possible correlation between diffusion-weighted imaging (DWI) data and different histological types of WT.

Methods and Materials: The study was based on data of 31 pediatric patients with histopathologically verified WT. Median age at the time of diagnosis was 5 years (from 1 to 8 years old), male to female ratio was 1:1.3. Imaging data was obtained with 3T MRI (magnetic resonance imaging) scanner. The apparent diffusion coefficient (ADC) value for each tumour was calculated using region-of-interest measurements. The mean ADC values and histological types of WT were compared using regression analysis method.

Results: Out of 31 patient 6/31 (19%) were low risk, 16/31 (52%) intermediate and 9/31 (29%) high risk. The mean ADC values were $0.34 \pm 0.05 \times 10^{-3} \text{ mm}^2/\text{s}$ for low grade WT, $1 \pm 0.12 \times 10^{-3} \text{ mm}^2/\text{s}$ for medium grade WT, and $0.6 \pm 0.06 \times 10^{-3} \text{ mm}^2/\text{s}$ for high grade WT. Intraclass correlation coefficient was 0.93.

Conclusion: In our study, we have found a significant correlation between ADC values and histological types of WT. MRI DWI can be a useful tool in the initial assessment and differential diagnosis in patients with nephroblastoma.

B-1062 11:51

Role of intraarterial chemotherapy for retinoblastoma: our experience with review of literature

L.S.P. Karanam, S. Baddam, V. P. S. Honavar; Hyderabad/IN
(drklsp@gmail.com)

Purpose: To describe the role of ophthalmic artery chemotherapy in 78 children of intraocular retinoblastoma. Technical details, procedural events, complications and outcomes were analysed in this large single-centre cohort.

Methods and Materials: From April 2014 to February 2018, 78 patients with age group between 6 months to 83 months underwent IAC at our institution: 45 eyes of group D and 33 eyes of group E. Demographic details, no. of sessions, response to therapy, follow-up were documented in all the cases. We used techniques of direct ophthalmic artery catheterisation, middle meningeal artery cannulation and balloon occlusion methods for the targeted drug delivery with triple-drug regimen (topotecan, melphalan and carboplatin).

Results: 78 patients underwent a total of 228 sessions. Complications in the form of transient lid oedema, swelling, loss of eyelashes and conjunctival congestion occurred in 8 patients. Fever with neutropenia occurred in 2 patients. No procedural-related complications such as strokes or femoral artery puncture site haematomas occurred in any patient. Recurrent tumour was seen in 3 eyes, persistent sub-retinal seeds in 2 eyes and persistent vitreous seeds in 1 eye. 15 patients underwent enucleation and globe salvage was achieved in 80.7% of overall patients and 87.3% in treatment-naive eyes in a follow-up of 2 years in 85% of the patients.

Conclusion: OAC achieves greater biological effect while minimizing systemic effects and plays important role in globe salvage especially in places with advanced retinoblastoma. It can be done safely and should be considered as first-line treatment with acceptable risks.

The impact of imaging receptor technology on workflow, patient dose values and image quality of bedside chest radiography

J. Santos¹, S. Carmo², A.R. Cardoso², C.M.D.S. Almeida²; ¹Coimbra/PT, ²Lisboa/PT (joanasantos@estescoimbra.pt)

Purpose: The aim of this study was to compare different image receptor technologies in order to optimise bedside chest radiography workflow and examination dose values.

Methods and Materials: The quality control of the portable equipment was verified. Exposure parameters and examination dose values were analysed for standard patients that were submitted to chest radiography using the existing computed radiology (CR) image detector (n=18). Experimental tests with an adult anthropomorphic phantom were performed in order to compare the CR image receptors and a digital radiography (DR) detector (n=12). Dose values (DAPmGy.cm²) and objective image quality was performed (image signal and noise) and new pre-set protocols for DR receptor were defined with clinical approval. Standard patient exposure parameters and examination dose values using DR were analysed for comparison (n=29). Images from patients submitted to chest radiography with both systems were selected (n=18). Three radiologists, using the European Criteria for chest radiography, performed subjective image quality analysis. The time between the radiographers start the examination and image availability on the system was quantified.

Results: Experimental phantom tests revealed the possibility to optimised the exposure and reduce dose values in 25%. The images were available in the system 30 minutes before with the DR system. With the new image receptor it was possible to reduce patient dose in 32% with similar image quality.

Conclusion: The technology allowed workflow time reduction and examination dose reduction maintaining image quality. The experimental tests and the results discussion contributed to radiographer's faster technology adaption.

The effects of weight-bearing and non-weight-bearing anteroposterior DR of feet in hallux valgus deformity

H. Zhang, Z. Wang, J. Liu; Tianjin/CN (15602179624@163.com)

Purpose: To measure and compare the angles about hallux valgus, using weight-bearing and non-weight-bearing anteroposterior DR to provide more reliable data for rectifying hallux valgus.

Methods and Materials: During 2016.12-2017.05, 15 patients (20 feet) (men:women=5:10; average age: 60.1±4.3y) with hallux valgus received weight-bearing and non-weight-bearing anteroposterior DR (GE Discovery XR656) before operation. Weight-bearing position: the patients stood on the special device for foot and ankle weight-bearing imaging. Both feet were separated and were equal to shoulder's width. Non-weight-bearing position: the patients sat on the photographic table, with feet close to the table. The X-ray tube inclined 15°cephaladly. The centre line was at the base of the third metatarsal of the foot with hallux valgus, the focus-film distance was 120cm. Voltage: 50KV; current: 4mAs. The hallux valgus angle (HVA), intermetatarsal angle (IMA) between first and second metatarsal bone, distal metatarsal articular angle (DMAA) of first metatarsal were measured using Image pro Plus 6.0. The HVA, IMA and DMAA of weight-bearing and non-weight-bearing groups were compared using paired t test.

Results: The HVA, IMA, DMAA in weight-bearing position was 38.18±11.69, 15.64±4.15, 18.23±8.36; in non-weight-bearing position was 35.15±10.77, 12.96±4.05, 15.00±7.96. The HVA, IMA, DMAA in weight-bearing position were larger than that of non-weight-bearing position, showing statistically significant differences (t = 2.98, 6.4, 2.21, P=0.010, P=0.000, P=0.044).

Conclusion: The HVA, IMA and DMAA in physiological weight-bearing group are larger than non-weight-bearing groups in patients with hallux valgus.

B-1065 08:46

Dose optimisation of lumbar spine radiographs using a phantom: what are the ideal exposure parameters?

Z. Lai, C. Sá dos Reis, Z. Sun; Perth/AU (claudia.sadosreis@curtin.edu.au)

Purpose: To investigate the optimal exposure parameters in lateral lumbar spine radiograph for dose reduction while maintaining adequate image quality.

Methods and Materials: 36 images were acquired manipulating exposure

parameters: source-to-detector distance (SDD) (100cm, 130cm, 150cm), beam energy (85kVp±10), beam intensity (4.5mAs, 9mAs, 18mAs) and additional copper filter (0mm, 0.1mm, 0.2mm, 0.3mm) to investigate their impacts on effective dose (ED) and IQ. IQ was assessed using objective approach (contrast-to-noise ratio/CNR and magnification) and perceptual approach (6 observers provided IQ score and drawn lines in relevant anatomical structures). The perceptual approach was repeated with two luminance levels (170lux and 25lux). PCXMC software with Monte Carlo simulation was used to estimate ED. Data were analysed using descriptive statistics, Student's t test and intraclass correlation coefficient (ICC) according to the nature of questions. **Results:** The highest ED (0.022mSv) was found at 100cm, 75kVp, 18mAs and 0-mm copper filter, while the highest CNR (7.23) was achieved at 130cm, 75kVp, 18mAs and 0-mm copper filter. The lowest ED and CNR were generated at 150cm, 95kVp, 4.5mAs and 0.3-mm copper filter. No significant difference was observed between the results for different luminance levels (p=0.9). All observers were able to identify relevant anatomical structures in all images. The intra- (0.61-0.79) and inter-observer ICC (0.55-0.82) varied between moderate and good.

Conclusion: This study showed that is possible to detect all relevant lumbar spine anatomical structures in lateral radiographs using 150cm, 95kVp, 4.5mAs and 0.3-mm copper filter. These parameters allowed the lowest ED (0.002mSv) and a CNR of 2.13. Further studies should be performed including different body habitus and equipment.

B-1066 08:54

An investigation into the effectiveness of breast and gonad lead shielding in abdominal radiography

Z. Kierans¹, A. Arrigo², J. Kotze³, L. Van Der Velde⁴, H. Zwaagstra⁴, K. Gronning⁵, M. O'Connor¹, I. Verzijlten⁴; ¹Dublin/IE, ²Lausanne/CH, ³Bloemfontein/ZA, ⁴Groningen/NL, ⁵Oslo/NO (zoe.kierans@ucdconnect.ie)

Purpose: Lead shielding can be applied to radiosensitive organs to minimise radiation dose and, therefore, the risk of stochastic effects. Using a phantom-based approach, this study assessed whether lead shielding for breast and gonads influences dose in abdominal radiography.

Methods and Materials: AP abdominal X-ray examinations were performed on six anthropomorphic phantoms: a neonate, 1-, 5-, 10- and 15-year-olds and an adult male phantom. Breast attachments were added to the 15-year-old and adult phantoms to mimic female patients. The radiation dose to the breasts and male gonads, shielded (lead equivalent 0.5mm thickness) and unshielded, was measured using a RADCAL dosimeter. Lead shields applied to these regions were positioned outside the primary beam. Five dose measurements were acquired and averaged for each protocol. Descriptive statistics were used to describe mean dose, standard deviation and percentage dose reduction with shielding. Wilcoxon signed rank tests were used to test significance of differences in organ doses with and without leads.

Results: Radiation dose to the breast tissue was reduced by 46-93% across all age groups, with the greatest reduction to breast dose found in the 15-year-old and adult phantoms. In adults, breast dose was reduced by 50.4µGy to 3.3µGy. A lesser dose reduction of 13-50% to the male gonads was achieved with shielding. The dose reduction observed with shielding in each age group was statistically significant (p<0.05).

Conclusion: During AP abdominal X-ray examinations, shielding of the breasts and male gonads is recommended to reduce radiation to these radiosensitive regions.

B-1067 09:02

The impact of different exposure factors on image quality of lumbar spine in five different sizes phantoms: a factorial design study

S.J.M. Alqahtani, J.R. Meakin, R.M. Palfrey, K.M. Knapp; Exeter/UK (salbeshri@hotmail.com)

Purpose: To investigate the impact of tube potential (kVp), source to image distance (SID) and Copper filtration on image quality score (IQS) of lumbar spine radiographs with different size bespoke phantoms (18, 29, 38, 42 and 46 BMI).

Methods and Materials: A factorial design study was conducted with a DR x-ray machine (Multi Fusion Max, Siemens, Germany), using three factors; kVp⁶ x SID³ x Cu filtration³. All images were subjectively assessed by two experienced reporting radiographers using the European Image Quality Criteria (CEC) with 2 alternative forced choice (2AFC) and a 5 point Likert scale. Analysis of variance was used to investigate the impact of each factor on the IQS.

Results: kVp has a significant negative impact on IQS, with ² decreases as the BMI increase (r²= 0.92, 0.91, 0.87, 0.52 and 0.25). SID has no significant impact on IQS across all phantoms. However, the IQS decreased along with the SID in the 18, 42 and 46 BMI phantoms while increased in the 29 and 38 BMI phantom. The filtration showed a negative non-significant impact on IQS in the first three phantoms. However, in the 42 and 46 BMI phantoms, the filtration has a significant negative impact on the IQS with r²= 0.17 and 0.21 respectively.

Conclusion: To achieve an optimal image across the different phantoms, lower kVp settings were the most effective; this might oppose what is in clinical practice. SID could be used in middle BMI range and filtration should be used with caution in morbidly obese range

B-1068 09:10

Lumbar spine imaging: can we reduce the effective and organ dose with the use of PA projection?

E. Alukic, N. Mekis; *Ljubljana/SI (erna.alukic@zf.uni-lj.si)*

Purpose: The aim of the research was to determine, whether the use of PA projection in lumbar spine radiography decreases the entrance surface dose (ESD), effective dose and organ dose to the patient in digital radiography.

Methods and Materials: The measurement were performed on 100 patients that were referred to lumbar spine radiography. Patients were randomly divided into two equal groups of 50. One group was imaged in the AP and the other in the PA projection. Body Mass Index (BMI) was calculated for each patient from their weight and height. Also, the Dose Area Product (DAP), exposure index (EXI), tube time-current (mAs), image field size and the source-patient distance were obtained. Both effective dose and selected organ dose calculation were done according to the Monte Carlo simulation with the use of PCXMC 2.0 program and the ESD was calculated from the tube output. The selected organs in the study were the organs that lie in the primary field. Prior to the study the National medical ethic committee approval was obtained.

Results: In PA projection, the ESD was significantly reduced, by 33%, effective dose by 53% and the average absorbed organ dose by 64% respectively. There was no statistically significant difference in the BMI and EXI between the AP and PA projection.

Conclusion: Based on the results the use of PA projection in lumbar spine imaging should be the first method of choice in general radiography.

B-1069 09:18

Direct projection augmented reality-guided x-ray examination system: a preclinical study

N.-H. Koo; *Seoul/KR (kunoehyun@naver.com)*

Purpose: The aim of this study was to evaluate the utility of direct projection augmented reality-guided X-ray examination system.

Methods and Materials: An X-ray examination on the chest and abdomen were conducted using Definium 8000 DR system and Rando phantom. The resulting images were respectively extracted in the DICOM format through PACS system and were directly projected onto the phantom in the form of an augmented reality using a beam projector. To evaluate the utility of direct projection augmented reality-guided X-ray system, a radiologist and a radiological technologist indicated T3, T9 and L3 spine using metal rods before and after the application of direct projection augmented reality technique. The mean error of the initial indicated position from the center of the reference spine was measured and was compared using independent t-test.

Results: Mean errors significantly decreased after the application of direct projection augmented reality (T3:5.02±0.83mm, T9:4.81±0.87mm, L3:4.24±0.74mm) compared to before the application (T3:67.48±7.23mm, T9:78.59±9.83mm, L3:52.37±5.91mm), with statistical significance (p<.001).

Conclusion: It was confirmed that errors in the position significantly decreased when applied with direct projection augmented reality in the X-ray examination. Conclusion, It is expected that a clinical application of direct projection augmented reality-guided X-ray examination based on the study results will be a great help in minimizing re-examination due to position errors and radiation exposure.

B-1070 09:26

Pelvis imaging: achieving dose reduction with different patient position

A. Resnik¹, J. Žibert², N. Mekis²; ¹Novo mesto/SI, ²Ljubljana/SI (anja.resnik13@gmail.com)

Purpose: The aim of the research was to determine the effect on the radiation dose to the patient and image quality in pelvis radiography when cranially or caudally positioned on the table according to AEC chambers.

Methods and Materials: The research was carried out in two parts on two x-rays: Siemens Ysio and Siemens Axiom Luminus. In the first part of the study we measured DAP on the phantom, where 10 images were taken in cranial and 10 in the caudal layout. The second part of the study was expanded to 200 patients, one hundred per each digital x-ray. We measured DAP, field size, height and mass from which we calculated ITM. The effective dose and absorbed dose to selective organs were calculated using PCXMC2.0. The image quality assessment was performed by three experienced radiologists with the use of ViewDEX imaging software. Prior to the study the National medical ethic committee approval was obtained.

Results: When patients were caudally orientated on the examination table (Siemens Ysio), DAP value was reduced by 37.7% (p=0.002), average effective dose by 35.7% (p=0.002) and mean absorbed dose to selective organs by 33.4% (p=0.001) while image quality was better by 5.2% (p=0.041).

We did not find any significant difference between orientations on Siemens Axiom Luminus due to specific AEC chambers.

Conclusion: We conclude that positioning patients caudally (HA) orientated according to AEC chambers is a method of selection.

B-1071 09:34

Geometric efficiency: measuring methods' comparison

C. Dionisi, M. Coppo, R. Villa, M. Brambilla; *Novara/IT (maga.coppo@gmail.com)*

Purpose: To assess the reliability and the uncertainty related to two different methods for geometric efficiency (GE) evaluation.

Methods and Materials: CT Scanners: two different multi-detector computed tomography (MDCT) Philips Ingenuity 128 (Philips, The Netherlands) and Philips iCT Brilliance 256 (Philips, The Netherlands) were used for the measurement of GE. Gafchromic films: after a proper calibration in air kerma the Gafchromic films were acquired in free air for different nominal collimations. The geometric efficiencies were obtained from the analysis of the profiles converted in air kerma. CT Dose Profiler: this solid-state detector was scanned in helical mode in free air for different nominal collimations; its dedicated software allows to automatically estimate the effective field width and the geometric efficiency.

Results: The analysis of geometric efficiencies obtained with the Gafchromic method underlines a good agreement with the expected values, characterised by a difference lower than 8%. Nevertheless, the accordance decreases for thinner collimations (under 5mm), up to 17%. Similar results were found for the evaluation performed throughout the CT Dose Profiler probe. The probe is designed to measure GE automatically only with spiral acquisitions, making it unable to measure GE for collimations only available on axial mode.

Conclusion: This study shows how both methods, through the use of radiochromic films or Dose Profiler, can measure geometric efficiency for both thin and wide beam collimations. Nevertheless, the automatic evaluation performed by the CT Dose Profiler probe makes it feasible for periodically constancy check.

B-1072 09:42

Optimisation of shunt radiography

A. Bremnes, B. Ween; *Oslo/NO (alexabre@odont.uio.no)*

Purpose: Hydrocephalus shunt protocols vary. To maintain high accuracy using flat panel detectors, an investigation of grid versus air gap with respect to image quality and doses was done.

Methods and Materials: A phantom study included 15 images. A panel of 16 professionals graded image sharpness subjectively, in grades of lines per millimetre (lp/mm). Dose-area product (DAP) and signal noise ratio (SNR) values were measured. Images represented a grid/non-grid situation, whereas non-grid images were measured with air gaps in steps up to 50cm.

Results: Images were rated within the range of 1.2-1.6 lines per mm. Highest spatial resolution represents 1.6 lp/mm, which were rated 99 times (41%) of the total of 240 evaluations for all images. The other ratings (59%) were distributed over a wide area. DAP values showed little variations: 12.6 (+/- 0.4) mGycm² for grid, and 12.6 (+/- 0.2) for air gap, respectively. SNR variations were not important. The results indicate that air gap is preferable over the grid. Longest air gap (50cm) got highest scores, followed by 45 and 40cm.

Conclusion: Longer air gaps are better than grid when the aim is to achieve the best image quality without increasing doses.

B-1073 09:50

Optimisation of collimation and its impact on patient dose in radiography of lumbar spine in anteroposterior and lateral projection

A. Pažanin¹, D. Škrk², N. Mekis²; ¹Dubrovnik/HR, ²Ljubljana/SI (apazanin@gmail.com)

Purpose: To determine the change of radiation dose to the patient when the collimation referred in the literature is used for the lumbar spine radiography in AP and lateral projection.

Methods and Materials: The study was performed on 90 patients that were referred to the lumbar spine radiography in one of the Croatian hospitals. Patients were randomly divided into two equal groups. First group was imaged with the current collimation protocol and the second group with the collimation mentioned in the literature. For each patient DAP, image field size, source-to-patient distance, weight and height were collected. From that data using the PCXMC Monte Carlo simulation method effective dose and absorbed organ dose were calculated.

Results: There was no statistically significant difference in BMI between the group of patients with and without collimation. The reduction of primary field in AP projection when the collimation was used was by approximately 36% (p<0.001) and DAP by 49% (p<0.001). The reduction of the primary field in the lateral projection was 40% (p<0.001) but we didn't find any statistically significant difference in DAP. The effective dose in PA projection was decreased by 50% and average organ dose by 43% respectively. After the

image quality assessment, it was found that the central ray positioning in the lateral position in group without collimation was incorrect that resulted in lower DAP values, effective dose and organ dose.

Conclusion: Based on the results we can conclude that the use of proper collimation and central ray positioning is crucial to obtain ALARA principle.

Amide proton transfer MR imaging for cervical cancer: a preliminary study

Y. He, C. Lin, Y. Qi, X. Wang, H. Zhou, H. Xue, Z. Jin; Beijing/CN
(ylhe_526@163.com)

Purpose: To evaluate the feasibility of amide proton transfer (APT) MR imaging for detection of cervical cancer.

Methods and Materials: Between 10/2017 and 9/2018, 52 patients with pathologically confirmed cervical cancer and 49 healthy volunteers underwent APT MR imaging on a 3T MR scanner (Ingenia CX, Philips Healthcare, the Netherlands). APT values, calculated based on 3D TSE images acquisition with dual RF transmits interleaved labelling. The B0 artefact was corrected via 3 shifted echo times in the 3D TSE sequence; and APT contrast was generated in line. Results were blindly measured by two radiologists for cervical cancer lesions and normal cervical stroma with mean ROI area of 568.7 mm² and 557.5 mm² respectively. Inter-observer ICC was computed. Student's t-test was performed to compare the differences of APT values between cervical cancer and normal cervix. ROC analysis was performed to computationally determine the feasible threshold value, sensitivity and specificity.

Results: APT values of cervical cancer and normal cervical stroma were 2.716±0.060 and 1.853±0.059 (mean±standard error of mean) respectively with statistical significant difference ($p < 0.0001$, 95%CI 0.6931-1.033). Motion artefact was not significant in region of cervix. Inter-observer ICC was 0.988 (95%CI 0.978-0.993). The AUC for differentiating cervical cancer from normal cervical stroma was 0.916. The feasible threshold values was determined as 2.221 with sensitivity of 81.25% and specificity of 83.67%.

Conclusion: APT MR imaging is feasible in cervical cancer detection. Cervical cancer showed significant higher APT values than those of normal cervical stroma.

B-1075 08:34

Correlation of three-dimensional computerized tomographic renal volumetry with DTPA split renal function in prospective donors for renal transplantation

G. Choudary, P.G. Kale, S. Peddi; Tirupati/IN (gpvchowdary777@gmail.com)

Purpose: Evaluation of split renal function (SRF) in living donors is important to ensure that the donor retains the better functioning kidney. The SRF is traditionally measured by means of renal scintigraphy. Recent studies have reported the utility of three-dimensional (3D) computerised tomographic (CT) renal volumetry as an alternative to renal scintigraphy in estimating SRF. The purpose of the current study is to compare the split renal volume (SRV) obtained from 3DCT with split renal function obtained from scintigraphy.

Methods and Materials: This is a retrospective study over 5 years that included 23 prospective renal donors who underwent CT and renal scintigraphy. Renal volume was calculated using Siemens syngo volumetry software. Pearson's correlation coefficient was used to determine the correlation between quantitative data sets.

Results: 23 donors were evaluated. The mean body weight and surface area were 57.3±9.3 kgs and 1.56±0.13 m², respectively. The mean total renal volume was 212.7±38 cm³ and mean split renal volume was 49.76±2.86 and 50.23±2.86 on right and left sides, respectively. No significant correlation was found between uncorrected SRV and SRF. Significant correlation was found between renal volume and function when both were corrected to body surface area (p value < 0.0001).

Conclusion: Renal volume calculation can be done on CT data set already acquired for the assessment of renal vascular anatomy. The simple volumetric method with 3DCT has the potential to replace renal scintigraphy for the assessment of SRF as a preoperative imaging examination for living-donor transplantation.

B-1076 08:38

Prostate magnetic resonance imaging with and without contrast medium: is biparametric MRI sufficient for routine examinations?

D. Junker¹, F. Steinkohl², B. Sztankay¹, U. Nagele¹; ¹Hall in Tirol/AT, ²Innsbruck/AT (daniel.junker@tirol-kliniken.at)

Purpose: Biparametric (bpMRI) and multiparametric (mpMRI) magnetic resonance imaging of the prostate were compared to investigate if and how diagnostic accuracy and tumour detection rates of prostate MRI are influenced by omitting dynamic contrast-enhanced imaging (DCE).

Methods and Materials: In this retrospective study, the results of bpMRI and mpMRI were compared when using the PI-RADS version 2 scoring system for 236 included patients. The distribution of tumours to PI-RADS score levels, tumour detection rates, diagnostic accuracy, and RoC analysis were calculated and compared to the results of histopathological analysis.

Results: The PI-RADS scores were changed in 9.75% of patients when using bpMRI instead of mpMRI, increasing the number of PI-RADS 3 scores by 8.89%. No changes of more than one score level were observed. BpMRI did not show significant differences in diagnostic accuracy or tumour detection rates (AuC of 0.914 vs 0.917 in ROC analysis). Of 135 prostate carcinomas (PCa), 5.93% were downgraded from PI-RADS 4 to PI-RADS 3 when omitting DCE, while 94.07% were scored identically. Changes were observed for only low-grade PCa with Gleason score 6 or 7a.

Conclusion: BpMRI did not lead to significant differences in diagnostic accuracy when compared to mpMRI. Accordingly, it seems reasonable to use a biparametric approach for initial routine prostate MRI to reduce risks, examination time and costs without significantly lowering the diagnostic accuracy.

B-1077 08:42

Benefit of diagnostic support of PI-RADS assessment by quantitative ADC measurements and radiomics in MR diagnosis of prostate cancer

P. Schelb, S. Kohl, J.-P. Radtke, M. Wiesenfarth, M. Hohenfellner, H.-P. Schlemmer, K. Maier-Hein, D. Bonekamp; Heidelberg/DE

Purpose: We investigate the added benefit of quantitative mean ADC (mADC) and radiomic machine learning (RML) when used in combination with clinical decision-making according to PI-RADS.

Methods and Materials: Previously published mADC and RML models developed and validated on a cohort of 316 consecutive patients (training cohort, 183 patients; test cohort, 133 patients) have shown increased performance compared to PI-RADS. Here, we combine both models with PI-RADS by allowing the models to downgrade (Design A) or upgrade (Design B) PI-RADS reports. Clinically significant prostate cancer (csPC) was defined as Gleason Grade Group ≥ 2 and a positive MRI as PI-RADS ≥ 4 . The McNemar test was used to compare differences in sensitivity and specificity.

Results: On a patient basis, compared to PI-RADS, specificity increased from 43% to 65% (mADC, $p < 0.001$) and 62% (RML, $p < 0.001$), while sensitivity decreased marginally from 89% to 87% (mADC, $p = 1.0$) and remained unchanged at 89% (RML) in the test cohort for Design A. For Design B, specificity decreased from 43% to 30% (mADC, $p = 0.002$) and 32% (RML, $p = 0.004$), while sensitivity increased from 89% to 96% for both designs ($p = 0.25$) in the test cohort.

Conclusion: Significant diagnostic improvement can be achieved by downgrading clinical PI-RADS reports based on mADC or RML, suggesting an approach to effectively incorporate quantitative and radiomic information into current PI-RADS reporting.

Multiparametric MRI outperforms three popular clinical models in predicting pT3 prostate cancer in patients undergoing radical prostatectomy

E. Zanelli¹, L. Cereser¹, G. Glannarini¹, V. Ficarra², C. Zuiani¹, R. Girometti¹; ¹Udine/IT, ²Messina/IT (rgirometti@sirm.org)

Purpose: To compare clinical models (CM), mpMRI alone, and mpMRI plus clinical models (mpMRI-CM) in predicting pathologic stage T3(pT3) in patients with clinically-localized prostate cancer (PCa).

Methods and Materials: Over two years we prospectively performed staging 3.0T mpMRI in patients referred to radical prostatectomy for biopsy-proven $< cT3$ PCa, assessing the risk for extraprostatic extension (EPE) and/or seminal vesicle invasion (SVI) with the Partin tables (PT), Memorial Sloan Kettering Cancer Center nomogram (MSKCCn), and Cancer of the prostate risk assessment (CAPRA) score. Two radiologists, blinded to pathology, reviewed

mpMRI independently using the prostate imaging reporting and data system version-2 (PI-RADSv2), and assessed EPE/SVI with a PI-RADSv1- and v2-derived score. Receiving operating characteristics and logistic regression analyses were performed to determine the per-patient accuracy of mpMRI vs CM vs mpMRI-CM in predicting pT3 (EPE and/or SVI).

Results: We included 73 patients, most with cT1c (67.1%) and/or grading group 1-2 (86.2%) cancers. Median risk for EPE/SVI was 27.3/1.9% (PT) and 47.0/2.0% (MSKCCn); median CAPRA score was 3. On pathology, 32.9% of patients showed pT3. Areas under the curve (AUCs) for pT3 were 0.62 for PT, 0.64 for MSKCCn, 0.64 for CAPRA, and 0.73-0.74 for mpMRI readers ($p < 0.05$). AUCs of mpMRI-CM were similar or lower compared to those of mpMRI alone. mpMRI was the only independent predictor of pT3 (OR 7.40/5.53 for readers 1/2, respectively).

Conclusion: mpMRI outperformed CM in predicting pT3. Adding mpMRI to CM did not improve predictive accuracy compared to mpMRI alone, suggesting a stand-alone use for staging PCA.

B-1079 08:50

Do DCE-derived quantitative parameters predict clinically significant prostate cancers? A study on patients referred to radical prostatectomy

F. Greco, R. Girometti, L. Cereser, G. Como, C. Zuiani; Udine/IT (rgirometti@sirm.org)

Purpose: To investigate whether dynamic contrast-enhanced (DCE)-derived parameters predict clinically significant prostate cancer (csPCa).

Methods and Materials: We retrospectively included patients with biopsy-proven csPCa referred to radical prostatectomy who underwent staging multiparametric magnetic resonance imaging (mpMRI) over a two years period. mpMRI was acquired on a 3.0T magnet with a prostate imaging reporting and data system version 2 (PI-RADSv2)-compliant protocol, including a DCE sequence (44 acquisitions of a 8.8 sec-long T1-weighted fat-saturated 3D sequence). Image analysis was performed by two readers in consensus, placing a region-of-interest on (1) non-affected prostate and (2) PI-RADS \geq 3 findings proven to be a cancer on pathology, measuring the transfer constant (k^{trans}), rate constant (k_{ep}), extravascular extracellular volume fraction (v_e), and fractional plasma volume (v_p) (Extended-Toft model). Receiver operating characteristic analysis and logistic regression were run to assess the prediction of csPCa compared to non-affected prostate, on a per-lesion basis.

Results: Included were 59 patients with 51 csPCas. Of the investigated parameters, those showing a significant difference compared to non-affected prostate ($p < 0.01$; U Mann-Whitney-test) were k^{trans} (0.50 vs. 0.30 min^{-1}) and k_{ep} (1.66 vs. 0.93 min^{-1}). Despite k^{trans} and k_{ep} showed an area under the curve of 0.84 (cut-off $> 0.28 \text{ min}^{-1}$) and 0.88 (cut-off 1.18 min^{-1}) in assessing cancer, respectively, none of them was a predictor of csPCa in a multivariate model including all DCE parameters and PI-RADSv2-related features ($p > 0.01$).

Conclusion: DCE quantitative parameters do not predict pathology-proven csPCa, suggesting they have no diagnostic role at the moment.

B-1080 08:54

Transperineal thermoablation in patients with benign prostatic hyperplasia: our experience

R. Regine¹, F. Palmieri², F. Zanfardino¹, G. Fatigati¹, A. Martino¹, M. Cornacchia¹, P. Cozzolino¹; San Giorgio a Cremano/IT, Caserta/IT (francescopalmieri@hotmail.com)

Purpose: To evaluate the feasibility and safety of trans-perineal laser thermoablation (TPLT) of the prostate in patients with benign prostatic hyperplasia (BPH).

Methods and Materials: Twenty-two patients with age range 53-87 y.o. with obstructive BPH underwent a trans-perineal laser thermoablation treatment. Clinical examination, PSA serum analysis, trans-rectal ultrasound and urodynamic examinations were performed for all patients. Under sedoanalgesia, all patients underwent a TPLT treatment for each prostatic lobe by means of two 21-gauge 15-cm needle connected to 980-nm diode laser (3600 J energy; 4 W power). Every patients used a urinary catheter for 15 days after treatment. Prostate volume and uroflowmetry were measured 1, 3, 6 and 12 months after TPLT.

Results: No major complications from TPLT treatment were noted. In particular, no patients reported local, pelvic, or abdominal pain during the procedure or subsequent alterations of defaecation rhythm, ano-rectal/intestinal problems, or haematuria. Prostate volume reduced of 15-20% and of 35-59%, respectively, 1 month and 12 months after TPLT; uroflowmetry results improved in all patients.

Conclusion: In our experience, transperineal laser thermoablation in patients with benign prostatic hyperplasia was demonstrated to be a safe, well-tolerated, and repeatable method to treat BPH, reducing prostate volume and improving uroflowmetry results. Using a trans-perineal approach we avoided the complications that a trans-urethral surgery can cause.

Kidney stone composition analysis using machine learning and spectral detector CT: an ex-vivo study

N. Grosse Hokamp, J. Salem, S. Lennartz, R.P. Reimer, A. Heidenreich, D. Maintz, S. Haneder; Cologne/DE (nils.grosse-hokamp@uk-koeln.de)

Purpose: Several recent studies suggest using dual energy CT for differentiation of kidney stones by means of HU-measurements on low and high energy datasets; however, most studies focused on single component stones. This study aimed to determine, if machine learning enables a more precise differentiation with respect to the main component on a per-voxel basis.

Methods and Materials: 202 stones harvested from patients were scanned in a non-anthropomorphic water phantom using a spectral detector CT scanner. Virtual monoenergetic images (VMI) of 40 keV and 200 keV as well as conventional CT images (CI) were reconstructed. All stones were semi-automatically segmented on CI, the resulting volume of interest was transferred to VMI datasets. All pixel values were exported and served as input functions in an available machine learning framework (Matlab, MathWorks, Natick, USA). The main component of the stone was determined using infrared-spectroscopy.

Results: Segmentation resulted in a total of 74.769 voxels, average voxels per stone was 370. An unweighted k-nearest neighbor classification (KNN) with 10 neighbors and Euclidean distance metric performed best. This KNN yielded an overall accuracy of 82.2% using 5-fold cross-validation with a prediction speed of approx. 1200 observations per second. Greatest overlaps were found between stones which's main component was calcified (whewellite, weddellite and brushite).

Conclusion: Machine learning enables accurate analysis of kidney stone composition. Even in mixed stones the main component may be predicted.

Comparison between biparametric MRI (bp-MRI) and multiparametric MRI (mp-MRI) for the diagnosis of prostate cancer (PCa): preliminary results of a prospective randomised trial

G. Giannetto¹, L. Pusceddu¹, V. Doronzio², V. Vani¹, V. Romano³, C. Maglia⁴, S. Mazzetti⁵, D. Regge⁶, F. Russo⁷; Turin/IT, Candiolo/IT, Candiolo TO/IT, Torino/IT, Candiolo-Torino/IT (ggiannetto27@gmail.com)

Purpose: To compare bp-MRI and mp-MRI in a prospective randomised clinical trial including biopsy-naïve subjects at risk for PCA.

Methods and Materials: Biopsy-naïve men with increased PSA values ($\leq 15 \text{ ng/ml}$) and negative digital rectal examination were randomised into two arms. Subjects in arm A underwent fast bp-MRI protocol (axial T2W and DWI) with no endorectal coil (ERC) and no iv contrast agent. Men in arm B underwent mp-MRI including T1W, T2W, DWI and DCE with ERC and iv contrast agent administration. After MRI, all subjects underwent biopsy, which was considered the reference standard of this study. Patients with positive MRI and biopsy Gleason Score \geq 3+4 were defined as true positives.

Results: Overall, 143 men underwent MRI examination. 99/143 (69%) were randomised in arm A and 44/143 (31%) in arm B. In the bp-MRI arm, 32/99 (32%) men had a suspicious lesion and in 23 cases biopsy was positive for PCA. In the mp-MRI arm, 23/44 (52%) men were positive at imaging and 15 were PCA at biopsy. In arm A, sensitivity and specificity were 74% and 87%, respectively; in arm B, 88% and 70%, respectively. Considering only PIRADS 4-5 subjects, 19/23 (83%, $p=0.35$) and 13/15 (87%, $p=0.14$) were positive at biopsy in arm A and B, respectively. In 7/67 (10%) subjects with negative bp-MRI, a biopsy revealed a clinically significant PCA (csPCa). In 1/21 (5%) man negative at mp-MRI, a biopsy found a csPCa.

Conclusion: Mp-MRI has higher sensitivity than bp-MRI in identifying csPCa in biopsy-naïve men, while bp-MRI reveals higher specificity.

B-1083 09:06

Application of intravoxel incoherent motion imaging (IVIM) in patients with hyperuricemia

Z. Cheng, X. Cai, Y. Feng; Guangzhou/CN (zhongyuancheng08@163.com)

Purpose: The objective of this study was to evaluate the utility of IVIM parameters to identify the early changes in patients with hyperuricemia.

Methods and Materials: A total of 84 male participants, asymptomatic hyperuricemia (27 cases), gout patients (31 cases) and 26 age- and sex-matched healthy volunteers were enrolled in this study. All subjects underwent IVIM sequence ($b=0, 30, 50, 80, 100, 150, 200, 300, 500, 800, 1000 \text{ s/mm}^2$) on a 3.0T MRI scanner. Mean cortical and medullary IVIM parameters (ADC, D, D' and f values) were calculated by setting multiple regions of interest. Differences in every IVIM parameter among the three groups were assessed. Also, they were correlated with estimated glomerular filtration rate (eGFR).

Results: The D values in the renal cortex and medulla were significantly decreased from the control group, AH to GA group ($p < 0.05$). The cortical and medullary ADC values were significantly decreased across the three groups, except for the comparison between HA and GA group ($p < 0.05$). The f values of the three groups were decreased in turn, the control group was significantly higher than the HA group and GA ($p < 0.05$), whereas the cortical f values has only difference in the HA group and the GA group ($p < 0.05$); There was no statistically significant difference between the D* values among the three groups. No significant correlation were found between IVIM parameters and eGFR ($p > 0.05$).

Conclusion: IVIM demonstrated potential useful to assess early hyperuricemia with renal dysfunction in patients with hyperuricemia. Its evaluation index D value was more sensitive to the early renal function impact by hyperuricemia than eGFR.

B-1085 09:10

Explorative investigation of whole-lesion histogram MRI metrics for differentiating uterine degenerative leiomyomas and leiomyosarcomas
K. [Ma](mailto:Ma;Zhengzhou/CN(1322725260@qq.com)); [Zhengzhou/CN\(1322725260@qq.com\)](mailto:Zhengzhou/CN(1322725260@qq.com))

Purpose: The purpose of this study is to assess the utility of texture analysis of multiple MRI sequences for the differentiation of uterine degenerative leiomyomas and leiomyosarcomas.

Methods and Materials: 12 leiomyosarcomas and 29 degenerative leiomyomas undergoing MRI before resection were included. DICOM images for the following three sequences were exported for subsequent analysis using the software named Mazda: ADC map, and delayed axial contrast-enhanced T1-weighted image. Using the software, a Whole-lesion volumes of interest incorporating all lesion voxels on all slices was placed on the largest uterine lesion. The diagnostic performance of histogram metrics was assessed. The ROC curves were compared in pairs by the Delong method, and $P < 0.05$ was considered statistically significant.

Results: For the ADC maps, significant differences were observed for mean, skewness, 10th percentile, 50th percentile, 90th percentile; For T1-weighted contrast-enhanced images, significant differences were observed for mean, standard deviation, 10th percentile, 90th percentile, 99th percentile ($p < 0.05$). ROC analysis indicated that 90th percentile of ADC had the highest diagnostic accuracy, the maximum area under the ROC curve was 0.891 with a specificity of 72.7% and a sensitivity of 81.8%.

Conclusion: For whole-lesion histogram metrics obtained on various MRI sequences, 90th percentile of ADC provided the highest performance for differentiating degenerative uterine leiomyomas and leiomyosarcomas. Although these findings require validation in larger studies, they have implications for facilitating improved treatment selection for these two entities.

B-1086 09:14

Imaging surveillance in operable invasive transitional cell carcinoma of the bladder

S.A. Ahmed, M.M. [El Barody](mailto:Elbarody;N.A.A.ElMalek;M.A.ElSalamEbrahim;Assiut/EG(Elbarody_radiol@yahoo.com)), N.A.A. El Malek, M.A. El Salam Ebrahim; [Assiut/EG\(Elbarody_radiol@yahoo.com\)](mailto:Assiut/EG(Elbarody_radiol@yahoo.com))

Purpose: To evaluate diagnostic accuracy of abdominopelvic ultrasound (US), virtual cystoscopy (VC) and MRI diffusion (MRI DWI) with conventional cystoscopy (CC), in diagnosis of bladder lesions after transurethral resection (TUR).

Methods and Materials: Forty-five patients with bladder cancer underwent complete TUR and received chemoradiation schedule, they imaged prospectively by US, VC and MRI DWI followed by CC and histopathology of any detected abnormality. Sensitivity, specificity, positive and negative predictive values and accuracy were calculated and compared to CC and histopathology as gold standard.

Results: After median 24 months of follow up, US, VC and MRI DWI detected 23, 28 and 29 lesions, respectively, of the 30 lesions detected by CC. Pathology confirmed local recurrence in 18 lesions (40%) and benign post-operative changes in 12 lesions (27%), while remaining 15 patients were negative. Eighteen lesions (60%) were larger than 1 cm, twenty-three lesions showed polypoidal morphology (77%). Accuracy of US, VC, and MRI DWI in diagnosis of bladder lesions was 73%, 93%, and 93%, respectively ($P > 0.10$).

Conclusion: MRI DWI and VC were of comparable accuracy in diagnosing bladder lesions after TUR; US had lowest sensitivity while DW-MRI was more accurate in recurrence characterization in masses less than 1 cm and focal wall thickening.

B-1087 09:18

Contrast-enhanced T1 mapping MR imaging for evaluation of myometrial invasion in endometrial cancer: initial experience

Y. [He](mailto:He;C.Lin;Y.Qi;X.Wang;H.Zhou;H.Xue;Z.Jin;Beijing/CN(yilhe_526@163.com)), C. Lin, Y. Qi, X. Wang, H. Zhou, H. Xue, Z. Jin; [Beijing/CN\(yilhe_526@163.com\)](mailto:Beijing/CN(yilhe_526@163.com))

Purpose: To assess diagnostic performance of contrast-enhanced T1 mapping images for evaluation of myometrial invasion in endometrial cancer.

Methods and Materials: Institutional review board approval and informed consent were obtained. From 12/2017 to 9/2018, 31 consecutive patients with endometrial cancer, aged 26-72 years (mean age, 51 years), were prospectively enrolled for preoperative evaluation by multi-parameter pelvic MR imaging on a 3T MR scanner (Ingenia CX, Philips Healthcare, the Netherlands). MOLLI sequences (enhanced scheme, 13 seconds) for T1 mapping were appended after clinical routine sequences after contrast Gadopentetate Dimeglumine injection. Two radiologists blindly interpreted myometrial invasion on T2-weighted, DWI, DCE and contrast-enhanced T1 mapping images. Inter-observer agreement was evaluated by Kappa analysis. According to surgical pathologic findings, accuracy assessment, receiver operating characteristic analysis for diagnostic performance was compared.

Results: Reader agreement was excellent for contrast-enhanced T1 mapping images ($\kappa > 0.75$). Diagnostic accuracy of contrast-enhanced T1 mapping to assess existence of myometrial involvement was 0.94, and sensitivity, specificity, PPV, NPV were 1.0, 0.67, 0.92, 1.0 respectively. AUC was 0.833 (95%CI 0.656-0.942), which was significant better than those of T2-weighted, DWI and DCE images ($p = 0.017$). Diagnostic accuracy of contrast-enhanced T1 mapping for evaluating deep invasion of myometrium was 0.94, sensitivity and specificity was 0.83 and 0.96. AUC was 0.897 (95%CI 0.743-0.977), revealing similar diagnostic performance compared with clinical routine sequences (all $p > 0.05$).

Conclusion: Contrast-enhanced T1 mapping images could provide elevated accuracy for detecting superficial myometrial invasion. It showed similar diagnostic performance compared with the common sequences in differentiating FIGO IA and IB endometrial cancer.

B-1088 09:22

Evaluation of a semi-automated segmentation tool for volumetric analysis of the renal cortex and medulla in non-contrast T1-weighted MR images

H. [Seuss](mailto:Seuss;R.Janka;P.Dankerl;A.Cavallaro;M.Uder;M.Hammon;Erlangen/DE(hannes.seuss@uk-erlangen.de)), R. Janka, P. Dankerl, A. Cavallaro, M. Uder, M. Hammon; [Erlangen/DE\(hannes.seuss@uk-erlangen.de\)](mailto:Erlangen/DE(hannes.seuss@uk-erlangen.de))

Purpose: A semi-automated segmentation tool was evaluated for its accuracy regarding the volumetric analysis of the total kidney parenchyma and the differentiation of the cortex and medulla in non-contrast T1-weighted (T1w) magnetic resonance imaging (MRI) scans.

Methods and Materials: Two readers performed a semi-automated segmentation of the renal parenchyma in axial, non-contrast-enhanced T1w MRI images. The segmentation was itemized into the total kidney volume (TKV) and cortex volume (CV). The volume of the medulla was calculated. 78 patients (278 kidneys) with healthy kidneys that received an MRI for the evaluation of the liver were included into the study. The MRI protocol was adapted to fit the 'German National Cohort' (T1w Dixon gradient echo). For the segmentation of the kidney, we developed a semi-automated threshold-based segmentation tool. Manual segmentation served as the reference standard.

Results: There was no significant difference between semi-automatically and manually segmented volumes of the TKV ($p > 0.456$). The CV, however, differed significantly ($p < 0.002$). The mean volume for the TKV was 156.0 ± 37.8 ml for the right kidney and 162.5 ± 39.8 ml for the left kidney. For the CV it was 61.3 ± 23.2 ml for the right kidney and 62.8 ± 23.3 ml for the left. No significant interreader variability was present.

Conclusion: Semi-automated segmentation and volumetric analysis of the TKV in native T1w MRI images deliver accurate and reproducible results. However, the differentiation of the renal cortex and medulla has a high error and can only be used for approximations of the volume.

B-1089 09:26

Correlation of erectile dysfunction after radical prostatectomy with findings of preoperative multiparametric prostate MRI

M. [Sauer](mailto:Sauer;P.Tennstedt;C.Berliner;H.Huland;G.Adam;D.Beyersdorff;Hamburg/DE(m.sauer@uke.de)), P. Tennstedt, C. Berliner, H. Huland, G. Adam, D. Beyersdorff; [Hamburg/DE\(m.sauer@uke.de\)](mailto:Hamburg/DE(m.sauer@uke.de))

Purpose: To evaluate whether preoperative multiparametric prostate MRI (mpMRI) can help to stratify the risk of erectile dysfunction (ED) after radical prostatectomy (RP) based on specified imaging parameters.

Methods and Materials: 102 patients (median age: 63 years) underwent standardized mpMRI at 3T prior to prostatectomy. Erectile function was assessed before and after RP using the Expanded Prostate Cancer Index Composite Questionnaire score (EPIC). Tumour stage, extracapsular extension (ECE), prostate volume, membranous urethra length/angle (MUL/MUA), apex form according to Lee et al., apex infiltration (AI) and PI-RADS scores were determined for every patient's MRI. Additionally, various clinical parameters including age, preoperative EPIC score and the degree of nerve sparing surgery were registered. All parameters were correlated to the postoperative EPIC scores determining the degree of erectile dysfunction.

Results: The median preoperative and postoperative EPIC scores for all patients were 79% and 43%, respectively (with 100% representing best functionality). Of all patients 21% demonstrated tumours $> T2$ with 18%

positive ECE and 75% positive AI. Median PI-RADS score was 4 with dominance of Apex Type C (58%), a median MUL/MUA of 10mm/120° and a median volume of 43 ml. However, none of these imaging parameters correlated to the postoperative EPIC scores ($p>.05$). Of all clinical parameters, there was significant correlation of preoperative EPIC score ($p<.001$), and the extent of surgical nerve sparing ($p<.05$).

Conclusion: None of the investigated imaging parameters of mpMRI correlates with the degree of postoperative erectile dysfunction.

Can MRI including DCE and DWI improve characterisation of endometrial carcinosarcoma?

L. Rivière¹, L. Rossi¹, T. Lam Giang², E. Laas¹, G. Bataillon¹, P. Chere³, H. Brisse¹, F. Reyat¹, C. Malhaire¹; ¹Paris/FR, ²Genève/CH, ³Saint-Cloud/FR (luctkd@hotmail.fr)

Purpose: To describe the MRI characteristics of endometrial carcinosarcoma (CS), including dynamic contrast-enhanced (DCE) and diffusion-weighted imaging (DWI), in comparison with those of endometrioid carcinoma (EC).

Methods and Materials: In a retrospective study of our institute histopathologic database from 2003 to 2018, patients with CS or EC who received a preoperative MRI were included. Morphological, perfusion (maximum relative enhancement (SIRel)) and wash-in rate (WIR) and DWI were analysed. The T2 signal heterogeneity, necrosis, haemorrhage, intensity and heterogeneity of enhancement were recorded by two radiologists. Inter-reader agreement was calculated.

Results: Ninety-one patients (36 CS and 55 EC) were included. The CS size and cavity dilatation were greater than those of EC (82 mm vs 38mm, $p<0.001$; 43 mm vs 19 mm, $p<0.001$, respectively). In comparison with EC, CS more often showed heterogeneity in the T2 signal (97% vs 38%, $p<0.001$; $k=0.88$), necrosis (70% vs 13%, $p<0.001$; $k=1$) and haemorrhage (83% vs 25%, $p<0.001$; $k=0.95$). CS was enhanced more often greater or equal to the myometrium (94% vs 44%, $p<0.001$; $k=0.85$) and heterogeneously (97% vs 55%, $p<0.001$; $k=0.94$) in comparison with EC. SIRel and WIR were greater in CS than in EC (92% vs 63% and 46% vs 36%, $p=0.01$). CS more often showed a high signal intensity on DWI in comparison with EC (100% vs 65%, $p=0.02$); however, no significant difference was found regarding the ADC values.

Conclusion: A bulky endometrial mass containing necrosis and haemorrhage with an enhancement greater or equal to the myometrium suggests a diagnosis of CS.

B-1092 09:34

Prostate cancer lesion characterisation: rapid acquisition using compressed sensing in combination with semi-automatic lesion segmentation for dual-parameter decision support

D.J. Winkel, T. Heye, M.R. Benz, B. Stieltjes, D. Boll, V. Hofmann; Basle/CH (verena.hofmann@usb.ch)

Purpose: To investigate the diagnostic performance of dynamic contrast-enhanced (DCE) MRI to detect prostate cancer comparing high-spatiotemporal resolution golden-angle radial sparse imaging (GRASP) with standard-of-care sequences (volumetric interpolated breath-hold examination; VIBE) and to assess whether dual-parameter decision support, using perfusion and diffusion characteristics, can achieve higher diagnostic accuracy compared to single-parameter assessments.

Methods and Materials: 101 peripheral zone prostate cancer lesions in 94 patients and a clinical suspicion for prostate cancer were evaluated by 3T MRI. Histopathological confirmation on MRI-TRUS fusion biopsy was matched with normal prostate parenchyma contralaterally. MRI was performed with DWI and DCE using two acquisition schemes: GRASP (temporal resolution 2.5s, in-plane resolution 0.56x0.56mm) or VIBE (temporal resolution 10s, in-plane resolution 1.25x1.25mm). Quantitative perfusion (Ktrans, Kep) and diffusion (ADC) parameters were assessed using univariate general linear model analyses defining processing (planimetry/volumetry), histopathology (normal/pathologic), and sequence (VIBE/GRASP) as independent variables. Receiver operating characteristics (ROC) and accuracies were determined.

Results: DCE with GRASP yields diagnostic accuracy comparable to standard-of-care sequences [volumetric: .81 vs .83Ktrans, .79 vs .75Kep] ($p<0.05$). Single-parameter analyses: ADC outperformed both Ktrans/Kep in the detection of prostate cancer [volumetric: 94ADC] ($p<0.001$). Dual-parameter analyses: combining ADC with Ktrans or Kep obtained from GRASP [volumetric: .97ADC/Ktrans and .97ADC/Kep], improved performance compared to any single-parameter evaluation and any assessment based on VIBE [volumetric: .94ADC/Ktrans and .94ADC/Kep] ($p<0.001$). Planimetric analyses of DCE-MRI with GRASP showed similar results.

Conclusion: Diagnostic performance of DCE-MRI using GRASP is comparable to standard-of-care sequences. When GRASP is employed in combination with volumetric lesion processing in a dual-parameter discrimination system, it showed better diagnostic performance compared to single-parameter methodologies as well as any evaluation approach using the VIBE sequence.

B-1093 09:38

Pitfalls in reporting fast biparametric magnetic resonance imaging of the prostate: what kind of cancers do we miss? A preliminary retrospective analysis

L. Pusceddu¹, G. Giannetto¹, V. Romano¹, V. Van², F. Cortese¹, G. Desi², S. Mazzetti¹, D. Regge¹, F. Russo²; ¹Candiolo/IT, ²Turin/IT (laura.puscd@gmail.com)

Purpose: The aim of the study was to assess the causes of diagnostic failure in the identification of prostate cancer (PrCa) in patients who underwent fast biparametric MRI (bpMRI).

Methods and Materials: We retrospectively evaluated data from a randomized trial in which men with increased PSA values (4<PSA≤15 ng/ml) and without previous prostate biopsy were considered for inclusion in a fast bpMRI protocol (axial T2W and DWI with no endorectal coil and no i.v. contrast agent administration). After MRI, all patients underwent biopsy, which was considered as the reference standard. An experienced radiologist reviewed all cases with no suspicious lesion at MRI but with PrCa revealed by biopsy, in order to assess if lesions could be visible but incorrectly interpreted and their characteristics.

Results: 23/99 patients included in the study had a positive biopsy; bpMRI did not identify 11/23 cases (47%). Four missed lesions had a biopsy Gleason Score (bGS) 3+3, five had a bGS 3+4 (2/5 with pattern 4<10%) and 2 cases had a Gleason primary 4. At the image review, 4 missed lesions, described as microfoci of PrCa at biopsy (<1 mm), were not visible. Among tumors detected during MRI review, the following characteristics were responsible for the missed identification: triangular or striped shape, proximity to the adenoma pseudocapsule and intermediate ADC values.

Conclusion: BpMRI shows some limitations in the identification of tumors with specific MRI features. These missed lesions are usually less aggressive from a pathological standpoint.

Diagnostic accuracy of CT features and CT texture analysis in differentiating focal autoimmune pancreatitis from adenocarcinoma: a retrospective study

G. Cardano, A. Figuera, A. Campagnola, G. Zamboni, L. Frulloni, G. Mansueto; Verona/IT (drpeppex@gmail.com)

Purpose: To assess the value of morphological criteria and texture analysis in differentiating between focal autoimmune pancreatitis (AIP) and pancreatic adenocarcinoma (PDAC) at CT.

Methods and Materials: We reviewed the multiphase MDCT scans of 60 patients with solid pancreatic lesions: 30 focal AIP, 30 PDAC. Each scan was evaluated for: lesion size and margins, main pancreatic duct (MPD) intraluminal stenosis and upstream dilation, upstream chronic pancreatitis, biliary dilation. Attenuation was measured in the lesion and the unaffected parenchyma in all phases. Texture-analysis of the lesion was performed with LIFEX.

Results: Significant differences were observed between AIP and PDAC in unenhanced ($p=0.010$), arterial ($p=0.008$) and venous ($p=0.006$) lesion attenuation, unenhanced normal parenchyma attenuation ($p=0.048$), biliary dilation ($p=0.004$), and texture-Entropy in the delayed phase ($p=0.00$). Univariate logistic regression analysis confirmed significance of lesion density in unenhanced ($p=0.014$), arterial ($p=0.014$) and venous phases ($p=0.011$) as "AIP risk factors". Upstream MPD dilatation ($p=0.004$), biliary dilatation ($p=0.007$), upstream chronic pancreatitis ($p=0.01$) are "PDAC risk factors". Multivariate regression analysis confirmed the predictive capacity of upstream chronic pancreatitis ($p=0.011$) for adenocarcinoma. The whole logistic binomial univariate model showed a significant predictive value for diagnosis of PDAC, with a COX-SELL $R^2=0.422$; the ROC curve confirmed its accuracy, with $AUC=0.918$ ($p=0.037$).

Conclusion: Upstream MPD and chronic pancreatitis, biliary dilatation, lesion density at unenhanced, arterial and venous phases were statistically significant in differentiating between AIP and PDAC. Progressive enhancement significantly increases the probability of AIP; upstream MPD dilatation, biliary dilatation and chronic pancreatitis increase the probability of PDAC.

B-1095 10:38

Contrast-enhanced ultrasound for differentiation of pancreatic carcinoma (PC) from mass-forming chronic pancreatitis (MFCP)

P. Gupta, S. Sinha, N. Dhaka, A. Rajwanshi, K. Vaiphei, R. Kochhar; Chandigarh/IN (pankajgupta959@gmail.com)

Purpose: To evaluate the diagnostic performance of contrast-enhanced ultrasound (CEUS) in the differentiation of PC from MFCP.

Methods and Materials: Consecutive adults with a mass in the head of the pancreas underwent a CEUS of the pancreas. Parameters assessed were the pattern of enhancement (hypoenhancing/isoenhancing and complete or incomplete) and dot and lace vascular pattern (defined as visualisation of dot or lace-like vessels within the lesion). Cytology or histopathology was used as the reference standard.

Results: Of the 48 patients, the diagnosis of PC was confirmed in 27 (72.9%) and MFCP in 10 (27.1%). Eleven patients were excluded as sampling could not be performed (n=6), and diagnosis other than PC (n=5). There were 23 males and 14 females with a mean age of 55.14 years. Hypoenhancement was documented in 25 patients with PC and only 1 patient with MFCP. Iso-enhancing mass was seen in 9 patients with MFCP and only 2 patients with PC. A complete enhancement was seen in 3 patients with MFCP and only 1 patient with PC. Dot and lace pattern was seen in 20 patients with PC and only 2 patients with MFCP. The sensitivity, specificity, PPV, and NPV of the degree of enhancement for differentiation of PC from MFCP was 96.15%, 81.82%, 92.59% and 90%, respectively. Complete vs incomplete enhancement had a high sensitivity (96.15%) but lower specificity (30%).

Conclusion: CEUS is a useful imaging modality in the differentiation of PC from MFCP. Hypoenhancement has the highest diagnostic accuracy among all the CEUS parameters.

B-1096 10:46

Quantitative analysis of arterial-phase MR images in differentiating focal-type autoimmune pancreatitis from pancreatic ductal adenocarcinoma

J. Kwon, J. Kim; Seoul/KR (wisewisdom.rad@gmail.com)

Purpose: To assess whether quantitative analysis of arterial-phase MR images is helpful to differentiate focal-type autoimmune pancreatitis (AIP) from pancreatic ductal adenocarcinoma (PDA).

Methods and Materials: Thirty-six patients with focal-type (single mass forming) AIP and 72 patients with surgically resected PDA, who underwent dynamic contrast-enhanced MR imaging (DCE-MRI) were included. The signal intensity (SI) of the pancreatic mass and normal parenchyma and the lesion contrast ($SI_{\text{normal pancreas}}/SI_{\text{mass}}$) were measured on each phase of DCE-MRI. The lesion contrast on arterial phase (AP) ($\text{contrast}_{\text{AP}}$) and the contrast ratio between AP and unenhanced phase (UP) ($\text{contrast}_{\text{AP/UP}}$) were compared between AIP and PDA groups. The specificity of $\text{contrast}_{\text{AP/UP}}$ using appropriate cutoff values for the diagnosis of AIP and PDA was compared with those of previously known key MRI features of both diseases.

Results: The $\text{contrast}_{\text{AP}}$ and $\text{contrast}_{\text{AP/UP}}$ were significantly lower in AIP than in PDA (1.23 vs. 1.84, $P < 0.001$; 0.84 vs. 1.15, $P < 0.001$). The specificity of $\text{contrast}_{\text{AP/UP}}$ for AIP when using cutoff value < 0.9 was 97.2%, which was comparable to those of the key MRI features including non-discrete mass, delayed homogeneous enhancement, halo sign, and duct penetrating sign (94.4%-100%; $P \geq 0.500$). The specificity of $\text{contrast}_{\text{AP/UP}}$ for PDA when using cutoff value ≥ 1.0 was 97.2%, which was comparable to or slightly higher than those of the key MRI features including target appearance, main pancreatic duct (MPD) abrupt narrowing, upstream MPD marked dilatation, and pancreatic atrophy (88.9%-94.4%; $P \geq 0.375$).

Conclusion: Quantitative analysis of the lesion contrast on arterial-phase MR images is helpful to differentiate focal-type AIP from PDA.

B-1097 10:54

Comparison of reduced field-of-view and large field-of-view diffusion-weighted 3T MR imaging in the evaluation of solid pancreatic lesions

P. Boraschi, F. Donati, G. Tarantini, R. Cervelli, F. Pacciardi, C. Lombardo, U. Boggi, F. Falaschi, D. Caramella; Pisa/IT (p.boraschi@gmail.com)

Purpose: To compare image quality and apparent diffusion coefficient (ADC) values of reduced field-of-view (rFOV) and large field-of-view (lFOV) diffusion-weighted MR imaging (DW-MRI) at 3T-device in the evaluation of solid pancreatic lesions.

Methods and Materials: Forty-eight patients with histologically proven solid pancreatic lesions (ductal adenocarcinoma, n=22; invasive adenocarcinoma accompanying IPMN, n=8; neuroendocrine tumour, n=15; autoimmune pancreatitis, n=3) who underwent MRI at 3T-device (GE DISCOVERY MR750; GE Healthcare) were retrospectively included. In all cases, DW-MRI was performed using both rFOV FOCUS and lFOV respiratory-triggered spin-echo echo-planar sequence, each with multiple b-values (0, 500, 1000 sec/mm²). Two radiologists in conference assessed a series of subjective image quality parameters (sharpness; distortion; ghosting, motion and susceptibility artefacts; lesion conspicuity, and overall image quality) of both

diffusion-weighted sequences, using a 4-point-scale semiquantitative grading system. ADC values were calculated by another radiologist by drawing the ROI on the central slice of the pancreatic lesion for both rFOV and lFOV DW-MRI (b=500,1000 sec/mm²). Radiologists were blinded to the corresponding patient information, especially lesion location and pathological results.

Results: More artefacts were present on lFOV compared with rFOV FOCUS diffusion-weighted images ($p < 0.01$). Lesion conspicuity and overall image quality of rFOV DW-MRI were rated superior than those of lFOV DW-MRI ($p < 0.01$). All ADC values were significantly lower when calculated from rFOV images than lFOV ones.

Conclusion: The rFOV DW-MRI provided reduced artefacts, better lesion conspicuity and overall image quality than the lFOV sequence. ADC valued derived from rFOV DW-MRI were significantly lower when compared with those derived from lFOV DW-MRI.

B-1098 11:02

Assessment of pancreatic ductal adenocarcinoma lesion using virtual monoenergetic images from dual-layer spectral detector CT

Y. Yang, Q. Han, X. Chen, F. Yan; Shanghai/CN (yyz01a15@rjh.com.cn)

Purpose: To quantitatively and qualitatively assess the image quality of virtual monoenergetic images (VMI) derived from dual-layer spectral detector CT for pancreatic ductal adenocarcinoma (PDA) lesion detection in comparison to 120-kVp conventional polyenergetic images (PI).

Methods and Materials: Forty-six patients underwent multiphase pancreatic imaging protocols for PDA were retrospectively identified. PI were reconstructed at 120kVp, and VMI with spectral reconstruction at 40keV(VMI₄₀), 50keV(VMI₅₀), 60keV(VMI₆₀), and 70keV(VMI₇₀). CT value and noise were measured in the lesion and normal pancreatic parenchyma. SNR and CNR were calculated for all VMIs and PI. Using a 5-point scale (5-excellent; 1-markedly limited), images were qualitatively assessed by 2 radiologists for lesion detection. Paired t test was used to compare the qualitative measures and Wilcoxon signed rank test was used to compare the qualitative assessment.

Results: The mean CT value, noise, SNR and CNR were 76.3±50.4HU, 12.5±1.4HU, 6.1±3.9, 7.8±5.9 for VMI₄₀; 61.1±33.5HU, 11.4±1.5HU, 5.4±2.9, 5.4±4.3 for VMI₅₀; 52.1±23.4HU, 10.9±1.5HU, 4.9±2.2, 3.8±3.2 for VMI₆₀; 46.8±17.8HU, 10.6±1.6HU, 4.5±1.8, 2.8±2.6 for VMI₇₀; 46.2±18.4HU, 13.2±2.3HU, 3.6±1.5, 2.2±2.1 for PI. VMI₄₀ VMI₅₀ VMI₆₀ revealed significantly higher attenuation values compared to PI ($p < 0.01$). All VMIs showed significantly lower noise levels compared to PI (all $p < 0.01$). SNR and CNR increased from VMI₇₀ to VMI₄₀, and all were higher than PI (all $p < 0.01$). In qualitative assessment, VMI₄₀ and VMI₅₀ demonstrated better in lesion detection than PI (4.8, 4.5 vs 4.0, $P < 0.05$).

Conclusion: VMI₄₀ and VMI₅₀ showed superior image quality in comparison to conventional images and could provide more diagnostic information for PADC lesion detection.

To provide evidence for early diagnosis of pancreatic cancer: magnetic resonance spectroscopy

X. Fang; Shanghai/CN (fx0412@foxmail.com)

Purpose: To analyse the metabolites of tumours and peritumoural pancreatic duct intraepithelial neoplasia (Pan IN) tissue in pancreatic cancer by ¹H magnetic resonance spectroscopy (¹H MRS).

Methods and Materials: Before operation, respiration-triggered water suppression point-resolved spectroscopy (PRESS) sequence of ¹H MRS was used for the detection of metabolites in tumours and peritumoural Pan IN tissue. This study calculated the ratio of choline-containing metabolite (CCM) peak area to lipid (Lip) peak area (CCM/Lip), cholesterol and the unsaturated parts of the olefinic region of fatty acid (Chol+Unsat) peak area to Lip peak area (Chol+Unsat/Lip), Chol+Unsat peak area to CCM peak area (Chol+Unsat/CCM) in every ¹H MRS data. The paired sample t test was used for comparing metabolites in tumours and peritumoural Pan IN tissue.

Results: 24 patients with pancreatic duct adenocarcinoma were confirmed by histopathology. The ratio of CCM/Lip in tumours (2.66 ± 0.84) $\times 10^{-1}$ was higher than peritumoural Pan IN tissue (2.00 ± 0.81) $\times 10^{-1}$. The ratio of Chol+Unsat/Lip in tumours (3.24 ± 1.09) $\times 10^{-1}$ was higher than peritumoural Pan IN tissue (2.58 ± 0.92) $\times 10^{-1}$. There were statistically significant differences ($P < 0.05$). The ratio of Chol+Unsat/CCM had no statistical difference between tumour tissue and peritumoural Pan IN tissue.

Conclusion: ¹H MRS can distinguish tumours tissue and peritumoural Pan IN tissue in pancreatic cancer. To provide evidence for early diagnosis of pancreatic cancer.

B-1100 11:18

Evaluation of vascular and local lymph node invasion, resectability of pancreatic ductal adenocarcinoma with spectral detector CT

Y. Yang, Q. Han, X. Chen, H. Dong; Shanghai/CN (yyz01a15@rjh.com.cn)

Purpose: The aim of this study was to compare the predictive accuracy of 120kVp conventional dataset and spectral dataset derived from spectral detector CT (SDCT) in predicting vascular and local lymph node invasion in patients with pancreatic ductal adenocarcinoma (PDAC).

Methods and Materials: Forty-three patients with surgical and pathologic confirmation of PDAC were retrospectively analysed by 2 radiologists independently. All patients had SDCT examination and two setup datasets were created: 120kVp conventional images and spectral images which included virtual monochromatic image and iodine density image. Peripancreatic arterial invasion, venous invasion and local lymph node invasion were measured using two setup datasets respectively. NCCN criteria guidelines were used in predicting the correlation between the resectability, surgical grade and pathology.

Results: The mean sensitivity (Se), specificity (Sp), positive predictive value (PPV), and negative predictive value (NPV) of 120kVp conventional dataset were as follows: 60.0%, 83.3%, 84.2%, and 62.5% for arterial invasion; 63.0%, 87.5%, 89.5.8%, and 58.3% for venous invasion; 56.7%, 84.6%, 89.5%, and 45.8% for lymph node invasion; those results of spectral dataset were 84%, 88.9%, 91.3% and 80.0% for arterial invasion; 85.2%, 93.8%, 95.8%, and 78.9% for venous invasion; 83.3%, 84.6%, 92.6%, and 68.8% for lymph node invasion. To predict tumour resectability using spectral dataset, Se, Sp, PPV and NPV were 92.1%, 80.0%, 97.2%, 57.1% respectively, and compared with surgery and pathology with good agreement ($\kappa = 0.73-0.78$).

Conclusion: Spectral datasets improve assessment of arterially invasion, venous invasion and lymph node invasion, predictive resectability in PADC with increasing conspicuity and margin sharpness of the lesion.

B-1101 11:26

Perfusion parameters quantified with perfusion CT in pancreatic adenocarcinoma before and after neoadjuvant chemoradiotherapy: comparison between responders and non-responders

A. Hamdy, Y. Ichikawa, Y. Toyomasu, M. Nagata, N. Nagasawa, H. Sakuma; Tsu/JP (ahmed.hamdy@kasralainy.edu.ej)

Purpose: To monitor serial changes of blood flow (BF), blood volume (BV) and permeability-surface area product (PS) before and after neoadjuvant chemoradiotherapy (CRT) in patients with pancreatic ductal adenocarcinoma (PDA) using perfusion CT, and to compare tumour perfusion in responders and non-responders to therapy.

Methods and Materials: Perfusion CT before and after CRT was acquired in eighteen patients with pathologically proven PDA who underwent pancreatotomy after completing neoadjuvant CRT. Quantitative maps of BF, BV and PS were generated from 4D perfusion images acquired with dual-source CT. After pancreatotomy, patients were categorised into responders and non-responders according to histopathological grade of response to therapy. Correlations among pre- and post-CRT perfusion, histopathological response, CA 19-9 and RECIST were assessed.

Results: Baseline BF was significantly higher in responders compared to non-responders to CRT (48 ± 12.4 vs 34.2 ± 18 mL/100g/min, $P = 0.03$) while no significant difference was found for BV and PS ($BV = 5.2 \pm 2$ vs 3.7 ± 2.7 mL/100g, $P = 0.2$ and $PS = 26.2 \pm 6.9$ vs 22.3 ± 13.3 mL/100g/min, $P = 0.4$). In responders, all perfusion parameters increased significantly after CRT ($BF = 57.6 \pm 16.7$ mL/100g/min, $P = 0.004$; $BV = 7 \pm 2.5$ mL/100g, $P = 0.02$ and $PS = 33.4 \pm 10.2$ mL/100g/min, $P = 0.03$). In non-responders, perfusion increase was not significant ($BF = 42.7 \pm 14.8$ mL/100g/min, $P = 0.08$; $BV = 4.9 \pm 2.4$ mL/100g, $P = 0.07$ and $PS = 27.8 \pm 10.4$ mL/100g/min, $P = 0.1$). RECIST and CA 19-9 showed no correlation with perfusion parameters and correlated poorly with histopathological response ($r = 0.2$).

Conclusion: Quantitative perfusion CT is a promising tool for monitoring response to CRT in patients with PDA. Increased perfusion after CRT and higher baseline BF predict response to CRT.

B-1102 11:34

Perfusion vs metabolism: which functional parameter should we choose in patients with pancreatic adenocarcinoma to predict response to chemoradiotherapy?

A. Hamdy, Y. Ichikawa, Y. Toyomasu, M. Nagata, N. Nagasawa, H. Sakuma; Tsu/JP (ahmed.hamdy@kasralainy.edu.ej)

Purpose: Perfusion CT and ^{18}F -FDG PET/CT are used for functional assessment of pancreatic ductal adenocarcinoma (PDA). We aim to compare the ability of both techniques to predict histopathological response of PDA to neoadjuvant chemoradiotherapy (CRT).

Methods and Materials: Perfusion CT and PET/CT were performed before CRT in 14 consecutive patients with biopsy-confirmed PDA who were planned for neoadjuvant CRT and surgical resection. Blood flow (BF), blood volume (BV), and permeability-surface area product (PS) were quantified from dynamic perfusion CT covering the entire pancreas acquired with third-generation dual-source CT. SUV_{max} was determined for estimation ^{18}F -FDG uptake in PDA. Patients were classified as responders or non-responders to therapy according to the histopathological grade of response obtained after pancreatotomy. Baseline perfusion parameters and SUV_{max} were compared between both groups. Correlations among perfusion, SUV_{max} and histopathological response were assessed.

Results: Perfusion: responders showed significantly higher BF than non-responders to CRT (48.3 ± 11.4 vs 32.1 ± 12.5 mL/100 g/min, respectively, $P = 0.02$). Moreover, BF and BV showed significant correlation with histopathological grade of response (BF: $r = 0.70$, $P = 0.005$, BV: $r = 0.60$, $P = 0.03$). Metabolism: there was no significant difference in baseline SUV_{max} between responders and non-responders (5.5 ± 3.2 and 6.5 ± 5 , respectively, $P = 0.70$). SUV_{max} exhibited only weak negative correlations with perfusion and histopathologic response, without statistical significance (BF: $r = -0.22$, BV: $r = -0.31$, PS: $r = -0.29$, response: $r = -0.07$).

Conclusion: Tumour perfusion estimated with perfusion CT is a better functional imaging biomarker than tumour metabolism estimated with PET/CT for the prediction of histopathological response to therapy in patients with pancreatic adenocarcinoma.

CT texture analysis for detection of tumour recurrence in patients resected for pancreatic adenocarcinoma

A. Mazza, G. Zamboni, A. Fighera, A. Campagnola, G. Mansueto; Verona/IT (andrea.mazza1558@gmail.com)

Purpose: To compare the CT texture analysis features of local tumour recurrence and postoperative fibrosis in patients who underwent resection of pancreatic adenocarcinoma.

Methods and Materials: We reviewed the CTs of 61 consecutive patients with resected pancreatic adenocarcinoma that had an early detection of solid hypodense tissue in the surgical bed at the after-surgery follow-up CT. For all patients clinical data and further follow-up CTs were available. Two readers in consensus performed texture analysis of the tissue in the first CT by drawing a ROI in the most representative slice in the venous phase. First-order statistics CT texture data (variance, skewness and kurtosis) were extracted using Mazda software. An unpaired T-test was used for statistical analysis.

Results: Among the 61 patients, the further follow-up CTs revealed in 29 the development of local tumour recurrence and in 32 post-surgical scar tissue which remained stable in size and imaging features. Mean kurtosis was 0.459 for patients with local recurrence and -0.126 for patients with post-surgical fibrosis, with a significant difference between the two groups ($p < 0.0001$). Mean variance at the first CT was 315,13 for recurrence and 296,70 for fibrosis, with no significant difference between groups ($p = 0.55$). Mean skewness was 0.096 for recurrence and -0.057 for fibrosis, with no significant difference ($p = 0.67$).

Conclusion: Kurtosis appeared to be an effective parameter to differentiate between local recurrence and post-surgical fibrosis in patients resected for pancreatic adenocarcinoma. Other first-order statistics from CT texture analysis do not appear useful in the detection of local recurrence.

B-1104 11:50

Locally advanced and metastatic pancreatic cancer: the role of CT quantitative imaging biomarkers for predicting outcomes of patients treated with chemotherapy

S.-H. Cheng, H.-D. Xue, Z.-Y. Jin; Beijing/CN

Purpose: The primary aim of this study was to determine if CT texture analysis measurements of the tumor are independently associated with progression-free survival (PFS) and overall survival (OS) in patients with locally advanced or metastatic pancreatic cancer who were treated with chemotherapy.

Methods and Materials: 41 patients with locally advanced or metastatic pancreatic cancer who underwent contrast-enhanced CT before chemotherapy between 2014 and 2017 were analyzed with quantification of mean gray-level intensity (Mean), entropy, mean of positive pixels (MPP), kurtosis, standard deviation (SD), and skewness for fine to coarse textures (spatial scaling factor (SSF) 0-6, respectively). The association between pretreatment and posttreatment texture parameters, as well as Δ value (difference between posttreatment and pretreatment texture parameters), and survival time was assessed by using Kaplan-Meier analysis and a Cox proportional hazards model.

Results: Multivariate Cox model indicated that tumor size, tumor SD (HR, 0.942; 95% CI: 0.898, 0.988) and skewness (HR, 0.407; 95% CI: 0.172, 0.962) measurements with SSF=3, and tumor SD (HR, 0.958; 95% CI: 0.92, 0.997)

measurements with SSF=4 were significantly and independently associated with PFS, while tumor size and tumor SD (HR, 0.928; 95% CI: 0.882, 0.976) measurements with SSF=3 were significantly and independently associated with OS. None of the post-therapy Δ in texture parameters had a significant association with OS or PFS.

Conclusion: Pretreatment CT quantitative imaging biomarkers from texture analysis are associated with PFS and OS in patients with locally advanced and metastatic pancreatic cancer who were treated with chemotherapy.

Effect of adding charcoal capsule to abdominal ultrasound preparation on image quality

M. Tomehy, M. Wazan, A. Abdul Jabar, E. Abbass, N. Mishah; *Jeddah/SA* (mut315@hotmail.com)

Purpose: Patient preparation before abdominal ultrasound plays a major role to ensure better visualization of organs, but abdominal gases in many patients still exist in large amount causing artifacts; it is important to search for safe, efficient, reliable and cost effective method to improve patient preparation to eliminate abdominal gases.

Methods and Materials: Prospective Study on randomly selected sample size of 52 adult patients from different ages and mixed gender. Pediatric, pregnant, abdominal surgery, bedridden, and patients with bowel obstruction were excluded from this study. For accepted patients the routine upper abdominal ultrasound with usual preparation fasting instruction for 8 hours was followed, then same group of patients scanned again after 48 hours and instructed to follow the same standard preparation for but, in addition they were asked to take one capsule of charcoal 8 hours. Then we compared ultrasound image quality in abdominal region for the same patient before and after by focusing on pancreas as a reference.

Results: Improvement in pancreas head region was 50%, pancreas neck the improvement was 32.5%, pancreas body 57.45% and 32.5% in the pancreas tail. A significant improvement was noticed in overweight, obese patients group by 57.2% while in underweight & normal weight the improvement was 39.05%. The improvement in males 66.9% while 49.9% in females. Overall improvement in pancreas visualization was 63%.

Conclusion: Active charcoal can be used to reduce gastrointestinal gases in efficient, low cost, safe and ease of use to improve the visualization of adult abdominal ultrasound.

B-1107 10:46

Sonographic estimation of amniotic fluid volume using the amniotic fluid index and the single deepest pocket in a resource-limited setting

F.A. Burabe¹, G. Luntsi¹, N.I. Chigozie², F. Nkubli¹, J.Z. Dlana¹, P.A. Ogenyi¹; ¹Maiduguri/NG, ²Awka/NG (Falmata.Burabe@gmail.com)

Purpose: To determine the normal value of amniotic fluid (AF) volume among pregnant women in a Northern Nigerian population and to determine if there is a relationship between AF index (AFI) and single deepest pocket (SDP) with anthropometric variables.

Methods and Materials: A prospective cross-sectional study was conducted among singleton pregnant women at late second and third trimester attending the antenatal clinic in Abubakar Tafawa Balewa Teaching Hospital, Bauchi, from December 2016 to April 2017. The mean AFI and SDP were measured by sonography. Participation was voluntary. Descriptive statistics, i.e. mean, standard deviation, and correlation coefficient, were used for the analysis.

Results: A total of 206 women, aged between 18 and 40 years, with fetal gestational ages between 22 and 39 weeks were included in the study. The values for AFI in the study ranged from 12 to 28.7 cm, with a mean value of 19.84 ± 3.64 cm, and SDP ranged from 3.7 to 9.1 cm with a mean value of 6.04 ± 1.12 cm. This study found a weak relationship between the anthropometric variables and AFI and SDP and a strong relationship between AFI and SDP with a correlation coefficient of $R = 0.901$ and $P = 0.014$.

Conclusion: The mean values for AF volume using AFI and SDP in the studied population were 19.84 ± 3.64 cm and 6.04 ± 1.12 cm, respectively; a strong positive relationship between AFI and SDP; and a negative relationship between body mass index with AFI and SDP.

B-1108 10:54

Relation between fascia and pain by ultrasound

R.A. Santos, F. Couceiro; *Coimbra/PT* (rutemartinsantos@gmail.com)

Purpose: To compare the degree of fascia change through ultrasound/elastography and the pain scale: to evaluate, compare and standardize fascia changes degree and Visual Analog Scale for Pain.

Methods and Materials: Thirty individuals without associated pathology were evaluated. The ultrasound B-mode and elastography quasi-static scans were collected from the intersection point of the fascia through analysis of the myofascial vector of the lateromotion carpus (la-ca) The centre of coordination of these vectors is over the muscle belly of the two extensor carpi radialis muscles. Also all participants were asked, using the Visual Analog Scale for pain intensity, in the same intersession point of the fascia, between "no pain" (score of 0) and "worst imaginable pain" (score of 100). For B-mode images, ImageJ software was used to analyse the thickness and echo-intensity and for elastography images, the color fractions were measured with a custom MATLAB routine.

Results: In individuals with a higher pain intensity there were found a higher fraction of blue pixels (harder) ($p < 0.001$). There are no significant differences in fascia echo-intensity between the individuals with different intensity pain.

Conclusion: As the fascia connects with all structures of the body, an imbalance between its components, easily affects any part of the body, causing discomfort or pain. It's fundamental to find a method that helps in the diagnosis of the fascia changes, it was able to evaluate its characteristics. Elastography becomes an attractive method to better understand the fascia, its characteristics and its changes detection, thus aiding in diagnosis.

B-1109 11:02

Real-time sonography as a teaching aid of anatomy in undergraduate radiography institutions in Northern Nigeria

M.S. Umar¹, D. Joseph², A. Auwal³, S. Charbel⁴, P.A. Ogenyi¹, G. Njokwu¹, M.A. Fati³, A.S. Moi³, S.L. Shem⁵, ¹Bauchi/NG, ²Kano/NG, ³Maiduguri/NG, ⁴Beirut/LB, ⁵Gombe/NG (umar.sani888@gmail.com)

Purpose: To assess real-time ultrasound scanning as a teaching aid of human anatomy, and to determine what teaching methods radiography students consider effective for understanding human anatomy.

Methods and Materials: One hundred and ten self-administered, structured and pretested questionnaires were distributed to clinical radiography students in Northern Nigeria. The questionnaire consisted of two sections: demographics and preferred methods of delivery of anatomical information. Participation was voluntary. Comparisons among teaching methods were made using repeated measures ANOVA.

Results: With Duncan's multiple range test (MRT), it is clearly shown that 3D radiology imaging differ with mean value (5.2522) followed by computer programs (5.1292), anatomic models (4.7593), lab videos (4.5815), textbooks (4.5358), animal dissection (4.2568), lectures (3.2568) and finally ultrasound scan (3.6087), ($P < 0.0001$).

Conclusion: This study shows that 3D radiology imaging is the most preferred method of delivering anatomical information and ultrasound scanning is the least preferred method.

B-1110 11:10

Muscular changes with ageing: ultrasound evaluation

R.A.M. Santos¹, H.I. Ferraz²; ¹Coimbra/PT, ²Peso da Régua/PT (rutemartinsantos@gmail.com)

Purpose: To analyse and characterise the muscle in elderly individuals by ultrasound and to verify muscle changes with age.

Methods and Materials: 40 elderly participants, with a mean age of 80 years, were submitted to an ultrasound examination for quadriceps muscle characterisation. The quadriceps muscle was evaluated in a longitudinal view, using the same parameters in all acquisitions. All the images were analysed by Image J software and the results were obtained using SPSS v.24 software. The quadriceps muscle in elderly individuals showed an increase in echo-intensity values and a decrease in thickness values when compared with an young population. In participants with more advanced age the values were more evident.

Results: The quadriceps muscle in elderly individuals showed an increase in echo-intensity values and a decrease in thickness values when compared with an young population. In participants with more advanced age the values were more evident.

Conclusion: The ageing significantly affects human skeletal muscle architecture. These structural alterations are expected to have implications for muscle function in old individuals.

B-1111 11:18

The role of obstetric ultrasound in low resources setting: pilot survey done in Elgeyo-Marakwet and Kericho county from 2016 March to 2018 December

K. Clive; Kericho/KE (kosgeykips@gmail.com)

Purpose: There are vast inequalities across maternal and infant mortality with the developing world accounting for the majority of the burden and within countries rural areas expecting worse outcomes than urban. This review focuses on obstetric ultrasound service and its potential to improve maternal and newborn health in low resource settings. Recent advances in affordability, durability, and portability have brought ultrasound to the forefront as a sustainable and high impact technology for use in developing world clinical settings as well.

Methods and Materials: Ultrasound services were introduced at Elgeyo and Kericho county Data sheets for each ultrasound scan performed during routine clinical care were collected and analyzed to determine patient demographics, which ultrasound applications were most frequently used, and whether the use of the ultrasound changed patient management plan

Results: Adult women appeared to benefit most from the presence of ultrasound services. During these outreaches a total of 1029 women were scanned. Twenty percent of these scans showed abnormalities. These women were referred to the nearest health center or hospital where they received more check-ups.

Conclusion: We suggest ultrasound is a useful modality that particularly benefits women's health and obstetrical care in the developing world and it feasible, factual and accurate.

B-1113 11:34

An ethnographic study to investigate general practitioner's opinion of ultrasound services in primary care

M. Boland, L.A. Rainford, C. Byrne, M.-L. Ryan; Dublin/IE (mairead.boland@ucdconnect.ie)

Purpose: In Ireland, patients may wait 42 weeks for an ultrasound, which is detrimental to patient workflow and delays diagnosis. Research investigating increased imaging access in primary care shows that timely imaging corresponds to decreased unnecessary admissions to Emergency Departments (ED). GP opinions were sought of direct access ultrasound on: waiting lists, patient management, referral pathways and determining GP satisfaction with radiology report content and radiology accessibility for further consultation.

Methods and Materials: An ethnographic approach was applied to survey two groups of GPs - one who have direct access to ultrasound within a primary care setting and GPs who refer to regional hospitals with long waiting lists. Semi-structured interviews were completed, themes were identified and GP's responses compared.

Results: GPs with direct access (n=12) reported waiting times of 2/3 weeks compared to several months for hospital referrals. This group indicated the benefit of patients remaining within primary care, reporting potential reductions in unnecessary ED and consultant referrals and enhanced management of gynaecological conditions and abdominal presentations. GPs considered patient's preference, time to access services and ease of travel when referring. 50% of GP's with direct access indicated satisfaction with radiology reports and radiology accessibility, the remainder highlighted the importance of radiology guidance within reports.

Conclusion: Direct access to diagnostics was evidenced as beneficial to both patients and GPs in reducing waiting times and providing efficient diagnosis. Radiology guidance and consultation availability was highlighted as important for primary care imaging service users to support efficient patient management pathways.

B-1114 11:42

The effect of deep learning reconstruction on calcium scoring

C. Steveson¹, J.L. Schuzer², T. Acharya³, K. Bronson³, S. Rollison³, W. Bandettini³, S. Shanbhag³, M.Y. Chen³; ¹Kanagawa/JP, ²Vernon Hills, IL/US, ³Bethesda, MD/US (chloe.steveson@medical.canon)

Purpose: Assessing coronary artery calcium (CAC) is a valuable tool in individualizing cardiac risk assessment. Deep convolutional neural network image reconstruction has the potential to improve image quality. The aim of this study is to investigate the effect of a deep learning image reconstruction algorithm on Agatston calcium score accuracy and signal to noise ratio (SNR) in CAC scanning.

Methods and Materials: With institutional ethics approval, 40 consecutive patients underwent 2 EKG-gated coronary calcium score scans (120kV, 0.275s rotation speed, 100-140mm range, mA was calculated using automatic exposure control). Each scan was reconstructed with conventional filtered back projection (FBP) and deep learning reconstruction. Agatston score was calculated on a per patient basis using standard techniques utilizing a 130 HU threshold. SNR was calculated for each reconstruction. Data was analyzed

using linear regression and paired t-test.

Results: Patients averaged 63 ± 15 years old, 45% were male, and the median radiation exposure was 0.88 mSv (interquartile range 0.62-1.22). The median Agatston score was 61.7 (inter quartile range 0-315) with clinical FBP reconstruction. Deep learning reconstruction had excellent agreement with FBP (R=0.99) over a wide range (0-4121); however, it underestimated calcium score by 6%. SNR for deep learning reconstruction improved 37.1% compared to FBP (3.24 ± 0.43 vs. 2.46 ± 0.39, p<0.00001).

Conclusion: Deep learning image reconstruction has an excellent correlation with conventional FBP reconstruction for CAC imaging at standard radiation doses. The improved image quality and higher SNR may enable lower radiation while maintaining accurate Agatston scores.

Radiographer as RIS/PACS administrator: promoting professional networking and continuing professional education by the society of radiographers in Finland

H. Syysmäki¹, P. Wood², R. Laaksonen-Heikkilä¹; ¹Turku/FI, ²Helsinki/FI (hanna.syysmaki@edu.turkuamk.fi)

Purpose: The purpose of this study was to investigate the background information about Finnish PACS and RIS -administrators and what are their needs of professional networking and continuing professional education. This study was an empirical part of the master's thesis performed at Turku University of Applied Sciences.

Methods and Materials: A quantitative questionnaire survey was conducted in 2017. The questionnaire developed for the study was sent to all members of the Society of Radiographers in Finland (SORF), but targeted only to radiographers who works as PACS and RIS -administrators. Estimated number of Finnish PACS- and RIS -administrators were 60 persons. In total, 37 responses were received.

Results: The results of the questionnaire showed, that there is not enough continuing professional education for PACS and RIS administrators in Finland. In addition, the content of continuing professional education did not adequately support or enhance their professional competence. Professional support works best among the workers who work for the same employer. Networking seems to be valued and therefore respondents were interested in a wider professional network. However, there were also reservations about the benefits of networking through the professional division.

Conclusion: Finnish PACS and RIS administrators need more continuing professional education that adequately support and enhance their professional competence. Opportunities for professional support and networking should be developed.

Spectral photon-counting CT multi-phase liver imaging with dual contrast agent

S.A. Si-Mohamed¹, V. Tatard-Leitman¹, P. Coulon², P. Douek¹, P.B. Noel³, L. Bousset¹; ¹Bron/FR, ²Suresnes/FR, ³Munich/DE (salim.si-mohamed@chu-lyon.fr)

Purpose: To demonstrate the feasibility of dual-contrast multiphase liver imaging via K-edge imaging using Spectral Photon-Counting CT (SPCCT).

Methods and Materials: *In-vivo* experiments were conducted on 4 rabbits after approval by the local ethics committee. Data acquisition was performed at 120 kVp and 100 mA. The protocol was to inject the iodine contrast agent (400 mg/mL, 1.5 mL/kg) 21 seconds before the injection of gadolinium contrast agent (0.5 M, 5 mL/kg). The acquisition was performed 10 seconds thereafter. Conventional HU, and quantitative iodine and gadolinium images were analyzed.

Results: SPCCT allowed the discrimination between the two contrast agents; gadolinium led to an enhancement of the arteries and iodine of the liver parenchyma and portal veins. The attenuation values (HU) and concentrations

(mg/mL) of contrast agents were calculated for the aorta (CT = 1103.1 ± 3.2; gadolinium = 20.5 ± 0.5; iodine = 6.9 ± 0.2), hepatic arteries (CT = 605.6 ± 7; gadolinium = 8.5 ± 1.3; iodine = 0.7 ± 0.2), portal vein (CT = 247.3 ± 3.3; gadolinium = 0 ± 1.3; iodine = 4.2 ± 0.3) and liver parenchyma (CT = 145.3 ± 1.5; gadolinium = -0.3 ± 0.9; iodine = 2.1 ± 0.1). Finally, the pharmacokinetics of the two contrast agents were analyzed and found to be similar to those expected.

Conclusion: SPCCT allows *in vivo* dual contrast qualitative and quantitative multi-phase liver imaging in a single acquisition. A single acquisition has the major advantage of reducing patients' exposure to ionizing radiation.

Spectral CT of cancer cells with nanoparticles: in vitro and in vivo results

M. Moghiseh, D. Kumar, R. Aamir, C. Lowe, K. Chitcholtan, P. H Butler, P. Sykes, A.P. Butler, N. Anderson; *Christchurch/NZ* (mahdieh_moghiseh@yahoo.com)

Purpose: To determine if spectral CT can identify and quantify gold nanoparticles (AuNPs) targeted to specific cancer cells in vitro and in vivo. The long-term goal is to evaluate tumour response to treatment and to facilitate anti-cancer drug development.

Methods and Materials: Initially, two ovarian cancer cell lines (OVCAR5 and SKOV3) were studied. To evaluate the effect of AuNP size, plates of 600,000 of each cell line were incubated with four sizes particles (18, 40, 60 and 80nm) at four concentrations (6.4, 12.8, 25.8 and 38.5µg/mL). The cell plates were imaged with a MARS spectral CT working in clinical x-ray energy range. A second experiment was performed to validate the quantification method in a mouse model. The gold quantification results were confirmed using phantoms containing oil, water, gold chloride, and hydroxyapatite.

Results: The first experiment demonstrated that uptake of AuNPs into ovarian cancer cells varies according to particle size and cell type. The best size particle to detect SKOV3 were 18 and 80nm. However, uptake of the same size of particles was very low for OVCAR5 cells. Based on these results, 18 and 80nm particles were injected into the mouse model of ovarian cancer cell (in vitro results are under investigation).

Conclusion: This study has established a methodology to quantify drug delivery to specific ovarian cell. This is proof of principle that drug delivery to cells can be measured using non-invasive spectral CT. Our methodology is designed to accelerate advances in cancer research and translate it to human imaging using spectral CT.

B-1118 10:46

Quantification of gadolinium with 3rd generation dual source dual energy CT: role of spectral separation

A. Agostini, A. Borgheresi, A. Mari, A. Lorenzoni, L. Ottaviani, S. Maggi, A. Giovagnoni; *Ancona/IT* (andrea.agostini84@yahoo.it)

Purpose: To evaluate feasibility, accuracy and the role of spectral separation in Gadolinium quantification with a 3rd generation Dual Source Dual Energy CT (dsDECT) on a phantom model.

Methods and Materials: Preparation of phantom (Electron Density Model 062M, CIRS, USA) with 5 inserts containing scalar dilutions in distilled water solution (0.00375M- 0.05M) of Gadolinium chelate (Gd-BOPTA 0.5M, MultiHance, Bracco). Scanning parameters: 3rd generation dsDECT (Somatom Force, Siemens Healthineers); preliminary acquisitions at 70, 80, 90, 100, 140, Sn150 kV; Dual Energy acquisitions 70-100/Sn150 kV, 80/140 kV; modulated mA; rotation time 0.5s; pitch 0.7; slice thickness/spacing 2/1 mm. Dual energy indexes (DEI) were calculated with 5 identical cloned regions of interest (ROI) on each insert on preliminary acquisitions (ImageJ 1.52a, NIH, United States) and linear regression model (MedCalc v12.5, MedCalc Software). Gadolinium densities within inserts were calculated on Dual Energy acquisitions with Liver VNC (Syngo.via Frontier, Siemens Healthineers) and compared with actual Gd concentrations with Bland-Altman Analysis. Non-parametric tests were used with significant p<0.05.

Results: Linear regression models provided DEI ranging between 1.64 at 80/140 kV and 2.56 at 70/Sn150 kVp (R²>0.999; p<0.001). Quantification of gadolinium densities on dual energy acquisitions provided percentage errors of 7%-37% for acquisitions at 70/Sn150 kV and of 16%-76% at 80/140 kV with significant differences (Friedman p = 0.024) and a trend to increase at lower concentrations and spectral separation.

Conclusion: Gadolinium quantification is feasible with 3rd generation dsDECT with increasing accuracy at wider spectral separation and higher concentrations.

B-1119 10:54

Quantitative evaluation of nonalcoholic fatty liver disease using normalised local variance US in a rat model

J. Bae, J. Lee, D. Lee, H. Kim, J. Han; *Seoul/KR* (jaeseok.bae@gmail.com)

Purpose: To identify factors that influence the speckle pattern of hepatic parenchyma on ultrasonography (US) using a normalized local variance (NLV) technique in a dietary-induced nonalcoholic fatty liver disease rat model using histopathologic examination and magnetic resonance spectroscopy (MRS) as standards of reference.

Methods and Materials: Sixty-four male Sprague-Dawley rats were fed a methionine-choline-deficient diet with variable periods (0, 2, 4, 6, 8, 10, 12 days or 2, 3, 4, 5, 6, 8, or 10 weeks; four rats in each group except for eight rats in 8 and 10 weeks groups). At the end of each diet duration, NLV US and MRS were performed. Thereafter, the rats were sacrificed, and livers were histopathologically evaluated. The Spearman correlation was performed to assess the relationship between the NLV values and steatosis or fibrosis, and multivariate linear regression was used to determine factors for the NLV values.

Results: There was a negative correlation between the NLV value and the hepatic steatosis (Spearman ρ , -0.570 and -0.534 for histopathologic examination and MRS, respectively; $P < .001$ for both). The NLV value and the hepatic fibrosis showed negative correlation as well (Spearman ρ , -0.616; $P < .001$). Multivariate linear regression revealed that the stage of hepatic steatosis and fibrosis ($P = .002$ for both) were significant factors affecting the NLV values.

Conclusion: The NLV values have a negative correlation with the fat fraction measured at histopathologic examination and MRS. The stage of hepatic steatosis and fibrosis were significant factors that affected the NLV values.

Dual-targeting and excretable ultrasmall SPIONs for T1-weighted-positive MR imaging of intracranial glioblastoma by targeting lipoprotein receptor-related protein

C. Du, X. Liu, H. Li, L. Yu, D. Geng, Y. Chen, J. Zhang; *Shanghai/CN* (1944465685@qq.com)

Purpose: To more precisely delineate the boundary of intracranial glioblastoma pre-surgical operation, a multifunctional-targeted nanoprobe composed of PEGylated ultrasmall superparamagnetic iron oxide nanoparticles (USPIONs) with surface-conjugated Angiopep-2 was successfully stepwise constructed, which efficiently crossed the blood-brain barrier (BBB), targeted the glioblastoma and then generated positive contrast enhancement for T₁-weighted MR imaging.

Methods and Materials: The targeting capability and especially the biocompatibility/excretion of these ANG-modified MRI nanoprobe were systematically evaluated not only at intracellular level in vitro but also on tumour xenografts in vivo.

Results: The relaxivity r_1 was calculated to be as high as 4.68 mM⁻¹s⁻¹ and the relaxivity r_2 was determined to be 15.96 mM⁻¹s⁻¹, resulting in a relatively low r_2/r_1 ratio ($r_2/r_1 = 3.41$). For targeting ANG/PEG-USPIONs group, the enhanced bright contrast of tumour in T₁-weighted images was observed distinctly, and the boundary of tumour was delineated much clearer. The optimal T₁-weighted MR contrast enhancement of the tumour was at 1.5 h post-injection of ANG/PEG-USPION nanoprobe, and the enhanced signal intensities of ANG/PEG-USPION nanoprobe were maintained for at least 4 h, which was much longer than commercial Gd-DTPA contrast agents (1 h).

Conclusion: The as-constructed dual-targeting ANG/PEG-USPION nanoprobe has relatively high r_1 relaxivity and could be utilized as positive contrast agent for MR imaging of intracranial glioblastoma.

EGFR-targeted liposomal nanohybrid cerasomes: theranostic function and immune checkpoint inhibition in a mouse model of colorectal cancer

Y. Li, Y. Du, X. Liang, H. Xue, Z. Jin; *Beijing/CN* (shandongliyu1988@126.com)

Purpose: Epidermal growth factor receptor (EGFR) is a major target for the treatment of colorectal cancers (CRCs), and programmed death ligand-1 (PD-L1) is an attractive target for CRC immunotherapy.

Methods and Materials: Herein, we report the synthesis of porphyrin-containing liposomal nanohybrid cerasomes decorated with cetuximab, an anti-EGFR antibody, and conjugated with IRDye800CW and MRI-contrast DOTA-Gd, to enable *in vivo* tumour detection and photodynamic therapy (PDT). Moreover, PD-L1 was added as an adjuvant therapy. The antitumour efficacy of PDT combined with PD-L1 immunotherapy was assessed.

Results: EGFR-targeted nanoparticle showed targeted imaging of tumours. EGFR-targeted PDT combined with PD-L1 immunotherapy was more effective against tumour growth than simultaneous albeit non-targeted nanoparticle delivery with laser irradiation plus PD-L1 immunotherapy.

Conclusion: Thus, EGFR-targeted nanoparticle exhibited significant potential toward dual-modality imaging-guided precise PDT, combined with immunotherapy.

B-1124 11:18

Cell death PET imaging of rat liver cirrhosis with ⁶⁸Ga-NOTA-PEG₃-Duramycin

S. Shu, X. Xianhong, T. Ganghua; *Guangzhou/CN (15626214090@163.com)*

Purpose: The aim was to assess the value of ⁶⁸Ga-1,4,7-triazacyclononane-1,4,7-triacetic acid (NOTA)-tripolyethylene glycol (PEG₃)-Duramycin (⁶⁸Ga-NOTA-PEG₃-Duramycin) positron emission tomography (PET) imaging of liver cirrhosis in a rat model.

Methods and Materials: Male Sprague-Dawley rats (160~180g) were used to establish liver cirrhosis rat model via intraperitoneal injection of thioacetamide (TAA), control rats were treated with saline (n=3 per group). At week 10 of TAA administration, PET/CT with ⁶⁸Ga-NOTA-PEG₃-Duramycin or ¹⁸F-fluorodeoxyglucose (¹⁸F-FDG) was performed on TAA-induced and control rats. The liver accumulation of ⁶⁸Ga-NOTA-PEG₃-Duramycin or ¹⁸F-FDG, illustrated as percentage injected dose per gram (%ID/g) of tissue. Liver tissues were harvested and analyzed for histologic examination after PET/CT imaging. Binding assays of ⁶⁸Ga-NOTA-PEG₃-Duramycin with Juakat cells was performed. Data were analyzed by Student t test.

Results: Binding assays showed that ⁶⁸Ga-NOTA-PEG₃-Duramycin accumulated in both apoptotic and necrotic cells. After treatment with TAA or saline for 10 weeks, model rats showed a significantly higher liver accumulation of ⁶⁸Ga-NOTA-PEG₃-Duramycin than control rats (P<0.05). In TAA-treated rats, the liver-to-muscle uptake ratio of ⁶⁸Ga-NOTA-PEG₃-Duramycin was also significantly higher than that of ¹⁸F-FDG (P<0.05). Over-proliferation of fibroblasts and deposition of collagen was seen in TAA-induced rat liver samples sections via histologic examination. Compared with control rats, TAA-treated rats had higher liver hydroxyproline content (P<0.05). Immunofluorescence staining showed more apoptotic cells in the TAA-treated rats than those in the control rats.

Conclusion: ⁶⁸Ga-NOTA-PEG₃-Duramycin PET/CT imaging could be applied for noninvasive diagnosis of liver cirrhosis in a rat model.

B-1125 11:26

In vivo tracking of tumour-derived exosomes correlates with premetastatic cell infiltration to target-sites of metastasis

M. Gerwing, V. Kocman, A. Helfen, M. Stöling, L. Greune, A. Schmidt, W. Heindel, M. Wildgruber, M. Eisenblatter; *Münster/DE (Mirjam.Gerwing@ukmuenster.de)*

Purpose: Exosomes, small vesicles carrying inter alia proteins, miRNA and RNA, are important mediators in intercellular communication. The purpose of this project was to assess the *in vivo* biodistribution of exosomes from highly malignant breast cancer cells in comparison to exosomes from the serum of healthy mice, and their effect on the immune cell infiltrate in target organs of metastasis.

Methods and Materials: Exosomes were isolated from the tissue culture supernatant of highly malignant 4T1 breast cancer cells or the serum of healthy BALB/c mice. The purity of the isolate was checked by electron microscopy and western blotting. After labeling with the fluorescent dye DiR (750/780 nm), exosomes were injected i.v. into healthy BALB/c mice and their distribution was assessed using fluorescence-reflectance imaging (FRI). After *ex vivo* imaging of the organs, lungs and spleen were stained for FACS analysis of granulocytes, T- and B-cells to identify changes in the immune cell content.

Results: The assessment of the *in vivo* distribution of DiR-labelled exosomes with FRI showed exosomes from highly malignant 4T1 cells to preferentially accumulate in the target organs of metastasis, in this case lung, liver and spine (tumour-exosomes vs. serum-exosomes: lung 18.6 vs. 10.4, p=0.01; liver 72.2 vs. 56.5, p=0.02; spine 5.1 vs. 3.5, p<0.01). Furthermore, an increased infiltration of immune cells in these target-organs of metastasis after injection of tumour-derived exosomes was identified.

Conclusion: Exosome accumulation, which promotes the infiltration of immune cells in target-organs of metastasis, can be visualized by FRI.

Orthotopic hepatocellular carcinoma: molecular imaging-monitored intratumoural hyperthermia-enhanced direct oncolytic virotherapy

J. Song¹, F. Zhang¹, J. Ji¹, M. Chen¹, Q. Weng², X. Yang², M. Xu¹, C. Lu¹, Z. Zhao¹; ¹Lishui/CN, ²Seattle, WA/US

Purpose: To validate the feasibility of molecular imaging-monitored intratumoural radiofrequency hyperthermia (RFH)-enhanced direct oncolytic virotherapy for hepatocellular carcinoma (HCC).

Methods and Materials: This study included *in vitro* confirmation experiments using luciferase-labeled rat HCC cells and *in vivo* validation experiments on rat models with orthotopic HCCs. Both cells and HCCs in four groups (n=6/group) were treated by: (1) combination therapy of oncolytic virotherapy (T-VEC) plus RFH at 42°C for 30 minutes; (2) oncolytic virotherapy alone; (3) RFH alone; and (4) saline. For *in vitro* confirmation, confocal microscopy and bioluminescence optical imaging were used to evaluate the cell viabilities. For *in vivo* validation, oncolytic viruses were directly infused into rat HCCs through a multi-functional perfusion-thermal RF electrode, followed by RF hyperthermia. Ultrasound and optical imaging were used to follow up size and bioluminescence signal changes of tumours overtime, which were correlated with subsequent laboratory examinations.

Results: For *in vitro* experiments, confocal microscopy showed the lowest number of viable cells, as well as a significant decrease of bioluminescence signal intensity of cells with combination therapy group, compared to other three groups (P < .001). For *in vivo* experiments, ultrasound and optical imaging showed the smallest tumour volume, and significantly decreased bioluminescence signal intensity in combination therapy group compared to other three groups (P<.05), which were well correlated with pathologic analysis.

Conclusion: It is feasible to use molecular imaging to guide RFH-enhanced intratumoural oncolytic virotherapy of HCC, which may open new avenues for preventing persistency or recurrence of RFA-treated intermediate-to-large HCCs.

Super-resolution reconstruction of knee MR images

E. De Smet, B. Jeurissen, J. Sijbers, F. Vanhevel, P.M. Parizel, P. Van Dyck; *Antwerp/BE (elinedesmet@hotmail.com)*

Purpose: Super-resolution reconstruction (SRR) combines several distinct low-resolution images into a single high-resolution image. This study explores the feasibility of SRR for isotropic 3D knee MRI and compares this method to direct 3D acquisition.

Methods and Materials: Seventeen subjects (3 volunteers and 14 patients with knee pain) underwent 3T MRI with sagittal 2D TSE thick-slices (TR/TE=3080/36ms, voxel size=0.5x0.5x2.0mm³, number of slices=53, scan time=1min55s). The experiment was repeated 7 times, while the slice stack was rotated around the phase encoding direction in increments of 26 degrees (0°, 26°, 51°, 77°, 103°, 129°, 154°). SRR was performed to an isotropic high-resolution grid with voxel size 0.5x0.5x0.5mm³. Sagittal 3D TSE acquisition was also obtained (TR/TE=1300/38ms, voxel size=0.5x0.5x0.5mm³, number of slices=208, scan time=12min42s). Two radiologists evaluated subjective image quality using a Likert scale. Volunteers and a phantom (Newmatic Medical, MI, USA) were scanned twice for quantitative image evaluations. Findings were analysed using the Friedman test (p<0.05).

Results: Overall image quality and visibility of anatomic structures were significantly better with SRR than with 3D TSE, exhibiting blurring artefacts and poor low-contrast object detectability (p<0.05). Meniscal lesions were better depicted with SRR (p<0.05), whereas observer ratings for cartilage and ligamentous lesions were similar. Relevant SNRs and CNRs were significantly higher for SRR than for 3D TSE (p<0.05). Clear improvement in resolution achievable by SRR was also confirmed by the edge response curve in the phantom study.

Conclusion: SRR of knee MRI is feasible and represents a promising alternative for high-resolution isotropic 3D imaging of the knee.

B-1128 10:38

Identification of bone marrow oedema and osteochondral injuries of the knee: diagnostic accuracy of dual-energy CT and virtual non-calcium techniques

G. Foti¹, M. Catania², A. Beltramello¹, G. Carbognin¹; ¹Negrar/IT, ²Verona/IT (gforti81@yahoo.it)

Purpose: To prospectively evaluate the diagnostic accuracy values of dual-energy computed tomography (DECT) to identify bone marrow oedema and osteochondral injuries of the knee.

Methods and Materials: This prospective study included 33 consecutive patients studied with DECT (80 kV and tin filter 150 kV) and MRI with short tau

inversion recovery images (STIR) within 7 days. DECT data were post-processed on a dedicated offline workstation (SynngoVia®) using a three-material decomposition algorithm. Two experienced radiologists, blinded to MRI, evaluated the presence of abnormal attenuation of each knee on DECT maps. STIR images served as the standard of reference. Diagnostic accuracy values of the DECT maps and of the CT numbers using receiver operator curves (ROC) and inter- and intra-observer agreements were calculated. A value of $p < 0.05$ was considered statistically significant.

Results: MRI revealed the presence of bone marrow oedema of the knee in 17/33 cases (51.6%), with 10 osteochondral injuries. DECT numbers were significantly different between positive (mean -5.5 ± 32.6 HU) and negative cases (mean -72.4 ± 41.6 HU) with a p value < 0.001 . Using -15 HU cutoff to identify bone marrow oedema, the sensitivity, specificity, PPV and NPV and accuracy of DECT were 89.5, 92.9, 94.4, 86.6 and 90.9%, respectively. The inter-observer and intra-observer agreements were near perfect ($k=0.82$ and $k=0.86$, respectively).

Conclusion: DECT represents a reliable imaging tool for demonstration of bone marrow oedema and osteochondral injuries of the knee.

B-1129 10:46

Dixon imaging of bone stress injury of the knee: comparison to conventional proton density-weighted MR imaging

A. Chhabra¹, P. Pezeshk¹, R. Dessouky², O. Morales¹, J. Shah¹;
¹Dallas, TX/US, ²Zagazig/EG

Purpose: Dixon sequence is a chemical shift-based MR sequence that produces four sets of images (water only, fat only, in-phase, and out-of-phase) and is currently being used in various musculoskeletal applications. The aim of this study was to compare the extent of lesion detection and inter-reader performance of Dixon versus conventional proton density-weighted (PDW) imaging in bone stress injuries (BSI).

Methods and Materials: In this retrospective cross-sectional study, 32 consecutive BSI were compared on both conventional versus Dixon images. Both sequences were compared in terms of area of bone marrow oedema, inter-trabecular fracture detection, and fracture conspicuity. Inter-reader reliability was also evaluated. p value < 0.05 was considered statistically significant.

Results: Dixon images showed excellent quality except in two cases with some motion degradation. BSI detection on Dixon water image was equivalent to the routine fat-suppressed PDW sequence. BSI area on water image was not significantly different from the inter-trabecular lesion area on opposed-phase imaging ($p=0.9531$). Opposed-phase images detected more number of fractures than the water, PDW and in-phase images (p value < 0.0001 , $=0.0008$ and < 0.0001 , respectively) with superior fracture conspicuity than water, PDW and in-phase images (p value < 0.0001 , $=0.0085$ and $=0.0035$, respectively). Inter-reader agreement was excellent for bone marrow area measurements and fair to moderate for fracture detection and conspicuity.

Conclusion: Dixon imaging is as sensitive as conventional fat-suppressed PDW imaging of the knee for the identification of bone bruise with superior detection and improved characterization of the inter-trabecular fractures on opposed phase images.

Evaluation of MRI findings for association between patella baja and quadriceps fat pad oedema

S. Sajid¹, P. Nepal², S.I. Alam¹, M. Warfa¹, S. Sajid¹; ¹Doha/QA, ²Connecticut, CT/US (dia_saji@yahoo.com)

Purpose: Quadriceps fat pad oedema is a finding, commonly overlooked. So far, no study could be found in literature describing the association between patella baja and quadriceps fat pad oedema. The purpose of our study is to determine the association between patella baja and quadriceps fat pad oedema.

Methods and Materials: This was an institute ethics committee approved study carried out in tertiary center for Bone and Joint disease at Doha, Qatar. Retrospective case control study was performed between September 2017 to August 2018; selecting 50 patients in each study and control group. MRI findings of 50 patients with Patella Baja were compared with 50 patients with normal patella. Presence or absence of quadriceps fat pad oedema was evaluated in both groups. Patellar position was assessed on T1 weighted sagittal sequence using Insall-Salvati ratio; whereas quadriceps fat pad oedema was evaluated on sagittal fat suppressed Proton Density sequence. Patients with trauma and contracture deformities were excluded from the study.

Results: Mean age of patients was 39 years (range 25-56). 82 were male and 18 were female. Indication of performing knee MRI was pain in all cases. Out of 50 cases with patella baja; 41 cases (82%) were found to have significant oedema in quadriceps fat pad. In cases with normal position of patella, only 6 cases (12%) were found to have oedema in quadriceps fat pad.

Conclusion: Patella baja is strongly associated with oedema in quadriceps fat pad.

B-1131 11:02

Integrated analysis reveals disturbed metabolic pathway and identifies potential biomarker panel for the prediction of cartilage degeneration

Y. Hu, H. Tao, S. Chen; Shanghai/CN (huyiwen2016@163.com)

Purpose: The purpose of this study was to identify potential synovial fluid (SF) biomarkers for diagnosis and monitoring the early course of cartilage degeneration using integrated analysis.

Methods and Materials: Cartilage degeneration was surgically induced by anterior cruciate ligament (ACL) transaction in right knee of twelve New Zealand White rabbits. MRI scanning and SF sample collection was performed pre-surgery, and post-surgery at time points of 4, 8 weeks. Ultra-performance liquid chromatography - mass spectrometry combined with multivariate statistical analysis was used to distinguish between samples from ACL-transaction knees and healthy controls. UTE- T2* measurements, pathway analysis and receiver operating characteristic analysis were also performed to select the potential metabolite biomarkers.

Results: UTE- T2* values of lateral tibia (TL) cartilage showed significant decreases over the study period. Statistical analysis of metabolic data found a total of 103 identified metabolites were markedly different between the three groups, particularly those related to the lipid and amino acid metabolisms. Furthermore, the SF levels of 24 metabolites were found to be inversely correlated with UTE- T2* values of TL, while hippuric acid positively correlated with quantitative MRI. Among the 25 potential markers, N1-acetylspermidine, 2-amino-1,3,4-octadecanetriol, L-phenylalanine, 5-hydroxy-L-tryptophan, L-tryptophan, hexanoylcarnitine were identified as potential biomarkers with high area under the curve values.

Conclusion: Taken together, we identified the six small molecules in SF, which exhibited inflammatory and oxidant-related property, as promising biomarkers to facilitate early diagnosis of cartilage degeneration.

B-1132 11:10

Retrospective comparative study to assess the pitfalls of CartiGram and the complementary role of FSPD in the evaluation of cartilage lesions of the knee joint

R. Thaha, S. Jogi, S. Rajan, A. Singh, V. Mahajan, A. Mehndiratta, V.K. Venugopal, H. Mahajan; New Delhi/IN (drsiramrajan@gmail.com)

Purpose: To analyse the common pitfalls in T2 cartilage maps of the knee joint. To compare visualization of normal cartilage and chondral pathology on fat-saturated proton density (FSPD) and T2 CartiGram by contrast ratio measurements.

Methods and Materials: The contrast ratio of weight-bearing and non-weight bearing cartilage was calculated on the CartiGram and FSPD images of 54 consecutive knee MRI scans performed on a 3.0 T MRI by selecting one slice each from the lateral and medial compartments and placing 3 ROIs on lateral and 2 on medial compartment. Mean of these T2 values was used to estimate contrast ratio of normal weight-bearing and non-weight-bearing segments on both sequences. The contrast ratio of the chondral lesions and the normal cartilage on both sequences was calculated. The pitfalls of CartiGram and additive value of FSPD were studied.

Results: The contrast ratio between weight-bearing and non-weight-bearing cartilage was statistically significantly higher ($p < .05$) on the CartiGram for normal cartilage. For chondral pathologies, contrast ratio difference was higher on FSPD images, but statistically insignificant ($p = 0.91$). The common pitfalls encountered on cartigram included 47 studies with joint capsule overlapping cartilage, 10 with cartilage fissures seen only on FSPD images, 28 with wider cartilage lesions on FSPD, and 5 with synovial thickening.

Conclusion: Overlapping of joint capsule tissue with posterior femoral cartilage leads to a spurious assumption of intact femoral cartilage on CartiGram. Cartilage fissures and wider cartilage lesions are better seen on FSPD whereas smaller lesions are better seen on T2 CartiGram.

B-1133 11:18

Evaluating variability of T2 values of the cartilage, menisci and muscles around knee joint on CartiGram sequence at 1.5 T and 3.0 T MR

R. Thaha, S. Jogi, S. Rajan, V. Venugopal, R. Bhattacharjee, A. Mehndiratta, A. Singh, M. Barnwal, V. Mahajan, G. Nanda; New Delhi/IN (geetutomar@yahoo.co.in)

Purpose: To evaluate the temporal and inter-magnetic field strength variability of T2 values of the cartilage, menisci and muscles of the knee joint using healthy volunteer data.

Methods and Materials: T2 CartiGram (CG) sequence of knee joint was performed on four healthy asymptomatic volunteers (age 32±3 years) on 3.0T and 1.5T (GE Healthcare) MRI scanners in addition to the standard MRI. In the first part of the study, for evaluating the same day variability at 1.5T and 3.0T, CG was performed twice with a break of 5 minutes and subject lying in the same position inside the scanner. In the second part, for evaluating inter-day variability on the same scanner, CG was performed twice with a gap of 1 month on 3.0T scanner. From the T2 map, mean values and coefficient of variation were calculated.

Results: The intra-day coefficient of variations for the lateral and medial side were 0.49%, 0.77% for the cartilage, 1.57%, 1.60% for muscle and 2.2%, 2.7% for meniscus on 1.5 T whereas the similar values were 0.69 %, 0.6 % for cartilage, 0.66 %, 1.2 % for muscle and 3.0 and 1.8 for meniscus on 3 T. The temporal coefficient of variations for the lateral and medial side were 3.2%, 4.7% for the cartilage, 1.17%, 0.46% for muscle and 7.8%, 4.3 % for meniscus.

Conclusion: The intra-day variability of the T2 values was lowest for the cartilage on 1.5 T and 3T scanner whereas the temporal variability was lowest for the muscles.

B-1134 11:26

Time-saving opportunities in radiology: accurate structural imaging and T₂ mapping of cartilage and meniscus in knee osteoarthritis using a 5-minute DESS MRI scan

S.M. Eijgenraam¹, A.S. Chaudhari², M. Reijman¹, B.A. Hargreaves², G.E. Gold², E.H.G. Oei¹; ¹Rotterdam/NL, ²Stanford, CA/US (s.eijgenraam@erasmusmc.nl)

Purpose: Quantitative T₂ measurements and structural assessment of knee osteoarthritis (OA) currently require multiple separate MRI sequences, resulting in long acquisition times. We evaluated a 5-minute double-echo steady-state (DESS) sequence for simultaneous T₂ relaxometry of cartilage and meniscus, and structural OA assessment, in patients with no, mild and moderate knee OA.

Methods and Materials: We scanned 53 patients using a 5-minute 3D DESS-sequence: 20 patients with no OA (Kellgren-Lawrence grade (KLG) 0), 18 patients with mild OA (KLG2) and 15 patients with moderate OA (KLG3). We performed single-slice T₂ measurements of four cartilage and four meniscus ROIs and structural OA evaluation with the MRI Osteoarthritis Knee Score (MOAKS) using DESS with multiplanar reformatting. Statistical testing between KLG for T₂ and MOAKS was performed using ANOVA, correlations between KLG and T₂ or MOAKS per ROI were assessed using linear regression analyses.

Results: In cartilage, mean T₂ values were 36.1±4.3, 40.6±5.9 and 47.1±4.3 ms for KLG0, KLG2 and KLG3, respectively (p<0.001). In menisci, mean T₂ values of 15±3.6, 17.5±3.8 and 20.6±4.7 ms were found for KLG0, KLG2 and KLG3, respectively (p<0.001). The correlation between KLG and T₂ ranged from 0.43 to 0.71 and from 0.39 to 0.51 in cartilage and meniscus ROIs, respectively. The correlation between KLG and MOAKS ranged from 0.50 to 0.62 and from 0.29 to 0.52 in cartilage and meniscus ROIs, respectively.

Conclusion: T₂ measurements and structural imaging biomarkers of cartilage and meniscus, simultaneously acquired with a 5-minute DESS-scan, can distinguish different stages of OA, making this sequence an accurate and time-saving tool for knee OA research.

Do Ahlbäck scores identify subgroups with different magnitudes of cartilage thickness loss in patients with moderate to severe radiographic osteoarthritis? Data from the OAI

S. Hangaard¹, M. Boesen², H. Bliddal², W. Wirth³; ¹Frederiksberg/DK, ²Copenhagen/DK, ³Salzburg/AT (stine.hangaard.01@regionh.dk)

Purpose: To investigate if the Ahlbäck scoring system of radiographic knee osteoarthritis (OA) is able to further subdivide KLG-3 and -4 patients into groups with different sensitivity to change in cartilage thickness over one year in patients with moderate to severe knee OA.

Methods and Materials: One-year femorotibial cartilage thickness change was obtained from 3D-cartilage sensitive MRI data in 108 osteoarthritis initiative (OAI) participants with moderate to severe radiographic knee OA KLG-3/4. KLG-scores were available from the public available OAI-database. Ahlbäck scores were performed using the same baseline x-rays. Subregional change in cartilage thickness was assessed after manual segmentation of weight-bearing femorotibial cartilage at baseline and 1 year. Cartilage thickness change was analysed in the entire femorotibial joint (FTJ), the medial compartment (MFTC) and the lateral compartment (LFTC). One-year change was calculated for FTJ, MFTC, LFTC and the location-independent ordered values 1 and 16 (OV1/OV16) representing the subregions with largest loss (OV1) and gain (OV16) within each knee.

Results: Of the 108 patients, n=30/78 had KLG-3/4. The corresponding Ahlbäck scores (1-5) were n=30/33/36/9/0. Cartilage thickness changes between Ahlbäck groups showed no statistical significant difference for FTJ, MFTC, LFTC and OV1, but change in OV16 was significantly higher in Ahlbäck-4 knees (p=0.03) compared to Ahlbäck 1-3 knees.

Conclusion: Radiographic knee OA grading with Ahlbäck scores was not superior to KLG for prediction of cartilage thickness loss over one year, in patients with moderate and severe knee OA supporting the continuous use of the easier and more widely used KLG in clinical trials.

B-1136 11:42

Association between baseline meniscal extrusion on MRI and long-term incident knee osteoarthritis in two different cohorts

J. Van der Voet, D. Schiphof, D. Vroegindewij, S. Bierma - Zeinstra, J. Runhaar, E. Oei; Rotterdam/NL (javandervoet@gmail.com)

Purpose: Previously, we identified a significant association between meniscal extrusion and short-term incident knee osteoarthritis (KOA). To validate these findings, we evaluated long-term incident KOA in knees with meniscal extrusion, using two cohorts.

Methods and Materials: We used data from the PROOF study, which evaluated a high-risk population of overweight women, and the Rotterdam Study (RS), a prospective population-based cohort study. Meniscal extrusion was defined as ≥ 3 mm on MRI. Outcomes were incident radiographic (KL ≥ grade 2) or clinical KOA according to the ACR criteria, assessed at 6.6 years (PROOF) and 5.1 years (RS). With generalized estimating equations, we determined the association of knees with and without baseline meniscal extrusion and incident KOA, adjusted for baseline differences. Furthermore, we computed the population attributable risk percentage (PAR%) of meniscal extrusion.

Results: PROOF: 421 knees were available for analysis of which 23% had baseline meniscal extrusion. Incident radiographic KOA was borderline significantly higher in knees with meniscal extrusion compared to those without (OR 1.95, 95% CI 0.95, 3.98 PAR 11%). Incident clinical KOA was significantly higher (OR 2.33, 95% CI 1.19, 4.59, PAR 18%).

RS: 891 knees were analyzed of which 46% showed meniscal extrusion. Incident radiographic KOA was significantly higher in knees with extrusion (OR 2.54, 95% CI 1.12, 5.76, PAR 30%). Incident clinical KOA was borderline significantly higher (OR 2.05, 95% CI 0.9, 4.65, PAR 31%).

Conclusion: Meniscal extrusion is significantly associated with long-term incident KOA. A high number of incident cases were attributable to meniscal extrusion.

B-1137 11:50

The prevalence of Baker's cyst in relation to the arrangement pattern between medial head of gastrocnemius tendon and semimembranous tendon

D.Y. Han, K.N. Ryu, J.S. Park, W. Jin, S.Y. Park, S.J. Yun; Seoul/KR (koreahdy@naver.com)

Purpose: To investigate the cause of Baker's cyst by analyzing the arrangement pattern that can give much friction between medial head of gastrocnemius tendon (MHGCT) and semimembranous tendon (SMT).

Methods and Materials: From August 2017 to February 2018, patients who underwent knee MRI with "Baker's cyst" in PACS were searched. Patients(control group) who did not have "Baker's cyst" in the knee MRI performed in the same period were also searched. For screening purpose, age and gender were adjusted by propensity score matching and 116 patients were selected. For the imaging analysis, the arrangement pattern between MHGCT and SMT was classified into 3 types (type 1: concave SMT, type 2: flat SMT, type 3: round SMT) and type 2 and 3 hypothesized that they would induce Baker's cyst better. When imaging analysis was performed, presence of osteoarthritis, major ligaments and tendons tear were also described. Demographic findings was investigated through medical chart review. Univariable logistic regression was performed on all variables and the odds ratio was calculated.

Results: The frequency of type 1, 2 and 3 was statistically significant depending on the presence or absence of Baker's cyst(p<0.001). The frequency of type 3(n=33, 70.21%) was the highest in Baker's cyst group and type 1(n=70, 64.81%) was the highest in non-Baker's cyst group. Baker's cyst was more common in type 2(OR: 2.59, CI: 1.30-5.17, p=0.0068) and type 3(OR: 4.11, CI: 1.91-8.83, p=0.0003).

Conclusion: The arrangement of MHGCT and SMT is considered to be a factor affecting the formation of Baker's cyst.

Which is the accuracy for malignancy of contrast-enhanced ultrasound of Bosniak ≥2F cystic renal lesions incidentally found on CT and MRI?

A. Cretese, G. Como, R. Girometti, L. Cereser, G. Giannarini, C. Valotto, C. Zuiani; Udine/IT (andrea.cretese@gmail.com)

Purpose: To investigate the accuracy of contrast-enhanced ultrasound (CEUS) in detecting malignancy in incidentally found complex renal cysts (CRC) previously categorized as Bosniak ≥2F.

Methods and Materials: We analyzed a retrospective cohort of 18 patients who underwent CEUS between July 2015/July 2018 to assess CRC categorized Bosniak ≥2F after incidental detection on computed tomography (CT) or magnetic resonance imaging (MRI). CEUS was performed by one radiologist with 15 years of experience using a Logiq E9 ultrasound system (GE healthcare, Chicago, USA) and i.v. administration of 2.4 mL INN-sulphur hexafluoride, categorizing CRC according to Bosniak classification. After matching CEUS with the standard of reference (postoperative pathology or imaging follow-up up to 12 months), we calculated per-lesion sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for malignancy, using a CEUS-based Bosniak ≥3 categorization.

Results: CEUS found a total of 20 CRC, categorizing them as Bosniak ≤2F, Bosniak 3, and Bosniak 4/solid in 8/20 (40%), 7/20 (35%), and 5/20 (25%) cases, respectively. Based on CEUS findings, patients were referred to surgery (10/18 cases) or imaging follow-up (8/18 cases), with a final diagnosis of malignancy in 10/20 CRC (50%). Sensitivity, specificity, PPV and NPV of CEUS were 100%, 80%, 83%, and 100%, respectively. CEUS changed initial Bosniak categorization in 7/20 lesions (35%) ($p < 0.05$; McNemar test), including 3 upgraded cases (all malignant on pathology) and 4 downgraded cases (all stable at follow-up).

Conclusion: CEUS was accurate in assessing malignancy in incidental CRC, changing initial Bosniak categorization in about one third of patients.

B-1139 10:38

Contrast-enhanced computed tomography (CECT) quantitative radiological parameters to predict outcome in patients with renal cell carcinoma (RCC)

L. Basso¹, G. Buonomenna², A. Sorrentino³, G. Perugin¹, F. Rosa¹, A. Olivero¹, N. Testino¹, C. Terrone¹, C. Neumaier⁴; ¹Genoa/IT, ²Avellino/IT, ³Siena/IT, ⁴Genova/IT (lukabasso89@gmail.com)

Purpose: Visceral and subcutaneous adipose tissue (VAT and SAT) are clinically associated with increased risk of chronic kidney disease (CKD), due to chronic inflammatory response after surgery. The aim of this retrospective study was to evaluate the usefulness of computed tomography (CT) in patients with renal cell carcinoma (RCC) for the evaluation of kidney volumes and its relationship with VAT and SAT in the prediction of a decrease of estimated glomerular filtration rate (eGFR) 12 months after surgery.

Methods and Materials: We enrolled 112 patients who underwent radical nephrectomy. Pre-operative and follow-up eGFR was calculated using the CKD epidemiology study equation. CT performed prior to surgery was evaluated by two expert radiologists. VAT, SAT, total adipose tissue (TAT) and abdominal circumference were calculated on an axial plane passing through umbilical plane. VAT%, tumour volume (TV), functioning resected volume (FRV) and contralateral kidney volume (CKV) were calculated using dedicated segmentation protocol and analysed with a simple linear regression model.

Results: Mean BMI was 26.0 kg/m. Mean eGFR was 70.1 ml/min decreasing to 53.68 ml/min at 12 months. Mean VAT was 158.48 cm. Mean SAT was 200.25 cm with a mean VAT% of 44%. Mean CKV was 162.31cm. Mean FRV of 139.96 cm. Pre-op eGFR ($p < 0.001$), BMI ($p = 0.021$), CKV ($p = 0.02$) and %VAT ($p = 0.007$) showed significant correlation with decrease of eGFR 12 months after surgery.

Conclusion: Other than the well-known factors predicting the decrease of renal function after nephrectomy, the CKV and VAT% could predict patient outcome in pre-operative evaluation.

B-1140 10:46

Kidney volumes in living donors: does size really matter?

F.R. Schwartz¹, B. Shaw¹, R. Lerebours¹, F. Vernuccio², F. Gonzalez¹, L. Hurwitz-Koweek¹, K. Ravindra¹, D. Marin¹; ¹Durham, NC/US, ²Palermo/IT (fidesreginadorotheaann.schwartz@duke.edu)

Purpose: Computed tomography angiography (CTA) is performed before transplant surgery to assure the smaller donor kidney is transplanted and assess for blood supply and possible disease. This study assesses the relationship between renal diameters and renal volumes, as well as the frequency of appropriate renal selection for transplant using conventional renal diameters and the long-term outcome in donors.

Methods and Materials: This is a HIPAA-compliant, IRB-approved study. 50 renal donors were identified from 2010-2018 (mean age 40 years; 30 F, 20 M). Renal size was assessed by measuring renal diameters in three dimensions and volume; arterial supply and venous drainage were assessed. Glomerular filtration rates (GFR) were documented before surgery, within 24 hours post-transplant, at 6, 12 and 24 months. Descriptive statistics (means, SD, IQR), paired t tests and Spearman's rank correlations were used for comparisons.

Results: The left kidney had a larger average volume (165 vs 154.6 cm³; $P < 0.01$) than the right but craniocaudal lengths were similar (10.9 vs 10.8 cm). 10% of kidneys had two or more arteries, 6% had abnormal venous drainage. GFR recovered from 51.8 mL/min/1.73 m² directly to 63.9 mL/min/1.73 m² 24 months after surgery. There was a strong correlation between craniocaudal and laterolateral diameters and volume ($P < 0.01$). The larger kidney was transplanted in 28% of cases which had no statistically significant impact on long-term renal function ($P < 0.01$).

Conclusion: Renal volume correlates well with conventional diameters and transplanting the larger donor kidney had no long-term detrimental effect on donor kidney function.

Native T1 mapping as an in vivo biomarker for the identification of higher grade renal cell carcinoma

L.C. Adams; Berlin/DE

Purpose: To identify higher grade clear cell renal cell carcinoma (cRCC) with native T1 mapping and to histologically correlate the results with the collagen volume fraction.

Methods and Materials: For this institutional review board-approved, single-center prospective study, 68 consecutive patients received abdominal MRI scans at 1.5 T between January 2017 and July 2018, using a modified Look-Locker inversion recovery (MOLLI) sequence. 30 patients with cRCC (20 men, mean age 61.9 years ± 13.1), who underwent partial or radical nephrectomy and histological grading according to the ISUP classification, and a separate healthy cohort of 30 individuals without renal malignancies or complex cysts (16 men, mean age 59.7 ± 14.6 years), met the eligibility criteria. T1 values were quantitatively measured with region of interest (ROI) measurements in T1 maps. Quantification of the collagen volume fraction was performed on histological sections (picrosirius red staining).

Results: Native T1 values were significantly lower for lower grade cRCC (ISUP 1-2) compared to higher grade cRCC (ISUP 3-4) ($p < 0.001$). A cut-off value of 1101 ms distinguished higher grade from lower grade tumours with a sensitivity of 100% (95% CI: 0.69-1.00), a specificity of 85% (95% CI: 0.62-0.97) and an accuracy of 90% (95% CI: 0.73-0.98). Native T1 values were significantly associated with the histological collagen volume fraction ($p < 0.05$). Furthermore, T1 times in the renal cortex, medulla and tumour tissue showed an excellent inter-observer agreement.

Conclusion: Native T1 mapping could represent an in vivo biomarker for the differentiation of lower and higher grade cRCC, providing incremental diagnostic value beyond qualitative MRI features.

Reducing radiation dose while maintaining observer performance using prior iterative reconstruction (PIR) in multiphase dual energy renal CT

P. Navin¹, A.F. Halaweish², B. Schmidt², B. Kim², M. Wells², A. Khandelwal², T. Moen², C. McCollough², J. Fletcher²; ¹Galway/IE, ²Rochester, MN/US (paddynavin@yahoo.co.uk)

Purpose: To investigate the dose reduction potential using a novel prior iterative reconstruction (PIR) algorithm in multiphase renal dual-energy (DE) CT.

Methods and Materials: Projection data from multi-phase renal DECT examinations was collected and noise inserted (using a validated technique) to simulate 60% dose reduction and reconstructed images were used as input to the PIR algorithm. Three GU radiologists blindly examined datasets (two reading sessions) using either full dose or 40% dose PIR image sets.

Probability of malignancy was assessed [0 (no chance) to 100 (definite)] with malignancy assumed at probability ≥ 70 . Area under the ROC curve (AUC), sensitivity and specificity were compared on a per-patient and per-lesion basis. CT number accuracy and subjective image quality were assessed (5 point Likert scale).

Results: Twenty-three patients had 49 renal lesions (11 solid renal-neoplasms). CT number was nearly identical between techniques. AUC was similar between multiphase routine dose and lower dose PIR [per patient: 0.950 v 0.916 ($p=0.356$); per lesion: 0.931 v 0.884 ($p=0.304$)]. Per patient sensitivity was similar (78% routine dose [95% CI 37-90%] v 82% lower dose PIR [CI 35-93%] [$p = 0.37$]), as was specificity (91% routine dose [CI 51-98%] v 93% lower dose PIR [CI 50-99%] [$p > 0.99$]), with similar findings on a per lesion level. Subjective image quality demonstrated no statistical difference between the two groups ($p = 0.34$).

Conclusion: PIR is a new reconstruction method for multi-phase CT examinations that promises to facilitate radiation dose reduction by over 50% for multiphase DECT renal exams.

Differentiation of adrenal adenomas from adrenal metastases using single-phased dual energy CT: a comparison to MRI

M.T.O. [Winkelmann](mailto:Winkelmann@med.uni-tuebingen.de), M.N. Bongers; *Tübingen/DE*
(moritz.winkelmann@med.uni-tuebingen.de)

Purpose: Aim of this study was to evaluate accuracy of dual energy CT (DECT) iodine and fat quantification and virtual-unenhanced imaging (VNC) for differentiation between adrenal adenomas and metastases using MRI as a reference.

Methods and Materials: 47 patients with 51 lesions (female:male=29:18, mean age:67 years) having received clinically indicated DECT and MRI (mean interval: benign 2.9 months/ malignant 0.28 months). Quantitative parameters such as VNC values, fat fraction, iodine density and mixed image (CT-mixed) values were collected. MRI in- and opposed phase and contrast enhanced imaging were used as a reference. Mean values of VNC, fat fraction, iodine density and CT-mixed in DECT images were compared between adenomas and metastases using non-parametric tests. Diagnostic accuracy was assessed by calculating receiver operating characteristics (ROC). Results are given as median with interquartile ranges.

Results: Iodine density and fat fraction values in DECT showed significant differences between adrenal adenomas (2.4mg/mL [1.7, 2.9]; 31.1% [27.1, 34.6]) and metastases (1.6 mg/mL [0.4, 2.5], 16.6% [12.4, 23.4])(all $p \leq 0.03$).

Analysis of VNC revealed significant differences between adrenal adenomas (5.4HU[-2.6, 12.7]) and metastases (27.6HU[15.8, 32])($p \leq 0.0001$). No significant differences between adenomas (59.3HU [46.7, 75.4]) and metastases (62.4HU [43.3, 89.2]) were detected in CT-mixed. ROC analysis revealed significantly higher AUC values and increased sensitivity for VNC and fat fraction (AUC = 88%/sensitivity = 71.4%; 88%/92.9%) than for CT-mixed (53.6%/50%; $p \leq 0.005$).

Conclusion: DECT is suitable for differentiation between adenomas and metastases by quantification of fat fraction and computation of VNC images with high diagnostic accuracy.

B-1144 11:18

Incidental adrenal masses (IAM) at basal CT or enhanced CT: differentiating non-functioning adenomas from tumour lesion using histogram and texture analysis (TA)

G. [Stranieri](mailto:Stranieri92@gmail.com), A. Priola, D. Basile, S. Priola, A. Veltri; *Turin/IT*
(giuseppestrانieri92@gmail.com)

Purpose: Usefulness of CT histogram and texture analysis to differentiate non-functioning adenomas from malignant lesions in the setting of IAM found at basal CT or enhanced-CT.

Methods and Materials: We extracted retrospectively patients who underwent basal CT (IAM: medium density>10HU; % negative pixels<10%) or in portal phase CT (medium density>20HU) from January to December 2017. We included 70 IAM: 46 non-functioning adenomas and 24 malignant lesions. The reference standard was histological response or their typization with multiphase enhanced-HCT, chemical-shift magnetic resonance or PET-CT. A commercial software (LifeX) was used to obtain textural parameters and histogram analysis. The results were compared with logistic regression model to estimate discrimination capability.

Results: At basal CT, the two groups shown significant differences in minimal value HU ($p=0.02$) and in LRHGE of GLRLM matrix ($p=0.02$) with AUROC of 0.822 and 0.856 (LRHGE: sensitivity 79%; specificity 90%). The logistic analysis demonstrated the LRHGE as an independent predictive parameter at univariate (Odds Ratio[OR]=1.0001; $p=0.04$) and multivariate analysis after correcting for age and size. At enhanced-CT, the two groups

shown significant differences in GLRLM and GLZLM matrices: RLNU and GLNU were the best discriminators ($p=0.03$, AUROC=0.719, sensitivity 70%, specificity 86%; $p=0.04$, AUROC=0.719, sensitivity 60%, specificity 79%; respectively). The logistic analysis found RLNU as the only significant parameter at multivariate analysis (OR=1.0012; $p=0.04$). The Histogram analysis didn't show difference between groups, either at basal or enhanced-CT ($p>0.05$).

Conclusion: Our study shows that TA could be useful to characterize IAM at CT, avoiding additional risks or costs linked to other studies.

B-1145 11:26

Reassessment the ability of renal CE-CT for avoiding pathological upstaging of clinical T1 to pathological T3 renal cancer in the era of robotic partial nephrectomy

S. [Takahashi](mailto:Takahashi2@mac.com)¹, Y. Ueno², K. Sofue², N. Negi², K. Kagawa², T. Murakami², U. Tanaka²; ¹Takatsuki/JP, ²Kobe/JP (satorutakahashi2@mac.com)

Purpose: Tumour invasion into the renal sinus fat or segmental branches of the renal vein are now attracting increasing attention for avoiding upstaging to pT3 and early recurrence of small RCC after partial nephrectomy. We evaluated the ability of multiphase renal CECT with focusing on the tumour extension into the renal sinus.

Methods and Materials: We retrospectively evaluated surgically proven 214 RCCs in 212 patients underwent preoperative multi-phasic thin-slice(≤ 1 mm) CECT on 3rd generation dual-source CT scanner. A board-certified radiologist blinded to the surgical finding scored probability of sinus fat invasion (SFI), perinephric fat invasion (PFI), and renal vein invasion (RV) using a 5-point scale with evaluating the contour of tumours.

Results: 46 RCCs were diagnosed as $\geq pT3a$ (SFI, 13; PFI, 28; RV, 33). Sensitivity, specificity, accuracy and Az-value for diagnosing each pT3-factor were 85%, 95%, 95%, 0.81 for SFI; 71%, 98%, 94%, 0.88 for PFI; and 85%, 85%, 0.94 for RV; respectively, while overall performance of diagnosing pT3 disease were 89%, 76%, 79%, 0.88. Smooth bulging into the sinus fat was demonstrated in 41% of $\leq pT2$ tumour and 17% of $\geq pT3$ tumour, while irregular bulging was found in 19% (32/168) of $\leq pT2$ tumour and in 78% (36/46) of $\geq pT3$ tumour.

Conclusion: Detailed analysis of thin-slice renal CECT could predict the possible tumour invasion into the renal sinus fat or the peripheral branches of the renal vein, and could be useful for preventing pathological upstaging of cT1 to pT3 in cases of small RCC treated with partial nephrectomy.

B-1146 11:34

Low energy imaging for depicting renal venous tumour thrombus on multi-phasic contrast-enhanced dual-energy CT with 3rd generation dual-source CT scanner

S. [Takahashi](mailto:Takahashi2@mac.com)¹, T. Itoh², Y. Ueno³, N. Negi³, K. Kagawa³, K. Sofue³, U. Tanaka³, A. Kusaka³, T. Murakami³; ¹Takatsuki/JP, ²Tokyo/JP, ³Kobe/JP (satorutakahashi2@mac.com)

Purpose: Accurate diagnosis of tumour venous thrombus in the segmental branch is attracting increasing attention for avoiding unanticipated upgrading to pT3 in partial nephrectomy for small RCC. We evaluated the ability of low energy CECT with either low-kVp or low-keV Mono+ image for depicting renal tumour thrombus.

Methods and Materials: We evaluated preoperative multi-phasic CECT images at 3rd generation DECT for RCC with surgically proven tumour thrombus ($n=36$). Mono+ (40 to 190keV) and mixed images were generated for nephrographic phase (NP) and excretory phase (EP) DE acquisition, while arterial phase (AP) images were scanned at single-energy 70kVp. HU values of the renal parenchyma, tumour, tumour thrombus, the renal vessels, and fat were measured. SNR, contrast ratio (CR) and dose-weighted CNR (CNRD=CNR/CTDIvol^{0.5}) of tumour and tumour thrombus were compared.

Results: CTDIvol and DLP were below the national DRL for dynamic body CT. HU values of tumour thrombus varied in cases (AP, 249 \pm 116; mixed NP, 189 \pm 27; mixed EP 136 \pm 21). Although there were no statistically significant differences in CR of tumour thrombus among phases (AP, 0.97 \pm 0.06; NP, 0.91 \pm 0.06; EP, 0.94 \pm 0.06; respectively), CNRD in AP (2.2 \pm 1.7) were significantly greater than those in NP and EP (0.17 \pm 0.15, 0.41 \pm 0.22, 0.22 \pm 0.14, respectively). CNRD for tumour thrombus was the highest at 40keV both in NP and EP, and average CNRD for tumour thrombus in NP were statistically significantly greater than in EP ($p<0.001$).

Conclusion: 40-keV NP Mono+ images were useful for depicting renal tumour thrombus in multi-phasic DECT, while 70kVp AP images could also satisfactory demonstrate venous thrombus.

Trends in frequency and outcome of high-risk breast lesions at percutaneous biopsy in women recalled at biennial screening mammography

B. Korte¹, J.D. Luiten², L.E.M. Duijm³, ¹Eindhoven/NL, ²Tilburg/NL, ³Nijmegen/NL (bramkorte_@hotmail.com)

Purpose: To determine the incidence, management and outcome of high risk breast lesions among women recalled at biennial screening mammography.

Methods and Materials: We included a consecutive series of 376519 screens of women who received biennial screening mammography in a Dutch breast cancer screening region between January 1, 2011 and December 31, 2016. During 1-year follow-up, radiological reports and biopsy reports were collected of all recalled women to determine final outcome.

Results: During this 6-year screening period, the proportion of recalled women who underwent percutaneous biopsy remained fairly stable (range: 39.2%-48.1%, mean: 44.2%, 5212/11783), whereas the proportion of high risk lesions at percutaneous biopsy (e.g., flat epithelial atypia, atypical ductal hyperplasia, lobular carcinoma in-situ, papillary lesions) gradually increased from 3.6% (28/775) in 2011 to 9.5% (86/901) in 2016. The proportion of high risk lesions at percutaneous biopsy that underwent a subsequent surgical excision fluctuated between 41.0% (2013) and 65.5% (2014) through the years (mean: 52.5%, 177/337), but the excision biopsy rate for high risk lesions per 1000 screens and per 100 recalls increased from 0.31 (2011) to 0.70 (2016) and from 0.99 (2011) to 2.50 (2016), respectively. The malignancy rate of the excision biopsies ranged from 21.1% (8/38, 2014) to 31.3% (5/16, 2011), with 27.7% (49/177) of all excision biopsies being malignant.

Conclusion: The proportion of high risk lesions at percutaneous biopsy almost tripled, with a concomitant increased excision biopsy rate for these lesions per 1000 screens and per 100 recalls. The malignancy rate at excision biopsy remained stable.

B-1150 10:38

External validation of the STAR (suspicion type age response of biopsy) score for risk stratification of B3 breast lesions detected at ultrasound-guided biopsy

C. Grippo¹, P. Jagmohan², A.M. Stoeger³, P. Kapetas³, T.H. Helbich³, P.A.T. Baltzer³, P. Clauser³, ¹Rome/IT, ²Singapore/SG, ³Vienna/AT (cris.grippo@gmail.com)

Purpose: The STAR (suspicion type age response of biopsy) score is a newly developed risk stratification algorithm to be used as a decision-making tool for the management of breast B3 lesions detected on ultrasound (US)-guided biopsy. The purpose of this study was to investigate the robustness of this score by an external validation.

Methods and Materials: We retrospectively reviewed all consecutive histologically confirmed B3 lesion diagnosed at US-guided biopsy at our institution and included all lesions with subsequent open surgery or radiological follow-up 24 months. The STAR score was independently assessed by two breast radiologists (R1, R2) by assigning each feature a score from 0 to 2 (maximum score of 5) and results were tested by ROC-curves. A threshold of ≥ 1 was applied to calculate sensitivity, specificity, positive and negative predictive value (PPV and NPV).

Results: 129 B3 lesions were evaluated. Surgery was performed on 117/129 (90.6%) lesions and 11/117 (9.4%) lesions were malignant. Follow-up of remaining lesions was negative. The area under the ROC-curve ranged from 0.75 to 0.79, with no significant difference between the two readers ($p=0.5$). At a threshold of ≥ 1 , a sensitivity, specificity, PPV and NPV of 90%/90% (R1/R2), 39%/38% (R1/R2), 11%/12% (R1/R2) and 97%/98% (R1/R2) were identified. In both readings, 46 lesions had a score ≤ 1 and could have avoided surgery. Of these, only one malignant lesion was underdiagnosed (DCIS-G1).

Conclusion: The STAR score showed a high NPV upon external validation and therefore has the potential to reduce unnecessary surgeries for US-detected B3 lesions in clinical practice.

B-1147 11:42

Efficacy of Raysum image in urolithiasis detection

K.K. Lau, S. Deb, A. Kuganesan; Melbourne/AU (kenkplau@gmail.com)

Purpose: Baseline abdominal radiographs (AXR) are commonly performed for computed tomography urinary tract (CTU) proven calculi. Subsequent AXR may be used to assess urolithiasis progression. A virtual ray sum image (RSI) from CTU dataset can be created with a similar AXR appearance. The aim of this retrospective study was to determine the efficacy of the RSI in detecting urolithiasis.

Methods and Materials: All consecutive adult patients with urolithiasis positive CTU and an AXR within 24 hours of CTU and similar patient number with negative CTU in 5 month-period were included. Patients who had the baseline AXR > 24 hours after CTU were excluded. AXR and RSI were blindly reviewed by two radiologists. Patient thickness, presence of excess gas/faecal material, calculus size, mean calculus Hounsfield unit (HU) and location were analysed to determine effect on the AXR and RSI.

Results: 152 calculi in 50 adult patients were included with RSI sensitivity of 44% (95% CI 36-52) and AXR 30% (95% CI 22-38). There was substantial agreement between the two techniques with Kappa=0.70 (95% CI 0.58- 0.81, $p<0.001$). No invisible calculus on RSI became visible on AXR. No false positive was seen on RSI. Logistic regression analyses demonstrated calculus size and mean calculus HU significantly affected sensitivities of both RSI and AXR.

Conclusion: Raysum Image as a post processed image derived from CTU dataset may remove the baseline AXR in patients with CT proven urolithiasis. This would reduce patient radiation dose and streamline workflow in busy radiology departments.

Diagnostic accuracy of dual-energy CT for renal mass evaluation: systematic review and meta-analysis

N. Panvini¹, D. Bellini¹, A. Laghi², D. Marin³, B.N. Patel⁴, C.L. Wang⁵, I. Carbone¹, A. Mileto⁵, ¹Latina/IT, ²Rome/IT, ³Durham, NC/US, ⁴Stanford, CA/US, ⁵Seattle, WA/US (npanvini88@gmail.com)

Purpose: To perform a systematic review and meta-analysis to evaluate the diagnostic accuracy of dual-energy CT (DECT) for renal mass evaluation.

Methods and Materials: In March 2018, we searched MEDLINE, Cochrane Library, Embase and Web of Science databases. Analytic methods were based on Preferred Reporting Items for Systematic Reviews and Meta-Analyses. Pooled estimates for sensitivity, specificity, and diagnostic odds ratios were calculated for DECT-based virtual monochromatic imaging and iodine quantification techniques as well as for conventional attenuation measurements from renal mass CT protocols. I^2 was used to evaluate heterogeneity. Methodological quality of included studies and potential bias were assessed using items from Quality Assessment Tool for Diagnostic Accuracy Studies-2.

Results: Of the 1043 articles initially identified, 13 were selected for inclusion (969 patients, 1193 renal masses). Cumulative data of sensitivity, specificity and summary diagnostic odds ratio were 83% (95%CI: 76-89%; I^2 : 88.1%), 75% (95%CI: 70-80%; I^2 : 99.1%), 183.4 (95%CI: 30.7-1093.4; I^2 : 61.6%) for virtual monochromatic imaging; 99% (95%CI: 97-100%; I^2 : 17.6%), 91% (95%CI: 89-94%; I^2 : 84.2%), 511.5 (95%CI: 217-1201; I^2 : 0%) for iodine quantification, respectively. No significant differences in area under the curve were found between iodine quantification and conventional attenuation measurements ($P=0.79$).

Conclusion: DECT yields high accuracy for renal mass evaluation. Determination of iodine content with the iodine quantification technique demonstrates diagnostic accuracy similar to conventional attenuation measurements from renal mass CT protocols. The iodine quantification technique may be used to characterize incidental renal masses when a dedicated renal mass protocol is not available.

B-1151 10:46

Should atypical ductal hyperplasia be surgically excised after percutaneous needle biopsy: systematic review and meta-analysis

S. Schiaffino¹, M. Calabrese¹, E.F. Melani¹, E. Massone¹, A. Villa², G. Di Leo³, M. Zanardo⁴, F. Sardaneli³; ¹Genoa/IT, ²Sarzan/IT, ³Milan/IT (schiaffino.simone@gmail.com)

Purpose: To assess the reported underestimation rate (UR) of atypical ductal hyperplasia (ADH) diagnosed percutaneously using surgical excision (SE) or follow-up for conservative management (CM).

Methods and Materials: A systematic search was performed in October 2018 using MEDLINE and EMBASE for studies reporting the UR for pure ADH cases diagnosed at percutaneous biopsy. The study was registered on PROSPERO and written following the PRISMA statement. The pooled UR (pUR) was calculated using the random-effect model; subgroup and meta-regression analyses for the assessment of potential UR-predictors. The Newcastle-Ottawa scale and Egger test were used for study quality and publication bias, respectively.

Results: Of 521 articles, 93 were analysed totalling 177,001 percutaneous biopsies, 7,425 of them (4.2%) being ADH (5,916 SE, 494 CM). Thirty-seven studies used core-needle, 36 vacuum-assisted biopsy, 17 mixed, 3 did not report; 32 stereotactic guide, 13 ultrasound, 9 MRI, 6 mixed, 33 did not report. Heterogeneity was high ($I^2=80\%$). pUR was 27.0% (95% CI 24.2-30.0%), 29.2% (95% CI 26.4% - 32.3%) for SE and 5.5% (95% CI 3.7% - 8.0%) for CM ($p<0.001$). When reported, the proportion of upgrade to invasive cancer versus ductal carcinoma in situ was 19.2%-9.2% overall, 29.2%-8.6% for SE, 5.5%-3.7% for CM ($p<0.001$). Subgroup analysis found significant impact of type of needle ($p<0.001$) and type of imaging guiding the biopsy ($p<0.001$) on the surgical pUR. Quality of studies was low-to-medium. No risk of publication bias ($p=0.081$).

Conclusion: The pUR for ADH was 27.0%, higher for SE (29.2%), but clinically relevant (5.5%) also for CM.

B-1152 10:54

Radiologic and clinicopathologic associations with upgrade to malignancy in high-risk breast lesions

C. You, Y.J. Gu, S. Chen, X.X. Shen, W.J. Peng; Shanghai/CN (youchao8888@aliyun.com)

Purpose: To assess the radiologic and clinicopathologic features of high-risk breast lesions (HRLs) diagnosed with biopsy and further to develop a prediction model to distinguish HRLs that upgrade to malignancy after surgery.

Methods and Materials: This retrospective study included 267 patients with biopsy-proven HRLs who performed both mammography (MG) and MRI preoperatively and underwent surgical excision between January 2017 and March 2018. Positive predictive value (PPV) for upgrade to malignancy in all HRLs and specific for each sub-category were evaluated. Multivariate analysis was conducted to identify association between clinical (age, family or personal history of breast cancer), radiological findings before biopsy (lesion size, imaging characteristics and final BI-RADS category of both MG and MRI) and final excision outcome.

Results: The overall upgrade rate of HRLs to malignancy was 31.4% (84 of 267). The most common HRL was ADH (58.8%, 157 of 267) and the most common upgrade type of malignancy was DCIS (54.8%, 46 of 84). At multivariate analysis, upgrade was more likely to be seen in mass lesion at MG (OR = 1.69; 95% CI: 1.28, 3.72) and in moderate or marked background parenchymal enhancement (BPE) breast at MRI (OR = 1.25; 95% CI: 2.3, 5.28). The category of BI-RADS 4-5 versus BI-RADS 1-3 was also independently associated with upgrade.

Conclusion: The rates of upgrade to malignancy in biopsy-proven HRLs were high, at around 31%. The presence of a mass at MG, moderate or marked BPE at MRI, and BI-RADS 4-5 category may represent useful predictors of upgrade.

B-1153 11:02

Positive predictive value for malignancy of uncertain malignant potential (B3) breast lesions diagnosed on vacuum-assisted biopsy: is surgical excision still recommended?

F. Ballati, P. Lomoro, M. Lucioni, G. Di Giulio; Pavia/IT (france.ballati@hotmail.it)

Purpose: Breast lesions classified as of "uncertain malignant potential" are a heterogeneous group of abnormalities with an increased risk of associated malignancy. Clinical management of B3 lesions diagnosed on vacuum-assisted breast biopsy (VABB) is still challenging: surgical excision is no longer the only available treatment and VABB may be sufficient for therapeutic excision. The aim of the study was to evaluate the positive predictive value (PPV) for malignancy in B3 lesions that underwent surgical excision, identifying possible up-grading predictive factors and characterizing the malignant lesions eventually diagnosed. These results were compared with a subset of patients with B3 lesions who underwent follow-up.

Methods and Materials: 1250 VABBs were performed between January 2006 and December 2017 at our centre. 150 B3 cases were diagnosed and 68 of them underwent surgical excision. VABB findings were correlated with excision histology. A PPV for malignancy for each B3 subtype was derived.

Results: The overall PPV rate was 28%, with the highest upgrade rate for atypical ductal hyperplasia (41%), followed by classical lobular neoplasia (29%) and flat epithelial atypia (11%). Only two cases of carcinoma were detected in the follow-up cohort, both associated with atypical ductal hyperplasia at VABB.

Conclusion: Open surgery is still recommended in case of atypical ductal hyperplasia while, for other B3 lesions, excision with VABB-only may be an acceptable alternative if radio-pathological correlation is assessed, if all microcalcifications have been removed by VABB and if the lesion lacks high-risk cytological features.

B-1154 11:10

Second-line vacuum-assisted excision biopsy with 8G needle for the management of B3 microcalcifications: preliminary results

C.M. Weiss, E. Di Gaetano, S. Plataroti, E. Cattarin, D. Bragagnolo, G. Morana; Treviso/IT (cmweiss@me.com)

Purpose: To assess the clinical impact of the new management pathway incorporating a second-line vacuum-assisted excision biopsy (VAEB) with 8G needle for microcalcifications of uncertain malignant potential (B3).

Methods and Materials: A retrospective analysis was undertaken of all B3 lesions on first-line vacuum-assisted biopsy (VAB) with 10G needle for microcalcifications between January 2017 and January 2018. Following a VAEB, all cases were discussed at the multidisciplinary meeting (MDM) to decide upon management options, referral for 5 years of annual mammographic surveillance (MS) or surgical biopsy (SB). Outcome measures assessed included final diagnosis, frequency of SB, impact on management and comparison with previous results.

Results: In 143 VAB for microcalcifications we observed B3 lesions in 33/143 (23%) patients (mean age 54; range 42-76). 9/13 (27%) patients underwent subsequent SB due to imaging findings and pathological results (e.g. ADH expression in B3), 3/9 with a malignant result. The remaining 24/33 (73%) patients were referred to VAEB: 11/24 (46%) B2 lesions and 13/24 (54%) B3 lesions. After MDM, 21/24 (87.5%) patients with completely removed microcalcifications (11B2; 10B3) were referred to MS and 3/44 (12.5%) undergoing SB received a final benign diagnosis (3/3; 100%).

Conclusion: In our study, the overall malignant lesions' incidence in B3 microcalcifications was 3/33 (9%), similar to 10% (3/29) of the previous period January 2015 to December 2016 in which all VAB B3 underwent SB. The new pathway with second-line VAEB has reduced the number of benign SB by 62% while maintaining the same rate of malignancy. MS results are still ongoing.

B-1155 11:18

Percutaneous ultrasound-guided excision with vacuum-assisted breast biopsy (VABB) system of breast lesions with imaging-histology discordance

C. Depretto, F. Balestra, F. Cartia, C. Ferranti, G. Scaperrotta; Milan/IT (cathie.dp@gmail.com)

Purpose: To assess the performance of percutaneous ultrasound-guided excision of radiologically-histologically discordant breast lesions as an alternative to surgical excision.

Methods and Materials: We retrospectively evaluated 159 breast lesions in 159 patients which undergo a 14G ultrasound-guided biopsy and subsequent percutaneous ultrasound-guided excision with VABB system between January 2015 and April 2018. Lesions, with an average diameter of 10.3 mm (range 3-30 mm), showed suspicious ultrasound imaging (BI-RADS 4) but histological outcome non-malignant: B1 (n = 18 patients), B2 (n = 109) and B3 (n = 32). We assessed: the update rate (UR), the technical success (TS) and the technical efficacy (TE) of the procedure and the delayed false-negative results (DR), with radiological follow-up in the following two years; procedural complications were assessed.

Results: The post-VABB histological outcomes were B1 (n = 7), B2 (n = 117), B3 (n = 24) and B5 (n = 11), of which 5 CDI (2 associated to DCIS) and 6 DCIS, all surgically radicalized. The UR was 6.9%. The TS was 100%. The TE was 87.9%. The DR was 0%. There were only 7 minor complications (4.4%): haematomas, seromas and liponecrosis.

Conclusion: The study demonstrates that VABB excision can be an effective alternative to surgery for all discordant lesions; it allows to adequately diagnose malignant lesions not identified with the CNB, without determining either diagnostic delays or major complications. Compared to surgical treatment, it has lower costs, more simplified and rapid management and almost no cosmetic impact for patients.

B-1156 11:26

Minimally invasive excision of suspicious breast lesions

N.M. [Abdel Razek](#); *Cairo/EG (naglaabdelrazek@yahoo.com)*

Purpose: To assess the diagnostic efficiency of BLES is a management option for small suspicious breast lesions.

Methods and Materials: The study is a prospective one conducted during the period from February 2011 to January 2018. approved by the ethical committee. The study included 435 patients with small suspicious non-palpable breast lesions categorized as BIRADS 4 & BIRADS 3 with positive family history for breast cancer. All cases were histopathologically diagnosed and the results were compared to the results of open surgery .

Results: 435 suspicious lesions were successfully removed using the BLES, 19.3 % (84/435) were benign including fibrocystic disease, sclerosing adenosis ,radial scars and papillomas without atypia. 38.2% (166/435) were high risk lesions including papillomas with atypia, ALH, ADH & 48.4 % (142/435) were malignant including DCIS, LCIS, IDC&ILC. The maximum size removed was 12 mm .The margin was free in 40/142 (28.2%) and the margin was close in 45/142 (31.7%) & the margin was involved in 57/142 (40.1%) of the malignant cases (all were below 8 mm size . 22/142 proven malignant lesions were exposed to Re-surgery and in 20/142, no surgery after BLES, only radiotherapy and sentinel node diagnosis. BLES is 100% as sensitive as the OB regarding the concordance and sensitivity with no underestimation.

Conclusion: BLES could be an efficient management for small breast carcinomas if complete excision with free margin was achieved yet still it is the decision of the MDT. Further group work and multicenter studies are required to set guidelines for its use as an optional management for T1 cancer

B-1157 11:34

Performance of breast lesion excision system (BLES) in a complete removal of small clusters of suspicious microcalcifications proved malignant

A. [Christou](#)¹, V. Koutoulidis², D. Koulocheri², E. Panourgias², C. Zografos², G. Zografos²; ¹*Brighton/UK*, ²*Athens/GR (alexandrachristou@gmail.com)*

Purpose: To retrospectively assess the role and performance of BLES in excision of small clusters of microcalcifications proved histopathologically to be cancers.

Methods and Materials: Between January 2014 and 2016, 90 cases of microcalcifications were diagnosed as cancers in our department through the course of BLES biopsy under stereotactic guidance. 20-mm probe was used in all cases. From these, 54 had an initial mammographic size up to 14 mm and selected for statistical analysis to assess the success of the method in excision. The histopathology result of the BLES specimens were compared with the final surgical result. The mean age of our target population was 58.2 years (st dev=8.2, range 43-79 years).

Results: 41/54 were invasive cancers (IDC, ILC, tubular) and 8 had both invasive (6) or microinvasive (2) and DCIS components. Complete removal was achieved in 31/54 cases (57.4%). The initial mammographic size and the histopathologically free disease margins of BLES specimen were the only statistically significant predictive factors for excision. At a cut off initial size of 5 mm ROC analysis showed specificity 95.7% and AUC 72% and free disease margins revealed specificity 80.6% and AUC 78% (success rate 78.2%, p<0.001). The radiology (absence of calcifications on post-BLES mammogram)-BLES pathology concordance in BLES excision showed sensitivity 89.3%. The underestimation rate was 11.1% (6/54 cases).

Conclusion: BLES under stereotactic guidance is an accurate biopsy technique with potential use as a therapeutic tool of selected cases of small cancers expressed as suspicious microcalcifications.

B-1158 11:42

Utility of diagnostic breast excision biopsies during two decades of screening mammography

J.D. [Luiten](#)¹, A.C. Voogd², V.C.G. Tjan-Heijnen², J. Wesseling³, E.J.T. Luiten⁴, L.E.M. Duijm⁵; ¹*Tilburg/NL*, ²*Maastricht/NL*, ³*Amsterdam/NL*, ⁴*Breda/NL*, ⁵*Nijmegen/NL (jackyluiten@hotmail.com)*

Purpose: We evaluated the use and value of breast surgical excision biopsies for diagnostic purposes over the last decades in women undergoing mammographic screening, either as a primary procedure or following an inconclusive percutaneous biopsy.

Methods and Materials: All women with an excision biopsy among 777,151 screens, obtained from January 1996 until December 2015, were included.

Results: Of 17,001 (2.2%) women referred with screen-detected abnormalities, 1007 (5.9%) underwent excision biopsy. Whereof 550 (54.6%) performed as first diagnostic intervention, decreasing from 4.2 per 1000 screens in 1996-1997 to 0.02 per 1000 screens in 2014-2015. The remaining 457 (45.4%) excision biopsies were performed secondary to pathologic findings at percutaneous biopsy. During 1996-1997, 0.8 secondary biopsies per 1000 screens were performed, decreasing to 0.3 per 1000 in 2006-2007

and afterwards increased to 0.6 per 1000 in 2014-2015 (p=0.005). Of all 457 secondary biopsies, 274 (60.0%), had a benign pathology outcome, increasing from 30.8% in 1996-1997 to 76.3% in 2014-2015. Of the 30 patients with a (pre-) malignant pathology at secondary biopsy in the two most recent cohorts (2012-2015), 11 (37%) showed invasive carcinoma and 19 (63%) DCIS (of which 13 low grade DCIS).

Conclusion: Although the use of excision biopsy significantly decreased over the past two decades, we observed a significant increased rate in more recent years. Since the vast majority of currently performed excision biopsies reveals a benign diagnosis or show low grade DCIS, a secondary excision biopsy should only be considered if radiologic surveillance and repeated percutaneous biopsy continues to yield indeterminate results.

B-1159 11:50

A retrospective analysis comparing radioactive seed and wire localisation in breast surgery

P.G. [Kumar](#), J. Young, H. Chen, Y. Li, Q. Qi, X. Peng, T. Khoury; *Buffalo, NY/US (prasanna.kumar@roswellpark.org)*

Purpose: The aim of this study is to compare radioactive seed localization (RSL) to wire localization (WL) in breast surgery to compare positive surgical margins, post-operative upgrade rate. Secondary aim was to analyze the specimen size, volume and operating room (OR) time.

Methods and Materials: Out of a total 297 patients, 145 WL and 152 RSL breast excision procedures were collected and analyzed. Surgical, radiological and pathological data for each procedure were collected, including pre-operative biopsy diagnosis, final (post-operative) pathological diagnosis, margin status, upgrade rate, lesion size, OR time usage. The final pathological diagnoses were divided into three categories including invasive carcinoma, ductal carcinoma in-situ (DCIS), and benign/high risk lesions.

Results: RSL procedures had a lower positive margin rate than WL procedures (2.6% versus 11%, P=0.005). There were no statistical differences in the specimen volume, lesion size to specimen volume ratio and OR time usage between RSL and WL groups. In a multivariable logistic regression model, the WL procedure had a significantly higher odds of positive margin compared to RSL (odds ratio=3.91, P=0.021) adjusted for the final pathology finding and post-operative upgrade of diagnosis. In addition, our data showed that post-operative upgrade of a patient's diagnosis was significantly associated with increased rate of positive surgical margin (25% versus 5.7%, P=0.016).

Conclusion: RSL performed better than WL in regard to lower rate of positive surgical margins and lower post-operative upgrade for both invasive cancers and DCIS. This finding favours increased use of RSL as a replacement of WL in the future.

Can MR and CT imaging features differentiate benign from malignant meningiomas?

F. [Salah](#), A. Tabbara, N. Al Arab, A. Sibahi, K. Asmar, H. Tamim, M. Makki, R. Hourani; *Beirut/LB (fatima.a.salah@gmail.com)*

Purpose: This study aims to highlight MRI and CT characteristics that plays a valuable role in distinguishing benign from high-grade meningiomas pre-operatively.

Methods and Materials: Seventy-one patient with intracranial meningiomas who underwent surgical resection at the American University of Beirut Medical Center between 2008 and 2017 were evaluated for various CT and MR imaging features. The correlation between imaging findings, operative reports and histopathological grading was analyzed via univariate and multivariate logistic regression analysis. We analyzed the relation between ADC ratio and tumor recurrence. MRI accuracy in detecting brain invasion was also studied.

Results: Univariate analysis results showed a significant correlation between high grade meningiomas (WHO grade II & III) and several MRI features including tumor size and volume (p=0.002,0.02), heterogeneous enhancement (p<0.0001), presence of intra tumoral necrosis (p<0.0001), ill-defined margin (p=0.003), bone necrosis (p=0.004), and brain invasion (p=0.001). High grade meningiomas proved to have a higher rate of recurrence (p=0.007) and higher incidence of brain invasion in pathological reports (p=0.01). However, no significant correlation was established in multivariate analysis while imposing

for tumor volume except for older age and presence of intra tumoral necrosis ($p=0.04$ and 0.001) respectively. The ADC value was not reliable in predicting the tendency to recur. Studying the accuracy of brain invasion detection by MRI, in comparison to the operative report, showed high specificity (83%) and low sensitivity (31%).

Conclusion: MR imaging has a promising role in predicting meningioma grade prior to resection which can directly impact future management protocols regarding surgical planning and complications.

B-1160 10:38

Paediatric cerebellar tumours: how useful is the apparent diffusion coefficient?

A. Arous¹, E. Jemel², M. Krichene³, O. Zayani³, M. Mahmoud², C. Drissi², S. Najji², N. Hammami², M. Ben Hammouda²; ¹Paris/FR, ²Tunis/TN, ³Sfax/TN (eya_d@yahoo.fr)

Purpose: Determination of histological types of paediatric cerebellar tumours determines the prognosis. Diffusion-weighted imaging (DWI), through apparent diffusion coefficient (ADC), allows evaluating water diffusion within tissues which can help to appreciate tumour cellularity. The aim of our study is to evaluate the ability of ADC values to differentiate between the most common cerebellar tumours in children.

Methods and Materials: Children operated for cerebellar tumours between 2010 and 2014 were retrospectively included in this study. The minimum ADC value of solid component of tumours (ADC_{min}) and the ratio of ADC_{min} compared to normal tissue (ADC_{ratio}) were measured by two radiologists blinded to the histopathological diagnoses and compared using one-way analysis of variance (ANOVA). A receiver operator curve (ROC) analysis was also performed to generate optimal cutoffs for which the ADC_{min} would predict tumour histology.

Results: Our study included 31 cerebellar tumour. There were 7 pilocytic astrocytomas (PA), 14 medulloblastomas (MB) and 10 ependymomas (EP). ADC_{min} values and ADC_{ratio} were significantly different in three types of tumours ($p<0.001$). ADC_{min} values were lowest for MB (0.49 ± 0.06) without overlap with ADC_{min} values of EP (0.96 ± 0.12) and PA (1.27 ± 0.18). For the ROC analysis, ADC_{min} ≥ 1.21 distinguished PA from the other tumours with a sensitivity of 71.4% and a specificity of 100%. MB was discriminated from PA and EP by an ADC_{min} value ≤ 0.7 with sensitivity and specificity of 100%.

Conclusion: ADC_{min} and ADC_{ratio} values are reliable parameters to distinguish the most common paediatric cerebellar tumours.

B-1161 10:46

The value of whole tumour volume-based ADC histogram analysis of differential diagnosis in paediatric posterior fossa tumours

S. Yuanyuan; Zhengzhou/CN (857435584@qq.com)

Purpose: To study the value of whole tumours ADC histogram analysis of differential diagnosis in two paediatric posterior fossa tumours (ependymoma and astrocytoma).

Methods and Materials: A retrospective analysis was conducted by brain MRI examination and pathology diagnosis of 77 cases of posterior fossa tumors in children patients in our hospital. Among them, there were 41 cases of ependymoma (there were 21 males and 20 females) and 36 cases of astrocytoma (there were 19 males and 17 females). To draw the region of interest (ROI) in the ADC MR transaxial images of two groups on each layer of tumour level using Mazda software and analyse the whole tumours gray histogram, performing a statistical analysis on the two sets of parameters obtained from histograms to find out statistical significance of each parameter.

Results: Through histogram analysis of 9 parameters, these 6 parameters were statistically significant (all $P<0.05$), including mean, skewness, Perc.10%, Perc.50%, Perc.90% and Perc.99%, the remaining 3 parameters, variance, kurtosis, Perc.01%, had no significant (all $P>0.05$).

Conclusion: The whole tumours ADC grey histogram analysis of two kinds of paediatric posterior fossa tumours in the differential diagnosis has certain value. It can be used as a new auxiliary method of diagnosis in two paediatric posterior fossa tumours.

B-1162 10:54

Histogram analysis of enhancement MRI may predict relapse of primary CNS lymphoma after surgery-combined first-line chemotherapy

L. Hao; Zhengzhou/CN (18339298063@163.com)

Purpose: Primary central nervous system lymphoma (PCNSL) is defined as extranodal lymphoma confined to the central nervous system. Despite the high complete remission rate achieved with aggressive first-line therapy, 10-35% of PCNSL are treatment refractory and 35-60% of patients relapse. Our aim was to verify if T1 enhancement MRI histogram analysis is able to predict the relapse of PCNSL after surgery combined first-line chemotherapy.

Methods and Materials: Retrospective analysis of pathologically confirmed 60 cases of PCNSL was enrolled in this study. All patients who had undergone surgery and with histologically proved PCNSL, followed up with polychemotherapy, but suffering from a relapse were consecutively recorded 6 months later. Drawing the region of interest (ROI) on the maximum level of enhanced MR axial image and going on histogram analysis, these two steps are all performed on the software named Mazda. A statistical analysis was performed to find out the characteristics of the significant differences between the relapse and no relapse.

Results: Sixteen of 60 enrolled patients (26.7%, 8 men, 8 women, median age 50.5 years) relapsed. Histogram analysis of enhanced MRI included the mean, variance, skewness, kurtosis, and the 1, 10, 50, 90 and 99 percentile characteristics. The mean, variance, 90th and 99th percentile were detected for statistical significance. ROC curve analysis of the 90th percentile yielded the best area under the ROC curve (AUC 0.92), sensitivity of 91%, and specificity of 95%, with a cutoff value of 188.

Conclusion: Histogram analysis of T1 enhancement MRI can provide more quantitative information of characteristics, which provides a new way to predict the relapse of PCNSL.

B-1163 11:02

Analysis of clinical, imaging and pathological characteristics in patients with pineal parenchymal tumour of intermediate differentiation

T. Du, M. Zhu, X. Qi, K. Yao, L. Wang, X. Zhang, J. Hu, J. Gao; Beijing/CN (bridge_tq@163.com)

Purpose: To analyse the features of imaging, pathology and prognosis of patients with pineal parenchymal tumour of intermediate differentiation (PPTID).

Methods and Materials: 17 patients with PPTID, 10 male and 7 female (age range 4-65 years), underwent MR scanning and surgery. According to the proposal of the 2016 4th edition of WHO Classification of Tumors of Central Nervous System [1], the cases were graded and followed up.

Results: All the patients had supratentorial hydrocephalus, 6 and 11 of whom had tumours growing into aqueduct and squeezing aqueduct, respectively. 13 cases (76.5%) with clear boundaries between tumours and thalamus were observed by MR. The cases were divided into grade II (10 cases) and grade III (7 cases), and into 3 groups by Ki-67 index ($\leq 5\%$, 6-10% and $>10\%$). Ki-67 index of PPTID III was significantly higher than that of PPTID II ($\chi^2=11.102$, $P=0.004$). There were 6 cases (35.3%) with recurrence revealed by follow-up, including 2 of grade II and 4 of grade III, 3 (17.6%) of whom died, including one of grade II and 2 of grade III. χ^2 test on tumour recurrence and ki-67 index showed that patients with high ki-67 index had significantly higher recurrence rate than those with low ki-67 ($\chi^2=7.242$, $P=0.027$).

Conclusion: 76.5% of the tumours had clear boundaries with thalamus, suggesting that most of the PPTID had no obvious peripheral infiltration. That 35.3% of the tumours were observed growing along the aqueduct could be the imaging characteristic of PPTID. The patients with high ki-67 index in PPTID group were more likely to relapse.

B-1164 11:10

Correlation between [¹¹C]methionine PET uptake and apparent diffusion coefficient in patients with gliomas

Z. Savintseva, T. Skvortcova, D.V. Zakhs; St. Petersburg/RU (lycaidas@gmail.com)

Purpose: The aim of the study was to assess the value of apparent diffusion coefficient (ADC) from diffusion weighted imaging and PET/CT with [¹¹C]methionine (PET-MET) for glioma grading and to correlate these metrics.

Methods and Materials: 26 adults with untreated histologically proven brain gliomas were included. Patients underwent MRI with diffusion sequences and PET-MET. ADC maps and [¹¹C]methionine uptake maps were generated for each patient and then coregistered head-to-head using application software. Metrics evaluation included calculating minimum ADC (ADC_{min}) and maximum [¹¹C]methionine uptake index measured as the ratio of the highest tumour SUV to the that in the intact brain (T/B_{max}). Mean value of ADC and T/B were obtained for each tumor on the corresponding MR and PET images. Statistical analysis included Spearman's correlation coefficient and discriminant analysis.

Results: T/B_{max} and ADC_{min} values were negatively correlated (-0.85 , $p<0.05$). The localization of maximum [¹¹C]methionine uptake and minimal ADC did not match in 30% of cases. T/C_{mean} and ADC_{mean} also showed significant negative correlation (-0.5 , $p<0.05$). The T/C_{max} showed best accuracy to distinguish between low and high-grade gliomas using discriminant analysis. The combination of T/C_{max} and ADC_{min} reached of 100% accuracy.

Conclusion: We found a strong negative correlation between T/C_{max} and ADC_{min}. But areas of maximum MET uptake and minimal ADC within a tumour did not always matched. It could be a result of the different biological features visualized by PET-MET and ADC. The complementary use of those two methods could be of interest for the accurate preoperative grading of gliomas.

B-1165 11:18

Association between tumour acidity and hypervascularity within human gliomas using pH-weighted amine CEST-EPI and DSC-perfusion MRI at
Y. Wang¹, J. Yao², C. Raymond², B.M. Ellingson²; ¹Beijing/CN, ²Los Angeles, CA/US

Purpose: To investigate the association between image contrast obtained from pH-sensitive amine chemical exchange saturation transfer echo planar imaging (CEST-EPI) and relative cerebral blood volume (rCBV) measurements obtained from dynamic susceptibility contrast (DSC)-perfusion MRI in patients with glioma.

Methods and Materials: pH weighting was obtained using CEST-EPI estimation of the magnetization transfer ratio asymmetry (MTR_{asym}) at 3ppm and rCBV was estimated using DSC-MRI. The correlation between median [BE1] MTR_{asym} at 3ppm and rCBV within T2 hyperintense lesions was evaluated in a total of 81 patients with histologically proven gliomas (40 WHO IV, 23 WHO III, and 18 WHO II gliomas).

Results: Both MTR_{asym} at 3ppm and rCBV within T2 hyperintensity increased with increasing tumour grade. A strong correlation was observed between median MTR_{asym} at 3ppm and rCBV within areas of T2 hyperintensity ($R^2=0.335$, $P=0.0043$). No association was observed between MTR_{asym} at 3ppm and rCBV within areas of necrosis or enhancing tumour.

Conclusion: The general degree of tumour acidity, measured with amine CEST-EPI, was correlated with hypervascularity, measured with DSC-MRI. These data confirm a potential association between tumour glycolysis and angiogenesis in human gliomas.

B-1166 11:26

Differentiation of histologically proven intracerebral tumour entities with quantitative iodine mapping in dual-layer computed tomography

J. Borggrefe, M. Gebest, M. Hauger, C. Kabbasch, M. Schlamann, J. Dörner; Cologne/DE (Jan.Borggrefe@uk-koeln.de)

Purpose: Dual-Layer computed tomography (DLCT) allows for precise quantitation of iodine content and iodine homogeneity in cerebral tumor volumes with blood-brain barrier disruptions. We used iodine density mapping (IDM) to investigate feasibility for the discrimination of biopsy proven malignant cerebral lesions (MCL).

Methods and Materials: Retrospective study of 139 consecutive DLCT scans conducted prior to stereotactic needle-biopsy at one CT scanner (IQON, Philips, NL). Iodine density (ID) and contrast-to-noise-ratio (CNR) were determined in IDM using ROIs in MCL and healthy contralateral white matter. Size and localization of ROIs were kept constant between reconstructions. Standard deviation of IDM was considered representative of iodine inhomogeneity (IDI). ID, CNR and IDI were correlated with histopathology.

Results: Mean age was 59.4 (±sd 17.1) years, 52 female patients. There were no significant differences of ID in dependence of age but between genders in low-grade astrocytoma (m:0.42±0.09 (mean±sd) vs. f:0.92±0.16, p<0.002) and lymphoma (m:1.15±0.16 vs. f:1.47±0.19, p<0.05). Lymphomas showed strongest CNR (3.28±1.23) in IDM which was significantly higher than in glioblastoma (2.37±1.55, p<0.005) and metastases (1.95±1.14, p<0.02). Glioblastoma and metastases did not show significant differences. The strong enhancing lesions (lymphoma/metastases/GBM) had higher iodine content than oligodendrogliomas, Grad II and Grad III astrocytoma that showed IDM CNR in the range 1.22-1.27±0.45-0.82).

Conclusion: Quantitative IDM appears feasible to discriminate tumor lesions such as lymphomas from all other tumors and GBM from low and intermediate grade astrocytoma. It was not capable to discriminate metastases from GBM. Gender may be a significant confounder of IDM in certain brain lesions.

Consecutive acquisition of MRDSA and perfusion MRI in cases of brain metastasis through the addition of a supplementary dose of a Gd-based contrast agent at 3T

K. Tsuchiya, W. Watanabe, A. Abe, K. Uchida, J. Handa, S. Goto; Kawagoe/JP (tsuchiya-k@umin.ac.jp)

Purpose: To assess the feasibility and value of MR digital subtraction angiography (MRDSA) combined with perfusion imaging (PWI) by employing a dual injection of a Gd-based contrast agent in the diagnosis of brain metastasis.

Methods and Materials: Sixteen patients were imaged using a 3-T scanner. Imaging protocol included conventional pre-contrast T1/T2-weighted (T1/T2WIs), FLAIR, and diffusion-weighted images. After the first injection of gadoteridol at 0.1 mmol/kg, MRDSA and the first post-contrast T1WIs were obtained. After a second 0.1 mmol/kg injection of gadoteridol, PWI and a second post-contrast T1WIs were acquired. PWI maps and MRDSA images were evaluated in terms of lesion contrast using a 3-point scale

(1=poor/2=fair/3=good). Furthermore, assessment of whether these techniques added diagnostic information to conventional MR imaging was performed. Finally, contribution of the second injection in terms of number of lesions and their visibility was assessed.

Results: In all cases, MRDSA and PWI maps allowed assessment of tumour haemodynamics with average score of 2.9 ± 0.5 and 2.9 ± 0.5 , respectively. In 7/16 cases (43.8%), MRDSA and/or PWI provided additional diagnostic information to conventional MR imaging. While the number of detected lesions did not increase after the second injection, the lesion visibility improved in 14/16 cases (87.5%).

Conclusion: Consecutive acquisition of MRDSA and PWI by employing a dual single-dose injection of the macrocyclic agent gadoteridol, which can be used in such a cumulative administration scheme in our country in cases of suspected brain metastasis, improves the diagnosis as well as the visualization of brain metastasis at 3T.

The forgotten juxta-sellar mass: ectopic pituitary adenomas

A. Alagely, L. Okromelidze, G.K. Vilani, E.H. Middlebrooks, V. Gupta; Jacksonville, FL/US

Purpose: To increase awareness of ectopic pituitary adenoma (EPA) presenting as a juxta-sellar mass and review the radiologic features and management strategies.

Methods and Materials: This case series details four unique radiographic presentations and key imaging findings of EPA based on their anatomic location: suprasellar, cavernous sinus, sphenoid sinus, and clivus.

Results: Clinical and radiological manifestations of EPA are variable. The symptomatology depends on mass effect upon adjacent structures, hormonal activity, and rarely, CSF leakage into the sphenoid sinus. Measurement of hormonal titers can facilitate early diagnosis and avoid unnecessary biopsies and/or surgical intervention. On CT, EPAs are often isodense to gray matter and enhance moderately after intravenous contrast. Evaluation of adjacent bone involvement can also be performed using CT. On MRI, EPAs are often low signal on T1WI and variable signal on T2WI with mild to moderate enhancement after intravenous gadolinium. MRI also best reveals the anatomic location of the lesion relative to the pituitary gland, cavernous sinus, and suprasellar structures.

Conclusion: A high index of suspicion of EPA is warranted in the evaluation of juxta-sellar lesions located in the suprasellar cistern, cavernous sinus, sphenoid sinus, and clivus. Laboratory investigation of elevated pituitary hormones may help avoid invasive procedures in establishing the diagnosis, facilitate appropriate management, and achieve better outcomes.

Radiomics based on baseline DCE-MRI is predictive of tumour pathological complete response to neoadjuvant systemic therapy in breast cancer patients

R. Granzier¹, A. Ibrahim¹, H. Woodruff¹, T. van Nijnatten¹, M. de Boer¹, F. Hulsmans², P. Lambin¹, M. Smidt¹, M. Lobbes¹; ¹Maastricht/NL, ²Sittard-Geleen/NL (r.granzier@maastrichtuniversity.nl)

Purpose: To evaluate the applicability of radiomics models based on baseline dynamic contrast-enhanced MRI (DCE-MRI) for the prediction of pathologic complete response (pCR) of breast tumours to neoadjuvant chemo(targeted)therapy (NCT) in breast cancer patients.

Methods and Materials: Two independent cohorts from 2 centres were used to train and validate a radiomics-based classification model. The training cohort included 102 patients with 129 breast tumours. The external cohort (120 patients, 125 breast tumours) was split into testing (n=63) and validation cohorts (n=62). Patients received NCT and underwent baseline DCE-MRI scan. Tumours were delineated manually by 3 individuals on MRI acquired 2 minutes after contrast injection. Features were extracted using OncoRadiomics software. Overall concordance correlation coefficient was used to assess feature stability among observers. Stable features were ranked and selected via support-vector machine recursive feature elimination. Random forest binary classifications were generated using the training cohort and hyper-parameters tuned on training and test cohorts. Performance of the model was assessed using area under the curve (AUC).

Results: 30.2% of tumours in training cohort achieved breast pCR, 23.8% and 32.2% of tumours achieved pCR in test and validation cohorts. 1322 features were extracted, of which 1094 features were stable. The 20 top-ranked features were selected to build the pCR prediction model. The AUC of the model was 0.68 in both training cohort and external validation.

Conclusion: Our results demonstrate that baseline DCE-MRI radiomics analysis on pretreatment MRI can be used to predict tumour pCR after NCT. Further studies with larger sample sizes are needed to confirm these results.

Feasibility study of whole breast texture analysis for predicting tumour response to neoadjuvant chemotherapy

J.-Y. Zhou, H. Dan, G. Cheng; *Shenzhen/CN (aftdoctor@163.com)*

Purpose: To investigate the feasibility of whole breast texture analysis in predicting tumor response to neoadjuvant chemotherapy(NAC) for patients with non-mass breast cancer.

Methods and Materials: In this institutional review board approved study, 70 patients with non-mass breast cancer between March 2008 to March 2018 were included. Breast magnetic resonance(MR) imaging was performed before treatment(E1), after two cycles of NAC(E2), and after four cycles of NAC(E3, usually before surgery). Two-dimensional computerized analysis was performed and the texture features of the lesion side and the healthy side were obtained. Pathological results obtained by surgery and the Miller-Payne pathological grade was used as the gold standard. These quantitative parameters were analyzed by t-test and least absolute shrinkage and selection operator(LASSO) regression.

Results: Pathologic complete response(Miller-Payne grade 4 and 5) was achieved in 20 (28.6%) of 70 cases. Skewness(E3 lesion, E3 lesion/ E3 health, E3 lesion/E1 lesion), kurtosis(E3 lesion, E3 lesion/E3 health, E3 lesion/E1 lesion), consistency(E3 health), entropy(E1 lesion/E1 health), relevance(E2 lesion, E1 lesion/E1 health) showed significant differences in t-test($p < 0.05$). LASSO regression analysis showed that the whole breast texture features have a good performance in judging tumor response of neoadjuvant chemotherapy.(area under the receiver operating characteristic curve = 0.803).

Conclusion: It is feasible to use the whole breast texture analysis as a new method of predicting tumor response to NAC in non-mass breast cancer.

Tumour texture parameters of IDC in neoadjuvant chemotherapy: early identification of non-responders on breast MRI

M. Nadrijanski, Z. Milosevic; *Belgrade/RS (dr.m.nadrijanski@gmail.com)*

Purpose: Texture parameters (variance of SI, mean of gradient, variance of gradient, kurtosis of SI, and entropy) were evaluated on baseline MRI and following the 2nd cycle of neoadjuvant chemotherapy (NAC) in patients with IDC, to assess the tumour texture features in early identification of non-responders (NR) to NAC.

Methods and Materials: Fifty patients (N=50) were included in the retrospective analysis of baseline and MRI following the 2nd cycle of NAC. Texture parameters were computed and correlated to morphologic features and DWI-ADC in 25 NR with IDC. Additional matched 25 responders (R) served as the control group.

Results: Tumour size and ADC did not change significantly in NR after the 2nd cycle of NAC (2.88+/-0.38 vs. 2.76+/-0.36 [cm], $p=0.14$; 1.01+/-0.14 vs. 1.05+/-0.13 [mm²/s 10⁻³], $p=0.36$), tumour texture parameters changed significantly: variance of gradient (346.5+/-12.6 vs. 355.6+/-16.9, $p=0.01$), kurtosis of SI (1.47+/-0.09 vs. 1.54+/-0.11, $p=0.02$), entropy LH (60.39+/-4.34 vs. 64.42+/-3.05, $p=0.001$) and entropy HL (61.02+/-5.51 vs. 65.63+/-3.63, $p<0.00001$). Variance of SI, mean of gradient, variance of gradient and kurtosis of SI were significantly different between NR and R after the 2nd cycle of NAC ($p<0.00001$; $p=0.0008$; $p=0.047$, $p<0.0001$).

Conclusion: Tumour texture parameters: entropy HL, entropy LH, kurtosis and variance of gradient increase in NR following the 2nd cycle of NAC. Texture parameters (variance of SI, mean of gradient, variance of gradient and kurtosis of SI) significantly differ between NR and R after the 2nd cycle of NAC. Texture parameters may contribute to early identification of NR on breast MRI.

B-1173 10:54

Background parenchymal enhancement on breast MRI in patients undergoing neoadjuvant chemotherapy: is it a biomarker of tumour response?

C. Costanza¹, G. Mariscotti¹, M. Durando¹, A. Tagliafico², L. Bergamasco¹, I. Castellano¹, P. Fonio¹; ¹Turin/IT, ²Genoa/IT (dott.claudiacostanza@gmail.com)

Purpose: To evaluate if changes in background parenchymal enhancement (BPE) on breast MRI can be associated to tumour response in patients with locally advanced breast cancer undergoing Neoadjuvant Chemotherapy (NCT).

Methods and Materials: A retrospective review identified 55 patients with locally advanced breast cancer who underwent NCT between January 2015 and January 2018. All patients had breast MRI before, during and after NCT. Two dedicated breast Radiologist, blinded to clinical and pathological data, rated BPE level according to BI-RADS criteria (minimum=1, mild=2, moderate=3, marked=4) on pre- and post-NCT breast MRIs. A statistical analysis was performed to compare BPE changes and the pathological response after treatment (complete response versus non-complete response, including partial and non-response).

Results: In the study population, tumour size at diagnosis ranged from 2-9cm (mean:3.7cm); 30/55(55%) patients were pre/perimenopausal and 25/55(45%) postmenopausal. There was a complete pathological response post-CTN in 23 patients(42%), partial response in 27(49%) and non-response in 5(9%). At MRI pre-CTN, BPE level was minimum in 15/55 patients(27.6%), mild in 1/55(2%), moderate in 22/55(39.2%) and marked in 17/55(31.4%) and did not significantly ($p=0.995$) differ based on final pathological response. Post-CTN BPE levels were lower in complete pathologic response cases, although not statistically significant($p=0.885$). BPE level decreased after CNT in 21/55(38.2%) patients. The decrease in BPE occurred in 10/23(43%) cases of complete pathological response and in 10/32(31%) cases of non-complete response($p=0.60$).

Conclusion: Our preliminary results suggest that a decrease in BPE could have a role as a potential biomarker for predicting tumour response in patients undergoing NCT.

B-1174 11:02

A new objective mathematical tool for assessment of response and predicting residual disease in breast cancer using CESM

M. Gomaa, E. Kamal, R.M. Kamal, S. Mostafa, R. Mubarak, M. El-Adawy; *Cairo/EG (mohammedgomaa555@yahoo.com)*

Purpose: Initiating a new objective mathematical tool for evaluation of response post-neoadjuvant chemotherapy in breast cancer and residual disease using the CESM.

Methods and Materials: 42 breast cancer patients were included. All underwent 2 CESM; before and after NAC. We used a mathematical image analysis software (MATLAB and Simulink) (Release 2013b). The proposed technique used 42 CESM images as inputs. The technique consists of 3 main steps 1-preprocessing 2. Extracting the region of Interest (ROI) and 3-Assessment the response to chemotherapy. The technique depends on the analysis of the tumour number of pixels included within the ROI and intensity values to find the percentage between the ROI before and after chemotherapy. We compared the evaluation via mathematical objective technique, RECIST 1.1 & combined response evaluation approach using both RECIST 1.1 in addition to subjective visual evaluation.Results were correlated to postoperative pathology using Miller-Payne grades.

Results: Correlation with pathology between the proposed method, RECIST & combined method was 0.89,0.59&0.69 with accuracy 85.7%,54.8%&85.7% respectively. With classification of patients into responder and non-responders, the mathematical evaluation showed higher sensitivity, positive and negative predictive values (100, 97.5,100 % respectively) compared to the evaluation of RECIST method (87.2%, 97.1% 28.6%) and the combined response method (97.4%,97.4% and 66.7%). The pathology showed 39/42 patients were responders. Combined response evaluation approach; 38/39 patients were responders while using RECIST 1.1; only 34 patients and using the proposed method; 39/39 were responders.

Conclusion: Mathematical analysis of CESM allows objective evaluation of the response of breast cancer to chemotherapy.

Radiomic signatures derived from diffusion-weighted imaging for the assessment of breast cancer receptor status and molecular subtypes

D. Leithner¹, J.V. Horvat², M. Marino¹, B. Bernard-Davila¹, M.S. Jochelson¹, D. Martinez¹, E.A. Morris¹, S. Thakur¹, K. Pinker-Domenig¹; ¹New York, NY/US, ²Sao Paulo/BR, ³Vienna/AT (doris.leithner@googlemail.com)

Purpose: To evaluate the diagnostic performance of radiomic signatures extracted from diffusion-weighted imaging (DWI) for the assessment of breast cancer receptor status and molecular subtypes.

Methods and Materials: Ninety-one patients with biopsy-proven breast cancer (luminal A, n=49; luminal B, n=8; HER2 enriched, n=11; triple negative, n=23), who underwent multiparametric 3T MRI were included in this IRB-approved retrospective study. To compare annotation segmentation approaches (a) all lesions were manually segmented on high b-value DWI and propagated to ADC maps and (b) a subgroup (n=79) was directly segmented on the ADC map. Radiomics analysis included first-order histogram (HIS), co-occurrence matrix (COM), run-length matrix (RLM), absolute gradient (GRA), autoregressive model (ARM), discrete Haar wavelet transform (WAV), and lesion geometry (GEO) features. Fisher, probability of error and average correlation, and mutual information coefficients were used for feature selection. Linear discriminant analysis and k-nearest neighbor classification with leave-one-out cross-validation were used for pairwise separation of molecular subtypes. Histopathology was the gold standard.

Results: The following accuracies >90% were achieved for approach (a) segmented on DWI: luminal B vs. HER2-enriched, 94.7% (based on COM features); luminal B vs. others, 92.3% (COM, HIS); HER2 enriched vs. others, 90.1% (RLM, COM). Higher accuracies were achieved with approach (b) segmentation on ADC maps: luminal A vs. luminal B, 91.5% (COM, WAV); luminal B vs. HER2-enriched, 100% (COM, WAV); luminal B vs. others, 91.1% (WAV, ARM, COM).

Conclusion: DWI radiomic signatures enable the assessment of breast cancer molecular subtypes with high diagnostic accuracy. Higher accuracies are achieved when tumour segmentations directly are performed on ADC maps.

Radiomics signatures with contrast-enhanced magnetic resonance imaging for the assessment of breast cancer receptor status and molecular subtypes: initial results of a multicenter study

D. Leithner¹, J.V. Horvat², M. Marino¹, B. Bernard-Davila¹, M.S. Jochelson¹, D. Martinez¹, E.A. Morris¹, S. Thakur¹, K. Pinker³, A. Meyer-Baese⁴; ¹New York, NY/US, ²Sao Paulo/BR, ³Vienna/AT, ⁴Tallahassee, FL/US (doris.leithner@gmail.com)

Purpose: To evaluate the diagnostic performance of radiomic signatures extracted from contrast-enhanced magnetic resonance imaging (CE-MRI) for the assessment of breast cancer receptor status and molecular subtypes.

Methods and Materials: One-hundred and thirty-two patients with biopsy-proven treatment-naïve breast cancer (luminal A, n=49; luminal B, n=32; HER2-enriched, n=24; triple negative, n=27) who underwent CE-MRI at 3T were included in this IRB-approved HIPAA-compliant retrospective multicenter study. Radiomics analysis of manually segmented tumors included calculation of features derived from first-order histogram (HIS); co-occurrence matrix (COM), run-length matrix (RLM), absolute gradient (GRA), autoregressive model (ARM), discrete Haar wavelet transform (WAV) and lesion geometry (GEO). Fisher, probability of error and average correlation (POE+ACC), and mutual information (MI) coefficients were used for feature selection (optimal subsets of ten features each). Linear discriminant analysis followed by k-nearest neighbor classification (with leave-one-out cross-validation) was used for pairwise radiomics-based separation of receptor status and molecular breast cancer subtypes. Histopathology served as the standard of reference.

Results: Radiomic signatures yielded the following accuracies >80%: luminal A vs. luminal B, 85.2% (POE/mainly based on HIS and COM features); luminal A vs. HER2-enriched, 84.9% (MI/entirely based on HIS and COM features).

Conclusion: Radiomic signatures with CE-MRI enable the assessment of breast cancer receptor status and molecular subtypes with high diagnostic accuracy. In particular, luminal A breast cancers appear to have distinct radiomic signature on CE-MRI.

Radiogenomics of invasive breast cancer: association between ultrasound vascular imaging features and tumour genomic profiles for tumour angiogenesis

E. Park¹, B. Seo¹, M.-R. Han², J. Kim¹, H. Lee¹, K. Cho², O. Woo², S. Song²; ¹Ansan/KR, ²Seoul/KR (epark100@naver.com)

Purpose: To evaluate the relationship between ultrasound vascular imaging features and genetic alteration of tumour tissue for angiogenesis in invasive breast cancer patients.

Methods and Materials: This retrospective study was approved by the institutional review board. Preoperative ultrasound vascular imaging features were correlated with genomic characteristics in 31 invasive breast cancers. We evaluated quantitative and qualitative ultrasound vascular parameters on superb microvascular imaging (SMI) and contrast-enhanced ultrasound (CEUS); parameters of SMI (vascular index, vessel morphology, distribution, and penetrating vessel) and CEUS (time intensity curve parameters and enhancement pattern). Targeted next-generation sequencing of 105 genes was performed for the genomic DNA obtained from breast tumour and normal tissues. Single-variant association test was performed to evaluate relationship between ultrasound imaging features and genomic profiles. We used PLINK to detect the single variants associated with ultrasound features.

Results: Our targeted sequencing approach identified that ultrasound vascular features such as penetrating vessel, vessel distribution, vessel morphology and vascular index on SMI, and enhancement degree, enhancement order, area, slope, and time to peak on CEUS were associated with one or more somatic mutations in *APC*, *ATM*, *BRCA1*, *BRC1*, *CSF1R*, *FGFR1*, *HIF1A*, *KDR*, *MET* and *NTRK1*, with *FGFR1* being the most commonly mutated gene (p<0.05). The PolyPhen-2 analysis revealed that 33% of the identified mutations (39 of 119) were predicted to have damaging effects on protein function.

Conclusion: Our preliminary radiogenomic results demonstrate the potential of ultrasound vascular imaging to predict tumour angiogenesis and genetic variants associated with invasive breast cancer in a non-invasive manner.

Radiomics analysis of breast cancer on digital breast tomosynthesis

F. Valdora, C. De Luca, B. Bignotti, F. Rossi, J. Matos, M. Calabrese, A. Tagliafico; *Genoa/IT (valdorafrancesca@gmail.com)*

Purpose: To analyse Breast Cancers (BCs) on Digital Breast Tomosynthesis (DBT) in women with dense breasts and negative mammography using Radiomics.

Methods and Materials: This retrospective study is Institutional Review Board approved. We selected BC patients who underwent DBT evaluation from December 2017 to August 2018. N= 56 women (age range 34-83) with proven diagnosis and with Mammography-Negative Dense Breasts. N=28 controls (age range 40-80) were included. Using a Radiomics approach normal and pathological breast parenchyma were evaluated, and correlations among radiomics features and clinical and prognostic parameters were investigated. Regions of interest (ROIs) were done by two radiologists with different expertises. N=106 Radiomics features were extracted and evaluated. p<0.05 was considered as statistically significant.

Results: The median age of the patients was 55 years. After Radiomics feature number reduction (from 117 to 106). 13 out of 106 radiomics features significantly correlated to tumor size; the feature Entropy significantly correlated to histological subtype (r=0.413; p.002) and with ki67, the proliferation index (r=-0.280; p.004). the feature Energy correlated with Progesteron Receptor status (r=-0.281; p.004). ROC analysis identified seven features belonging to the first order (n=1), gray level Co-occurrence matrix (GLCM) (n=4) and gray level Run Length Matrix (glrlm) (n=1) and neighborhood gray tone difference matrix (NGTDM) (n=1) with an area under the curve for differentiation of normal and pathological tissue of at least 0.76 (0.75 to 0.86) with p<0.05.

Conclusion: The analysis showed a correlation with progesteron receptor and proliferation index. These information could improve understanding of breast cancer through imaging.

B-1179 11:42

Radiomics and deep learning can aid classification of contrast-enhanced spectral mammograms

Y. van Wijk, A. Jochems, S. Primakov, M.B. Lobbes, P. Lambin, H. Woodruff; Maastricht/NL (y.vanwijk@maastrichtuniversity.nl)

Purpose: Our aim was assessing the benefit of radiomics in tumor classification on contrast-enhanced spectral mammography (CESM). This could potentially reduce the number of unnecessary biopsies. Hypothesis: radiomics features extracted from delineated masses can help differentiate between benign and malignant tumors as determined by pathology.

Methods and Materials: Both low-energy and recombined CESMs were available for 968 patients, as well as golden standard pathology results. We delineated 1135 masses on 562 patients. 1864 radiomics features were extracted from the delineated masses, of which the eight most relevant were selected via correlation bias reduction and recursive feature elimination. The data was balanced based on outcomes using an adaptive synthetic sampling approach, and a random forest model was built to classify pathology as invasive ductal carcinoma (IDC) or non-IDC. The dataset was split into training (795) and validation (340), and model performance was evaluated as the AUC of the ROC.

Results: We found that 401 delineations were of IDCs. The most predictive features involved mean, median and 90th percentile of intensity. The model performed with an AUC of 0.86 (95% CI:0.82-0.90) on validation data.

Conclusion: The radiomics model was highly predictive in distinguishing between IDC and non-IDC. Future studies will include clinical features and we will validate on external data. We will also compare the model to deep learning methods and physician performance.

Texture analysis and machine learning for differentiation between phyllodes tumours of the breast from fibroadenomas in non-contrast MRI

M. Tsuchiya, T. Masui, M. Katayama, K. Terauchi, M. Sasaki, K. Kawamura, T. Yamada, H. Sakahara; Hamamatsu/JP (D16018@hama-med.ac.jp)

Purpose: To investigate whether magnetic resonance (MR) features can distinguish phyllodes tumours of the breast from fibroadenomas and assess the feasibility of machine learning based texture analysis (TA).

Methods and Materials: This retrospective study included 50 women with histopathologically proven phyllodes tumours of the breast (n=25; benign, 14; intermediate, 8; malignant, 3) or fibroadenomas (n=25) who underwent breast MRI between January 2004 and January 2018. Regions of interest for TA were manually drawn on axial fat-saturated T2-weighted images on the slice displaying the largest cross-sectional area of the tumour. First order, second order, and higher order texture features were extracted from each tumour by using a freely available software package. Texture feature selection based on machine learning analysis were performed for selection features and multiple logistic regression model. The accuracy of TA features for differentiating between phyllodes tumours of the breast from fibroadenomas was evaluated using a receiver-operating-characteristic (ROC) analysis.

Results: Five independent texture features allowed for differentiation between phyllodes tumours of the breast and fibroadenomas on fat-saturated T2-weighted images: WavEnLH.s-5, S(0,1) Contrast, S(0,2) Contrast, VertIRLNonUni, S(0,2) SumAverg (WavEnLH.s-5, P=0.017; S(0,1) Contrast, P=0.017; S(0,2) Contrast, P=0.011; VertIRLNonUni, P=0.025; S(0,2) SumAverg, P=0.017). Multiple logistic regression models revealed that the feature of S(0,2) Contrast resulted in the highest accuracy for differentiating phyllodes tumours of the breast and fibroadenomas, with an area under the curve (AUC) of 0.74 with a cut-off ≥ 4.24 (76.0% sensitivity, 76.0% specificity).

Conclusion: This machine learning based TA of non-contrast MR images allows for the distinguish phyllodes tumours of the breast from fibroadenoma.

Machine learning in radiology management: predicting ED workflow overloads

O. Pianykh, D. Parke; Boston, MA/US (opiany@gmail.com)

Purpose: The goal of our study was to investigate whether we can predict ED examination volume surges several hours in advance, so that additional resources can be allocated to keep ED reporting on time.

Methods and Materials: Complex and unpredictable ED workflow calls for advanced prediction tools, therefore machine learning was chosen. ED department defined 7 unread CT cases as overload threshold, leading to stress and delays. Therefore we developed a logistic predictive model to forecast the probability of overload several hours in advance. A full year of historical ED data was used to account for seasonal trends. More than 100 predictive features were derived from the HIS data, including current time and date, number of active radiologists, patient and examination counts and types, examination complexity scores, and more. Several machine-learning algorithms were evaluated to find the model with the optimal predictive quality.

Results: Random forest model provided the most accurate prediction, 79.5% accurate for 2-hour prediction. These results were found to be very satisfactory and sufficient for decision-making.

Conclusion: Large and noise ED workflow data presents a perfect target for machine-learning applications. Workflow overload predictions enable optimized resource management, help avoid stressful overloads, keep critical diagnostic time to the minimum.

B-1182 10:47

Performance of the competence centre for MRI and CT imaging in a network of diagnostic centres

A. Fedorov, N. Berezina, M. Cherkashin, A. Lavrenteva; St. Petersburg/RU (fedorov@ldc.ru)

Purpose: To evaluate the effectiveness of a centre of competence (CC) in a network of diagnostic centres of wide geography with remote medical personnel training and a quality control of examinations.

Methods and Materials: A common network of clinics has 100 units of multimodal diagnostic equipment in four countries. The CC works with VNC and VPN remote access technologies via secure communication channels with reliable storage of patient's personal data. The CC has three MR and CT technologists, who support each centre in conducting and maintaining the quality of examinations upon request. The specialist of the CC comes to the scanner via remote access and corrects the clinical protocols or solves the problem of visualization after received request.

Results: When training medical personnel, a webinar platform is used that supports the function of displaying the presenter's desktop, from which a remote access session is broadcast to one of the scanners where the examination is being conducted. During the commissioning of the CC, 74 scanners were connected in 57 cities. In the first year, the number of online consultations exceeded 400. After 5 years, more than 1,000 consultations were carried out in a year, approximately 4.2 per day. Over the 5 years of the centre's work, positive statistics on research cancellations due to various malfunctions has been noted - from 7% to 3.4%.

Conclusion: CC can provide online advice including emergency requests; there are standards of clinical protocols, updates, and developing new scanning techniques in the clinical practice.

B-1183 10:55

Fuzzy PACS: linking large unorganised image and report databases for development and validation of deep learning algorithms

R. Mukherji, V. Mahajan; *New Delhi/IN (vidur@mahanimaging.com)*

Purpose: Development and validation of deep learning (DL) algorithms for medical imaging requires access to large organised datasets of images and their corresponding reports. Currently, most medical imaging data in the world are unorganised and require images and text reports to be manually linked. An approach for linking medical images and reports of patients, where no unique identifier for linking them exists, is presented.

Methods and Materials: A DICOM image database of 311,694 studies and a separate MySQL database with 296,938 reports needed to be matched at study level. No unique identifier existed to link the two databases and not all reports had matching images, and there was only partial overlap between the databases. Additionally, patient names were inexactly entered with varied formats in the two databases making direct matching impossible. Fuzzywuzzy Python library, which incorporates fuzzy string matching, a technique based on Levenshtein distance between strings to estimate text similarity was used to match patient name in the two databases following date and modality-level filters. Four fuzzy matching techniques (simple, partial, token-set and token-sort ratios) were evaluated.

Results: Simple, partial, token-set and token-sort ratios gave 4.56%, 46.45%, 57.37% and 7.97% matches of reports, respectively, with 95% match confidence. Token set ratio, which had the highest match percentage, matched 170,336 reports to their corresponding studies.

Conclusion: Fuzzy matching is a promising technique to merge independent datasets without unique identifiers, saving thousands of man-hours, critical for development and validation of DL algorithms.

B-1184 11:03

Subspecialisation in radiology: effects on the diagnostic spectrum of radiologists and report turnaround time in a Swiss university hospital

M.H. Maurer¹, M. de Bucourt², A. Berghöfer², A. Huppertz³, A.B. Rosenkrantz⁴, F. Streitparth⁵, J.T. Heverhagen¹, T. Meyl¹; ¹Berne/CH, ²Berlin/DE, ³Potsdam/DE, ⁴New York, NY/US, ⁵Munich/DE (martin.maurer@insel.ch)

Purpose: To analyse the changes in radiologists' work profiles and the reporting time after the implementation of a professional subspecialisation in the radiology department of a Swiss university hospital.

Methods and Materials: In a retrospective analysis, the overall number of different radiologic examinations performed in the department of radiology of a large Swiss university hospital were documented for 2014 and 2016 before and after the implementation of subspecialised reporting (subspecialities: abdominal, musculoskeletal, cardiothoracic, emergency, and paediatric imaging) in May 2015. For six selected radiologists the number and types of reported examinations as well as the related radiology report turnaround times (RTATs) were analysed in detail and compared between the two 1-year periods.

Results: Overall, there was a significant increase of 10.3% in the total number of examinations performed in the whole department in 2016 compared with 2014. For 4 of the 6 radiologists, the range of different types of examinations significantly decreased with the introduction of subspecialised reporting (p<0.05). Furthermore, there was a significant change in the subset of the ten most commonly reported types of examinations reported by each of the 6 radiologists. Mean overall RTATs significantly increased for 5 of the 6 radiologists (p<0.05).

Conclusion: Implementation of subspecialised reporting led to a change in the structure and a decrease in the range of different examination types reported by each radiologist. Mean RTAT increased for most radiologists. Subspecialised reporting allows the individual radiologist to focus on a special field of professional competence but can result in longer overall RTAT.

Operational performance optimisation by means of an imaging analytics platform: a case study

P. Szatmari¹, P. Pytlewski², N. Papanikolaou³, R. Illing¹; ¹Budapest/HU, ²Warsaw/PL, ³Nicosia/CY (peter.szatmari@affidea.com)

Purpose: To optimize operational performance using an advanced imaging analytics platform in combination with lean management concepts.

Methods and Materials: Affidea is operating the public hospital of Walbrzych through a public-private partnership scheme, where the MRI scanner was connected to the MR Excellence Platform to monitor in real-time several key performance indicators including number of exams, examination time, non-scanning time and image resolution. Several interventions in the operational level were done following the six sigma and Kaizen philosophy to eliminate waste. The main interventions included elimination of free slots in the daily schedule, continuity of exam bookings, implementation of pre-built monthly scheduler and grouping of similar exams in designated scheduling blocks. All relative inputs were extracted from the MR Excellence Platform.

Results: There was a significant reduction in the waiting time to perform an exam from 8 days to 1.78 days after the implementation of the Operational Optimization project, while the average number of daily exams performed raised from 24.5 to 28.4 after the optimization of MRI protocols. All new sequences were evaluated in terms of diagnostic efficiency and image quality and approved by the local radiologists.

Conclusion: Imaging analytics-powered operational optimization can result in significant improvement in operational efficiency of an MRI department maintaining high diagnostic standards.

B-1186 11:19

Flagging of pathological head CT interpretations using natural language processing (NLP)

Y. Barash, T. Levy, Y. Elazar, E. Zimlichman, E. Konen, S. Soffer, G. Guralnik, M.M. Amitai, E. Klang; *Ramat Gan/IL (yibarash@gmail.com)*

Purpose: Alerting on pathological findings in imaging reports is a quality measure. We compared two NLP algorithms for flagging pathological head CT reports: the bag of words (BOW) algorithm and the long short-term memory (LSTM) deep learning algorithm.

Methods and Materials: Institutional review board approval was granted. The BOW model is used for text classification where the frequency of occurrence of each word is used as a feature for training a classifier. LSTM is a neural network that has some internal contextual cells that act as long-term or short-term memory cells. The output of the LSTM network is modulated by the state of these cells. This can be utilized in NLP as the sequence of words in a paragraph has contextual meaning. We collected consecutive head CT non-English (Hebrew) reports performed in our ER during annual January and February (2013 - 2017). Each report was labeled as either normal or pathologic (e.g. haemorrhage, infarct, mass). All the words in the dataset were tokenized. The BOW algorithm used unigrams and bigrams as features. For the LSTM network, we embedded each word after tokenization, MLP over the last hidden layer and cross-entropy loss for training. The algorithms' performances were assessed using the accuracy metrics.

Results: We retrieved 5,890 head CT reports. The incidence of pathological findings was 55%. The algorithm BOW algorithm showed an accuracy of 87.5% and the LSTM algorithm showed an accuracy of 89.1%.

Conclusion: The LSTM algorithm showed improved accuracy over the classic BOW algorithm on non-English reports.

B-1187 11:27

Fast displaying time of electronic patient record and PACS sharing system with IHE-XDS/XDS-I and cloud technology

H. Kondoh¹, T. Kawai¹, M. Mochida¹, T. Yamaguchi²; ¹Yonago/JP, ²Hino/JP (kondoh@med.tottori-u.ac.jp)

Purpose: EPR and PACS sharing system was demanded interoperability and quick viewing even on Internet. We developed that sharing system with IHE-XDS and XDS-I and cloud technology.

Methods and Materials: Global standard IHE-XDS and XDS-I was introduced on centre cloud server and thin-client infrastructure with one registry server. It was connected EPR server and DICOM server of regional eighteen hospitals and gathered HL7 based data and DICOM images. It showed the data and images on thin client infrastructure and IP-sec VPN through Internet. The image display time of the sharing system though internet seemed to be faster than intra-hospital PACS with RAID disc and gigabit ethernet. The display times were measured by video data and compared the sharing system access from PC with iPhone tethering and from PC in Heidelberg conference through Internet with intra-hospital PACS.

Results: The display times were 0.627 seconds (0.37-0.86) in intra-hospital PACS, 0.228 seconds (0.23-0.27) in the sharing system access with iPhone tethering, 0.250 seconds (0.198-0.297) access from PC in Heidelberg.

Conclusion: The thin client system was said to reduce the network load to 1/1000. And Large flash memory dramatically reduced data access in the server. So even if Internet used, the display time was seemed to be faster than intra-hospital PACS. Because the thin client system is sending the subtraction image on same matrix size, there are no data reduction in black and white image.

B-1188 11:35

Blended learning using radiology short video based lecture series improves medical school student performance and satisfaction

A. Vasseur, F. Muscarì, P. Otal, H. Rousseau, L. Dercle, F. Mokrane; *Toulouse/FR (vasseur.a@chu-toulouse.fr)*

Purpose: A shift in student's behavior has been observed in medical schools. Medical school students (MSs) are *millenniums* and part of a new 'YouTube' generation. Our purpose is to measure the impact of a combination of

educational resources as a blended learning (short video-based lecture (VBL), as part of the flipped classroom) among three promotions of MSs from our university hospital.

Methods and Materials: 3 consecutive promotions performed a pre-test, based on abdominal imaging (respectively 102, 93 and 109 students). Then, they had access to 61 VBLs focused on abdominal imaging (total duration of 5h 11m). VBLs were available over a period of 5 months via a dedicated educational online platform. Finally, MSs performed a post-test and a face to face course to correct it. The efficiency of this teaching format was measured quantitatively by a post-test and learner analytics, as well qualitatively (direct learner feedback using student's satisfaction questionnaire).

Results: Blended learning combining VBLs and face to face final course significantly improved student results. The average post-test results was 77.2% and significantly higher than the pre-test (53.8%; Student t-test: $P < 0.001$). Satisfaction surveys about this format showed that 99% of students were satisfied or very satisfied by this e-learning training. The amount of videos views was 91 views per student (average) and a total of 27662 views. Moreover, students adherence to this medical education format increased across promotions.

Conclusion: The flipped classroom based on short video based lecture attracts medical students, improve their performances in radiology and obtains their adherence.

B-1189 11:43

Automatic segmentation for coronary computed tomography angiography using convolutional neural networks

J. He¹, Q. Zhou¹, X. Li², X. Xu¹, X. Ding¹, X. Zhou¹, M. Zhang¹; ¹Hangzhou/CN, ²Beijing/CN (jiafa_he@zju.edu.cn)

Purpose: To present a convolutional neural networks (CNN) for automatic segmentation for Coronary Computed Tomography Angiography.

Methods and Materials: 115 patients were examined by 128-slice dual-source CCTA and then the CT images were automatic segmented by CNN technique, of which 91 patients is used for training and 24 for testing. We present a multi-scale 3D convolutional neural networks to segment the coronary artery for automatic segmentation and assisting the diagnosis of coronary artery disease (CAD). Specifically, the multi-scale 3D CNN was firstly utilized to segment coronary artery and aorta from the test dataset. Then a vessel-measurement-based region growing algorithm was proposed to refine the vessel segmentation, especially for the vascular branching, resulting a test Dice coefficient of 0.7833. In addition, several key indicators of coronary artery disease were derived automatically including starting point of artery vessels.

Results: Experimental results show that coronary artery and aorta were identified and segmented successfully while the maximum symmetric surface distances are 0.35mm and 0.42mm, respectively. Comparing with most proposed methods, our method is full-automatic and can realize the segmentation without any manual interaction. As for the efficiency, it takes only an average time of 3.4s to segment one volume of the CCTA.

Conclusion: In this study, we presented a multi-scale 3D convolutional neural networks and showed the feasibility of the proposed method on segmenting coronary artery from CT.

B-1190 11:51

Deep learning based chest x-ray whole-image search and retrieval

N. Ramanaukas, J. Dementaviciene, D. Barusauskas, J. Bialopetravicius, J. Armaitis, G. Rimeika; Vilnius/LT (naglisr@gmail.com)

Purpose: A typical hospital currently possesses more than a decade worth of digital radiological images with their radiological descriptions in the PACS/HIS system. We aimed to create a radiological chest x-ray search system.

Methods and Materials: In our solution, a deep learning neural network trained on a large set of radiographs with respective radiological findings is used in order to index the images. This indexing process takes into account not only the pathology, but also the localization of the pathology, and the overall features of the radiograph. In order to quantify the quality of the search system, a radiology resident was presented with a set of 77 challenging chest x-ray images. Each of the reference images was subsequently indexed by the search system, and used to retrieve 10 radiographs from the hospital database of more than 200 000 images. A radiology resident was asked to evaluate and write reports for each of the images initially without assistance. After each report he was asked to review the returned search matches and modify the report if he found it necessary. We evaluated the initial and the modified reports and extracted statistics.

Results: The report was modified after inspecting search matches for 56/77 cases. The impression was modified after inspecting search matches for 50/77 cases. The differential diagnosis was expanded for 28/77 cases.

Conclusion: An image search solution for frontal chest x-ray images based on a Deep Learning model has been created.

A proposed paradigm revision for recurrent radiation safety training

S. Balter¹, P. Abrams¹, S. Kalra², E.M. Leidholdt³; ¹New York, NY/US, ²Philadelphia, PA/US, ³Mare Island, CA/US (sb2455@cumc.columbia.edu)

Purpose: Designing a radiation training curriculum to meet the needs and concerns of clinical audiences can be perplexing. We formulated and tested a new teaching paradigm structured as a slow-motion, one-on-one conversation. We describe the results of a recent seminar that used this paradigm.

Methods and Materials: The test was conducted at a recent international interventional cardiology meeting. Topics were staff radiation safety and patient radiation management. Several weeks in advance of the session, two clinical faculty members polled their workplace colleagues and presented key 'audience' questions to two medical physicists. The clinical faculty presented expanded versions of their questions at the session, following which the physicist faculty answered these questions point-by-point. The session started with essential general topics not included in the clinical question list and ended with a discussion between the entire faculty and audience.

Results: Essential basic topics (e.g. dose) had to be added. Priority audience concerns about reproductive risks and clinical radiobiology were unanticipated. Enough time was allowed to circulate several versions of the entire training set to the faculty before going live. Faculty interactions resulted in major improvements in the questions, answers, and general topic sections. The audience remained engaged throughout the presentations and discussion and asked many additional questions.

Conclusion: This format was highly productive and generated high levels of audience participation. Audience members informally polled after the session felt that many of their a priori concerns were presented and appropriately discussed. The final topic list also provides insights into improvement of formal didactic training.

The reasons for practitioners' passive approach to informing patients prior to their radiological examinations

H. Oikarinen, L. Ukkola, A. Henner; Oulu/FI (helja.oikarinen@ppshp.fi)

Purpose: Despite requirements, there are suspicions that patients do not obtain adequate information from any source in connection with their radiological examinations. The aim was to survey whether practitioners in Northern Finland provide information, and if not, to elucidate the reasons for the passive approach.

Methods and Materials: Using a questionnaire, practitioners were asked whether they have informed patients about the necessity or radiation dose and risks of the examination during the past year. In case of a passive approach, the reasons were inquired. In all, 205/361 (57%) practitioners responded to the inquiry: 85% of the respondents were radiographers and 15% radiologists, and 53% were from the university hospital and 47% from other departments.

Results: Altogether 43% of the respondents did not inform about the necessity. 87% of them assumed that the referrer had already provided the information. Furthermore, 62% and 56% did not inform about the dose or risks, respectively. Regarding the passive approach to dose information, practitioners supposed that the referrer had already informed, information was not needed or might cause unnecessary fear (41, 47 and 41%, respectively). There were

similar reasons for avoiding risk information (63, 37 and 45%, respectively). According to the open question, many practitioners expect patients to ask questions before informing them.

Conclusion: Ignorance regarding responsibilities, assumption that patients are not interested and concern about causing unnecessary fear were the main reasons for the passive approach among the practitioners. There is a need to provide them education, practical guidelines and easy-access digital educational material.

B-1193 10:55 A retrospective review of justification of computed tomography examinations in Northern Ireland

Y. Sullivan, L. Fraser, G. Woodhouse; Oxford/UK
(yvonne.sullivan@phe.gov.uk)

Purpose: Justification is one of the key principles of radiation protection. The most appropriate use of CT relies on many factors which must be considered each and every time a scan is justified. The Regulation and Quality Improvement Authority (RQIA), commissioned this study to assess the justification rate of CT examinations in a single 24-hour period across NHS Trusts in Northern Ireland.

Methods and Materials: The study retrospectively reviewed the clinical information within 450 referrals for diagnostic CT scans against published referral guidelines to assess justification. Each referral was independently assessed by two consultant radiologists and where opinions differed, arbitration was carried out. The reviewers were also asked to indicate if an alternative modality would have been more appropriate in any referrals that they deemed unjustified. Results were analysed for variations in justification rate by patient gender, patient age, geographical location and anatomical region scanned.

Results: This study found that 94% of the CT referrals reviewed were justified. The number of justified scans varied with regard to the anatomical region being scanned, with the abdomen and pelvis being the only region that demonstrated any statistical significance in the number of unjustified examinations. The highest suggested alternative modality was MRI at 33% of the unjustified referrals.

Conclusion: The study compared favourably to a similar study carried out in Sweden from 2009 where the justification rate was 80%. This review shows that conventional systems utilising up-to-date referral criteria and robust justification processes can ensure that inappropriate examinations are rare.

B-1194 11:03 A radiation dose index monitoring (RDIM) systems comparison for CT procedures

A. Mazzilli¹, A. Loria¹, R. Castriconi¹, T. Lusa Aguero², R. Calandrino¹, A. del Vecchio¹; ¹Milan/IT, ²Valencia/ES (mazzilli.aldo@hsr.it)

Purpose: Since the issuing of the 2013/59/Euratom directive, several RDIM systems have been developed. The aim of this study was to compare Effective Doses (ED) and Organ Doses (OD) calculated by two different systems for Computed Tomography (CT) procedures.

Methods and Materials: Dosimetric data were collected for more than 30 cardiac acquisitions of adult patients performed with a dual-energy CT device. The ED and the OD for each acquisition were calculated by the two most widespread RDIM systems and the differences were evaluated. Both RDIM systems calculations are Monte Carlo (MC) based. The software allow an interactive dose calculation modifying acquisition parameters. In order to perform a more appropriate comparison, ED and OD differences between the two software were analyzed in automatic and interactive mode considering the same acquisition scan-length and target region. For the interactive mode comparison, the organs have been grouped into irradiated, partially-irradiated and not-irradiated.

Results: Statistical analysis of automatic and interactive mode yielded an ED median difference of 0.53mGy (25th-percentile: 0.16mGy; 75th-percentile: 2.4mGy) and 0.45mGy (25th-percentile: 0.21mGy; 75th-percentile: 2.11mGy), respectively. The median OD differences for interactive mode showed a similar behavior of the two software for partially-irradiated and not-irradiated organs (1.20mGy and 0.42mGy). For irradiated organs a greater dispersion of the doses (4.56mGy) was found.

Conclusion: Although the ED differences were quite small, a great variability in the OD was found, especially for the irradiated organs. Therefore, dose measurements in phantom or independent MC-simulations should be made to validate these kinds of software.

B-1195 11:11

Using an automatic patient dose registry to help in the optimisation of interventional radiology practice

E. Vano, J.M. Fernandez, R.M. Sánchez-Casanueva, J. Ten; Madrid/ES
(eliseov@med.ucm.es)

Purpose: Obtaining sufficient diagnostic information (image quality) during interventional procedures is a priority, but optimisation also requires considering patient radiation doses. This work presents the experience using a homemade automatic patient dose registry ("Dose On Line for Interventional Radiology" DOLIR) for optimisation.

Methods and Materials: The automatic patient dose registry allows collecting data for all the radiation events (when the Radiation Dose Structured Reports are available) and auditing the protocol of the examinations and their different imaging acquisition modes: fluoroscopy, cine, DSA and CBCT events. A continuous comparison (using samples of 30 procedures) with Diagnostic Reference Levels (DRLs) allows suggesting corrective actions when appropriate. The Medical Physics Service carries out periodic validation of patient dose quantities managed by the system.

Results: The system used in a large university hospital during the last two years is currently connected to the interventional systems of other 6 hospitals, so as to jointly manage the patient dose values and arrange intercomparison of protocols. The current number of interventional procedures available in the system is about 40.000. Kerma area product, kerma at the patient entrance reference point and some calculated skin dose maps (and peak skin doses) are included.

Conclusion: The use of the automatic patient dose registry allowed an easy auditing process of the individual patient dose values (in case of potential skin radiation injuries) and obtaining median patient dose values for groups of procedures (with the same or similar clinical indications). The easier comparison with DRLs helped suggest corrective actions when appropriate.

Update of the diagnostic reference levels for CT in Switzerland using dose management software

C. Aberle¹, N. Ryckx², R. Treier³, S. Schindera⁴, R. Menz¹; ¹Basle/CH, ²Lausanne/CH, ³Liebefeld/CH, ⁴Aarau/CH (roman.menz@usb.ch)

Purpose: To update the previous Swiss national diagnostic reference levels (DRLs) by acquiring big data on CT radiation doses with dose management software.

Methods and Materials: CT dose data from 14 radiological institutes in Switzerland, for a total of 50 CT scanners, were collected between 2014 and 2017 through local dose management software. Fifteen different standard CT protocols were compared. Data cleaning steps were adjusted individually for each participating institute and protocol. After data cleaning, 220,269 CT exams were available. The DRLs were calculated as the 75th percentile of median CTDI_{vol} and DLP values per scanner. They were compared to the previous DRLs published in 2010.

Results: The DRLs for single acquisitions were 51 mGy (CTDI_{vol}, -22%) and 890 mGy cm (DLP, -11%) for CT of the head, 7 mGy (CTDI_{vol}, -30%) and 250 mGy cm (DLP, -37%) for CT of the chest, 11 mGy (CTDI_{vol}, -27%) and 540 mGy cm (DLP, -17%) for CT of the abdomen and pelvis, 25 mGy (CTDI_{vol}, 0%) and 420 mGy cm (DLP, +20%) for CT of the facial bones/sinuses, and 8 mGy (CTDI_{vol}, -47%) and 300 mGy cm (DLP, -33%) for CT to exclude pulmonary embolism. The average relative change, compared to the previous DRLs, was -30% for CTDI_{vol} (0% to -47% depending on the protocol) and -22% for DLP (+20% to -40%).

Conclusion: The updated national DRLs for CT are substantially lower compared to the previous DRLs demonstrating the efforts of the radiological community in Switzerland to lower CT radiation exposure.

Exposure levels from radiology procedures used in myeloma diagnostics

L. Weber¹, J. Kristiansson¹, M. Hansson¹, R. Siemund¹, H. Geijer², M. Geijer¹; ¹Lund/SE, ²Örebro/SE (lars.weber@skane.se)

Purpose: Myeloma diagnostics have traditionally been performed using a radiographic skeletal survey. CT scanning has been suggested as a replacement and has been introduced in our institution. Effective doses have been reported in the literature, without correlation with body mass index (BMI). We have evaluated the effective doses imparted to the patients during this procedure.

Methods and Materials: Length, weight and dose-length product were collected for each patient and CT examination. Conversion factors based on BMI were generated using Monte Carlo-based simulations on voxel-based phantoms (n=5). For each phantom size a sex- and BMI-specific conversion factor was generated. Subsequently, individual conversion factors were generated through exponential curve fitting. Finally, the effective dose was calculated for each patient based on sex and BMI.

Results: The sex-averaged conversion factors for underweight, normal weight and obese patients (BMI = 18, 21 and 25, respectively) were 0.011, 0.011 and 0.010 mSv/mGycm, respectively. The median effective dose for a scan length from the top of the head to the knees was 5.1 mSv (n=256, range = [2.7, 12.6]) for all patients. Dose levels in our institution are comparable with published data but higher than that for conventional skeletal imaging.

Conclusion: CT scanning for myeloma diagnostics in our institution showed higher doses than have been published for conventional skeletal imaging but is still comparable to other investigations of this methodology. The advantages in terms of shorter examination times are perceived to be positive for the predominantly elderly patients where dose concerns are of less importance.

B-1198 11:35

A method to optimize DSA clinical protocols

V. Ravaglia, G. Venturi, N. Scrittori, S. Farnedi; Ravenna/IT (valentina.ravaglia@auslromagna.it)

Purpose: To optimize DSA vascular protocols using an objective method of evaluation, in terms of a figure of merit (FOM) that correlates patient entrance dose (ED) and image quality.

Methods and Materials: Measurements were performed on a Philips AlluraClarity FD20 angiographic system for 7 different clinical peripheral protocols. Exposure parameters and added filtrations F1, F2 and F3 (1 mm Al + respectively, 0.1, 0.4 and 0.9 mm Cu) were automatically selected by AEC. A dedicated DSA phantom with Al strips simulating vessels was imaged and ED was simultaneously measured. To evaluate image quality we measured and averaged the SNR on different subtracted images. A FOM was calculated as the ratio between SNR² and ED. We also evaluated "low-dose" protocols, obtained adding Cu filters at tube exit.

Results: AEC selected only 3 different configurations: C₁ (68kV and F2), C₂ (80kV and F1) and C₃ (65kV and F1) with ED per frame, respectively, 1.93, 2.87 and 2.29 mGy/min. ED per frame for C_{2-low} (80kV and F2) and C_{3-low} (65kV and F2) was 1.34 and 1.14 mGy/min. As example, we reported SNR and FOM (nGy/frame) for the thicker strip for clinical and "low-dose" protocols: C₁ 1.83 and 1727.7, C₂ 2.09 and 1514.0, C_{2-low} 2.20 and 3603.7, C₃ 1.25 and 687.7 and C_{3-low} 1.42 and 1763.5, respectively.

Conclusion: Among clinical protocols, the lower ED and higher FOM was for C₁, the unique configuration with F2. Even for other protocols, F2 reduces the dose but not the SNR, resulting in a higher FOM.

B-1199 11:43

Tissue equivalency in radiopaque 3D printing of patient phantoms over a wide range of radiation energies - applications in imaging and dosimetry

F.B. Schwarz, M. Ziegert, B. Hamm, M. Scheel, P. Jahnke; Berlin/DE (felix-benjamin.schwarz@charite.de)

Purpose: Radiopaque 3D Printing (R3P) is a method to produce patient specific phantoms with detailed anatomy, but was so far only demonstrated with iodine enhanced ink. The purpose of this work was to further develop R3P towards tissue equivalent phantoms.

Methods and Materials: Radiopaque inks were designed corresponding to the attenuation coefficients of human tissues over an energy range of 10 keV to 100 MeV. CT images were printed on single-side adhesive-coated paper with inkjet technology. The printed paper sheets were stacked, bonded together, and laser cut to shape, resulting in stable phantoms. Using a phantom manufactured from a CT data set of a porcine specimen, Hounsfield units (HU) and absolute dose measurements were compared against porcine tissue. In addition, tissue equivalent anthropomorphic breast phantoms were manufactured and evaluated in mammography and digital breast tomosynthesis (DBT).

Results: Linear attenuation coefficients of the developed materials had a mean deviation from human tissue by <3% over the entire energy range. HU showed similar energy dependency for the tissue equivalent phantom as for porcine tissue, with low energy influence on soft tissue and decreasing HU with increasing radiation energy for bone tissue. Dose measurements did not differ significantly between the phantom and the porcine sample when HU were adjusted. The breast phantoms provided realistic images and dose values in mammography and DBT.

Conclusion: Radiopaque 3D printing with tissue equivalent materials yields realistic patient phantoms for application over a wide range of diagnostic and therapeutic energies, including spectral CT and absolute dosimetry.

Should testing for lead contamination be included in lead radiation protection apparel quality control?

M. Barati¹, R. Illing², L. Kardos², C. Paraskevopoulou¹, K. Katsari¹; ¹Amsterdam/NL, ²Budapest/HU (milan.barati@affidea.hu)

Purpose: Lead Radiation Protection Apparel (RPA) is routinely used for radiation protection of patients, accompanying persons and personnel during diagnostic and interventional procedures. In 2017 an article, 'Lead Aprons are a Lead Exposure Hazard' was published, suggesting the addition of lead dust testing to the quality control (QC) process. The aim of this study was to assess whether this test should be included in our own process.

Methods and Materials: The QC program was performed on 212 RPAs from 11 Affidea centers in Hungary. RPA condition was evaluated through visual/tactile inspection and imaging. 'Damaged' is defined for aprons with defects >15mm² on parts shielding critical organs or defects >670mm² on any other area; collars/gonad shields with defects >11mm². 'Passed with limitations' includes all RPA with defects not greater than these criteria. RPA with no defects were 'passed'. LeadCheck (3M) colorimetry was used to test for lead dust.

Results: 84% RPA 'passed' QC, 9% 'passed with limitations' and 7% were 'damaged'. All RPA 'damaged' and 'passed with limitations' and 15% of 'passed' were tested for lead dust. 43% of 'damaged' RPA, 11% of 'passed with limitations' and 4% of 'passed' were found contaminated. Contaminated RPAs were cleaned, retested and found negative for lead dust.

Conclusion: Results prove the importance of lead dust assessment as part of QC. Further investigation of the reappearance of lead dust must be undertaken to establish the frequency of cleaning.

Comparison of quantitative regional perfusion-weighted phase resolved functional lung (PREFUL) MRI with pulmonary perfusion DCE-MRI in COPD patients

T.F. Kaireit¹, A. Voskrebenez¹, M. Gutberlet¹, J. Freise¹, B. Jobst², H.-U. Kauczor², T. Welte¹, F. Wacker¹, J. Vogel-Claussen¹; ¹Hannover/DE, ²Heidelberg/DE (till.kaireit@me.com)

Purpose: Perfusion-weighted non-contrast enhanced proton lung MRI during free breathing is maturing as a novel technique for assessment of regional lung perfusion, but has yet not been validated in COPD patients. The goal of this study was to determine if phase-resolved functional lung (PREFUL-) MRI correlates with dynamic contrast enhanced (DCE-)MRI as established reference and lung function testing.

Methods and Materials: Forty-seven patients with stable COPD were included as a single center subgroup analysis nested in the German COPD cohort study COSYCONET - a prospective, observational, multicenter cohort. For PREFUL-MRI a spoiled gradient echo sequence and for DCE-MRI a contrast-enhanced three-dimensional time-resolved spoiled gradient echo sequence was used at 1.5T. Slices of PREFUL and DCE-MRI were matched using a landmark based approach and co-registered. Perfusion defect percentages (QDP) were calculated for both methods and correlated with each other and lung function testing using Spearman's correlation coefficient (r), spatial overlap metrics and Bland-Altman plot analysis.

Results: PREFUL-MRI and DCE-MRI matched spatially with a spatial overlap of 62.2(57.2-67.2)%. QDP were comparable on a global 39.3(31.8-45.5)% vs. 44.7(35.4-50.0)%) as well as on a lobar level, although a systematic overestimation of PREFUL-QDP compared to PBF-QDP mainly in the lower lobes resulted in an overall overestimation for the whole lung with a mean difference of 5%(95% confidence interval [CI]: 3.0%;7.0%). Significant

correlations with lung function test parameters was found for both methods, such as PREFUL-QDP vs. FEV1, $r=-0.75$, $P<0.0001$.

Conclusion: PREFUL-MRI is a promising noninvasive, radiation-free tool for quantification of regional perfusion in COPD patients.

B-1202 10:38

Fully automated 3D quantification of the lung emphysema in COPD using 3D-UTE MRI

I. [Benlala](#), P. Berger, P.O. Girodet, C. Dromer, J. Macey, F. Laurent, G. Dournes; *Pessac/FR*

Purpose: To develop and validate a fully automated 3D quantification of emphysema extent in COPD patients using 3D-MRI with ultrashort echo time (UTE).

Methods and Materials: Twenty-nine COPD patients (21 males/ 8 females, age 70±7 years) and 11 healthy volunteers (10 males/1 female, age 64±4 years) were prospectively enrolled between 2014 and 2017. All patients underwent pulmonary function test, 3D-UTE MRI at millimetre spatial resolution (voxel size=1mm³) and MDCT scan the same day. Two readers experienced in chest imaging performed the evaluation. 3D automatic quantification of relative low signal area (LSA%) and relative low attenuation area (LAA%_{<-950HU}) were measured as a surrogate for emphysema using 3D-UTE MRI and MDCT, respectively. Skewness of lung MR frequency distribution histogram was also determined. Comparison of means was performed using t-test and correlation using Pearson test. Reproducibility was assessed using Lin's concordance correlation coefficient.

Results: Using 3D-UTE, LSA% was significantly higher in COPD patients than in healthy volunteers ($p<0.001$). Skewness of lung MR frequency distribution histogram was significantly right tailed towards the lowest signal values in COPD ($p<0.001$). In 29 COPD patients, both LSA% and skewness correlated well with LAA%_{<-950HU} ($r=0.77$, $p<0.001$; $r=0.87$, $p<0.001$, respectively) and FEV1 ($r=-0.43$, $p=0.01$; $r=-0.55$, $p<0.001$, respectively). Intra and inter-observer reproducibility of both LSA% and skewness were found perfect using Lin's concordance correlation coefficient ($\rho_c>0.99$).

Conclusion: 3D automatic quantification of the lung emphysema is feasible and reproducible using non-contrast enhanced 3D-UTE MRI and may prove useful in the follow-up of COPD patients without radiation exposure.

B-1203 10:46

Comparison of quantitative capability among DWI with FASE and EPI sequences at 1.5T or 3T systems and FDG-PET/CT: for differentiating malignant from benign solitary pulmonary nodules

Y. [Ohno](#)¹, M. [Yui](#)², H. [Lee](#)³, H. [Koyama](#)⁴, Y. [Kishida](#)¹, S. [Seki](#)¹, T. [Yoshikawa](#)¹, Y. [Kassai](#)², T. [Murakami](#)¹; ¹Kobe/JP, ²Otawara/JP, ³Seoul/KR, ⁴Osaka/JP (yosirad@kobe-u.ac.jp)

Purpose: To directly and prospectively compare the quantitative capability for diagnosis of solitary pulmonary nodules (SPNs) among diffusion-weighted imaging (DWI) with fast advanced spin-echo (FASE) and echo planar imaging (EPI) sequences in a 3T system, DWI with EPI sequence at a 1.5T system and FDG-PET/CT.

Methods and Materials: 97 consecutive patients with 129 SPNs underwent DWIs with FASE and/or EPI sequences at 3T and 1.5T systems, FDG-PET/CT, and pathological and/or follow-up examinations. According to final diagnoses, all SPNs were divided into malignant (n=87) and benign (n=42) SPNs. In each lesion, apparent diffusion coefficients (ADCs) from all DWIs (ADC_{3TFASE}, ADC_{3TEPI} and ADC_{1.5TEPI}) and SUV_{max} were assessed by ROI measurements. To compare all indexes between two groups, Student's t test was performed. Then ROC analyses were performed to compare diagnostic performance among all indexes. Finally, sensitivity, specificity and accuracy were compared among all methods by McNemar's test.

Results: There was significant difference of all indexes between two SPN groups ($p<0.0001$). ROC analyses showed area under the curve (Az) of ADC_{3TFASE} was significantly larger than that of others ($p<0.05$). Accuracy (Ac) of ADC_{3TFASE} (90.7%) was significantly higher than that of others (ADC_{1.5TEPI}: 84.4%, $p=0.008$; ADC_{3TEPI}: 82.9%, $p=0.002$; SUV_{max} 75.2%, $p<0.0001$).

Conclusion: DWIs with FASE sequence has a better potential for quantitative diagnosis of SPNs than DWI with EPI sequence at 1.5T and 3T systems and FDG-PET/CT. FASE sequence would be better to be applied for DWI at 3T system to improve diagnostic performance of SPNs.

B-1204 10:54

Paediatric Hodgkin's and non-Hodgkin's lymphoma on chest MRI: do we really need intravenous contrast agent?

C.T. [Arendt](#), M. [Beeres](#), D. [Leithner](#), P. [Tischendorf](#), M.C. [Langenbach](#), B. [Kaltenbach](#), T.J. [Vogl](#), T. [Gruber-Rouh](#); *Frankfurt a. Main/DE* (art.arendt@gmail.com)

Purpose: Increasing awareness of potential short- and long-term side effects from gadolinium-based contrast agents has underlined the need for contrast-free MR imaging. The aim of this study was to determine whether the intravenous administration of contrast media is necessary for thoracic imaging in children and adolescents with lymphoma.

Methods and Materials: Patients under 25 years of age who underwent histopathological examination of thoracic lymph nodes and at least one chest MRI with unenhanced and contrast-enhanced sequences (Jan 2010 - Oct 2016) were enrolled in this monocentric, retrospective study. Seven different thoracic lymph node stations, including mediastinal, hilar, periclavicular and axillar regions, were evaluated by two readers regarding lesion diameter, number, shape, necrosis and infiltration of surrounding structures. Findings were categorized into suspicious (>1 cm; round; necrosis; infiltration) and unsuspecting.

Results: 51 consecutive patients (mean age, 16.0 yrs; age range, 4-23 yrs; 60.8% male) with histologically proven diagnosis of thoracic Hodgkin's (70.6%) and Non-Hodgkin's lymphoma (25.5%) and lymphadenopathy (3.9%) were retrospectively included. 236 examinations were analysed, 36 study participants received additional follow-up studies (average number, 4.7; range, 1-15). Most lymph nodes categorized as suspicious were located in the mediastinum (89.5%). High agreement (lowest $\kappa=0.88$) between unenhanced and contrast-enhanced sequences was found for both suspicious and unsuspecting lymph nodes. The only significant difference was observed in sizing mediastinal lymph nodes with a deviation of 1mm ($p<0.001$; all other $p>0.05$).

Conclusion: Staging and disease surveillance in young patients with thoracic lymphoma can be safely done without contrast agent.

B-1205 11:02

Differentiation of inflammatory and fibrotic ground-glass opacity (GGO) with MRI: a pilot study

C. [Romei](#)¹, L. [Turturici](#)¹, L. [Tavanti](#)¹, M. [Marletta](#)¹, P. [Wielopolski](#)², S. [Colagrande](#)³, D. [Caramella](#)¹, F. [Falaschi](#)¹, P. [Ciet](#)²; ¹Pisa/IT, ²Rotterdam/NL, ³Florence/IT (chiara.romei@gmail.com)

Purpose: To differentiate fibrotic and inflammatory GGO using T2-weighted (T2-w) and contrast-enhanced MRI (CEMRI).

Methods and Materials: After consent, 3 patients with IPF/NSIP underwent CT and MRI on the same day, which were repeated after 6-month-therapy. MRI consisted of 3D-SPGR-PD-w, 2D-PROPELLER, 3D-CUBE-T2-w and CEMRI acquired at 5-10-20 minutes. Two main radiological interstitial lung disease (ILD) features were quantitatively scored with PRAGMA-ILD on MRI: Fibrotic (FL) and Normal Lung (NL) tissue. FL included all fibrosis-related changes (honeycombing, reticulation, GGO). Data were expressed as ml and % total lung volume. MRI data were compared with CT data scored with CALIPER-software and clinical data. Based on T2-w signal intensity (SI) and CEMRI, FL was classified as inflammatory. Statistic included Pearson correlation and Mann-Whitney-U test.

Results: MRI-score had excellent correlation with CALIPER ($r=0.97$, $p<0.00001$). MRI-score overestimated fibrosis (mean-difference 15.3 % SD 7.5 %) and underestimated normal lung (mean-difference 17.8 SD 7.5) compared to CT. 4/9 ROIs showed significant difference in T2-w SI and were labelled as inflammatory. The mean SI differences FL were 106.8 (SD 32.1) and 2.1 (SD 34.4) for the inflammatory and the stable ROI, respectively. Inflammatory ROIs had higher SI difference than stable ROI between baseline and follow-up ($p<0.0001$). Two inflammatory areas, as expected in the NSIP, evolved in fibrotic tissue. CEMRI showed rapid peak of enhancement in the FL suspicious for active inflammation.

Conclusion: In our pilot study ILD morphological changes can be reliably be quantified with MRI. T2-w SI and CEMRI can identify inflammation area and their evolution during ILD therapy.

B-1206 11:10

What is the contribution of MR spectroscopy in the differential diagnosis of solitary pulmonary masses?

A. [Hekimoglu](#), O. [Ergun](#), A. [Turan](#), T.T. [Turkmenoglu](#), B. [Hekimoglu](#); *Ankara/TR* (azadhekimoglu@gmail.com)

Purpose: The aim of our study was to evaluate the availability of Magnetic Resonance Spectroscopy (MRS), which is a non-invasive method for the differentiation of benign or malignant pulmonary masses.

Methods and Materials: A total of 59 patients (45 male, 14 female) with pulmonary masses were included in this prospective study. MRS was applied to the pulmonary lesions of the patients. Cholin (Cho), lipid and H₂O parameters were determined in TE 50, 135 and 270 bands in MRS. Afterwards CT-guided percutaneous needle biopsy was performed. According to the biopsy results, pulmonary masses in 25 patients were benign and pulmonary masses in 34 patients were malignant.

Results: Cho, Cho/H₂O and Cho/lipid levels were significantly higher in TE 50 band in malignant group compared to benign group ($p < 0.001$, $p = 0.011$ and $p < 0.001$). Cho, Cho/H₂O and Cho/lipid levels were significantly higher in TE 135 band in malignant group compared to benign group ($p < 0.001$, $p = 0.012$ and $p = 0.012$). Cho and lipid levels were significantly higher in TE 270 band in malignant group compared to benign group ($p = 0.050$ and $p = 0.013$).

Conclusion: When the other conditions were kept constant, the probability of malignancy was increased significantly 17.381 times (95% CI: 3.779-79.932) in those with Cho levels above 1.65 compared to those with Cho levels below 1.65 in the TE 50 band ($p < 0.001$). In conclusion, MRS can be used in the differential diagnosis of pulmonary masses.

B-1207 11:18

Imaging of thymic lesions in patients with myasthenia gravis: is dual energy CT superior to MRI?

N. Rajamohan, R. Sharma, K. Devasenathipathy, A. Goyal, A.S. Bhalla, R. Parshad, D. Jain; *New Delhi/IN (naveenrajamohan@gmail.com)*

Purpose: To compare imaging parameters of Dual energy CT (DECT) with MRI for differentiating Thymoma from Thymic Hyperplasia (TH) and correlate the imaging findings of thymoma with the WHO grade & Masaoka Koga (MK) stage among patients with Myasthenia Gravis (MG).

Methods and Materials: Fifty-four patients of MG were recruited and underwent a single venous phase DECT ($n=29$), a Dynamic Contrast Enhanced MRI (1.5T, $n=41$) or both ($n=23$). Based on the histopathology they were divided into two groups (i) Thymoma ($n=27$) & (ii) Thymic hyperplasia ($n=18$), while patients with normal thymus glands ($n=9$) were excluded. Statistical analysis was performed between the two groups for DECT and MRI.

Results: Quantitative MRI parameters including Signal intensity index (SII) and Chemical Shift Ratio (CSR) showed a sensitivity & specificity of 47%/75% and 65%/86% respectively for detecting thymoma, at present published cutoff values (SII<7.77, CSR>0.849). Using ROC analysis, we propose a cutoff for SII<38% & CSR>0.75 which improves the sensitivity and specificity to 65%/68% & 89%/86% respectively. Quantitative DECT parameters using our proposed cutoffs for attenuation on Virtual Non-Contrast image (>33.3 HU) and Venous Phase (>51.3 HU), & fat fraction (<17.8%) showed a sensitivity and specificity of 100%/100%, 89.9%/90.9%, & 100%/100% respectively. DECT was also superior to MRI in predicting WHO grade, however no quantitative parameter on either DECT or MRI could differentiate the MK stages.

Conclusion: DECT has the potential to provide equal if not greater information than MRI for characterizing thymic lesions in patients with MG, however further validation is required.

B-1208 11:26

Lung volumes and its association with subclinical impairment in whole-body MR imaging

R. von Krüchten¹, R. Lorbeer², C. Schuppert¹, H. Schulz³, H.-U. Kauczor¹, A. Peters³, S. Karrasch², F. Bamberg⁴, C. Schlett¹; ¹Heidelberg/DE, ²Munich/DE, ³Neuherberg/DE, ⁴Freiburg/DE (rvkruechten@gmx.de)

Purpose: A substudy of 400 whole-body MRI scans from the KORA-FF4 cohort showed good correlation between MRI-derived lung volumes and residual volume derived by pulmonary function tests and chronic obstructive pulmonary disease (COPD). As cardiac dysfunction often accompanies COPD, we aimed to evaluate this relationship using whole-body MRI.

Methods and Materials: 400 subjects without cardiovascular diseases from the KORA-FF4 cohort study underwent whole-body MRI. Pulmonary volumes were derived from coronal T1w-sequences. Cardiac function was assessed from cine-SSFP sequences using cvi42, and LV filling rates were assessed using pyHeart (in-house developed). Cardiac function parameters were standardized to body surface area, and its association to lung volume was analyzed using Pearson correlation and multivariate linear regression models.

Results: MRI parameters were available for 356 subjects (56.4±9.2 years). Cardiac measurements were within the normal physiologic range, and the mean lung volume was 4.0±1.1L. In a univariate model, left ventricle (LV) and right ventricle (RV) stroke volume were negatively correlated to lung volume. After multivariate adjustment, stroke volume as well as end-diastolic volume from LV ($\beta = -2.75$, $p = 0.001$; $\beta = -1.71$, $p = 0.001$) and RV ($\beta = -2.14$, $p = 0.02$; $\beta = -1.45$, $p = 0.004$) were negatively associated with lung volume. Myocardial mass, peak ejection rate and ejection fraction were not associated with lung volumes. For LV, the early diastolic filling rate was negatively associated with lung volume ($\beta = -17.3$, $p = 0.006$; $\beta = -11$, $p = 0.08$).

Conclusion: Using whole-body MRI, we observed an association between lung volume and biventricular end-diastolic and stroke volume, as well as LV filling rates, indicating potential for early detection of subclinical cardiac impairment.

B-1209 11:34

Multi-parametric approach among CEST imaging, DWI and FDG-PET/CT for diagnosis of solitary pulmonary nodule

Y. Ohno¹, M. Yui², Y. Kishida¹, S. Seki¹, T. Yoshikawa¹, T. Murakami¹; ¹Kobe/JP, ²Otawara/JP (yosirad@kobe-u.ac.jp)

Purpose: To determine the capability of multi-parametric approach among chemical exchange saturation transfer (CEST) imaging, diffusion-weighted imaging (DWI), and FDG-PET/CT for diagnosis of solitary pulmonary nodules (SPNs).

Methods and Materials: 113 consecutive patients with 122 SPNs underwent CEST imaging and DWI at a 3T MR system, FDG-PET/CT, and pathological and/or follow-up examinations. According to final diagnoses, all SPNs were divided into malignant ($n=76$) and benign ($n=46$) SPNs. In each patient, magnetization transfer ratio asymmetry (MTR_{asym}) was calculated from z-spectra at 3.5ppm in each pixel, and MTR_{asym} map was computationally generated from CEST data. In each lesion, MTR_{asym} , apparent diffusion coefficient (ADC) and SUV_{max} were assessed by ROI measurements. To compare all indexes between two groups, Student's t test was performed. Then ROC analyses were performed to compare diagnostic performance among all indexes as well as combined methods. Finally, sensitivity, specificity and accuracy were compared among all methods by McNemar's.

Results: Each index had significant difference between malignant and benign SPNs ($p < 0.05$). ROC analyses showed area under the curve (Az) of combined method (Az=0.92) was significantly larger than that of SUV_{max} (Az=0.77, $p < 0.05$). Sensitivity (SE) and accuracy (AC) of combined methods (SE: 85.5 [65/76]%, AC: 85.2 [104/122]%) were significantly higher than those of SUV_{max} (SE: 64.5 [49/76]%, $p < 0.05$; AC: 71.3 [87/122]%, $p < 0.05$).

Conclusion: Multiparametric approach among CEST, DWI and PET/CT has a significantly better potential for diagnosis of SPNs than PET/CT.

Potential of a machine learning model for dose optimisation in chest CT quality assurance

C. Rubbert¹, A. Meineke², L.M. Sawicki¹, Y. Klosterkemper¹, G. Antoch¹, J. Boos¹; ¹Düsseldorf/DE, ²Berlin/DE (Johannes.Boos@med.uni-duesseldorf.de)

Purpose: To evaluate the feasibility of machine learning (ML) for detection of dose optimisation potential in quality assurance of chest CT in a retrospective, cross-sectional study.

Methods and Materials: 3,199 chest CTs were used for training and testing of the neural network (01/2016-12/2017, 61% male, 62±15 years, 80/20 split). The model was optimised and trained to predict the volumetric computed tomography dose index ($CTDI_{vol}$) on scan and patient metrics (scanner, study description, protocol, patient age, sex and water-equivalent diameter (D_w)). The root mean-squared error (RMSE) was calculated as performance measurement. A validation dataset of 100 separate, consecutive examinations (01/2018, 60% male, 63±16 years) was independently reviewed by two blinded radiologists for dose optimisation potential and used to define an optimal cutoff.

Results: RMSE was 1.71, 1.45 and 1.52 for the training, test and validation datasets, respectively. CT scanner and D_w were the most important features. The radiologists found dose optimisation potential in 7/100 of the validation cases. A percentage deviation of 18.3% between predicted and actual $CTDI_{vol}$ was found to be the optimal cutoff. 8/100 cases were flagged by the model (range 18.3-53.2%), including all cases flagged by the radiologists. In the false-positive case, the model predicted a 33% lower $CTDI_{vol}$, which was due to a severe soft tissue emphysema leading to a very small D_w .

Conclusion: ML can comprehensively detect chest CT examinations with dose optimisation potential; however, a final human review is mandatory. A deviation of $\geq 18.3\%$ between the predicted and actual $CTDI_{vol}$ seems adequate for CT quality assurance.

AI-powered detection of pulmonary embolism in CT pulmonary angiograms: a validation study of the diagnostic performance of prototype algorithms

T.J. Weikert, D.J. Winkel, J. Bremerich, B. Stieltjes, A.W. Sauter, G. Sommer; Basel/CH (thomasjohannes.weikert@usb.ch)

Purpose: To validate the performance of deep convolutional neural networks optimised for the detection of pulmonary embolism (PE) on CT pulmonary angiograms (CTPAs).

Methods and Materials: We downloaded all CTPAs performed in 2017 along with the corresponding reports (n = 1,499) from our RIS/PACS archive using an in-house-developed search engine. The reports were manually reviewed by a radiologist. CTPAs with other clinical questions than PE or poor diagnostic quality were excluded. The remaining exams were then classified into positive (n = 232) and negative (n = 1,204) for PE. All emboli in positive exams were labeled by a radiologist using bounding boxes. The data served as ground truth for the validation of prototype algorithms (Aidoc, Tel Aviv, Israel) that had previously been trained on 28,000 independent CTPAs from other centres.

Results: Four trained prototype algorithms were tested on our CTPA dataset. The best performing algorithm was a fully convolutional neural network with a backbone based on the Resnet architecture. It achieved a sensitivity of 93% and a specificity of 95%. This corresponds to a positive predictive value of 77%.

Conclusion: The best-performing AI algorithm we validated is capable of detecting pulmonary embolism in CTPAs with a high sensitivity and specificity. In a clinical setting, this can complement conventional workflows with a worklist prioritisation and has the potential to improve the quality of healthcare by accelerating the diagnostic process and communication. We plan to further test the algorithm and finally implement it in the clinical routine to perform prospective evaluations.

Diagnostic accuracy of combined CCTA and low-dose dynamic stress CT myocardial perfusion with a whole-heart coverage CT scanner in patients with suspected CAD

A. Baggiano¹, M. Guglielmo¹, G. Muscogiuri¹, M. Soldi¹, A. Del Torto¹, A.I. Guaricci², M. Pepi¹, G. Pontone¹; ¹Milan/IT, ²Bari/IT (andrea.baggiano@gmail.com)

Purpose: Our purpose is to test the diagnostic accuracy of integrated evaluation of cCTA plus dynamic myocardial stress-CTP with low-dose protocol using a whole-heart coverage CT scanner as compared to ICA plus invasive FFR.

Methods and Materials: Eighty-five consecutive symptomatic patients scheduled for ICA were prospectively enrolled. All patients underwent rest cCTA followed by stress dynamic CTP with a whole-heart coverage CT scanner (Revolution CT, GE Healthcare, Milwaukee, Wisconsin). Diagnostic accuracy and overall effective dose were assessed and compared to ICA and invasive FFR.

Results: The prevalence of obstructive CAD and functionally significant CAD were 69% and 44%, respectively. cCTA alone demonstrated a per-vessel and per-patient sensitivity, specificity, negative predictive value, positive predictive value, and accuracy of 83%, 66%, 89%, 54%, 71% and of 96%, 32%, 86%, 65%, and 68%, respectively. Combining cCTA with stress CTP, per-vessel and per-patient sensitivity, specificity, negative predictive value, positive predictive value, and accuracy were 71%, 86%, 86%, 72%, 81% and 88%, 75%, 82%, 82%, and 82%, with a significant improvement in specificity, positive predictive value, and accuracy in both models. The addition of stress CTP to cCTA improved the area under the curve from 0.82 to 0.87 (p=0.011) and from 0.78 to 0.87 (p<0.011) in a vessel and patient-based model, respectively. The mean ED for cCTA and stress CTP was 2.8 ± 1.2 and 5.3 ± 0.7 mSv, respectively.

Conclusion: The addition of dynamic stress CTP to coronary artery imaging by cCTA provides additional diagnostic accuracy with acceptable radiation exposure.

B-1213 10:38

The value of low-dose dynamic CT myocardial perfusion imaging for accurate evaluation of microvascular obstruction in patients with acute myocardial infarction

J. Zhang; Shanghai/CN (andrewssmu@msn.com)

Purpose: To investigate the diagnostic performance of quantitative parameters generated from dynamic CT myocardial perfusion imaging (MPI) for the assessment of acute myocardial infarction (AMI) and microvascular obstruction (MVO) with reference to cardiac magnetic resonance (CMR) imaging.

Methods and Materials: Patients with AMI and successful reperfusion treatment within 1 week were prospectively enrolled. All patients were referred for CMR imaging and dynamic CT-MPI on the same day. Various quantitative parameters and late iodine enhancement (LIE) were analysed for the evaluation of AMI and MVO with reference to CMR findings.

Results: Twenty-seven patients with 442 segments were ultimately included for analysis. The mean radiation dose for dynamic CT-MPI and LIE was 3.3 ± 1.1 mSv and 2 ± 0.6 mSv, respectively. MBF was significantly lower in MVO (+) segments compared to MVO (-) segments and reference segments (23.08±7.95 ml/min/100ml vs. 44.60±14.97 ml/min/100ml and 75.07±7.34 ml/min/100ml, both p<0.001). According to ROC curve analysis, MBF was found to have largest AUC among all parameters for identifying AMI with and without MVO as determined by LGE (AUC=0.941 and 0.996, both p<0.001). The diagnostic accuracy of MBF-based assessment for identifying MVO was 99.2%, which significantly outperformed other quantitative parameters and LIE. There was good correlation between the AMI area and MVO area estimated by MBF and LGE (r=0.95 and 0.99, both p< 0.001).

Conclusion: MBF derived from dynamic CT-MPI is accurate and outperforms other quantitative parameters and LIE for diagnosing AMI and MVO. The AMI and MVO area can also be accurately estimated by MBF.

B-1214 10:46

Characteristics of first-pass myocardial iodine distribution as assessed by dual layer CT with different injection protocols

S. Boccia¹, S.A. Si-Mohamed¹, M. Matzuzzi², B. Plaine², D.C. Rotzinger³, L. Hanquier², L. Boussel¹, D. Revel¹, P. Douek²; ¹Bron/FR, ²Lyon/FR, ³Lausanne/CH (sara.boccia@yahoo.com)

Purpose: To compare iodine distribution in healthy myocardium at first-pass perfusion imaging between two different contrast injection rates using dual-layer CT (DLCT).

Methods and Materials: Between January and July 2018, patients with clinically indicated coronary CT were randomized to undergo spectral coronary DLCT-angiography with different injection protocols. The two protocols were: 35mL in patients <80kg and 0.5mL/kg in patients >80 kg (maximum 45mL) at 2.5mL/sec (A) or double contrast dose at 5.0mL/sec (B). Patients with coronary stenosis >50% were excluded. Regions-of-interest were manually drawn on the 16 AHA standard myocardial segments. Iodine concentration was measured on 2-material decomposition (iodine-water) maps in mg/mL.

Results: 25 and 28 patients for protocol A and B were included, respectively. With median values of 1.37mg/mL (IQR=0.53) at 2.5ml/sec and 1.74mg/mL (IQR=1.04) at 5.0mL/sec the overall iodine concentration was significantly different (p<0.01). For group A no significant difference was found between the 16 segments (p=0.8), between basal, mid and apical segments (p=0.34) and between coronary territories (p=0.31). In group B the homogeneity of iodine concentration between the 16 segments and basal, mid and apical segments was at the limit (p=0.06 and p=0.07) while being significantly different between the territory of the LCX (median=2.03 mg/mL; IQR=1.06) vs LAD (median=1.63 mg/mL; IQR=0.92) and vs RCA (median=1.69 mg/mL; IQR=1.12) (p<0.01).

Conclusion: Iodine concentration in healthy myocardium obtained with DLCT was higher at faster injection rate and greater dose. Iodine myocardial distribution was homogeneous at lower injection rate. Conversely, significant differences between coronary territories at higher flow rates were found.

B-1215 10:54

Feasibility of extracellular volume quantification using dual-energy CT

M. van Assen¹, C.N. De Cecco², P. Sahbaee², P. Griffith², M.J. Bauer², A. Varga-Szemes², M. Oudkerk¹, R. Vliegenthart¹, U.J. Schoepf²; ¹Groningen/NL, ²Charleston, SC/US (griffith@muscc.edu)

Purpose: To assess the feasibility of dual-energy CT (DECT) to derive myocardial extracellular volume (ECV) and detect myocardial ECV differences without a non-contrast acquisition, compared to single-energy CT (SECT).

Methods and Materials: Subjects (n=35) with focal fibrosis (n=17), diffuse fibrosis (n=10), and controls (n=9) underwent non-contrast and delayed acquisitions to calculate SECT-ECV. DECT-ECV was calculated using the delayed acquisition and the derived virtual non-contrast images. In the control and diffuse fibrotic groups, the entire myocardium of the left ventricle was used to calculate ECV. Two ROIs were placed in the focal fibrotic group, one in normal and one in fibrotic myocardium.

Results: Median ECV was 33.4% (IQR, 30.1-37.4) using SECT and 34.9% (IQR, 31.2-39.2) using DECT ($p=0.401$). For both techniques, focal and diffuse fibrosis had significantly higher ECV values (all $p<0.021$) than normal myocardium. There was no systematic bias between DECT and SECT ($p=0.348$). SECT had a higher radiation dose (1.1mSv difference) than DECT ($p<0.001$).

Conclusion: ECV can be measured using a DECT approach with only a delayed acquisition. The DECT approach provides similar results at a lower radiation dose compared to SECT.

Cardiac CT in the quantification of myocardial extracellular volume fraction (ECV) with a semiautomatic method: comparison with cardiac MR

D. Vignale, A. Palmisano, A. Del Maschio, F. De Cobelli, A. Esposito; Milan/IT (vignale.davide@hsr.it)

Purpose: To assess the potential of cardiac CT in the quantification of extracellular volume fraction (ECV), a parameter with increasing diagnostic and prognostic role, in comparison to cardiac MR as the reference standard.

Methods and Materials: 14 patients affected by various diseases (3 idiopathic dilated cardiomyopathy, 3 CAD, 2 acute myocarditis, 2 chronic myocarditis, 1 hypertrophic cardiomyopathy, 1 amyloidosis, 2 no overt cardiac pathology) underwent cardiac CT including a delayed low-kilovoltage scan (10 minutes after contrast injection). The same patients underwent cardiac MR at 1.5 T with native and post-contrast T1 mapping. ECV-CT is defined as the quotient between the density difference of myocardium and the density difference of blood pool before and after contrast injection, weighted to the haematocrit. With MATLAB®, basal and late-phase CT images were co-registered to create a map of the heart ECV on a short-axis mid-ventricular slice. ECV-MR is defined as the quotient between the relaxivity difference of myocardium and blood pool before and after contrast injection, weighted to the haematocrit. With the same MATLAB® toolkit, we co-registered T1-native and T1-enhanced MR images to create a map of the heart ECV on the same slice used for CT. ECV-CT and ECV-MR maps were segmented to extract ECV values of LV septum and lateral wall.

Results: 28 ECV values were compared. ECV-CT range was 23.4-72.3% (mean $33.1\pm 10.0\%$). ECV-MR range was 25.3-75.2% (mean $34.2\pm 11.0\%$). Correlation between ECV-CT and ECV-MR was optimal ($r: 0.943$, $p<0.001$).

Conclusion: ECV can be semi-automatically extracted from cardiac CT datasets, with a good correlation with cardiac MR.

B-1217 11:10

AI-based prediction of haematocrit values from non-contrast CT imaging data - towards fully automated CT-derived myocardial extracellular volume fraction quantification

M.J. Bauer¹, M. van Assen², C.N. De Cecco¹, J.A. Durden¹, M. Scarabello³, H.T. Hudson¹, L. Griffith¹, A. Varga-Szemes¹, U.J. Schoepf¹; ¹Charleston, SC/US, ²Groningen/NL, ³Milan/IT (email@bauermaximilian.de)

Purpose: Imaging approaches for the quantification of the myocardial extracellular volume fraction (ECV) require the patient's haematocrit as an input variable. We assessed the performance of a fully automated, in-house developed artificial intelligence (AI) approach to predict haematocrit values from multiple patient- and acquisition-related variables in comparison to a linear regression (LR) model employing HU values alone.

Methods and Materials: A total of 286 patients that had undergone non-contrast cardiac CT and had haematocrit values determined via blood sampling within 2 days of the scan were retrospectively included. For each case, we measured HU values in the ascending aorta both manually and by a fully automated deep learning (DL) segmentation approach. A LR analysis was employed to model the relationship between HU values and laboratory haematocrit values. In addition, a total of 31 features on patient demographics, clinical history, and imaging parameters were extracted for the machine learning (ML) approach and used to train a linear Support Vector Machine (SVM) employing repeated, nested k-fold cross validation.

Results: The HU values obtained by the manual (mean 44.0 ± 3.7) and the DL segmentation approach (mean 44.3 ± 3) were in excellent agreement ($R^2=.95$). The LR approach demonstrated a weak relationship between the model and the laboratory haematocrit values ($R^2=.46$, $MAE=2.4\%$) while the ML approach resulted in a moderate relationship ($R^2=.59$, $MAE=1.8\%$).

Conclusion: The use of AI is a promising approach for the calculation of CT-derived haematocrit values that benefits from additional information and comes with immediate potential for fully-automated ECV quantification approaches.

Could "synthetic hematocrit value" has a use on ECV calculating via cardiac MRI? A single centre study

A. Erdemir, O. Öcal, T. Hazirolan; Ankara/TR (a.gurkan.erdemir@gmail.com)

Purpose: Currently, myocardial extracellular volume (ECV) can easily get calculated on cardiac magnetic resonance imaging (MRI), by using patient's hematocrit values acquired via blood sampling. However, sometimes blood sampling can be missed out which makes ECV calculating difficult. Synthetic ECV estimation, by synthetic hematocrit value, may make the ECV calculating process much more applicable and comfortable. The aim of this study is to investigate synthetic hematocrit values' validity on ECV estimating in our center's routine practice.

Methods and Materials: Between November 2017 - July 2018, 327 patients with cardiac MRI were reviewed. 61 patients who have appropriate imaging and blood sampling included to study. Whole basal, middle and apical segments' native ECV and synthetic ECV values were assessed via cardiac MRI. The results of each segments' synthetic values compared with each segments' native values using both "ANOVA" and "Interclass Correlation Coefficient" analysis.

Results: The values of both "synthetic hematocrit and synthetic ECV" were significantly reliable as compared with the values of both "native hematocrit and native ECV" regardless of cardiac segments. ($p<0.0001$). The results of both synthetic hematocrit and synthetic ECV values had above 0,80 interclass correlation and above 0,95 unstandardized coefficient for each segments.

Conclusion: Synthetic ECV values, acquired via synthetic ECV calculation, can be accepted as native ECV values in routine practice, regarding increasing both ECV estimation rates and patients comfort.

B-1219 11:26

Safety and diagnostic accuracy of regadenoson as vasodilator in stress perfusion cardiovascular magnetic resonance

A. Ezponda Casajús, M. Calvo Imirizaldu, A. García Baizán, A. Paternain Nuin, J.C. Pueyo Villoslada, J. Gavira, G. Bastarrika Alemañ; Pamplona/ES (aezponda@unav.es)

Purpose: To assess the safety and diagnostic accuracy of regadenoson as vasodilator in stress cardiovascular magnetic resonance (CMR) studies performed in individuals with known or suspected coronary artery disease (CAD).

Methods and Materials: We prospectively recruited 217 patients (159 men, mean age 65 ± 11.9 years, 26.7% diabetic) with known or suspected CAD who underwent stress-CRM. Examinations were acquired in a 1.5-Tesla MR system (MAGNETOM Aera, Siemens Healthineers) using an intravenous bolus of 0.4mg (5mL) of regadenoson. Vital signs were monitored at rest and under stress and clinical symptoms and adverse events induced by the vasodilator were collected. Test results were confirmed by conventional coronary angiography (CCA) when available.

Results: Most patients remained asymptomatic (49.3%). The most frequent symptoms were chest pain (18.9%) and dyspnoea (17.1%). All symptoms were transient and well-tolerated. During the stress, the average increase in heart rate (HR) was 24.3 ± 13.7 bpm and the mean decrease in systolic and diastolic blood pressure (SBP and DBP) was 7.0 ± 17.4 mmHg and 4.9 ± 10.2 mmHg, respectively. In the obese ($BMI\geq 30$; $n=51$) a statistically blunted HR (mean difference of -5.9 ± 2.1 ; $CI-10.1,-1.6$; $p=0.07$) and SBP responses (mean difference of 8.3 ± 2.8 ; $CI 2.8,13.7$; $p=0.03$) were noted. The DM group had a significantly higher HR at baseline (67.7 ± 19.9 vs 62.5 ± 15.5 bpm; $p=0.03$) and lower increase in HR (19.1 ± 9.3 vs 26.1 ± 14.5 bpm; $p=0.001$), whereas symptomatic patients showed a greater increase in HR (27.4 ± 11.2 vs 20.6 ± 10.7 bpm, $p=0.001$). Compared with CCA, regadenoson stress-CRM showed 94.9% sensitivity, 68.8% specificity, 88.1% positive and 84.6% negative predictive values to detect significant coronary stenosis.

Conclusion: Regadenoson is a well-tolerated and effective vasodilator that can be safely used in stress-CMR.

B-1220 11:34

Prognostic value of myocardial perfusion reserve index in patients with coronary microvascular disease: a multi-centre study

W. Zhou, M. Chai, W. Wong, P. Yap, Y. Lai, T. Lee, S. Leung, J. Lee, M.-Y. Ng; Hong Kong/HK (zwl1993@hku.hk)

Purpose: Coronary microvascular disease (CMD) is an established cause of stable chest pain in patients without obstructive coronary artery disease (OCAD). CMD identification by myocardial perfusion reserve index (MPRI) on stress cardiac magnetic resonance (StCMR) has been

demonstrated with a cut-off of 1.4. However, the prognostic value of MPRI identification of CMD has not been established.

Methods and Materials: 106 StCMR studies of symptomatic patients (50% male) without OCAD performed at three different MRI units since 2009 were analysed retrospectively. OCAD (i.e. >50% narrowing or fractional flow reserve <0.8) was excluded by catheter angiogram or CT coronary angiogram. MPRI was derived semi-quantitatively as upslope ratio of stress and rest myocardial perfusion signal intensity curve corrected for arterial input function. A MPRI <1.4 was classified as having CMD. Primary outcome was a combined major adverse cardiovascular event(MACE) of acute coronary syndrome, heart failure hospitalization and all-cause death.

Results: 54.7% patients had CMD. Reduced MPRI was associated with older age ($p=0.03$), female ($p=0.02$), diabetes ($p=0.01$), hypertension ($p=0.03$), and hyperlipidemia ($p=0.004$). Median follow-up was 5.75 years (CI:5.51-6.00) and 12.2% MACEs happened. CMD patients had worse prognosis compared to non-CMD patients (hazard ratio 3.29; CI 1.04-10.4; $p=0.04$). MPRI remained an independent prognostic marker (hazard ratio=0.066; CI 0.01-0.77; $p=0.03$) after adjusting age, gender, BSA, cardiovascular risk factors and ejection fraction.

Conclusion: Reduced MPRI is an independent predictor of MACE and provides future therapeutic developments in CMD patients.

B-1221 11:42

Modification of left ventricle myocardial perfusion reserve after the implantation of coronary sinus stent: a stress-rest CMR study

A. Palmisano, A. Esposito, G. Benedetti, F. Giannini, L. Baldetti, A. Del Maschio, F. De Cobelli; *Milan/IT (palmisano.anna@hsr.it)*

Purpose: The treatment of refractory angina is a challenge. The implantation of a hourglass shaped stent (Reducer) in the coronary sinus showed to improve symptoms, but objective data demonstrating the effect on myocardial perfusion reserve are lacking. Aim was to evaluate the modification in myocardial perfusion reserve occurring after Reducer implantation through stress-rest CMR.

Methods and Materials: 15 patients underwent 1.5 T CMR and clinical evaluation [Canadian Cardiovascular Society grading of angina pectoris (CCSA Class) and six minutes walking test (6minWT)] before and 3 months after Reducer implantation. CMR examinations included stress-rest first-pass perfusion and LGE. Segmental and global Myocardial Perfusion Reserve index (MPRI) were measured, also accounting for myocardial layer.

Results: Thirteen out of 15 patients reported an improvement ≥ 2 CCSA class ($p<0.0001$) and a 60% increase in the average distance during the 6minWT ($p=0.004$). Stress-CMR demonstrated an improvement of myocardial perfusion reserve [ischaemic burden per patient from 13% to 10.88%, $p=0.0092$; median MPRI from 1.2 (0.9-1.5) to 1.3 (1.1-1.7), $p<0.0001$; number of segments with inducible perfusion defects (IPDs) from 92/240(38%) to 69/240(29%); $p<0.001$]. MPRI improvement was largely greater in more ischaemic segments at baseline: segments with IPDs vs without IPDs (Δ MPRI: 0.432 vs 0.183; $p=0.0051$) and with baseline MPRI <1.3 vs ≥ 1.3 (Δ MPRI: 0.355 vs -0.036, $p<0.001$). Moreover, MPRI improved according with a transmural gradient from epicardium to endocardium (Δ MPRI 0.4057 vs 0.3156, $p=0.0282$).

Conclusion: Clinical benefit from CS Reducer implantation was associated with a significant improvement in myocardial perfusion reserve driven by the more ischaemic segments.

B-1222 11:50

Left ventricular subclinical myocardial dysfunction in uncomplicated type 2 diabetes mellitus is associated with impaired myocardial perfusion

X. Liu, Z.-G. Yang, Y.-K. Guo, Y. Ren, Y. Gao; *Chengdu/CN (liuxihsd@163.com)*

Purpose: This study aims to investigate the association between left ventricular (LV) myocardial deformation and microvascular perfusion using cardiovascular magnetic resonance (CMR) imaging in patients with type 2 diabetes mellitus (T2DM).

Methods and Materials: We recruited 71 T2DM patients and 30 healthy individuals; the T2DM patients were subdivided into newly diagnosed T2DM group ($n = 31$, with diabetes for ≤ 5 years) and longer term T2DM group ($n = 40$, with diabetes >5 years). LV deformation parameters, including global peak strain (PS), peak systolic strain rate (PSSR), and peak diastolic strain rate (PSDR), and myocardial perfusion parameters such as upslope, time to maximum signal intensity (TTM), and max signal intensity (Max SI) were measured and compared among the three groups. Pearson's correlation was used to evaluate the correlation between LV deformation and perfusion parameters.

Results: The longitudinal PS and PSSR were significantly decreased in longer term group compared to the newly diagnosed group or normal subjects. Pooled data from T2DM patients showed a decrease in global PDSR compared to healthy individuals, apart from lower upslope and Max SI. Further, TTM was significantly higher in the longer term group compared to the other two groups. We also show a significant correlation between decreased longitudinal PDSR and increased TTX in the T2DM patients ($r = 0.515$, $p < 0.001$).

Conclusion: Our results imply that a contrast-enhanced 3.0T CMR can detect subclinical myocardial dysfunction and impaired myocardial microvascular perfusion in the early stages of T2DM, and that the myocardial dysfunction is associated with impaired coronary microvascular perfusion.

Model-based iterative reconstruction: is it relevant for reducing radiation dose in paediatric head CT?

P.K. Atri, K.S. Sodhi, A. Bhatia, A.K. Saxena, N. Khandelwal; *Chandigarh/IN (sodhiks@gmail.com)*

Purpose: To evaluate the potential of model-based iterative reconstruction (MBIR) technique on dose reduction and image quality in children undergoing computed tomography (CT) head examinations.

Methods and Materials: This was a prospective study approved by the institutional ethics committee. Eighty-eight children (age range 5-16 years) with a history of seizures underwent contrast-enhanced CT scan. 41 children underwent CT study according to the MBIR technique while 47 children underwent CT head with the non-MBIR protocol. Images were reviewed by two paediatric radiologists, who were blinded, in a random order. Mean dose-length product, CT dose index (CTDI) volume and mean effective dose was recorded for both groups. Image quality, image noise and diagnostic acceptability of two image sets were also recorded. Student t test, Mann-Whitney U test, kappa test and chi-square tests were used for statistical analysis.

Results: In the MBIR group, the mean dose-length product was reduced by 79.8%; the mean CTDI volume was reduced by 88.5%, while the mean effective dose was reduced by 81% when compared to the non-MBIR group. No significant difference was seen in diagnostic acceptability, image noise and image quality between the two groups.

Conclusion: Model-based iterative reconstruction technique is highly effective in reducing radiation dose in paediatric head CT examinations without any significant difference in image quality, image noise, and diagnostic acceptability.

B-1225 10:38

A systematic quantitative morpho-volumetric analysis in infants with sagittal craniosynostosis and relationship with the severity of scaphocephalic deformity

M. Panfilii, R. Calandrelli, F. Pilato, C. Colosimo; *Rome/IT (panfilimarco@gmail.com)*

Purpose: In Isolated Sagittal Synostosis (ISS) the severity of head-shape deformity can vary significantly among affected individuals. This study aimed to assess skull base morphometry and intracranial volume related to the severity of scaphocephaly.

Methods and Materials: 68 infants with ISS were divided in three groups according to the severity of cranial deformity (group I: mild deformity; group II: moderate deformity; group III: severe deformity), by combining two scaphocephaly severity indexes as descriptors of the relation of three morphological measurements (length, width and height). High-resolution CT images were quantitatively analyzed. Dimensions of cranial fossae, supratentorial (ICV) and infratentorial (PCFV) cranial volume, supratentorial (WBV) and infratentorial (PCFBV) brain volume, ICV/WBV ratio; PCFV/PCFBV ratio, supratentorial and infratentorial cerebrospinal fluid volumes (CSF) were calculated.

Results: In all groups, anterior and middle skull base length was found increased while posterior hemifossae lengths (MO) were unaffected. In mild group ICV/WBV ratio was significantly different and ICV, WBV and CSF supratentorial volume resulted increased ($p < 0.05$) compared with other groups. In moderate and severe groups FCPV/FCPBV ratio and CSF infratentorial volume resulted reduced ($p < 0.05$); FCPBV was found increased only in the severe subgroup ($p < 0.05$).

Conclusion: This study provides new insights in understanding the compensatory changes that occur in scaphocephalic patients with different degrees of severity. In particular our study suggests that patients with severe scaphocephaly had an earlier loss of secondary compensatory changes with a cranial volume insufficient to accommodate the cerebral growth and this may suggest the need of a prompt cranial expansion.

B-1226 10:46

MRI patterns of brain injury in neonates with pathology-proven placental abruption

P.A. Caruso, K. Buch, S. Bates, D. Roberts; Boston, MA/US
(pcaruso@partners.org)

Purpose: It is conventionally held that the MRI pattern of brain injury in neonatal hypoxic ischaemic encephalopathy (HIE) in term babies is determined by the duration and severity of hypoxic ischaemic injury (HII). Severe HII results in central patterns of injury (CP) that predilect the periorlandic cortex, basal ganglia, and thalami; moderate HII results in peripheral patterns (PP) that involve watershed territories. Placental abruption (PA), the classic mechanism for acute profound HII, would expectedly produce a CP. The purpose of this study was to determine the frequency of CP in a non-hypothermia-treated neonate (NHTN) cohort with HIE and placental abruption.

Methods and Materials: Between 2005 and 2018, 14 NHTN with pathology-proven PA and clinically diagnosed HIE underwent brain MRI. Patterns of injury were classified as CP, PP, and mixed.

Results: There were 6 males and 8 females (mean gestational age 36.5 weeks; range 26-41 weeks). Pure CP was identified in zero patients. 5 patients had a mixed pattern of injury. 5 had a normal MRI. 2 patients had a PP. 1 patient showed an isolated venous thrombosis. 1 showed isolated infarct.

Conclusion: In our cohort of neonates with pathology-proven placental abruption, the expected central pattern was the least frequently observed. Of the abnormal MRIs, mixed patterns of injury were most frequent, and pure peripheral patterns of injury were observed. Additional patterns with venous thrombosis and infarction were also seen. The results of this study challenge the convention that placental abruption is usually associated with a central pattern of HII.

B-1227 10:54

Frequency of optic nerve involvement in paediatric intracranial germ cell tumours

K. Buch, O. Rapalino, N. Tarbell, T. Yock, S. MacDonald, P.A. Caruso; Boston, MA/US (kbuch@partners.org)

Purpose: Of the three most common paediatric sellar/suprasellar brain tumours (germ cell tumours, craniopharyngiomas, and optic pathway hypothalamic gliomas), optic nerve (ON) involvement is traditionally thought to be associated more specifically with optic pathway hypothalamic gliomas. ON involvement may, however, rarely be observed in intracranial germ cell tumours (GCT). ON involvement thus may influence need for biopsy and may impact radiation planning as targeted imaging of the ONs may not be routinely included in pretreatment planning of GCTs. The purpose of this study is to determine the frequency of ON involvement in a large cohort of patients with intracranial GCTs.

Methods and Materials: All patients with intracranial pure germinoma and nongerminomatous germ cell tumours (NGGCTs) treated at our institution with proton radiotherapy between 1998 and August 2018 were reviewed. Pre-treatment brain MRIs were evaluated for the presence of ON involvement.

Results: 101 patients were identified with intracranial GCTs, including 61 pure germinoma and 40 NGGCTs. Of these patients, six (6%) demonstrated ON involvement. In those with CN involvement, the median age at diagnosis was 15.5 years, most were female ($n = 4$), and the majority had histologically proven pure germinoma ($n = 5$).

Conclusion: ON involvement may be seen in paediatric GCTs and thus should not be considered a specific feature of optic pathway hypothalamic gliomas. Dedicated orbital and ON sequences should be considered for radiation planning as it is important to identify ON involvement prior to treatment and to adjust radiotherapy field appropriately to ensure full radiation dose.

B-1228 11:02

MRI findings in Christianson syndrome

P.A. Caruso¹, M. Pescosolido², K. Buch¹, E. Morrow²; ¹Boston, MA/US, ²Providence, RI/US (pcaruso@partners.org)

Purpose: Christianson syndrome (CS) OMIM 300243 is an x-linked disorder caused by mutation in the SLC9A6 gene OMIM 300231 characterised by intellectual disability, seizures, ataxia, microcephaly, and ophthalmoplegia. MRI findings in CS have been reported only rarely and as case reports. Our purpose is to present the spectrum of imaging findings in the largest cohort of independent CS pedigrees.

Methods and Materials: 14 male patients with the CS phenotype and genetically proven deleterious SLC9A6 mutations were recruited for evaluation. MRIs on all 14 patients were retrospectively reviewed by two neuroradiologists. Images were reviewed for cerebellar pattern of atrophy, cortical, white matter, and nuclear signal abnormality, and supratentorial white matter and hippocampal abnormalities.

Results: Cerebellar atrophy was seen in 7/14 (50%) patients with a unique pattern of cerebellar atrophy that predilects the inferior cerebellar lobules, gracilis and biventer (lobules VIIIm, VIIIaM, VIIIbM), and that results in high T2/FLAIR signal in the depths of the cerebellar fissures, in 5/14 (36%) patients. A dragonfly cerebellum was seen in 2/14 (14%). Dentate nuclear abnormal high T2 signal was seen in 6/14 (43%). 9/14 (64%) patients had occipital white matter lesions. Hippocampal abnormalities were seen in 5/14 (36%).

Conclusion: Cerebellar atrophy and occipital white matter lesions are frequently seen in CS. The pattern of cerebellar atrophy predilecting the inferior hemispheres seen in 36% of patients presents a unique MRI endophenotype that in the setting of intellectual disability, seizures, and microcephaly is strongly suggestive of CS and may be seen as a potential useful imaging biomarker.

B-1229 11:10

Deep medullary venous thrombosis in neonates correlates highly with the development of shunt-dependent hydrocephalus

K. Buch, S. Rincon, K. Krishnamoorthy, G. Gomboli, P.A. Caruso; Boston, MA/US (kbuch@partners.org)

Purpose: Deep medullary venous thrombosis (DMVT) in neonates may lead to shunt-dependent hydrocephalus (ShDH). While 10% of newborns with IVH from germinal epithelial bleeds (GEB) eventually require intraventricular shunts, the frequency of ShDH in neonates with IVH from DMVT remains unknown. Our purpose is to study a cohort of neonates with DMVT to determine if DMVT is a risk factor for ShDH.

Methods and Materials: Between 2006 and 2016, 27 neonates were found to have DMVT by MRI. DMVT was scored as mild involving 1-3 central veins, moderate 4-6, or severe, greater than 6. The extent of DMVT, presence of hydrocephalus, IVH, seizures, and frequency of progression to ShDH were recorded.

Results: 17 males and 10 females with a mean gestational age of 37 weeks (range 26-41 weeks) were included. The majority of neonates were scanned at 1-10 days of life (average = 10.2 days, range 0-66 days). 12 patients had mild DMVT, 10 moderate, and 5 severe. 21 patients had IVH that ranged from trace to severe. Hydrocephalus was observed in 13/27 (48%) patients. 5/27 (19%) of neonates developed ShDH and 5/21 (24%) of the neonates with DMVT and IVH developed ShDH.

Conclusion: The frequency of ShDH in neonates with IVH and DMVT is 24%, over twice as high as the frequency of ShDH in neonates with IVH from GEB. Awareness of this increased risk may indicate closer imaging surveillance in this group of neonates.

B-1230 11:18

Characterising resting-state networks in bilateral severe-to-profound sensorineural hearing loss infants within an early sensitive period

S. Wang, G. Fan; Shenyang/CN (jelly_66@126.com)

Purpose: The development of central auditory system has a sensitive period during the first few years of life. This study was aimed to characterize the patterns of resting-state functional network connectivity in infants with bilateral severe-to-profound sensorineural hearing loss (SNHL) within an early sensitive period.

Methods and Materials: 36 infants with bilateral severe-to-profound SNHL (mean age = 16 months, range 6-35 months) and 33 age and sex matched healthy controls were recruited for the present study based on referral for clinical MRI and other inclusion criteria. All subjects underwent 3.0T anatomical and resting-state functional MRI. Independent component analyses (ICA) was applied to identify 20 spatially distinct brain networks including auditory, visual, somatosensory, executive control, default-mode networks (DMN), cerebellar, and subcortical networks. Participant-level network maps were obtained using dual-regression and functional network connectivity (FNC) was used to test within- and between- network connectivity differences between patients with SNHL and typically developing infants.

Results: We find that infants with SNHL exhibit significantly stronger connectivity within auditory, DMN and executive control network. Trends were also observed for stronger connectivity in the cerebellum network. In addition, we observed significant differences in the amplitudes of between-network correlations, which involved auditory, visual and somatosensory networks.

Conclusion: These novel findings provide valuable insights into the characteristics of early brain reorganization and compensatory activation changes in congenital bilateral severe-to-profound SNHL infants within early sensitive period.

B-1231 11:26

MRI in the preoperative diagnosis of medulloblastoma: correlation with molecular subgrouping

N. Plakhotina¹, E. Vázquez², I. Delgado Alvarez², A. Sanchez-Montanez Garcia-Carpintero³, E. Martínez², A. Llorca², G. Burcet Rodríguez², J. Camacho²; ¹St. Petersburg/RU, ²Barcelona/ES, ³Tarragona/ES (plakhotinadezhda@gmail.com)

Purpose: To determine the value of MRI for diagnosing the various molecular subgroups of medulloblastoma.

Methods and Materials: A retrospective analysis was performed of MRI findings in 28 patients with medulloblastoma, examined between January 2010 and January 2018. There were 10 (35.7%) female and 18 (64.3%) male patients with a mean age of 4.7 years. All patients underwent MRI of brain, including conventional sequences, DWI, MR spectroscopy, ASL perfusion, and dynamic enhanced perfusion, as well as whole-spine MRI, including sagittal T1 sequences with and without gadolinium enhancement and sagittal DWI. Based on the molecular analysis results, tumors were divided into 3 groups: wingless (WNT), sonic hedgehog (SHH), non-WNT/non-SHH (joining groups 3 and 4) for the purposes of the study.

Results: All cases showed a taurine peak at a TE of 135 msec, which was approximately 4.14 ± 2.4 . A taurine peak was found at 30-msec TE in only 19 cases (67.8%); hence, we suggest that execution of a long TE is more effective for identifying the main marker of medulloblastoma. As a work in progress, the MRI features obtained using the advanced techniques, mainly perfusion and spectroscopy, are undergoing statistical analysis to determine which parameters are useful for predicting the various medulloblastoma molecular subgroups.

Conclusion: Since determination of the molecular subgroup is an important factor for oncologists choosing a treatment strategy with regard to relapses, leptomeningeal distribution, and survival, we consider it important to determine the MRI signs that help in the identification of subgroups before starting treatment in these patients.

B-1232 11:34

The additive value of diffusion-weighted imaging in the initial workup for paediatric head and neck lesions

A.E. Gabr, A. Nada, M. Gomaa, R.H. Hashem, A. Shokry; Cairo/EG (ahmed_elshenawy.nci@yahoo.com)

Purpose: To assess the role of diffusion-weighted MR imaging and ADC value in the initial assessment of paediatric cases presented with head or neck lesions and its capability for differentiating benign from malignant masses.

Methods and Materials: Between March 2016 and October 2017, 56 patients (39 male patients, 17 female patients) presented to the Paediatric Oncology Department of the National Cancer Institute with head and neck lesions. These patients were subjected to conventional MRI to get an accurate characterization of the lesions. Then diffusion-weighted imaging echo planar sequence was added to the conventional MR examination to evaluate the role of DWIs in the diagnosis and characterization of the masses. These lesions were correlated to histopathological findings of the available specimens through image-guided FNAC, true-cut biopsies or surgically excised specimens.

Results: This study included 56 patients, their ages range from 1 to 16 years with the mean age of 9.2 years. The mean ADC values of malignant, benign solid and benign cystic lesions were found to be $0.64 \times 10^{-3} \text{ mm}^2/\text{sec}$, $1.58 \times 10^{-3} \text{ mm}^2/\text{sec}$, and $2.10 \times 10^{-3} \text{ mm}^2/\text{sec}$, respectively. ADC value of $1.25 \times 10^{-3} \text{ mm}^2/\text{sec}$ was used as a threshold value for differentiation between malignant and benign lesions with sensitivity 100% and specificity 94.1%.

Conclusion: Our study concluded that DWI is a significant and non-invasive technique that can be reliably used for characterization of and differentiation between malignant and benign lesions of the head and neck regions.

B-1233 11:42

Evaluation of white matter maturation in children with developmental delay using diffusion tensor imaging (DTI)

A. Yap, K. Rahmat, R. Muridan, P. Seow, C. Fong, L. Ong, L. Tan, N. Ramli; Kuala Lumpur/MY (katt_xr2000@yahoo.com)

Purpose: This study assessed the white matter maturation using diffusion tensor imaging (DTI) in paediatric patients with developmental delay to imply delayed white matter tract maturation.

Methods and Materials: Nineteen developmental delayed children and twenty-five neurodevelopmentally healthy children underwent MRI and cross sectional DTI scans. The developmental assessment of all the subjects was then performed. An automated processing pipeline for the white matter tracts assessment was comprised of DTI data pre-processing, image registration, DTI analysis and evaluation of tracts was implemented. Spearman test was used to establish correlations between the DTI metrics and developmental delay components.

Results: The results obtained from the developmental delayed group were compared with age-matched healthy group. Findings showed that majority of the 17 white matter tracts investigated demonstrated significant differences between the two groups. The FA values were lower while MD and RD values were higher in the delayed group. The AD values were slightly varied, where some white matter tracts in the delayed group showed higher and lower values. Correlations were seen between the DTI metrics with the developmental delay components in the white matter tracts such as corona radiata, medial lemniscus, cingulum, optic radiation, superior cerebellar peduncle, superior longitudinal fasciculus and posterior limb of internal capsule.

Conclusion: Most of the white matter tracts assessed showed diffusion changes that implied delayed white matter maturation in developmental delayed patients compared to control. The DTI metrics had potential as non-invasive imaging markers for delayed white matter maturation in children with developmental delay.

Enhancement of T1WI histogram in the identification with primary central nervous system lymphoma and glioblastoma

C. Chen, J. Cheng, Y. Zhang; Zhengzhou/CN (chrnchrn812@163.com)

Purpose: To investigate the diagnostic value of enhanced T1WI histogram analysis in the identification of primary central nervous system lymphomas and glioblastomas.

Methods and Materials: Retrospective analysis of pathologically confirmed 41 cases of primary central nervous system lymphoma and 30 cases of glioblastoma. T1, T2-weighted, and enhanced T1 magnetic resonance images of the two types of tumours were collected. The MaZda was used to extract the region of interest of the tumour. The histogram analysis was performed on the maximal area of interest of the tumour to observe the two types of tumours. The histogram features of the tumour, including the mean, variance, skewness, kurtosis, and the 1, 10, 50, 90, and 99 percentiles, were used to find significant differences between the two kinds of tumours. Statistical analysis was performed using SPSS 21.0 statistical software. The ROC curve was used to analyze the diagnostic efficacy of statistically significant parameters between the two groups of tumours.

Results: Among the nine parameters extracted using histogram analysis, the mean, variance, skewness, 1st, 10th, and 50th percentiles were statistically significant ($P < 0.05$), while there was no significant difference in kurtosis, 90th percentile, and 99th percentile ($P > 0.05$). In these parameters, the skewness was the most effective in identifying primary central nervous system lymphomas and glioblastomas, and the area under the ROC curve was 0.960, and the sensitivity and specificity were 80% and 100%, respectively.

Conclusion: Histogram analysis is helpful for the identification of primary central nervous system lymphoma from glioblastoma and the skewness has a high diagnostic efficiency.

B-1235 10:38

T2WI histogram analysis of whole tumour volume for differentiating glioblastoma from primary central nervous system lymphoma

C. Chen, J. Cheng, Y. Zhang; Zhengzhou/CN (chrnchrn812@163.com)

Purpose: To study the value of T2WI whole tumor volume histogram analysis in the diagnosis of primary central nervous system lymphoma and glioblastoma.

Methods and Materials: Retrospective analysis of 41 cases of primary central nervous system lymphoma and 29 cases of glioblastoma confirmed by pathology in our hospital. T2WI axial images were selected, Mazda software was used to map the regions of interest on each layer of the tumour in both groups, and a total tumour volume histogram analysis was performed to observe the histogram characteristics of the two tumours, including mean, variance, and skewness. The kurtosis, the 10th percentile, the 50th percentile, the 90th percentile, and the 99th percentile identify the significant differences between the two tumours. Statistical analysis was performed using SPSS 21.0 statistical software. The ROC curve was used to analyze the diagnostic efficacy of statistically significant parameters between the two groups of tumours.

Results: In the nine parameters obtained from T2WI whole tumour volume histogram analysis, the mean, variance, kurtosis, skewness, 50th percentile, 90th percentile, and 99th percentile were statistically significant ($P < 0.05$). Among these parameters, the variance identification of the primary central nervous system lymphoma and glioblastoma was the most effective, and the area under the ROC curve was 0.884, and the sensitivity and specificity were 69% and 90.2% respectively.

Conclusion: The whole tumour volume T2WI histogram analysis is helpful for the identification of primary central nervous system lymphoma from glioblastoma and the variance has a high diagnostic efficiency.

B-1236 10:46

Whole tumour histogram analysis of apparent diffusion coefficient for evaluation of histological grade and BRAF mutation status in pleomorphic xanthoastrocytomas

J. Yan, J. Cheng, F. Liu; Zhengzhou/CN (ayyj1986124@126.com)

Purpose: To investigate whether histogram-profiling of apparent diffusion coefficient (ADC) could stratify histological grade and predict BRAF mutation status of pleomorphic xanthoastrocytomas (PXAs).

Methods and Materials: The ADC maps of 61 patients with pathologically diagnosed PXAs were used for whole tumour histogram-profiling according to the 2016 WHO classification. The patients were firstly allocated to the grade II and grade III anaplastic PXA groups, and further divided into BRAFV600E-mutated and wild-type groups. Comparative statistics were performed to investigate the association of histogram parameters between groups. Receiver operating characteristic (ROC) curve was applied to decide the accuracy and optimum cut-off value of histogram parameters. Binary logistic regression analysis was used to determine the independent predictors of the BRAFV600E mutation.

Results: Various histogram parameters (ADCmean, ADCmax, ADCp10, ADCp25, ADCp75, ADCp90, ADCmedian) were significantly greater in the grade II PXA group than those in the grade III anaplastic PXA group (all $P < 0.05$). ROC analysis revealed that ADCp90 was the most accurate parameter for stratifying histological grade of PXAs, with a cut-off value of $1.34 \times 10^{-3} \text{ mm}^2/\text{s}$ (sensitivity 0.882 and specificity 0.889). Further, ADCmax and ADCp90 were significantly greater in the BRAFV600E-mutated group compared with the wild-type group ($P = 0.018$ and 0.027 , respectively). Binary logistic regression analysis revealed that ADCmax was independently associated with the BRAF mutation status ($P = 0.030$).

Conclusion: Whole tumor histogram-profiling of ADC was useful for histological grading of PXAs, rendering ADCp90 as the most accurate parameter with high specificity and sensitivity. Further, ADCmax was the independent predictor for BRAF mutation of PXAs.

B-1237 10:54

Prediction of the BRAF mutation status of pleomorphic xanthoastrocytomas using pre-operative multi-parametric MRI

J. Yan, J. Cheng, F. Liu; Zhengzhou/CN (ayyj1986124@126.com)

Purpose: We aimed to predict the BRAF mutation status of pleomorphic xanthoastrocytomas (PXAs) based on pre-operative multi-parametric MRI characteristics.

Methods and Materials: A set of 18 clinical and MRI features were evaluated in 33 patients with pathologically-confirmed PXAs for prediction of BRAFV600E mutation. The results obtained for the BRAF-mutated and wild-type groups were compared. Characteristics that were significantly more prevalent ($P < 0.05$) in the BRAF-mutated PXAs were defined as diagnostic features. The receiver operating characteristic curve and binary logistic regression analysis were carried out to determine diagnostic accuracy and optimal cut-off value.

Results: A comparison of findings between the groups showed that the cases with BRAF-mutated PXAs tended to be younger ($P = 0.010$), and more often had a history of epilepsy ($P = 0.047$). Though the difference in number was not significant in the two groups, all the multiple lesions were found in the wild-type group. Furthermore, BRAF-mutated PXAs tended to be superficial with obvious meningeal contact ($P = 0.040$), appeared as predominantly cystic with a mural nodule ($P = 0.024$). The mean ADC and normalized ADC ratio were significantly greater in the BRAF-mutated group ($P = 0.012$ and 0.003 , respectively). The optimal cut-off values of mean ADC and normalized ADC ratio were $0.86 \times 10^{-3} \text{ mm}^2/\text{s}$ (sensitivity 0.769 and specificity 0.824) and 1.07 (sensitivity 0.769 and specificity 0.882), respectively. The combination of all these significant features resulted in the highest sensitivity and specificity of 0.923 and 0.882, respectively.

Conclusion: The BRAF mutation status of PXAs may be predicted using pre-operative multi-parametric MRI with high specificity and sensitivity.

B-1238 11:02

To study the diagnostic value of adc global gray histogram in differentiating primary central nervous system lymphoma from pleomorphic glioblastoma and single brain metastases

Z. Ma, J. Cheng; Zhengzhou/CN

Purpose: To study the diagnostic value of adc global gray histogram in differentiating primary central nervous system lymphoma from pleomorphic glioblastoma and single brain metastases.

Methods and Materials: A retrospective analysis in our hospital had brain MRI examination and 95 cases of pathologically confirmed patients, including central nervous system lymphoma 38 cases, 29 cases of glioblastoma, 28 cases of solitary metastases. Three groups of MR ADC axial images were used to draw the region of interest on each level of tumour with MAZDA software, and the gray level global histogram was analyzed. The parameters of the three groups of histograms were tested by kruskal-wallis, and the comparison between groups was tested by bonferroni method. The statistical significance of each parameter was compared.

Results: Through histogram analysis of 9 parameters, these 9 parameters were statistically significant (all $P < 0.05$), including mean, variance, kurtosis, skewness, Perc.01%, Perc.10%, Perc.50%, Perc.90% and Perc.99%. The sensitivity of perc.50% between glioblastoma and central nervous system lymphoma was 84.21, specificity was 86.21. The sensitivity of mean perc.50% between glioblastoma and single metastatic tumour was 0.90%. The sensitivity of perc.90% perc.99% between the central nervous system lymphoma group and the single metastatic tumour group was 92.86% and the specificity was 63.16.

Conclusion: Histogram analysis is helpful for the identification of central nervous system lymphoma and glioblastoma and single metastatic tumour. The perc.50% between glioblastoma and central nervous system lymphoma, between glioblastoma and single metastasis, perc.90% between central nervous system lymphoma and single metastatic tumour has high diagnostic efficacy.

B-1239 11:10

A whole-tumour histogram analysis of apparent diffusion coefficient maps for distinguishing lateral ventricle central neurocytoma from ependymoma

W. Wang, J. Cheng; Zhengzhou/CN (weijianwang520@163.com)

Purpose: We explored the role of a whole-tumour histogram analysis of apparent diffusion coefficient (ADC) maps for discriminating lateral ventricle central neurocytoma from ependymoma.

Methods and Materials: We retrospectively evaluated findings in 35 patients with lateral ventricle central neurocytoma and 20 patients with ependymoma who underwent diffusion-weighted imaging ($b = 0,800 \text{ s}/\text{mm}^2$) at 3T with acquisition of corresponding ADC maps. We derived histogram data from regions of interest drawn on all slices of the ADC maps in which tumour was visualized, including areas of necrosis and haemorrhage in the tumour. We used the t test to evaluate the capacity of histogram parameters (variance, kurtosis, 1th, 10th percentiles) to discriminate central neurocytoma from ependymoma and analyzed the receiver operating characteristic (ROC) curve to determine the optimum threshold value for each parameter and its corresponding sensitivity and specificity.

Results: Lateral ventricle central neurocytoma demonstrated significantly lower variance, kurtosis, 1th, 10th percentiles than ependymoma ($P < 0.05$). ROC curve analysis of the variance yielded the best area under the ROC curve (AUC: 0.83), sensitivity of 80%, and specificity of 82%, with a cutoff value of 2012.

Conclusion: A Whole-Tumour Histogram analysis of ADC maps might be helpful for discriminating lateral ventricle central neurocytoma from ependymoma.

B-1240 11:18

Characterisation of peripheral nerve sheath tumours in patients with neurofibromatosis type 1 using diffusion-weighted magnetic resonance imaging

J. Salamon¹, L. Well¹, K.I. Geier¹, L. Späth¹, M. Kaul¹, J. Herrmann¹, V.-F. Mautner¹, G. Adam¹, T. Derlin², ¹Hamburg/DE, ²Hannover/DE

Purpose: To evaluate the potential of diffusion-weighted MRI (DW-MRI) for differentiation of malignant and benign peripheral nerve sheath tumors (MPNST/BNPST) in patients with neurofibromatosis type 1 (NF1) using apparent diffusion coefficient (ADC) and intravoxel incoherent motion (IVM) models.

Methods and Materials: 26 patients with NF1 were included in this prospective study resulting in n=67 tumors. DW-MRI was performed at 3T (T1wTSE, T1w mDixon with in- and opposed phase, T2wTSE and DWI). DW-MRI consisted of eleven b-values (0-800 s/mm²). A monoexponential function was used to calculate ADC maps and a biexponential function was applied for the IVIM model, generating diffusion coefficient (D) and perfusion fraction (f) maps. Regions of interest (ROI) were manually drawn to determine signal intensities. Mann-Whitney-U, Fisher's exact test, receiver-operating-characteristic (ROC) analyses and spearman correlation were performed. Inter-rater reliability was evaluated.

Results: MPNST compared with BNPST were characterized by lower mean ADC values (ADC_{mean} 1.23 vs. 2.09 x 10⁻⁶ mm²/s; p<0.0001) and lower mean diffusion coefficients (D_{mean} 1.03 vs 1.88 x 10⁻⁶ mm²/s; p<0.0001). Perfusion fraction f was significantly higher in MPNST than in BNPST (21% vs 11%, p=0.0003). For both entities, f was higher in the periphery compared to the center of the lesions (p<0.0001). ROC showed good levels of sensitivity and specificity for both ADC and D (sensitivity vs specificity: ADC_{mean} 92%/98%, AUC 0.983; D_{mean} 92%/98%, AUC 0.979). Inter-rater reliability was good to very good (kappa ADC_{mean} 0.898; D_{mean} 0.646).

Conclusion: Diffusion weighted imaging allows identification of MPNST in NF1 with high levels of sensitivity and specificity.

B-1241 11:26

ASL perfusion MRI reveals reduced cerebral blood flow in the hippocampal region in patients with former childhood medulloblastoma

Y. Tanyildizi, A. Kronfeld, M.-A. Neu, A. Wingertler, A. Russo, K. Khawaja, A. Tropine, M.A. Brockmann, J. Faber; ¹Mainz/DE (y.tanyildizi@gmx.net)

Purpose: The number of long-term survivors of former childhood Medulloblastoma is increasing. Therefore late sequelae of radiochemotherapy (RCT), such as reduced cerebral blood flow (CBF), are gaining importance. In this study changes of cerebral blood flow (CBF) were analyzed using arterial spin labeling (ASL) perfusion MRI.

Methods and Materials: Perfusion weighted images of 28 patients (mean age:25.2; range:10-55 years; mean years after primary radio-chemo-therapy 14.9, range:1-45) and 24 healthy subjects (mean age:32; range:22-63 years) were acquired using ASL. For each individual CBF-maps were calculated and brought into MNI-space using SPM12. Mean CBF in grey matter was determined for every group. A voxelwise two-sample t-test was performed (SPM12), and mean CBF was calculated in the regions showing a significant difference and compared on an individual basis.

Results: No significant differences regarding mean grey matter CBF-values between the two groups were observed. (patients (healthy):67.0 (66.4) ± 3.09 (1.24) ml/100g/minute, respectively). However, voxelwise t-test revealed a highly significant reduction of CBF in the hippocampal region (patients (healthy):68.1 (80.6) ± 3.95 (2.07) ml/100g/minute, respectively) between the healthy and the RCT group.

Conclusion: ASL perfusion MRI can be used as a noninvasive tool for imaging CBF reduction after RCT in patients with former childhood medulloblastoma. A significantly reduced CBF in the hippocampal region, which is known to be sensitive to ionizing radiation, was found. We suggest that ASL Perfusion sequences should be included in the regularly follow up MRI protocols. Furthermore the effects of the reduced CBF in the hippocampal region have to be investigated.

B-1242 11:34

Machine learning-based radiomics to predict molecular subgroups of medulloblastoma

J. Yan, Z. Zhang, J. Cheng; ¹Zhengzhou/CN (ayyj1986124@126.com)

Purpose: Novel biological insights have led to consensus of classifying medulloblastoma into four distinct molecular subgroups - wingless (WNT), sonic hedgehog (SHH), Groups 3, and Group 4. We aim to predict molecular subgroups of medulloblastoma by using advanced machine learning approach which extracts important information based on pre-operative MRI radiomics features.

Methods and Materials: Thirty-seven patients with medulloblastoma (WNT = 11, SHH = 9, Group 3 = 8, and Group 4 = 9) were enrolled, and all were scanned by using contrast-enhanced T1WI sequence. A total of 1089 radiomics features were extracted from contrast-enhanced T1WI images. Then, statistically significant different features in comparison among the four groups were selected for the subsequent model training and performance evaluation by employing one way-ANOVA. After feature selection, a support vector machine was used to predict molecular subgroups of medulloblastoma. Finally, predictive performance was assessed by accuracy, precision, recall and F1. To access algorithm generalization, we used a 2-fold cross-validation approach.

Results: The molecular subgroups of medulloblastoma can be classified by important radiomics features and machine-learning approaches with a 70% accuracy, a 67% precision, a higher recall of 92%, and a 77% F1.

Conclusion: Our findings suggest a great potential to use MR radiomics features-based machine learning method to predict the molecular subgroups of medulloblastoma.

B-1243 11:42

Delayed FDG PET/CT in differentiating true progression from pseudo-progression in glioblastoma treated with chemoradiation

M.K. Gule-Monroe, M. Chen, J. Li, B.J. O'Brien, C. Chung, S.D. Ferguson, S.S. Prabhu, J.M. Johnson; ¹Houston, TX/US

Purpose: Delayed 18F-FDG PET has been shown to increase the specificity of PET imaging for cerebral neoplasm. We sought to compare 1-hour and 5-hour imaging post-injection in patients with metastatic brain tumours treated with radiation.

Methods and Materials: 27 patients with suspicious enhancement following radiation were identified and imaged with this protocol. Diagnostic confirmation of progressive disease (PD) or radiation necrosis (RN) was by pathology (5 cases) and/or radiographic follow-up (16 cases). Maximum standard uptake values (SUV) were calculated for suspicious areas of MR enhancement (lesion) and compared to normal appearing brain (background) at both time points.

Results: 17 patients had pathology and/or imaging follow-up. 12 cases were classified as having PD and 5 as having RN. PET findings were concordant in all 5 cases with pathologic follow-up. PET findings were concordant in 14/16 cases based on radiographic follow-up imaging. The mean L/B for PD at the early time point (1.6±0.7) was significantly lower than L/B for the later time point (2.4±1.1), p=0.0013. The mean L/B for PD was 2.5±1.1 at the later time point compared to 0.8±0.2 for RN (p=0.001). For the earlier time point, L/B for PD was 1.6±0.7, compared to the L/B for RN, which was 0.7±0.2 (p=0.004).

Conclusion: L/B ratios at early and delayed time points successfully differentiate between PD and RN in the majority of cases, with significantly greater L/B ratios between TP and RN on delayed imaging versus 1-hour imaging. These results are promising and further investigation is warranted.

B-1244 11:50

Application of histogram analysis of diffusion Kurtosis imaging to tumour grading and tissue heterogeneity

A. Gao¹, J. Cheng¹, J. Bai¹, Y. Zhang¹, Y. Hong², D. Kong²; ¹Zhengzhou/CN, ²Hangzhou/CN (annygao456@163.com)

Purpose: The aim of this study was to evaluate the significance of DKI parameters in grading glioma.

Methods and Materials: DKI (541s) and conventional sequence at 3.0T MR scanner (Prisma Siemens Healthcare, Erlangen, Germany). DKI acquires data with 5 b values (0-2500sec/mm²) and 30 directions for every b value. DKI was scanned using a SE-EPI sequence and the parameters were: FOV =220x220mm², slice thickness = 5mm, slices = 20, TR/TE = 3500/78ms. Matlab platform was used to calculate diffusion parameters Kapp and Dapp value based on TRACEW parameter image. ROIs were manually drawn around the solid part of the tumour. Histogram analysis from these parameters were correlated with glioma grades. Independent-samples T test or Mann - Whitney - Wilcoxon test was used. The parameters with the best percentile from cumulative histograms were identified by analysis of the AUC of the ROC analysis.

Results: 25 low grad gliomas and 49 high grad gliomas were observed. Kapp values increased with increasing glioma grade, but the Dapp values decreased. There were significant difference between high and low grade glioma groups on the Kapp value of maximum, mean, standard deviation, 75th percentile, 95th percentile, and the Dapp value of minimum, mean, 25th percentile, 50th percentile, 75th percentile, 95th percentile, skewness coefficients. According to the ROC, the highest AUC were found at Dapp minimum value (AUC,0.829), Kapp 75th percentile value (AUC,0.819).

Conclusion: Histogram analysis of DKI parameters from solid part of the tumour data can be a useful method for glioma grading and Tissue Heterogeneity.

Perfusion MRI with high spatial and temporal resolution in the head and neck region using golden angle radial sampling

A. Tomppert, M.S. May, M. Wiesmüller, R. Heiß, A. Nagel, M. Uder, W. Wuest; Erlangen/DE (andrea.tomppert@uk-erlangen.de)

Purpose: Conventional perfusion sequences often provide either poor spatial or poor temporal resolution. Our aim was to set up a golden-angle radial sparse parallel (grasp) sequence to overcome this problem in head and neck perfusion MRI.

Methods and Materials: We prospectively included 60 patients for examination on a 3 T MRI using the study protocol. Grasp was applied to a volume interpolated gradient echo perfusion sequence (vibe) with 135 measurements and a resulting temporal resolution of 2.5 s and a spatial resolution of 0.94 x 0.94 x 3.00 mm (A). Additional sequences with matching spatial (B: 1 measurement, 145 s, 0.94 x 0.94 x 3.00 mm) and temporal (C: 3 measurements, 2.5 s, 1.88 x 1.88 x 3.00 mm) resolution without grasp were obtained subsequently. Image quality was evaluated as overall diagnostic quality, mucosal and vessel delineation, lesion enhancement and edge sharpness, artefacts and fat suppression quality on a five point Likert scale.

Results: Overall diagnostic image quality, vessel delineation and lesion contrast was highest in A. Mucosal fold and edge sharpness of lesions was comparable to B and superior to C. Slight radiating artefacts, not affecting the diagnosis, were found using the grasp technique in A. Pulsation, moving and susceptibility artefacts were comparable to B and C. Quality of fat suppression was very high and comparable to B and C.

Conclusion: High temporal and spatial resolutions can be obtained synchronously using the grasp-vibe sequence for perfusion evaluation in head and neck MRI.

Preliminary diffusion kurtosis imaging study of head and neck squamous cell carcinomas associated with histologic grades

T. Su, Y. Chen, X. Chen, T. Zhang, X. Shi, H. Xue, Z. Zhang, Z. Jin; Beijing/CN (angelasu.love@163.com)

Purpose: To preliminarily investigate the clinical value of diffusion kurtosis imaging (DKI) in head and neck squamous cell carcinomas (HNSCCs), and to evaluate its correlation with different histologic grades.

Methods and Materials: Total 22 HNSCCs patients who underwent tumour resection and lymphadenectomy were involved. DKI data were obtained by a single-shot echo-planar imaging sequence with three b values of 0, 800 and 1600 s/mm². Diffusivity (D) and kurtosis (K) and conventional apparent diffusion coefficient (ADC) were calculated. The MR images were compared with the histopathologic findings. One-way ANOVA, spearman correlation and receiver operating characteristic curve (ROC) analysis were analyzed, with P value of ≤ 0.05 indicating significance.

Results: In correlation analysis, ADC value was negatively correlated with kurtosis ($r = -0.511$, $p = 0.003$), and positively correlated with diffusivity ($r = 0.882$, $p < 0.001$). And kurtosis value was negatively correlated with histologic grades ($r = -0.384$, $p = 0.030$). In ROC analysis, AUC of the kurtosis and diffusivity values for differentiating well-differentiated from poorly-moderately differentiated carcinomas were 0.753 and 0.729 separately, higher than that of ADC values. And AUC of combined three parameters together was 0.965, with 94.1% sensitivity and 100% specificity, higher than combinations of either two.

Conclusion: In this preliminary study, kurtosis derived from DKI was negatively correlated with histologic grades of HNSCCs. And the relatively high diagnostic accuracy of combined ADC and DKI parameters may be helpful for the preoperative differentiation of histologic grades.

B-1247 10:38

Radiohistological comparison study of temporal bone specimen after CI electrode array insertion: is CBCT superior to MSCT?

I. Burck, S. Schneider, I. Yel, A. Lehn, S. Balster, S. Helbig, T. Stöver, T.J. Vogl, B. Kaltenbach; Frankfurt a. Main/DE (iris.burck@kgu.de)

Purpose: To evaluate subjective image quality and diagnostic accuracy of cone-beam CT (CBCT) images in temporal bone specimen with implanted CI electrode array in comparison to histological assessment.

Methods and Materials: In this retrospective study, two radiologists independently reviewed CBCT (96kV vs. 120kV setting) and CT images of 20 temporal bone specimens after electrode implantation. Qualitative evaluation of bone structures of the otic capsule, inner and outer cochlear wall, lamina spiralis ossea, intracochlear electrode position with regard to lamina spiralis ossea, visualization of single electrode contacts on the array, metal artefacts and overall image quality was performed using a 5-point scale. Intracochlear electrode position was subsequently correlated by histological examination.

Results: Radiological assessment of bone structures of the otic capsule, inner and outer cochlear wall, lamina spiralis ossea, electrode position with regard to lamina spiralis ossea, visualization of single electrode contacts on the array, metal artefacts and overall image quality were significantly higher in CBCT at both tube voltages compared to CT ($p \leq 0.025$). No significant differences were found between CBCT at 96kV and 120kV ($p \geq 0.532$). The mean intraclass correlation was good (0.651). The determination of the intracochlear electrode position with histological correlation was highly correct in 120kV (100%) and 96kV CBCT (97.5%) images, in CT only 77.5% were determined correctly.

Conclusion: Our data suggest that CBCT may significantly improve diagnostic accuracy of temporal bone imaging after CI compared to CT, in particular, to determine the intracochlear localization of the implant. There is no significant difference using 120kV or 96kV CBCT protocols for the assessment.

B-1248 10:42

Utility of histogram analysis of ADC maps in differential diagnosis of Pleomorphic adenoma and Acinar cell carcinoma originated from parotid gland

X. Zhang, J. Cheng, K. Ma; Zhengzhou/CN (zx9725651@126.com)

Purpose: To explore the diagnostic value of the histogram analysis derived from apparent diffusion coefficient (ADC) maps in the differential diagnosis of Pleomorphic adenoma and Acinar cell carcinoma.

Methods and Materials: 22 cases of parotid neoplasms confirmed by pathology who underwent MRI scanning were retrospectively analysed, including 10 cases of Pleomorphic adenoma and 12 cases of Acinar cell carcinoma. Drawing the region of interest (ROI) on the maximal section ADC maps and going on histogram analysis. Performed a statistical analysis on the histogram parameters to find out the characteristics of the significant differences between the two groups. The ROC curve was analysed to determine the optimum threshold value for each parameter and its corresponding sensitivity and specificity.

Results: In the 9 parameters which are extracted from histogram, ADC mean, ADC variance, ADC 10th percentile (ADC_10th), the 90th percentile (ADC_90th), the 99th percentile (ADC_99th) have the statistical significance ($P < 0.05$). ROC analysis indicated that (ADC_99th) had the highest diagnostic accuracy for differentiating the 2 groups, with the area under the curve being 0.891, a cutoff value of 186.50, and a sensitivity of 100.0% and a specificity of 72.7%.

Conclusion: The ADC histogram is useful for the differential diagnosis of pleomorphic adenoma and acinar cell carcinoma and can accurately distinguish between them. Histogram analysis of ADC maps can provide reliably objective basis for differentiating pleomorphic adenoma and acinar cell carcinoma.

B-1249 10:46

The value of ADC histogram in differentiating nasopharyngeal carcinoma from nasopharyngeal lymphoma

K. Ma; Zhengzhou/CN (1322725260@qq.com)

Purpose: The purpose of this study is to assess the utility of texture analysis of apparent diffusion coefficients (ADC) maps for the differentiation of Nasopharyngeal Carcinoma (NPC) and Nasopharyngeal Lymphoma (NPNHL).

Methods and Materials: 79 patients with diagnosis of nasopharyngeal malignant tumours including 45 NPCs and 34 NPNHLs in our hospital from June 2015 to March 2018 were retrospectively enrolled in this study. All the patients were proved by pathology and examined by sequence of T1WI, T2WI and DWI. Drawing the region of interest(ROI) on the selected MR images and going on histogram analysis, these two steps were all performed on the software named Mazda. Performed a statistical analysis on the histogram parameters to find out the characteristics of the significant differences between the two groups and ROC were used to describe its efficiency in differential diagnosis.

Results: Significant differences were observed for mean, standard deviation, and 10th, 50th, 90th, and 99th percentiles of the ADC values. ROC curve analysis showed that the sensitivity and specificity of these parameters were 62.2% and 82.4%, 88.9% and 64.7%, 100% and 35.3%, 80.0% and 61.8%, 80% and 55.9%, 80.0% and 79.4%, successively, and the areas under ROC were 0.801, 0.813, 0.731, 0.797, 0.795, 0.838, respectively.

Conclusion: The histogram analysis of the ADC maps can be used to identify nasopharyngeal cancer and nasopharyngeal lymphomas. Although these findings require validation in larger studies, they have implications for facilitating improved treatment selection for these two entities.

B-1250 10:50

Prognostic value of restaging 18-FDG PET/CT volumetric parameters for post-index irradiation recurrence of head and neck squamous cell carcinoma

K. [Musaieva](#), B. Musaiev, Y. Kmetyuk; Kiev/UA (kitylboo@gmail.com)

Purpose: The purpose of this study was to define the prognostic value of metabolic and volumetric parameters for recurrent HNSCC and the role of salvage re-irradiation in overall survival in this cohort.

Methods and Materials: Pretreatment PET/CT scans and after treatment PET/CT scans of 69 patients who underwent salvage treatment for recurrent HNSCC, were retrospectively evaluated. Metabolic response was assessed using PET response criteria for solid tumors (PERCIST). Multiple statistical image features related to the standard uptake value (SUV) were computed: metabolic tumor volume, maximumSUV, meanSUV, total lesion glycolysis. The correlation between the image features and local control and overall survival was calculated.

Results: In this study we reported on the utility of PET/CT in survival prognostication for recurrent head and neck cancer. Analysis indicates that whole body metabolic tumour volume WB MTV has potency in estimating the overall survival. High WB MTV (over 21,5 cc) corresponds with poor prognosis and low one-year survival rate (56,0% of patients will not survive over 12 months); on the other hand, one-year survival at WB MTV < 21,5 cc is estimated as 93,2%. This observation remained robust even after accounting for other known prognostic factors including salvage re-irradiation and recurrence location.

Conclusion: With this study we established a pre-salvage volumetric cut-off point (whole body metabolic tumour volume WB MTV of 21,5 cc) that predicts one-year survival with high accuracy. A more extensive study is warranted to decide if this cut-off point is acceptable for subgroup of patients who will undergo a salvage re-irradiation.

B-1251 10:54

Update of old thyroid US reports to EU-TIRADS with AI

A. [Mereu](#), L. Saba; Cagliari/IT

Purpose: To assess the ability of AI to update old thyroid US free-text reports of patients with Hashimoto's disease to the 2017 European Thyroid Imaging and Reporting Data System (EU-TIRADS) categories.

Methods and Materials: 500 thyroid US free-text reports of subjects with Hashimoto's disease were retrospectively assessed. All reports were manually categorized accordingly to the 2017 EU-TIRADS. An ensemble of 7 algorithms (based on bagging, boosting, classification trees, maximum entropy, neural networks, random forests and support vector machine) was employed by an AI to assign a single EU-TIRADS category to each report. To simulate a real world situation, only a randomized sample consisting of 10% (50 reports) of the dataset was provided to the AI to train itself. All the main tasks involved were handled with the free and open source programming language R.

Results: A Kappa statistic of 0.402 indicated fairly good predictions for all classes. EU-TIRADS categories 2, 3, 4 and 5 were predicted with overall precision of 0.930, recall of 0.564, F-score of 0.702 and Kappa statistic of 0.566.

Conclusion: Study results showed that the AI categorized old reports in accordance with the latest EU-TIRADS classification with fair performance, although provided with only one tenth of the total dataset to train itself. Even if a human second-look is mandatory, that might be a viable approach to update old reports to new risk levels for scopes such as patient recall, modify follow-ups and research.

B-1252 10:58

Application of RESOLVE-DWI ADC maps based on whole-tumour histogram analysis in differentiating common parotid gland tumours

C. [Song](#), J. Cheng, Y. Zhang; Zhengzhou/CN (songchengru@126.com)

Purpose: The purpose of this study was to evaluate whether whole-tumour histogram-based analysis of RESOLVE-DWI ADC maps can help in the discrimination of parotid gland tumours (pleomorphic adenoma, Warthin tumour, malignant parotid gland tumour).

Methods and Materials: The MR images of 36 patients with a biopsy- or surgery-proven pleomorphic adenomas, 14 patients with Warthin tumours and 19 patients with malignant parotid gland tumours were retrospectively analysed. Histogram-based analysis was performed with the software MaZda. ROIs were drawn on every section of the ADC map containing the tumour, then 12 parameters derived from histogram were calculated. Statistical analysis among the three groups were performed to find out the statistical significance of each histogram parameter. And the differential efficiency of each parameter was determined using a receiver operating characteristic curve (ROC) analysis.

Results: Totally 9 parameters (MinNorm, MaxNorm, mean, variance, skewness, Perc.10%, Perc.50%, Perc.90%, Perc.99%) among three groups were statistically significant (P<0.05). Between the pleomorphic adenomas and Warthin tumours, these 9 parameters were of statistical significance. Mean, skewness and Perc.50% revealed high diagnostic efficiency with the areas under the ROC curve (AUC) of 0.976, 0.970, 0.970, respectively. Between the pleomorphic adenomas and malignant parotid gland tumours, also these 9 parameters were of statistical significance. Mean, Perc.10% and Perc.50% revealed high diagnostic efficiency with AUC of 0.851, 0.866, 0.841, respectively. But between the Warthin tumours and malignant parotid gland tumours, only 3 parameters (mean, skewness, Perc.50%) was statistically significant.

Conclusion: Whole-tumour histogram analysis of ADC maps are effective in differentiating common parotid gland tumours.

B-1253 11:02

Diagnostic utility of mean peak systolic velocity of superior thyroid artery (STA PSV) in the differential diagnosis of thyrotoxicosis

P.K. [Sarangi](#), S. Parida, B.K. Mohanty, S. Mangaraj, J. Mohanty, B.M. Swain; Cuttack/IN (lipu90sarangi@gmail.com)

Purpose: To evaluate the utility of mean peak systolic velocity of superior thyroid artery (STA PSV) in differentiation of Graves' disease (GD) and thyroiditis presenting with thyrotoxicosis.

Methods and Materials: A total of 111 patients with newly diagnosed thyrotoxicosis (82 with GD and 29 with thyroiditis) without antithyroid medication or β -blockers intake, history of neck irradiation, neck surgery, radioiodine therapy were included. 45 age and sex matched healthy subjects were included as control. Thyroid function tests (FT3, FT4, and TSH) and serum TSH receptor antibody (TRAb) were done. All subjects underwent a detailed colour Doppler ultrasonography of the thyroid gland and spectral flow analysis of both superior thyroid arteries using 5-12 MHz linear transducer of PHILIPS HD 7 USG machine. Mean STA PSV was obtained by averaging right and left STA PSV. Receiver operating characteristic curve (ROC), sensitivity, and specificity for mean STA PSV was calculated using SPSS 24.0 software.

Results: On color Doppler study, the mean STA PSV of patients with GD was significantly higher than thyroiditis and control group [(92.79±44.95 cm/sec, 37.89±15.33 cm/sec, 20.07±6.77 cm/sec respectively (p<0.001)]. Mean STA PSV greater than 54.275 cm/s had 82.9 % sensitivity and 86.2 % specificity in diagnosing Graves' disease. Mean STA PSV greater than 84.925 is 100% specific for GD.

Conclusion: The mean STA PSV has high sensitivity and specificity in differentiating Graves' disease from thyroiditis and can be used routinely in clinical practice as a cheap diagnostic tool where serum TRAb test is not available or affordable.

B-1254 11:06

Visualisation of the trigeminal nerve branches on enhanced 3D-SPACE-STIR sequence: initial experience

C. [Chen](#), H. Haiwei, S. Yunkun, H. Xu; Xiamen/CN (fjmucf@163.com)

Purpose: To investigate the value of magnetic resonance (MR) three-dimensional sampling perfection with application optimized enhanced using different flip angle evolution short time inversion recovery (3D-SPACE -STIR) sequence in detecting the trigeminal nerve branches.

Methods and Materials: Eleven patients who underwent non-enhanced and enhanced 3D-SPACE-STIR MR scan were enrolled prospectively. Imaging scores were evaluated by three radiologists according 3 levels. Weighted k analysis was used to assessment the interobserver variability. Displaying rates of the ophthalmic branch (V1), maxillary branch (V2), mandibular branch (V3) trunk and divisions of V3 were analysed. Signal intensity of the V1, V2, V3 trunk and lateral pterygoid muscle (LPM) were measured to calculate the signal intensity ratio (SIR) and contrast ratio (CR).

Results: It showed higher imaging scores (2.85±0.36) on enhanced 3D-SPACE-STIR MR imaging than non-enhanced imaging (1.18±0.39), with excellent interobserver variability. The SIR and CR values of V1, V2 and V3 trunk were higher on enhanced MR imaging. Displaying rates for the three trunks on enhanced MR imaging were 97.73%, 100% and 100%, respectively, while 93.18%, 95.45% and 100% on non-enhanced MR imaging. A similar tendency was observed for the divisions of V3. Displaying rates for inferior alveolar, lingual, buccal, masseteric, auriculotemporal and deep temporal

nerves on enhanced MR imaging were 100%, 100%, 86.36%, 97.73%, 100% and 90.91%, respectively, while 100%, 97.73%, 84.09%, 90.91%, 93.18% and 79.55%, respectively, on non-enhanced MR imaging.

Conclusion: Enhanced 3D-SPACE-STR MR imaging demonstrates better background suppression and excellent visualization of the trigeminal nerve branches.

B-1255 11:10

Three-dimensional shear wave elastography for differentiating benign from malignant thyroid nodules

C.-K. Zhao; Shanghai/CN (798434308@qq.com)

Purpose: To prospectively evaluate the diagnostic performance of three-dimensional (3D) shear wave elastography (SWE) for assessing thyroid nodules.

Methods and Materials: A total of 176 surgically or cytologically confirmed thyroid nodules (malignant 63, benign 113) in 176 patients who had undergone conventional ultrasound (US), two-dimensional (2D) and 3D SWE examinations were included in this study. Quantitative elasticity values were computed on 2D and 3D SWE (E_{mean}, E_{max} and E_{SD} of a large region of interest (ROI) and E_{mean} of a 2 mm ROI). Diagnostic performances of conventional US, 2D SWE and 3D SWE were assessed. The role of 2D SWE and 3D SWE in reducing unnecessary fine-needle aspiration (FNA) for low suspicious nodules was also evaluated.

Results: The diagnostic performances in terms of area under the receiver operating characteristic curve (AUC) were 0.612 for conventional US, 0.836 for 2D SWE ($P < 0.001$ in comparison with conventional US), and 0.839 for 3D SWE ($P < 0.001$ in comparison with conventional US). E_{max} achieved the highest diagnostic performance in 2D SWE while E_{SD} in 3D SWE, whereas no significant difference was found between them ($P > 0.05$). 3D SWE increased the specificity in comparison with 2D SWE (88.5% vs. 82.3%, $P = 0.039$). For the 37 nodules with low suspicion on conventional US, 2D SWE was able to avoid unnecessary FNA in 77.1% (27/35) of benign nodules and 3D SWE further increases the number to 88.6% (31/35).

Conclusion: 3D SWE is a useful tool in predicting thyroid nodule malignancy and reducing unnecessary FNA procedures in low suspicious thyroid nodules.

B-1256 11:14

DWI-associated entire-tumour histogram analysis for the differentiation of nasopharyngeal carcinoma from nasopharyngeal lymphoma

K. Ma, J. Cheng, X. Zhang, C. Song; Zhengzhou/CN (1322725260@qq.com)

Purpose: To investigate the diagnostic efficiency of DWI using entire-tumour histogram analysis in differentiating the nasopharyngeal carcinoma (NPC) from nasopharyngeal lymphoma (NPNHL) in comparison with conventional ROI-based measurement.

Methods and Materials: DW images (b of 0-1000 s/mm²) from pathology confirmed 45 NPCs and 34 NPNHLs were retrospectively collected. The measurement of tumour apparent diffusion coefficients (ADCs) was performed with using histogram-based and ROI-based approach, respectively. The diagnostic ability of ADCs from two methods for differentiating NPC from NPNHL was determined by ROC regression, and compared by McNemar's test.

Results: Histogram-based ADCs (mean, standard deviation, 10th, 50th, 90th, 99th) and ROI-based ADCs (mean) reflected significant difference between NPC and NPNHL (all p values < 0.05). Histogram 99th ADCs had dominantly high Az (0.838), Youden index (0.594), and positive likelihood ratio (LR₊, 3.89) in differentiating NPC from NPNHL against standard deviation, 10th ADCs, 50th ADCs, 90th ADCs, and ROI-based ADCs. Histogram standard deviation, 10th ADCs and 99th ADCs showed higher sensitivity (80.0%-88.9% vs. 70.6%, $p < 0.05$), but lower specificity (78.6%-79.4% vs. 83.3%, $p < 0.05$) than ROI-based ADCs in differentiating NPC from NPNHL.

Conclusion: DWI-associated histogram analysis had higher sensitivity, Az, Youden index, and LR₊ for differentiation of NPC from NPNHL than ROI-based approach. It can be speculated that the histogram has certain auxiliary value in clinical diagnosis.

B-1257 11:18

Assessing the skull base: CT-guided submaxillary core needle biopsy for the diagnosis of skull base lesions

I. Burck, M. Rosenzweig, N.-E. Nour Eldin, H. Kvasnicka, T. Stöver, V. Jacobi, T.J. Vogl; Frankfurt/DE (iris.burck@kgu.de)

Purpose: To assess the time efficiency and evaluate the diagnostic accuracy of CT-guided submaxillary core needle biopsy (CNB) for the diagnosis of deep-seated head and neck masses.

Methods and Materials: Twenty-seven patients with skull base lesions underwent CT-guided submaxillary CNB between 2003 and 2018. All CNB were performed under CT guidance and local anaesthesia using an 18-gauge-needle for biopsy, 2-4 histological specimens were obtained for histopathological analysis. Histological findings were classified as "benign", "suspicious for malignancy" or "malignant". Medical records were reviewed with regard to therapy, in case of operative strategies surgical results, histological findings or in case of chemotherapy or radiotherapy treatment response. Additionally, clinical follow-up was evaluated. Prevalence, CNB-sensitivity and specificity, positive predictive value as well as negative predictive value were calculated.

Results: Eighty-nine percent of specimens from CNB were considered accurate, 11% of the histological specimen were non-diagnostic, so re-biopsies were performed in 3 cases. There were no postinterventional complications. All patients could be released from the hospital after at least 8 hours (7.87h±3.4). Histological diagnosis could be delivered within on average 2 days (2.14d±0.7). CNB sensitivity was 90%, specificity was 100%, positive predictive value was 100% while negative predictive value was 94.4%.

Conclusion: Based on our findings, we conclude that CT-guided submaxillary CNB is a time-saving procedure that has a high diagnostic accuracy and, therefore, allows for major clinical decisions on the basis of histopathological diagnosis from histological specimen, as well as preventing patients from undergoing open surgical procedure to obtain adequate histological specimen.

B-1259 11:26

3D imaging of the paranasal region with a multipurpose cone beam detector system: image quality and radiation exposure

S. Ohlmeyer, T. Buder, M. Uder, W. Wuest; Erlangen/DE (sabine.ohlmeyer@uk-erlangen.de)

Purpose: In times of cost efficiency multi-purpose devices are increasingly offered on the market. Besides x-ray and fluoroscopy, a previously introduced twin robotic x-ray scanner offers a 3D cone beam option. Aim of this study was to evaluate various scan parameters and post-processing steps to optimize image quality and exposure values for imaging of the paranasal region.

Methods and Materials: Four human cadaver heads were examined with different tube voltages (90 - 121 kV), dose levels (278 - 2180 nGy) and prefiltration methods (Cu 0.2/0.3 mm, Sn 0.4 mm). Datasets were reconstructed in 0.2-cm slices with and without metal artefact reduction algorithm in three different kernels. In total, 80 different scan protocols and 480 datasets were evaluated. Image quality was rated in 10 anatomic regions on a 5-point Likert scale reaching from 5 excellent to 1 insufficient.

Results: For the diagnosis of sinusitis a scan protocol with 121 kV/DL 278/Cu 0.3 mm proved to be sufficient (Score 2). The mean CT volume index (CTDI_{vol}) was 1.70 mGy and the mean effective dose 77 µSv. Scan protocols with 121 kV/DL 1090/Cu 0.3 mm were rated sufficient for preoperative diagnostics (Score 3), resulting in a mean CTDI_{vol} of 4.66 mGy and an effective dose of 212 µSv. Metal artefact reduction algorithm was beneficial in all scan protocols.

Conclusion: Sinusitis and preoperative planning of paranasal surgery can be performed with low radiation dose and diagnostic image quality with a multipurpose cone beam system. Imaging parameters must be adapted to the clinical indication.

B-1260 11:30

Structural changes of the disc of temporomandibular joint in the first stage of dysfunction

D.V. Dushkova, Y. Vasilev; Moscow/RU (ddushkova@yandex.ru)

Purpose: To assess the structure of the intraarticular disk (meniscus) of the temporomandibular joint (TMJ) in patients with complaints of discomfort during opening of the mouth, as well as in patients undergoing orthodontic treatment.

Methods and Materials: The study included 107 patients with symptomatic dysfunction of the TMJ, aged 13 to 68 years. All patients underwent magnetic resonance imaging (MRI) in the position of occlusion, in the open mouth position, as well as a pseudodynamic series of images using high-resolution T1-weighted images (WI) and dynamic T2WI. The studies were performed on a MR-tomograph Siemens Essenza 1.5 T using a head coil.

Results: 214 joints were examined, in 127 (63 right and 64 left TMJ) there were no signs of disc displacement, which corresponds to the first stage of dysfunction. Seventy-nine TMJ revealed an asymmetric arrangement of the meniscus bulges: much of it is in the back, the front pole of the meniscus has a flattened shape. The difference in height between the anterior and posterior thickening varied from 35% to 77%. When analysing a series of successive pseudo-dynamic T1WI, the lag of the anterior thickening of the intraarticular disc during movement is tracked in five positions, as well as its deformation between the aspects of the articular tubercle and the head of the condyle.

Conclusion: MRI using a static and dynamic protocol with symptomatic dysfunction of the TMJ revealed 62% of the structural changes in the disk without signs of its displacement.

B-1261 11:34

Correlation between the size of the inferior orbital wall defect and treatment tactics in orbital trauma according to the MSCT data

O. Pavlova, N.S. Serova, D. Davydov, S.K. Ternovoy; *Moscow/RU*
(dr.olgapavlova@gmail.com)

Purpose: To establish the correlation between the size of the defect within the inferior orbital wall and proper treatment tactics in patients with orbital trauma according to the multi-slice computed tomography (MSCT) data.

Methods and Materials: A total of 91 patients with orbital trauma (100%) were admitted to the hospital during the 1-2 day after the injury. MSCT was performed using Toshiba Aquilion One 640. The size of the inferior orbital wall defect was measured using volumetric analysis and calculation of the defect square. According to the acquired size and square, the classification of defects was established: small (below 54 mm²), moderate (from 54,1 mm² to 117,2 mm²), severe (from 117,3 mm²) and total.

Results: According to the classification 9 small inferior orbital wall defects (10%) were revealed, in 19 patients - moderate (21%), in 27 cases - severe (29%) and in 36 patients - total defects (40%). According to acquired data conservative treatment was performed in patients with small defects with additional diagnostic control. Patients with moderate defects underwent implantation of endoprosthesis of inferior orbital wall. Patients with severe and total defects underwent implantation of inferior orbital wall endoprosthesis combined with osteosynthesis fixation within midface structures.

Conclusion: The classification of the inferior orbital wall defects according to the MSCT data provide additional diagnostic information about the patients with orbital trauma. Developed classification allows to define the correct treatment tactics in order to select conservative or surgical treatment as well as to establish the correct size of orbital wall endoprosthesis.

B-1262 11:38

Anatamage table: a possible new tool for diagnosis and classification of Le Fort fractures

Z. Falaschi, S. Cavalieri, I. Valente, G. Mazzucca, A. Carisio, S. Bor, A. Carriero, F. Boccafoschi, A. Stecco; *Novara/IT* (zenofalascchi@gmail.com)

Purpose: Anatomage is a virtual anatomic dissection table. Despite it being widely used for students' education, there are still few clinical studies about its usefulness as a diagnostic tool. The purpose of this study is to evaluate Anatomage's capability to improve maxillo-facial CT scan's diagnostic accuracy.

Methods and Materials: Ten trauma patients who performed a maxillo-facial CT scan were enrolled. Five patients were diagnosed with a type I, II or III Le Fort fracture, while five had no evident maxillary bones fracture (control group). Data obtained from the exams were uploaded on the Anatomage table for reading. Four different groups of readers were identified: attending doctors, senior residents, junior residents and students. They evaluated CT scans on the radiological workstation (RW) first, and 37 days later reviewed the Anatomage-generated 3D models. Each group included two reciprocally blinded readers. Four parameters were assessed: grade of Le Fort fracture, confidence, anatomic resolution and 3D-model handling. Qualitative parameters were assessed using Likert scale.

Results: Intra-reader agreement of Le Fort grade, measured with Cohen's kappa, was above 90% in all readers. Kappa values showed almost perfect agreement in 7/8 readers and substantial agreement in 1/8. Qualitative parameters scores were higher on Anatomage than on RW: Confidence 3.53/4 vs. 3.13/4; Anatomic Resolution 3.51/4 vs. 2.96/4; 3D-Model Handling 3.70/4 vs. 2.79/4.

Conclusion: Anatomage Table can be a valid aid in diagnosis and classification of complex maxillo-facial injuries, both for residents, students and attending doctors.

B-1263 11:42

Functional multi-detector computed tomography (FMDCT) for various orbital pathologies

N.D. Kudryavtsev, M.V. Malakhova, Y.O. Grusha, S.S. Danilov, V.V. Khovrin, K.B. Puzakov, T.N. Galyan; *Moscow/RU* (nikita_kudryavtsev@hotmail.com)

Purpose: Modification of methodology of orbital functional computed tomography with the aim to reduce radiation exposure and to increase quality of generated images.

Methods and Materials: For modification of the method, 17 patients with thyroid eye disease (TED), orbital tumours and parietic strabismus were chosen. During the study patients moved globes in the following order: center, top, down, left, right and orbits were scanned only after globes were fixed in end points. 5 scans were carried out within one study. Studies were performed with volume mode in 640-MDCT.

Results: For patients with TED, alongside with increase of muscle size, we detected evolution of their activity vector, decrease of contractive function, optic nerve compression at the top of the orbit by enlarged muscles. For patients with posttraumatic parietic strabismus, we detected total absence of

functional activity of the lateral rectus muscle. In two cases we detected extraconal tumours, slow-moving when the eyeball is in motion and pressing the lateral rectus muscle inwards. In 3 cases, we diagnosed moving intraconal tumours of the orbit that were not intimately connected to the optic nerve and not bringing pressure to it when patient changed point of gaze.

Conclusion: FMDCT is a valuable method that allows to reduce radiation exposure (average dose 400-500 DLP), to detail topography of different orbital structures and reveals features of dynamic relationships of soft and bone tissues (including pathologic).

B-1264 11:46

Value of ADC and DCE-MRI in differentially diagnosing of angiomatous meningioma and solitary fibrous tumours/haemangiopericytoma

C. Chen, C.-P. Ren, R.-C. Zhao, J.-L. Cheng; *Zhengzhou/CN*
(934717369@qq.com)

Purpose: This study aimed to assess the value of ADC and DCE-MRI in differentially diagnosis of angiomatous meningioma and solitary fibrous tumours/haemangiopericytoma.

Methods and Materials: A total of 17 cases of AM and 18 cases of the SFT/HPC confirmed by pathology were analysed retrospectively. All of patients underwent ADC and DCE-MRI. Age, gender, ADC, TIC, SImax, TImax, MCER and EER were measured and compared AM to SFT/HPC. The diagnostic efficacy of ADC and DCE-MRI in distinguishing AM and SFT/HPC were calculated. Whether or not ADC and DCE-MRI were correlated with age. Two independent samples t tests, t' test, chi-square test, Wilcoxon rank sum test and Pearson correlation were used.

Results: The ADC value [(0.91±0.03)×10⁻³mm²/s], MCER [(304.59±34.43)%] of 17 cases of AM were statistically different from 18 cases of SFT/HPC [(1.20±0.05)×10⁻³mm²/s, (179.88±27.54)%] and gender, too (P<0.05). The cut-off value of ADC and MCER was, respectively, 1.03×10⁻³mm²/s and 226.7% in differential diagnosis of AM and SFT/HPC. There were 6 I type TICs, 10 II type TICs, and 1 III type TICs in 17 cases of AM. There were 5 I type TICs, 9 II type TICs, and 4 III type TICs in 18 cases of SFT/HPC. The age, SImax, TImax and EER were not statistically different between the two tumours (P>0.05). The age of AM and ADC value, age of SFT/HPC and ADC value were all linearly dependent.

Conclusion: ADC value of AM is less than SFT/HPCs; MCER of AM is greater than SFT/HPCs, and ADC is more valuable than MCER, and these parameters can help diagnosis.

The assessment of diffusion tensor imaging parameters of visual pathways in patients with primary open-angle glaucoma: preliminary study

A. Piekarek, P. Podgórski, M. Czarnecki, W. Rydel, A. Turno-Krecicka, M. Misiuk-Hojło, A. Zimny; *Wroclaw/PL* (alina1979@op.pl)

Purpose: The aim of our study was to estimate the value of quantitative diffusion tensor imaging of the optic pathways in primary open-angle glaucoma.

Methods and Materials: Sixteen glaucoma patients (34-84y; mean 62.8) and 16 healthy age-matched individuals (37-75y; mean 58.7) underwent diffusion tensor imaging of the brain using 1.5T MR scanner (FOV 24, matrix 96x96, b=0, b=1000,15 directions, TE =100, TR=11000, NSA=4, slice thickness=2.5). Based on the Johns Hopkins University single-subject JHU-MNI SS BPM Type II V2.1 atlas for every participant were extracted 12 regions of interest (ROIs) along optic pathways and additional tracts in which measurements of averaged fractional anisotropy (FA) and diffusivity (total diffusivity-trace) automatically were performed. For statistical analysis, Student's t test was indicated (p=0.05).

Results: For the optic tracts, posterior limbs of internal capsules, right posterior thalamic radiation (including optic radiation), right posterior superior temporal gyrus FA values were significantly lower (p<0.05) in glaucoma patients vs. controls. Trace values increased significantly in POAG group for

the retrolenticular parts of internal capsule, posterior limb of right internal capsule and right posterior thalamic radiation (including optic radiation) ($p < 0.05$). Considering the cingulum, superior longitudinal fasciculus, sagittal stratum and posterior parts of middle and inferior temporal gyrus no significant difference in DTI parameters in both hemispheres was found ($p > 0.05$).

Conclusion: Diffusion tensor imaging (DTI) can detect glaucomatous optic pathway degeneration and differentiate involved from not involved areas.

B-1266 10:47

Diffusion tensor imaging in trigeminal neuralgia caused with neurovascular conflict and in estimation of long-term results of microvascular decompression

M. Amelin, J. Rzaev, G. Moysak, A. Tulupov; *Novosibirsk/RU (amelin_me@mail.ru)*

Purpose: To estimate fractional anisotropy changes in trigeminal nerve root in patients with trigeminal neuralgia, caused by neurovascular conflict before and in long term after microvascular decompression.

Methods and Materials: Study included 33 patients (23 female, 10 male, aged 26 to 81 years (mean 60 years,)) with TN, who underwent microvascular decompression. Before microvascular decompression, in a day after it and in a long term after (up to 19 months) diffusion-tensor imaging of trigeminal nerves was performed using 1.5-Ti MR unit Siemens Magnetom Avanto.

Results: In all patients in affected side we found statistically significant ($p < 10^{-10}$) drop of fractional anisotropy comparing to healthy side. After successful MVD FA on affected side also had difference from healthy side ($p < 0.001$). In 6 patients with recurrent pain after MVD FA of trigeminal nerve root in affected side decreased comparing to level before MVD, all of them had a long story of pain and poor FA dynamic right after MVD.

Conclusion: Difference of FA between affected and healthy side in patients with TN is related to microstructural changes of affected side. Microstructural recovery changes in trigeminal nerve root in patients with disappearing of pain related with increase of FA and recurrence or persisting of pain related to decrease or absence of FA dynamic comparing to pre-operational data. Application of DTI could be helpful in selection of treatment tactics. Recovering of FA after MVD is an objective criterion of success of MVD.

B-1267 10:55

Diffusion tensor imaging for vascular dementia prediction: threshold level of fractional anisotropy in liable white matter tracts

I. Levashkina¹, S.V. Serebryakova¹, O.V. Kitaigorodskaya²; ¹St. Petersburg/RU, ²Kyiv/UA (levashkina ldc@yandex.ua)

Purpose: To develop criteria of cerebral tracts integrity using DT-MRI to predict vascular dementia. To find the threshold level of fractional anisotropy (FA) in liable tracts to measure dementia risk.

Methods and Materials: Characteristics of 235 subjects with diagnosed encephalopathy participated in the study: age 65.29 ± 7.49 , 79 subjects with cognitive impairment and 156 with no disorders. DT-MRI was done on 3T Siemens Magnetom (Neuro 3D package). To receive FA in 11 regions of interests, manual free-hand method was applied.

Results: Statistically significant ($p \leq 0.05$) FA decrease was identified in three regions for cognitive impairment group: front sections of corona radiata (ROI1), inferior longitudinal fasciculi (ROI2), anterior horn of internal capsule (ROI3). ROC analysis showed FA values lower than 0.280 for ROI1, 0.400 for ROI2 and 0.520 for ROI3 mean highest risk of dementia. FA values higher than 0.400 for ROI1, 0.505 for ROI2 and 0.625 for ROI3 mean low risk. FA between threshold levels - higher risk as closer to the low bound. To make the results independent from MRI type and measurement method, authors suggest to use not absolute values of FA, but index ratio of FA in liable ROI to splenium of corpus callosum, which shows no difference for groups with and without cognitive impairment. The index also was calculated for three main ROIs and can be disclosed.

Conclusion: Three ROIs, correlated with cognitive disorders risk, were identified. For dementia prediction recommended to use index - FA value in each ROI to splenium of corpus callosum.

B-1269 11:11

Determination of fractional anisotropy cut off values on diffusion tensor imaging in differentiating recurrence versus radiation necrosis in gliomas

P. Asokan¹, S.S. Shivalingappa¹, A.A. Rao Kesari¹, M. Ashok Kumar², I. Desai¹, S. Sampangi¹; ¹Bangalore/IN, ²Bikaner/IN (asokaprakash@gmail.com)

Purpose: To compare FA values extracted from DTI MR images in differentiating recurrence and necrosis in gliomas. To develop cut off values for tumour recurrence. To develop cut off values for differentiation of tumour recurrence from radiation necrosis.

Methods and Materials: This is a single institutional retrospective study from March 2015 to May 2018, evaluating the role of DTI FA values in differentiating recurrence from radiation necrosis. Patients of all ages with glioma treated with surgery/chemotherapy and radiotherapy who are referred to the radiology department for magnetic resonance imaging evaluation. Total 82 cases are evaluated with DTI FA values.

Results: Out of 82 cases, 57 cases are with residual disease, 25 cases are with radiation necrosis. Results between residual and radiation necrosis is highly significant between two groups with $p < 0.001$. The mean score of minimum FA ratio in residual disease is 0.26 ± 0.18 and radiation necrosis is 0.13 ± 0.055 . The mean score of maximum FA ratio in residual disease is 0.15 ± 0.06 and radiation necrosis is 0.08 ± 0.030 .

Conclusion: Hence with MRI Diffusion tensor imaging FA values we can differentiate between residual disease and radiation necrosis and the cut off value for residual disease is between 99 to 182, the cut off values for radiation necrosis is 47 to 80. The FA ratio in residual disease is high ranges between 0.26 to 0.15 and low in case of radiation necrosis is 0.13 to 0.8.

B-1270 11:19

White matter involvement in young non-demented Down's syndrome subjects: a tract-based spatial statistic analysis

A. Guarnera, A. Romano, M. Moraschi, A. Pierallini, A. Bozzao; *Rome/IT (guarneralessia@gmail.com)*

Purpose: Cognitive decline in Down syndrome shows neurodegenerative aspects similar to what is observed in Alzheimer's disease. Few studies reported information on white matter integrity. The aim of this study was to evaluate white matter alterations in young, non-demented Down's syndrome subjects, by means of DTI technique, compared to a normal control group, to define whether these changes are present in asymptomatic subjects.

Methods and Materials: The study group consisted of seventeen right-handed subjects with DS and seventeen control subjects. All individuals were examined by MR exam including DTI acquisition (32 non-coplanar directions); image processing and analysis were performed using FMRIB Software Library software package. Finally, the diffusion tensor was estimated voxel by voxel and the fractional anisotropy, mean diffusivity, axial and radial diffusivity map derived from the tensor. A two-sample T test was performed.

Results: A FA decrease and a MD, RD and AD increase were found in DS subjects, compared to control subjects, in the region of the anterior thalamic radiation, the inferior fronto-occipital fasciculus, the inferior longitudinal fasciculus and the cortico-spinal tract, bilaterally. In addition, MD, AD and RD showed changes in more white matter tracts, suggesting greater sensitivity for WM damage than FA.

Conclusion: We demonstrated white matter changes in specific regions of young, non-demented DS subjects and that MD changes seemed to precede FA ones. These parameters could be used as predictive/early biomarkers of cognitive decline and could have great impact in better adapting the timing of therapies.

B-1271 11:27

Diffusion tensor imaging in intractable unilateral mesial temporal lobe epilepsy

A.N. Parimalai, A. Chelladurai, M. Logudoss; *Chennai/IN (anand7687@gmail.com)*

Purpose: To confirm the efficacy of Diffusion Tensor Imaging (DTI) parameters in the diagnosis of unilateral mesial temporal lobe sclerosis (MTS) and to know the extratemporal and contralateral hemisphere involvement in intractable MTS.

Methods and Materials: We evaluated 25 patients with intractable unilateral MTLs by using DTI, MRI, clinical and EEG parameters. Out of these 12 were right sided and 13 were left sided MTLs. We compared the mean diffusivity (MD) and fractional anisotropy (FA) values in hippocampus, parahippocampus, fimbriae, fornix middle cerebellar peduncle, corpus callosum, inferior fronto occipital fasciculus, superior longitudinal fasciculus, anterior and posterior cingulum, thalamus, internal capsule, caudate and lentiform nucleus.

Results: There was significant decrease in FA values with increased mean diffusivity in ipsilateral hippocampus, parahippocampus, fimbriae and fornix, inferior fronto- occipital fasciculus and posterior cingulate, contralateral hippocampus, parahippocampal white matter, fimbriae, fornix, middle cerebellar peduncle, corpus callosum, uncinate fasciculus, inferior fronto occipital fasciculus, superior longitudinal fasciculus, and cingulum.

Conclusion: DTI shows microstructural abnormalities beyond the involved hippocampus extending to ipsilateral and contralateral major white matter tracts that is not apparent on conventional MRI. These observations shows epileptogenic focus and spread in the neural network, which may be responsible for secondary generalization.

B-1272 11:35

Excessive alcohol consumption in adolescent men compromises frontal white matter integrity via disruption of myelin (and axons): a combined DTI-metabolic study

Q. Shen¹, N. Heikkinen², O. Kärkkäinen², M. Kononen², H. Gröhn², Y. Liu², Z. Zhang¹, T. Tolmunen², R. Vanninen², ¹Changsha/CN, ²Kuopio/FI (uuqo@163.com)

Purpose: To investigate influences of subclinical alcohol use during adolescence on WM microstructure and to characterize those with serum metabolic alterations.

Methods and Materials: Thirty-five moderate-to-heavy drinkers (15 males, 20 females) and 27 light-drinking controls (12 males, 15 females) were included based on their consumption items of Alcohol Use Disorders Identification Test (AUDIT-C) scores measured at three time points over ten years. Magnetic resonance imaging (MRI) was conducted at study endpoint. Whole brain analysis of fractional anisotropy (FA) was performed using tract-based spatial statistics (TBSS). FA, radial diffusivity (RD), axial diffusivity (AD) and mean diffusivity (MD) values within the significant regions on FA map were computed for subsequent between-group comparisons and correlation analyses with serum metabolite concentrations.

Results: Decreased FA was found in moderate-to-heavy drinking men in bilateral genu and body of the corpus callosum, superior and anterior corona radiata, and right inferior fronto-occipital fasciculus (Pfamily-wise-error-corrected<0.05), accompanied by increased RD and a smaller area of reduced AD (P<0.05). No significant difference in FA was detected in moderate-to-heavy drinking women. Among those affected regions in moderate-to-heavy drinking men, DTI metrics correlated with serum level of metabolites (P<0.05) playing roles in energy metabolism, myelination and axonal degeneration.

Conclusion: Long-term subclinical alcohol use during adolescence is associated with altered white matter integrity in frontal inter- and intra-hemispheric fibers in men. No such observations were found in women, suggesting different effects of excessive alcohol use on male and female adolescents. The compromised WM integrity in moderate-to-heavy drinking men is correlated to serum metabolic alterations.

B-1273 11:43

Revealing the microstructure abnormalities of spinocerebellar ataxia by fMRI and DKI: from ROI based analysis to a VBA and TBSS study

H.S. Qiu, J.P. Chu, J. Zhao, M.S. Hu, C. Wu; Guangzhou/CN (handsome_yau@163.com)

Purpose: To investigate potential abnormalities in spinocerebellar ataxia (SCA) patients by fMRI and DKI, and correlate them with the score on the scale for the assessment and rating of ataxia (SARA) of SCA.

Methods and Materials: Prospectively involved 25 patients (male:10; mean age: 36.3y) with genetic diagnosis as SCAs (SCA1: 5; SCA2: 2; SCA3:13; SCA6:1; presymptomatic SCA3:4). All patients underwent whole brain fMRI and DKI examinations. DKI (FA, MD, MK, Ka and Kr) parameters in cerebellum and dental nucleus were obtained. Further analyzing the association between whole brain DKI parameters and SARA by TBSS and VBA. In addition, correlations between fMRI parameters (ALFF, fALFF and ReHo) and SARA were analysed by VBA as well.

Results: Irrespective of SCAs types and duration, FA of cerebellum was negatively correlated with SARA ($r = -0.419$, $P = 0.03$). Whereas, at VBA, the reduction of FA value was detected in left inferior frontal gyrus and inferior temporal gyrus ($P_{FWE} < 0.05$) while the MK and Kr had significant decreases in the left anterior central gyrus ($P_{FWE} < 0.05$). Furthermore, at TBSS, significantly decreasing FA, MK and Kr values were found in widespread white matter regions, especially in MK and more pronounced were demonstrated in callosum and cerebellar peduncle ($P_{TFCE} < 0.05$). However, there weren't significant associations found among all fMRI parameter and SARA.

Conclusion: DKI, especially MK, was superior than fMRI for detecting the severity of SCA, and TBSS was the most sensitive way to reveal the white matter abnormality of SCA.

B-1274 11:51

Cerebral white matter structural integrity in patients with mild cognitive impairment: evaluation with diffusion tensor imaging and morphometric assessment on 3T MRI

A. Haris Phuah, K. Rahmat, N. Ramli, F.I. Rozalli, F.B. Fadzli, L. Tan, N.I. Saedon, M. Tan; Kuala Lumpur/MY (katt_xr2000@yahoo.com)

Purpose: To investigate the differences in diffusion tensor imaging (DTI) metrics, morphometry assessment and white matter (WM) integrity between patients with mild cognitive impairment (MCI) and normal healthy control.

Methods and Materials: 33 subjects prospectively underwent brain MRI (17 MCI and 16 controls). Using template-based ROI technique to process the DTI, the fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD) and radial diffusivity (RD) values in 50 WM tracts were obtained. Visual rating

for WM scoring, WM lesion volume and cerebral morphometric analysis were performed.

Results: The MCI group had significantly lower FA and higher MD, AD as well as RD in WM tracts predominantly involving corpus callosum, corona radiata and cingulate gyrus when compared to the normal controls ($p < 0.05$). DTI parameter changes in these areas were also significantly associated with lower MoCA scores ($p < 0.05$). The MCI group had significantly higher WM lesion volume. With morphometry analysis, the MCI group had significantly smaller hippocampal volume ($p < 0.05$). Smaller hippocampal volumes and increased WM lesion volumes were significantly associated with poorer MoCA scores ($p < 0.05$). Although there were no significant differences in the Fazekas scores between the 2 groups, a higher Fazekas score was significantly correlated with a lower MoCA score ($p < 0.05$).

Conclusion: DTI, morphometric analysis and WM lesion assessments are useful for detecting MCI. DTI is useful in detecting WM tracts compromise seen early on in MCI patients. Early therapeutic interventions could potentially halt the deterioration and prevent the onset of dementia.

Advanced gastric cancer response to neoadjuvant chemotherapy: is CT texture analysis a reliable imaging biomarker? A multi-centre study from Italian research group for gastric cancer

L. Di Giacomo¹, G. Bagnacci¹, V. Nardone², P. Tini¹, F. Gentili¹, D. Marrelli¹, F. Roviello¹, L. Volterrani¹, M.A. Mazzei¹; ¹Siena/IT, ²Naples/IT (digileti@libero.it)

Purpose: To evaluate the reliability of CT texture analysis (CT-TA) in predicting histological response to neoadjuvant chemotherapy (NAC) in patients with resectable advanced gastric cancer (AGC) before surgery.

Methods and Materials: 70 patients from five GIRCG centres, with a pre-surgical biopsy-proven diagnosis of GC, treated with NAC followed by surgery. All patients were classified as T_{≥3} or N₊(M0) at CT staging and underwent a pre-surgical restaging CT after NAC. The population was divided in two groups as follows: 29 internal patients (Siena University Hospital) and 41 from the other four GIRCG centres. Gross tumour volume (GTV) was segmented on pre- and post-NAC CT by the dedicated contouring software RayStation and TA parameters were extrapolated through LifeX software. A correlation between preselected TA parameters and development of complete pathological response (TRG 1) was searched.

Results: TA parameters significantly related to the endpoint were the same for both groups, except for delta Grey-level co-occurrence matrix (GLCM) entropy (p: 0.006 and 0.152) and included post-GLCM contrast (p: 0.017 and 0.001), post-GLCM dissimilarity (p: 0.027 and 0.001), delta entropy (p: 0.002 and p: 0.006), delta GLCM contrast (p<0.001), and delta GLCM dissimilarity (p<0.001). At multivariate analysis only delta GLCM contrast was significant (p: 0.001 and 0.014, Nagelkerke R²: 0.546 and 0.435). ROC curves were generated from the logistic regression of all the cohort of patients (AUC 0.763; standard error: 0.098; p: 0.006).

Conclusion: TA could be a reliable tool to select responder patients in a pre-surgical time. Further prospective studies are required to confirm our results.

B-1276 10:38

Diagnostic accuracy of CT for lymph node metastasis in gastric cancer: comparison of spectral parameters developed dual-energy CT and conventional CT

Y. Chai; Zhengzhou/CN (chaiyayucyr@163.com)

Purpose: To investigate the optimal diagnostic threshold and accuracy of spectral parameters for metastatic lymph nodes of gastric cancer with dual-energy CT and to compare with conventional CT parameters.

Methods and Materials: This study received institutional review board approval and all participants provided written informed consent. 86 patients with gastric cancer underwent preoperative enhanced CT in Discover GSI CT. The spectral parameters (iodine value) and the conventional parameters were measured. The diagnostic efficiency of each factor was assessed using t test and ROC.

Results: Among 552 lymph nodes found in CT images, 338 nodes were positive and 214 were negative with pathological results. The results of t test showed that the short diameter, the ratio of short to long diameter, the CT

number and iodine value in AP and VP of positive lymph nodes were higher than those of negative lymph nodes (all $P < 0.05$), the areas under curve were 0.600, 0.880, 0.832, 0.755, 0.864, 0.835, respectively. The diagnosis accuracies of iodine value in AP and VP were 86.9%, 82.2%, higher than the CT number in AP and VP (69.9%, 66.9%). Taking the ratio of short to long diameter over 7.25 as optimal diagnosis threshold, the diagnosis accuracy was 75.6%. Combined the ratio of short to long diameter with the iodine value in AP, the diagnosis accuracy was 89.2%.

Conclusion: The diagnosis accuracy of dual-energy CT parameters was higher than conventional CT for lymph node metastasis in gastric cancer and could be improved by combining size and spectral CT parameters.

B-1277 10:46

Applying extended texture features to identify quantifiable changes in gastrointestinal stromal tumours undergoing tyrosine kinase inhibitor (TKI) therapy

K. [Ekert](mailto:Ekert@med.uni-tuebingen.de); Tübingen/DE (kaspar.ekert@med.uni-tuebingen.de)

Purpose: Applying extended texture features to identify quantifiable changes in gastrointestinal stromal tumors undergoing tyrosine kinase inhibitor (TKI) therapy. Our aim was to identify quantitative texture features which could be used complementary to modified Choi criteria or even as a substitute helping radiologists to determine response categories in GIST.

Methods and Materials: We identified 25 GIST patients with 124 scans, each examined with a standardized CT protocol at one scanner between 1/2014-7/2018. 92 texture features, based on pyradiomics library, were extracted and correlated to response categories as well as vitality of tumor lesions based on mCHOI criteria. Inter-rater testing was performed by a second experienced radiologist. Regression and AUC analysis was performed. First and second order features were included, higher order features were excluded due to the small patient number.

Results: Ten variables could be confirmed to be significantly associated with disease progression. Of them, four textural parameters were significantly positively associated with disease progression and negatively with progression free survival (Glcml Id, Glcml Idn, Glrlm and Ngtdm). Single variables were shown to be significantly inferior to the combination of all variables. Glcml Id, Glcml Idn and Glrlm non-uniformity were associated with the number of pre-treatments, Glrlm non-uniformity also with tumor vitality (enhancement) whereas Glcml Idn and Ngtdm coarseness were associated with the number of mutations.

Conclusion: CT-texture analysis seems to work well for both assessment of tumor vitality and response to treatment which could therefore be used either complementary to mCHOI criteria or even for automated (e.g. computer-aided) diagnosis.

Small (<5cm) gastric sub-epithelial tumours: identification of gastrointestinal stromal tumours using CT with a practical scoring method

L. [Liu](mailto:Liu@119821@163.com), S. Rao, M. Zeng; Shanghai/CN (119821@163.com)

Purpose: To determine significant CT features that can identify gastrointestinal stromal tumours (GISTs) among small (< 5cm) SETs and to explore a practical scoring method based on these features.

Methods and Materials: Forty-two patients with small (< 5cm) gastric SETs (31 GISTs and 11 non-GISTs) from hospital I were included for primary analyses, and 66 (48 GISTs and 18 non-GISTs) from hospital II constituted a validation cohort. Pre-operative CT images were reviewed for imaging features: lesion location, growth pattern, lesion margin, enhancement pattern, dynamic pattern, attenuation at each phasic image and presence of necrosis, superficial ulcer, calcification and peri-lesion enlarged lymph node (LN). Clinical and CT features were compared between the two groups (GISTs vs non-GISTs) and a GIST-risk scoring method was developed at the step of primary analyses, and then its performance for identifying GISTs was tested in the validation cohort.

Results: Seven clinical and CT features were significantly suggestive of GISTs rather than non-GISTs: older age (> 46.5 y), non-cardial location, irregular margin, lower attenuation on unenhanced images (<45 HU), heterogeneous enhancement, necrosis and absent of enlarged LN ($p < 0.05$). At validation step, the established scoring method with cut-off score dichotomised into ≥ 4 vs < 4 for identifying GISTs revealed an AUC of 0.86 with an accuracy of 92%, a sensitivity of 100% and a negative predictive value (NPV) of 100%.

Conclusion: With a simple and practical scoring method based on the significant CT features, GISTs can be accurately differentiated from non-GISTs.

Prediction of surgery requirement in mesenteric fibrosis on CT using a radiomics approach

M.P.A. [Starmans](mailto:m.starmans@erasmusmc.nl), A. Blazevic, S.R. van der Voort, T. Brabander, J. Hofland, W.J. Niessen, W.W. de Herder, S. Klein; Rotterdam/NL (m.starmans@erasmusmc.nl)

Purpose: Mesenteric fibrosis (MF) surrounding a mesenteric mass is a hallmark feature of small intestinal neuroendocrine tumours. Since this can induce severe abdominal complications, prophylactic resection of the primary tumour and mesenteric mass is often recommended. However, there is a need for better prediction of abdominal complications to prevent unnecessary surgery. We present a radiomics approach to identify patients prone to develop complications due to MF.

Methods and Materials: CT scans were gathered for 43 patients who had MF, of which 20 required palliative surgery within one year. The resulting dataset originated from 17 different scanners and thereby showed heterogeneity in the imaging protocols. The mass and mesenterium were delineated by a clinician. Within both regions, radiomics features quantifying shape, intensity, texture and orientation were extracted. Patient age and gender were added as semantic features. Radiomics was performed using harmonised adaptive workflow optimisation including various feature selection, oversampling and machine learning approaches. Evaluation was implemented through a 100x random-split cross-validation, with 80% of the data used for training and 20% for independent testing. Performance was given in 95% confidence intervals (CIs).

Results: The AUC, sensitivity and specificity were, respectively (0.56, 0.92), (0.43, 0.96) and (0.43, 0.85). The positive class consisted of patients who required surgery.

Conclusion: Although the CIs of the performance measures are wide due the small sample size, the results suggest there is a relation between CT imaging features and the need for surgery. Hence, radiomics shows the potential to identify patients prone to develop complications due to MF.

Assessment of metastatic GIST heterogeneity using texture analysis: ADC texture as a potential biomarker of 5-year survival

J. [Fu](mailto:Fu@18410259295@163.com), F. Mengjie, J. Li, X. Li, L. Tang, D. Dong; Beijing/CN (18410259295@163.com)

Purpose: To determine if ADC texture features of metastatic GIST are related to 5-year overall survival.

Methods and Materials: The study was approved by the institutional review board. This retrospective study included 51 patients selected from 205 consecutive patients from 2006 to 2012. Texture features of the entire maximum metastatic GIST tumour were assessed with DWI (0, 1000 s/mm²) using in-house software. The features were divided into four groups: histogram features, grey-level co-occurrence matrix (GLCM) features and grey-level run-length matrix (GLRLM) features and were extracted from the ROI images in T2, DWI and ADC images. Patients were followed up until death and were censored at 5 years if they were still alive. Kaplan-Meier analysis was performed to determine the relationship. The curves of the high- and low-risk groups were compared using log-rank testing. The prognostic abilities of the predictors were assessed by calculating the concordance probability.

Results: All patients had more than five liver metastases. There were 35/56 (68.62%) deaths for five years. Four DWI texture features and three ADC texture features were statistically significant in univariate analysis ($p < 0.05$). DWI_L_GLCM_maximum_probability (HR2.06,1.36-3.13) and ADC_H_GLRLM_mean (HR2.17,1.46-3.24) and ADC_O_GLCM_cluster_shade (HR1.88,1.32-2.67) were identified as representative prognostic indicators. The optimum threshold points of those were 1.19, 1.71 and 2.19, respectively.

Conclusion: Metastasis GIST imaging features were independently associated with survival. Worse heterogeneity is associated with poor prognosis.

Lymphadenectomy of small intestine neuroendocrine neoplasias (si-NEN): testing the most recent preoperative classification with contrast-enhanced computed tomography (CT)

F. [Zugni](mailto:Zugni@unimi.it), L. Funicelli, E. Bertani, M. Bellomi; Milan/IT (fabio.zugni@unimi.it)

Purpose: To test the most recent classification for resectability of si-NENs in a retrospective series of patients operated in our centre (European Institute of Oncology, Milan).

Methods and Materials: We blindly analysed the pre-surgical CT of 40 consecutive patients that underwent abdominal surgery for si-NENs between 2008 and March 2018. We assessed the resectability of the lymph node metastases using the classification proposed by Lardièrre-Deguelte et al. based

on the degree of involvement of the superior mesenteric artery (SMA). In addition, we evaluated the involvement of the superior mesenteric vein (SMV) and the presence of fibrosis and retraction in the mesentery. We finally analysed the surgical reports to assess whether the primary tumour and all lymph node metastases had been completely resected.

Results: Of the three tumours classified as unresectable, none received a complete resection (conversion to explorative intervention). Out of the 37 classified as resectable, 32 received a complete resection. Among the five tumours classified as resectable that did not receive a complete resection, three had CT signs of mesenteric retraction, and two showed an involvement of the SMV that was more severe and proximal than the involvement of the SMA.

Conclusion: Using the classification based on the involvement of the SMA we correctly evaluated the resectability of 35 out of 40 tumours (87.5%). In five cases (12.5%), the tumour was incorrectly classified as resectable. Evaluating the severity of involvement of the SMV and the presence of mesentery retraction might be helpful for improving the preoperative assessment of these patients.

Newly appearing hepatic lesions on follow-up CT after curative-intent surgery for colorectal cancer: when and why should we order liver MRI?

D.K. Kim, C. An; Seoul/KR (kdk7118@yuhs.ac)

Purpose: To develop a prediction model to assess the likelihood of metastasis for newly appearing hepatic lesions found on computed tomography (CT) after colorectal cancer surgery, and to examine the added value of magnetic resonance imaging (MRI).

Methods and Materials: Of 1,676 patients who underwent curative surgery for colorectal cancer between Jan 2008 and Dec 2009, 89 patients with newly appearing hepatic lesions on follow-up CT after surgery (metastasis, n=64; benign, n=25) were included in this retrospective study. Two radiologists analysed the CT features of the hepatic lesions. Clinical information and prospectively written reports of CT and MRI were reviewed. Decision tree analysis and chi-square test were performed.

Results: Independent CT features associated with metastasis were spherical shape with circumscribed margin ($P<0.001$), heterogeneous attenuation ($P=0.024$), and bulging appearance ($P=0.008$). In the decision tree, 52 patients with at least one of the CT features or elevated CEA level belonged to the high-risk group. Of non-high-risk patients, 15 with stage 1 cancer or time interval (from surgery to finding new hepatic lesion on CT) > 3 years belonged to the low-risk group. The remaining 22 belonged to the intermediate-risk group. For high-, intermediate-, and low-risk groups, 92.3%, 63.6%, and 13.3% proved to have liver metastasis, respectively. Subsequent MRI was useful in making more correct and confident diagnosis, and detecting additional metastatic lesions.

Conclusion: Decision tree model using CT and clinical information, and subsequent MRI could be useful in assessing the likelihood of liver metastasis after colorectal surgery.

Effect of dual-energy CT single-energy imaging on image quality of mesenteric vessels and segmental thickening intestinal wall

J. Yang, B. He; Nantong/CN (75002213@qq.com)

Purpose: To evaluate the image quality of mesenteric vessels and thickened intestinal wall in a dual-energy CT single-energy image.

Methods and Materials: Retrospective analysis of 30 patients with dual-energy bowel imaging data, using dual-energy mono to reconstruct eight single-energy images of arterial phase, small intestine phase (45keV, 50keV, 55Kev, 60keV, 65Kev, 70keV, 75Kev, 80Kev), compared with 120 kv images, to analyse the SNR, CNR, and image quality subjective scores of mesenteric artery and thickened intestinal wall.

Results: The mesenteric artery: the SNR of the 120 kv group was the highest, the SNR of the 60Kev and 65Kev groups was higher than other groups ($P<0.05$). The CNR of the single-energy group was higher than 120Kvp group, and the CNR of the 60Kev and 45Kev groups was the highest ($P<0.05$). Subjective scores of all groups were above 4 points ($P>0.05$). Segmental thickening intestinal wall: the SNR of the 120 kv group was the highest, the SNR of the 50Kev, 55Kev, 60Kev, 65Kev groups was higher than other groups ($P<0.05$). The single-energy group CNR was higher than 120Kv group, and the 55Kev and 50Kev groups were the highest ($P<0.05$). The subjective scores of the 45Kev and 50Kev images were the highest ($P<0.05$).

Conclusion: The 120kv group image has obvious advantages in SNR, but the single-energy image has obvious advantages in CNR; the 60Kev group image has the best CNR in mesenteric vascular; The 50kev group image can improve the CNR of the intestinal wall of the lesion without affecting the diagnosis.

Peritoneal carcinomatosis extent evaluation: radiologic, laparoscopic and pathologic

S.A. Ahmed, D. Fouad, H.A. Taleb, D. Badary; Assiut/EG (Doaafouad11@gmail.com)

Purpose: To evaluate preoperative categorization of peritoneal carcinomatosis by MDCT and laparoscopy compared with pathology and to evaluate its impact on surgical decision-making.

Methods and Materials: Forty ovarian cancer patients who underwent preoperative CT and diagnostic laparoscopy were included in the study. Calculation of peritoneal cancer index was done using Sugarbaker's method and then peritoneal carcinomatosis extent was categorized into low, moderate and large. Agreement in general and in each category between CT, laparoscopy, surgery and pathology was assessed using kappa agreement.

Results: Complete CRS was performed in 35 and incomplete in 5 patients; preoperative peritoneal carcinomatosis extent categorization in general showed good agreement between CT and laparoscopy (kappa =0.79), between CT and surgery (kappa =0.80), and excellent agreement between laparoscopy and surgery (kappa =0.89) ($p<0.001$). Agreement between CT and pathology was good (ICC = 0.63) in low-category group and excellent (ICC = 0.93) in moderate and large group (ICC = 0.94) ($p<0.02$). Agreement between laparoscopy and pathology was excellent in all categories, in low-category group (ICC = 0.91), in moderate group (ICC = 0.90) and in large group (ICC = 0.92) ($p<0.04$). Agreement between CT and laparoscopy was moderate in low-category group (ICC = 0.60), and excellent in moderate group (ICC = 0.89) and large group (ICC = 0.91) ($p<0.01$).

Conclusion: Although both CT and laparoscopy generally correlate with surgery in preoperative categorization of peritoneal carcinomatosis extent, laparoscopy is more accurate in low category, both accurately reflect disease burden and can be helpful for surgical mapping.

Using 2-mSv appendiceal CT in usual practice for adolescents and young adults: willingness survey of 579 radiologists, emergency physicians, and surgeons from 20 hospitals

H. Kim¹, K. Lee¹, Y. Ko², J. Choi¹, J. Sim³; ¹Seongnam/KR, ²Anyang/KR, ³Seoul/KR (iamjust@naver.com)

Purpose: To survey care providers' willingness to use 2-mSv CT in their usual practice for adolescents and young adults with suspected appendicitis.

Methods and Materials: An ethical committee approved this prospective study. We introduced 2-mSv CT in 20 hospitals through a pragmatic clinical trial. At the final phase of the trial, we invited 698 potentially involved care providers in the survey regarding their willingness to use 2-mSv CT. Multivariable logistic regression analyses were performed to identify factors associated with the willingness. Nine months after the completion of the trial patient recruitment, we surveyed whether the hospitals were using 2-mSv CT in usual practice.

Results: The analyses included responses from 579 participants (203 attendings and 376 trainees; 221 radiologists, 196 emergency physicians, and 162 surgeons). Regarding the willingness to immediately change their standard practice to 2-mSv CT, 158 (27.3%), 375 (64.8%), and 46 (7.9%) participants responded as "yes" (consistently), "partly" (selectively), and "no", respectively. The willingness varied considerably across the hospitals, but only slightly across the participants' departments or job positions. The willingness was significantly associated with attendings ($p = 0.004$), intention to maintain the dedicated appendiceal CT protocol ($p < 0.001$), belief in compelling evidence on the carcinogenic risk of conventional-dose CT radiation ($p = 0.028$), and hospitals having more than 1,000 beds ($p = 0.031$). Fourteen of the 20 hospitals kept using 2-mSv appendiceal CT in usual practice after the trial.

Conclusion: Most of the care providers were willing to use 2-mSv CT selectively or consistently.

European multi-centre study on technical success and long-term clinical outcome of radiofrequency ablation for the treatment of spinal osteoid osteoma and osteoblastoma

T. Bever¹, C. Rehnitz², K.M. Thierfelder¹, C.S.P. van Rijswijk³, J. Martel Villagrán⁴, M. Muto⁵, C. von Falck⁶, J. Gielen⁷, M.-A. Weber¹; ¹Rostock/DE, ²Heidelberg/DE, ³Leiden/NL, ⁴Madrid/ES, ⁵Naples/IT, ⁶Hannover/DE, ⁷Edegem/BE (thomas.beyer@med.uni-rostock.de)

Purpose: To evaluate technical success and clinical long-term outcome of CT-guided radiofrequency ablation (RFA) of spinal osteoid osteomas (OO) and osteoblastomas (OB) in six different European centres.

Methods and Materials: A total of 87 patients with the diagnosis of spinal OO (77) or OB (10) were treated with CT-guided RFA, after three-dimensional CT-guided access planning. Patient's long-term outcome was assessed by clinical examination and questionnaire-based evaluation including 10-point visual analogue scales (VAS) regarding the effect of RFA on severity of pain and limitations of daily activities. Clinical success was defined as a reduction of >30% in the VAS score and patient's satisfaction.

Results: Overall, RFA was technically successful in 82/87 cases (94.3%) with no major complications; clinical success was achieved in 78/87 cases (89.7%). The OO/OB were localized in the cervical (n=9/3), the thoracic (n=27/1), the lumbar (n=29/4) and the sacral spine (n=12/2). The RFA procedure was performed with a mean of 1.08±0.31 RF-electrode positions. A decrease in severity of pain after RFA was observed in 86/87 patients (98.9%) with a persistent mean reduction of overall pain score from 8.04±0.96 to 1.46±1.95 (p<0.001) after a median follow-up time of 29.35±35.59 months. VAS scores significantly decreased for limitations of both daily (5.70±2.73 to 0.67±1.61, p<0.001) and sport activities (6.40±2.58 to 0.67±1.61, p<0.001).

Conclusion: Even in a multi-centric setting, this trial proves that RFA is a safe and efficient method to treat spinal OO/OB and should be regarded as first line therapy after interdisciplinary case discussion.

B-1287 14:17

Who gets kyphoplasties and how much height is restored: a single-centre demographic profile

P.R. Javaram, T. Marshall; Norwich/UK (premruben@yahoo.com)

Purpose: To describe the demographic profile of patients who received kyphoplasties and the degree of height restoration.

Methods and Materials: All patients between January 2010 and June 2018 were included. Patients must have reported pain and bone oedema signal changes on MRI to qualify for treatment. The age, gender, indication, DEXA results, and original, pre- and post-procedural height of the target level were recorded. The original height was taken as the mean height of the nearest adjacent normal vertebral bodies. Heights were measured on CT or MRI scans immediately preceding and following the procedure.

Results: 114 kyphoplasties were performed (M=52, F=62). The mean age was 66.9 (range 28-89). 48 procedures (42.1%) were performed for osteoporosis, for whom DEXA results were available for 16 (33.3%), showing a mean T score of -1.82 (range -4.3 to 1). A further 48 procedures were performed for malignancy, 15 for trauma (13.2%), and 3 for pain/collapse secondary to a haemangioma (2.6%). There were 61 wedge, 38 biconcave, and 1 posterior fractures. 81 were performed as single-level procedures and 33 were performed as part of a multi-level operation. The mean original height was 29.6mm (range 22-43mm), the mean height lost was 12.4mm (41.4%, range 0-32mm), including 14 without height loss, and the mean height restored was 3.7mm (27.9%, range 0-16mm). No immediate major complications were recorded.

Conclusion: Osteoporotic and malignant pathological fractures formed the majority of caseload. Kyphoplasties should focus on other treatment goals, such as pain relief, as only a quarter of height loss was restored.

B-1288 14:25

Long term efficacy of a dorsal indirect approach for CT-guided cervical nerve root injections

S. Billingsley¹, C. O'Neill¹, D. McKean²; ¹Aylesbury/UK, ²Oxford/UK (sarah.billingsley123@gmail.com)

Purpose: Catastrophic complications have been rarely reported for selective cervical nerve root via an anterolateral transforaminal approach. We assess the short and long term efficacy of a dorsal indirect approach for CT guided cervical nerve root injection.

Methods and Materials: We performed a retrospective study of patients who had undergone CT guided nerve root injections for cervical radicular symptoms between March 2012 and July 2018 at our hospital. Spinal needles were advanced to at the dorsal border of the facet joint under CT fluoroscopy guidance. Contrast was injected to demonstrate foraminal flow and a non-particulate corticosteroid dexamethasone preparation was gently instilled. The primary outcomes measures were pain before the procedure then 2, 4 and 8 weeks after the procedure, length of analgesic benefit and complications.
