The spatial and temporal distribution of population are the critical attributes of hazard bearing body. Long period and high resolution of the distribution of population are important to the research of the exposure and risk of the population to natural disasters. This study was based on 6 times' Chinese census data from 1953—2010. The results showed that: from 1953 to 2010, the spatial distribution of Chinese population was rarely changed, a wide range of high population density areas are concentrated in the North China Plain, the Yangtze River region and the Sichuan Basin region; besides the little people area, the population density was gradually increased, the high population density area was gradually expanded, the area ratio of population density > 300 people / km² was increased from less than 15% in 1953 to 30% in 2010. In economic zone scale, the ratio of the area of high population density in Eastern area was the largest and increased fastest. The area ratio of population density > 300 people / km² was increased from 20% in 1953 to 40% in 2010. In basin scale, the ratio of the area of high population density in the Huaihe River and Haihe River Basin was the largest and increased fastest. The area ratio of population density > 300 people / km² in Huaihe River Basin was increased from 35% in 1953 to 60% in 2010. This study provides a powerful support for the accurately estimate of the number of the population exposed to the natural disasters.

Why Are Population Growth and Housing Price Growth Coexistent in China's Metropolitan Area?

Chen Le, Li Xun

Sun Yat-sen University, China, chenle198783@126.com

Abstract

Population growth and housing price growth are significant in China's Urbanization process, but why are the contradicting phenomenon could coexistent in China's Metropolitan Area? In this article, we choose a sample of 287 cities in China from 2005 to 2014, present a simple model that provides a framework for doing empirical work that integrates the heterogeneity of housing supply into population and housing price development. The results show that: coexistent between population and housing price growth is durable for metropolitan cities but not for small urban. High amenity investment plays the dominant role in explaining the coexistent phenomenon, the share of skilled workers could significantly affect housing price growth, but could not significantly affect population growth in current China.

Key words:

population growth; housing price growth; housing supply elasticity; metropolitan area

Analysis of Development Features, Mechanism and Strategy of the In-situ Urbanization in Metropolis Fringe Area: A Case study of Wenzhou

Zhang Mingyu, Li Wangming

Zhejiang University, Hangzhou, P. R. China, 597426861@qq.com

Abstract

Due to the typical urbanization mode, 'Wenzhou mode', which is based on the rural industry development, the metropolis fringe area of Wenzhou changed from dualistic structure to ternary structure gradually. Meanwhile, with the transformation of regional growth mode and the adjustment of industry structure, there are new development features presented in the regional spatial pattern and urban system. So, this article thinking, the dualistic structure of household registration system, land property system, primary administration system and the social-economic ternary structure are the reasons for the in-situ urbanization dilemma in Wenzhou metropolis fringe area, and the comprehensive dynamic mechanism of in-situ urbanization also makes contribution to the lack of urban infrastructure construction. Based on the analysis above, this paper illustrates the connection between the updated social-economic background and the modern growing tendency, trying to explore the suitable development strategy of urban planning and government management, in order to promote a healthy, energetic and harmonious metropolis fringe area.

Key words:

Wenzhou Mode; In-situ urbanization; Dualistic Structure; Ternary Structure; Dynamic Mechanism

Differences of the Construction of Social Network of the New Generation Rural

Migrant Workers Under Different Housing Morphologies

——A Case Study of Beijing

Wei Xinyu, Zhu Qing, Kong Cuicui, Ji Xuze, Zhou Yongru, Ma Qiuchen

School of Geography, Beijing Normal University, Beijing, 100101, P. R. China, zhuqing@bnu.edu.cn

Abstract

With the rapid development of urbanization, more and more rural migrant workers move into cities, looking for jobs and other opportunities. Compared with the first generation of rural migrant workers, new generation rural migrant workers are much more desired to integrate into urban society. Under the background of new urbanization, the citizenship of new generation rural migrant workers has caused high attention. Accordingly, the study about the way of new generation rural migrant workers adapt themselves and develop in urban society is of great significance. Under geographical perspective, this paper used questionnaire survey method for data collection. And then measured the social networks of new generation rural migrant workers and analysed the relationship between different types of residential space and the construction of social network based on factor analysis method. The results show that scattered residence is of great benefit for rural migrant workers to expand their social network size, enhance the heterogeneity and increase levels of their social network. While concentrated residence can help rural migrant workers fasten the strength of ties. Concentrated residential spaces, such as urban villages and collective dormitories is useless for rural migrant workers to construct social network. New generation rural migrant workers should live together with other social groups, so as to improve the quality of their social network and help themselves to integrate into urban society better.

From Urban Village to International Community: Space Production of South Korean Enclave in Yuanjing Road, Guangzhou

ZHOU Wenting, LIU Yungang, HUANG Xulu

SUN YAT-SEN University, Guangzhou, 510275, P. R. China, zhouwentinghai@163.com

Abstract

With a near-20-year development, the Yuanjing Road, Guangzhou got rid of the label of impoverished urban village and transformed into an international community mainly resided by South Korean Transmigrants. With the theory of space production, this research shed light upon Yuanjing Road, taking it as a case to examine the space production of South Korean enclave. Based on first-hand data gathered from field surveys and interviews in February, May and October 2015, we found that Yuanjing Road's transformation from an urban village into an international community, is a joint product of the local government, investors, villagers, migrant population, and South Korean Transmigrants. The South Korean Transmigrants, especially the businessmen, mainly clustered in Yuanjing Road due to two factors: first, the geographical accessibility to land and air transport hubs and large-scale wholesale markets; second, the cheap rental estates provided by urban villages cut the living costs. Meanwhile, the South Korean ethnic economy has developed and conducted trade activities. The South Korean ethnic economy was provided for South Korean Transmigrants' daily needs, which were owned and managed by both self-employed South Koreans and Chinese people. As a result, the development of South Korean Enclave in Yuanjing Road has resulted in the following changes: (1) provided employment opportunities for urban villagers and migrant population alike; (2) stimulated the economic growth of Yuanjing Road, with a general revaluation of real estates as an international community; and (3) reshaped its space landscape and reproduced the social relations of production.

Key words:

Space Production; Urban village; International community; South Korean Transmigrants; Guangzhou; Yuanjing Road

Spatial Pattern and Dynamic Mechanism of Rural-town Migration in China

Wang Shaofei

Beijing Normal University, Beijing China, 1564391414@qq.com

Abstract

Urbanization in China is a highlighted character since reform and opening-up. With the development of megacities, rural-town migration feels huge flow under the surface of water in the new stage. By comparing and analyzing the data from the Sixth Population Census in 2010 and the Fifth Population Census in 2000, the fact that the growth rate of town population was 61% from 2000 to 2010, and city was only 23%. Overall, through the spatial analysis by GIS, it is these places, where are traditional inland and relatively far from megacities, are the agglomeration areas of town development in attracting much more external population, which are the majority of North China Plain, Jiangxi province and Hunan province in Southeast Hills, Yungui Plateau, west of Sichuan Basin and the southwest of Loess Plateau. It's also clear that the external population of town are most from nearby rural area. The social survey and quantitative analysis indicate two main categories of rural-town migration in dynamic mechanism. One is rooted in the huge disparity between urban and rural areas, such as income, education, infrastructure and so on. Towns are living and consumption space rather than working and production space. Though part capital comes from the income in megacities, towns have been attracting rural migration for its modern life, lower housing price and consumption, relaxed household registration policy and local culture. The other rural-town migration is promoted by industrialization. Typically, Jiangxi province has been receiving the industrial transfer from Pearl River Delta for its location advantage and presented brilliant balanced development of town all over the province. According to the study, rural-town migration is intertwined with megacities in China, and alternative paths in different regions and social factors deserve attention.

Key words:

rural-town migration; China; spatial pattern; dynamic mechanism

Changement Climatique, Mobilités et Migration en Afrique de l'Ouest : le cas du Sénégal

Sakho P., Lo H. M., Coulibaly-Tandian O. K.

Université Cheikh Anta Diop de Dakar, Dakar, Sénégal, papa.sakho@ucad.edu.sn

Résumé

Les liens entre Changement climatique et mobilité humaine sont aujourd'hui au cœur du débat international. Depuis le rapport 2007 du GIEC, il est généralement admis qu'en Afrique les manifestations selon les régions en seront l'élévation des températures, la désertification, la rareté de l'eau et une fréquence accrue des phénomènes météorologiques extrêmes (Chemnitz et Höffler, 2011 : 54). Les prévisions controversées du nombre de migrants et de réfugiés climatiques induits (Afifi et Warner, 2008, Morton et al., 2008; Black et al., 2011, Piguet et al., 2010), illustrent cet intérêt. Et il est majeur pour l'Afrique de l'Ouest et en particulier le Sénégal marqué par une économie basée sur les productions agricoles sous pluies et une urbanisation littorale. Que sait-on des liens entre les manifestations et les mouvements de population dans la sous-région ?

Pour répondre à la question, la communication exploite une revue de la littérature sur la question en Afrique de l'Ouest et les données d'une enquête qualitative réalisée au Sénégal en 2012.

La communication a pour objet un exposé des principales conclusions de la revue qui sont ensuite confrontées aux données de terrain du Sénégal

Climate Change in the Pamir Region of Tajikistan: Towards New Internal Mobility and Migration?

Suzy BLONDIN

University of Neuchâtel, Switzerland, suzy.blondin@unine.ch

Abstract

Natural disasters that occurred in the Gorno-Badakhshan region of Tajikistan recently resulted in a lot of material destructions and numerous human displacements and resettlements. These events stress the need of new researches on the effects of climate change in the region and the new movements and migrations they are very likely to induce. Tajikistan is socioeconomically vulnerable, landlocked and highly exposed to geophysical related disasters such as earthquakes and landslides and to weather related disasters such as droughts, floods and avalanches.

Lately, studies on the region focused especially on the socio-economic importance of the international, seasonal and very manly migrations to Russia, but the internal migrations, for the purpose of work or in the context of forced resettlements are still to be analyzed.

The paper is a preliminary attempt at synthesizing the main environmental issues at stake in Takjikistan as well as to observe the resilience of the local population, the risk management issues and the projects implemented to assist the populations affected. New environmental issues will very probably give a new shape to the Tajikistani territory by enhancing rural-to-urban migrations and resettlements to less-exposed lands.

Very recently, various humanitarian associations conducted assessments of the immediate and mid-term needs of last year's disasters' affected populations and presented the repairing and relocation strategies managed by the associations and the government. Our paper will be mainly based on these data and on the existing literature regarding the Pamir region.

Key words:

Environmental change; socio-economic vulnerability; resilience; internal migration; resettlement

Climate Change, Mobility and Resettlement: Policies and Conflict in the Pacific Islands

Weber, E.

The University of the South Pacific, Suva, Fiji Islands, weber_e@usp.ac.fj

Abstract

Climate change has the potential to trigger large migration flows. Atolls, coastal areas and low lying river deltas / estuaries are particularly exposed to climate change impacts. In countries such as Bangladesh huge populations are threatened not only by sea-level rise, but also by other impacts such as intensifying tropical cyclones.

Also islands in the Pacific are severely exposed. In extreme cases entire states can become inhabitable and then challenges of unprecedented dimensions come up when entire states disappear. People living in these states need to resettle to other countries. For the Pacific Islands *Campbell* (2009) estimates that by 2050 between 665,000 to 1,725,000 people will be displaced because of climate change; some 320,000 live on atolls and low lying coral islands and require international resettlement. In other cases, resettlement within the same country might be an option.

The paper looks at Kiribati and the Fiji Islands and analyses risk scenarios for these countries. The paper uncovers political discourses about resettlement as they emerge on national and international fora. Based on this the paper reflects on challenges that relate to international movement as a result of climate change in the case of Kiribati and small-scale local relocations in the Fiji Islands.

Besides new insights in climate change migration and resettlement the paper also discusses appropriate methods to conduct research on such issues.

Key words:

Climate change; mobility; resettlement; Kiribati; Fiji Islands

From Data to Argument: The Challenges of Generating Policy-Operable

Understanding from Empirical Knowledge on Climate Change's Relationship with Migration

Nicholson, CTM.

Refugee Studies Centre, Oxford University, Oxford, United Kingdom. nicholson.cal@gmail.com

Abstract

Since the mainstreaming of climate change as a key topic of public and political debate a decade ago, its relationship with human migration has gained increasing prominence among researchers and policy-makers.

However, among the most common refrains (and conclusions) of empirical research is that climate change is one among many variables interacting - in a complex manner - to 'drive' migration. In other words, the framework for determining the causal relationship between climate change and migration, and the threshold by which we might distinguish such migrants from any other sort of migrant, remains unclear.

The paper will argue that considering such frameworks and thresholds is an integral step in any attempt to assess the state of empirical knowledge on the topic of climate change and migration. Only with such thresholds and frameworks in place may data lead to persuasive arguments for institutional investment in particular policies, actions, and interventions.

Given the currency of both climate change and migration as themes of political and popular concern, and the associated risk of their expedient use and abuse in the service of private agendas that are not in the public interest, addressing these two considerations is especially important.

In light of the panel's focus on assessing the state of empirical knowledge in China and Asia, this paper will therefore do three things: argue that a recognition of multi-causality and complexity is widespread in research; discuss the importance of attending to frameworks and thresholds; and emphasise the potential real-world ramifications of failing to do so.

Key words:

Climate change; environment; migration; causality; epistemology; knowledge; understanding; policy; displacement.

jmccaughey@ntu.edu.sg

Abstract

Resettlement choices after a disaster often involve a tradeoff between the risk of recurrence of a disaster and the risks that relocation may pose to livelihoods, social patterns, and land rights. Many studies find that people tend to return after a disaster; consistent with this, a consensus has emerged in the humanitarian sector that it is best to avoid relocation. We ask whether this is what people actually want, using the case of post-tsunami Banda Aceh City, Indonesia. Following the 2004 tsunami there, survivors were generally offered housing aid only to return to their original land. We find that this did not suit a substantial proportion of the affected population, using new quantitative and qualitative evidence from 1160 households and 121 village leaders. While many survivors wanted to return, some wanted to relocate further from the coast but did not have the chance to do so. Since that time, selective out-migration by those with the means and socioeconomic sorting of newcomers have led to a new socioeconomic segregation of the tsunami-affected parts of the city. More broadly, these findings suggest that short-distance socioeconomic sorting into and out from exposed areas may be an important migratory response to a newly recognized risk.

Key words:

post-disaster resettlement; migration; natural hazards; tsunami; Aceh; post-disaster relocation

‘Trapped Populations’ in Coastal Odisha, India: Understanding Environmental Migration Discourse beyond Dichotomies

Mohapatra SUBHAKANTA

Department of Geography, School of Sciences, Indira Gandhi National Open University (IGNOU), New Delhi, 110068, India,
subhakanta@ignou.ac.in

Abstract

Climate change has brought a range of calamities in coastal areas like cyclone and sea ingress. It has wide spectrum of impacts on vulnerable people in India. As a result, people are either migrating or helplessly stranded depending on the sources of income, types of assets and availability of choices. To understand the complexity, the paper argues that there is a need to relook at the mainstream discourse in India which is mainly dichotomous in nature-voluntary vs. forced migration, adapted vs. maladapted and security vs. development etc. The study was conducted in coastal villages of *Satabhaya* (Odisha), India located in the east coast, having long coast line and one of the most disaster prone states of India-Odisha. *Satabhaya*, a cluster of seven villages, has already lost five villages due to sea ingress. People of these villages are shifted many times during their life time. The idea of ‘Trapped Population’ is taken from the Foresight Report and contextualized in the study area. This is a unique case in which these villages are trapped between fury of advancing sea, frequent cyclones and legality of *Bhitarkanika* Biosphere Reserve and Government of Odisha. The study analyzed the processes which lead to migration that look beyond these dichotomies. The paper also critically reviewed policies, legality prevalent in the country to find out gaps to address the emerging situation and has used narratives, concepts of geographies of everyday life and affects to understand this complex and non-linear events.

Key Words:

Environmental migration; trapped population; narratives; Geographies of everyday life; Geographies of affect

Vertical Differentiation of Vegetation Cover Related to Population Migration of Mountain Areas: Taking Taihang Mountain Areas as a case

Li W, Tan MH, Li XB

Institute of Geographic Sciences and Natural Resources Research, Beijing, 100101, P. R. China, liw.14b@igsnr.ac.cn

Abstract

With the rapid advance of urbanization, rural population emigration has become a key indicator of transformation relationship between people and land in mountainous areas. Using trend line analysis method based on pixels and multi-regression model, this paper presented regional trends in vegetation greenness in different elevation of Taihang Mountain during the period of 2000~2010 based on MODIS data, using average NDVI (Normal Difference Vegetation Index) of growing seasons as the most important index. The relationship between vegetation greenness change in different elevation and population emigration were also explored based on the analyses of DEM data and the change of temperature and precipitation. The results included: 1) Over the past 11 years' rural population emigration is significant in taihang mountain areas, and the rural population emigration rate is 16.3%. 2) Taken as a whole, the vegetation in Taihang Mountain has improved. That is to say, during the specific period NDVI showed a trend of increase: it has increased 19.0%. About 96.2% of vegetation cover in this area has increased and this ratio increases with the increase of elevation: low, middle, high elevation are 92.5%, 96.2% and 98.8% respectively. 3) NDVI change trend is different in different elevations: NDVI growth increased slow in high elevation while NDVI growth increased obviously in middle and low elevations. 4) The main influence factors of NDVI were different in the regions with low, middle and high elevations: in the region with low elevation, NDVI was mainly influenced by both natural factors and the factors of human activities; In middle and high elevations, the effects of natural factor become more significant and the effects of human activities got weaker.

Key words:

Population migration; Vertical differentiation; Vegetation cover; NDVI; Taihang Mountain areas

The Impact of Soil Erosion on Human Migration in China

Zhuang L, Zhang H, Liang J

Institute for Urban and Environmental Studies, Chinese Academy of Social Science, Beijing, 100028, P.R. China,
zhuangli@126.com

Abstract

The impact of environmental change on human migration has been widely paid attention in recent years. However, there are still many problems that remain arguable and need to be resolved. Mass human migration has been a significant social phenomenon in China, while soil erosion is a major environmental problem that impacts socio-economic sustainable development. This study is aimed to identify the impact of soil erosion on human migration in China at the county level by analyzing related data. Results of spatial overlay could not identify an obvious relationship between soil erosion and net out-migration in China. We modified the gravity model of human migration to isolate soil erosion from other factors. The estimate results indicate that only serious soil erosion could increase the possibility of migration, and the impact is way higher in agricultural counties than in non-agricultural counties. In general, the impact of soil erosion on human migration is far less than the impact of socio-economic factors.

Key words:

soil erosion; human migration; gravity model; county level; China

A Review of Interventions to Break the Link between Food Insecurity and Conflict in Ethiopia

Abate, ESUBALEW, Semie, NEGUSSIE

Assistant professor, Institute of Development and Policy Research (IDPR), Addis Ababa University, Addis Ababa, Ethiopia, esubalewabate@gmail.com

Abstract

The link between food insecurity and conflict is context-specific and varies according to a country's level of development and the strength of its political institutions and social safety nets. Other factors that heighten the chance of conflict include demographic factors such as whether a country has a relatively large number of unemployed youths, coinciding with high rates of urbanization which increases the ratio of food consumers to producers.

Moreover, it is becoming apparent that food security is a pre-condition for stability and stability is a condition for food security particularly in low income countries. Furthermore, food shortage and high food prices should be seen as signals of potential conflict breaking out and governments need to be alert in taking actions like reducing import tariffs and taxes on food items and increasing subsidies to lower food prices, as well as releasing grain buffer-stock to increase supplies. In line with these, governments of low income countries like Ethiopia must strengthen the capacity of institutions responsible for addressing and watching food insecurity and the drivers of conflict in both urban and rural areas of the country to ensure peace and stability.

Key words:

Food insecurity; conflict; institutions; urban and rural areas; stability

An Analysis of the Income Components of Rural Households in Xinjiang, China

Chen Jianying¹, Wang Zhe², Wang Yan³

¹Department of Geography, Shaanxi Normal University, Xi'an, 710062 Shaanxi, China

²Department of Geography, Xinjiang Normal University, China

³Xinjiang Education Institute, Xinjiang, China, xjsfdxcjy123@163.com

Abstract

Using data from 1982 to 2009, this paper examines how components of rural household income contribute to the major income gap between 30 poverty-stricken counties in Xinjiang and the national average in China. Income from family businesses account for 80% in Xinjiang, while income proportions from wages and salaries, property and transfers are very low. The analysis shows that farmers' income depends on the family business for regular income and that the regional economy in rural areas is still dependent on direct consumption by producers. Living standards are declining because of extra educational expenditure for children, modern medical services and inflation. Income growth from wages and salaries is the major driving force for poverty reduction in Xinjiang. Fundamental ways to address poverty are to establish training programmes for farmers, improve employment opportunities, hasten construction of towns and small cities, promote the transfer of rural surplus labour, and escalate the proportion of income from wages and salaries, property and transfer.

Key words:

income components; income growth; labour transfer; Xinjiang

Assessment of the Rurality and its Driving Mechanism of Oasis City in Arid Zone— —A Case Study in Wuwei

NIE Xiao-ying, SHI Pei-ji, ZHANG Xue-bin, LV Rui, ZHU Yan-fen, WEI Wei

College of Geography and Environment Science, Northwest Normal University, Lanzhou, 730070, Gansu, China, nxy_nwnu@163.com

Abstract

Basing on 65 years social and economic statistical data and taking the counties as the basic spatial unit, we evaluate the rurality indexes by using factor analysis and examine the spatial-temporal differentiation of rurality in Wuwei with the help of one-dimensional linear regression model, wavelet analysis and differentiation index model, and then discuss the influencing factors of rurality development from social economic and technical economic aspects. The conclusion as follows: ①rurality indexes showed a trend of weakening in counties of Wuwei during 1949-2013, while there are differences around decreased amplitude and speed. ②the rurality differentiation index presents a fluctuates growth trend and rose sharply after 2000 which indicate an increasing rural difference. ③social economic and technical economic are two main factors of rurality variation, with the development of industrial structure, traffic, policy, labor force, agricultural mechanization and agricultural structure, the value of rurality become smaller and smaller and the urbanization level is on the contrary.

Key words:

rurality; differentiation index; driving mechanism; Wuwei City

“Città Slow”: Catalyst and Anchorage for Rural Sustainable Development

Firmino, Ana

CICS.NOVA, Universidade Nova de Lisboa, 1069-061 Lisboa, Portugal, am.firmino@fcsh.unl.pt

Abstract

Pursuing the ideal of sustainable development in the rural areas is often rather illusory or transitory since many initiatives are lacking a specific frame that may give them local anchorage in the medium/long run and thus, many of these projects are ephemeral.

The concept of “città slow” created in Italy in the late nineties, aims at supporting quality of life in small municipalities/cities with less than 50 000 inhabitants, this quality being measured in 7 categories:

Environmental policies, infra-structures policy, technologies for the urban quality, promotion of local products, inhabitants’ awareness, social cohesion and networking.

Since 2011 the municipality of Vizela has been one of the 6 certified città slows in Portugal and will be presented as a case-study.

In the last 5 years the municipality has worked in favour of the local community, starting with the youngest ones at school, who attend a special program tailored according to the concept of città slow. Furthermore they have been active in initiatives aimed at strengthening the ideals subjacent to the concept, i. e. encouraging the diversity and originality, supporting the local culture and traditions, gastronomy and wines, handicraft, developing a better environmental quality and creating conditions which offer a healthier life style based on the Slow Food Movement.

The “città slow” can thus act as catalyst and anchorage for different activities in the rural areas, attracting visitors who ensure the sustainability of the local economy.

città slow; smart projects; local economy; rural areas; sustainable development

Construction of Agricultural Innovation System Based on Agricultural Cluster: A Case Study of Vegetable Cluster in Shouguang City, Shandong Province

Li Erling, Shi Yanwen

College of Environment and Planning, Henan University, Kaifeng, Henan 475004 P. R. China, erlingli@126.com

Abstract

Agricultural innovation in developing countries has attracted the attention of many scholars. Constructing agricultural innovation system is an effective way to develop modern agriculture and agricultural innovation, and agricultural industrial clusters are effective carriers for agricultural innovation system. This paper constructs the theoretical framework of agricultural innovation system, through field survey of 68 households, 32 agricultural enterprises, local government and industrial association in vegetable industrial cluster in Shouguang City, Shandong Province, using social network analysis to conduct an empirical analysis on the structure of agricultural innovation system. It is shown that, agricultural innovation system is composed of three parts of innovation subject, innovation networks and innovative environment. Local large enterprises and corporate group play a leading role in the vegetable cluster innovation; The small businesses and farmers have a key function on the popularization and application of innovative technology; Higher heterogeneity of the status of innovation in local enterprises; the direct role of government in the innovation of agricultural clusters is smaller, but the hybrid organizations set up by government, enterprises and the non-government institutes have a significant function of incubation; Close linkages among enterprises, universities and research institutes can significantly improve the innovation capacity of cluster enterprises. Relative to the cooperative networks, knowledge networks show a mononuclear structure and the centralization and density of the networks are higher. Although there is strong international and domestic environment for cooperation in Shouguang cluster, the institutional construction for improving the local innovation environment still needs to be strengthened.

Key words:

agricultural innovation system; agricultural industrial clusters; social network analysis; vegetable industrial cluster in Shouguang city

Coping with the End of the Commodities Boom: A Socioeconomic Analysis of Rubber Smallholders in Southern Thailand

Andriesse E, Tanwattana P, Andriesse SS

Department of Geography, Seoul National University, Seoul, 08826, Republic of Korea, e.andriesse@gmail.com

Abstract

The ongoing slowdown of the Chinese economy has triggered serious economic geographical repercussions across the globe. Most remarkably, countries dependent on exporting commodities to China have witnessed profound challenges with respect to maintaining economic growth as well as maintaining employment in commodities' industries. Several reports claimed that we are now seeing the end of the commodities boom. This paper focuses on the steep fall in the international natural rubber price, and investigates its impact on the socioeconomic situation of rubber smallholders in southern Thailand. In light of the highly volatile rubber price the aim of this paper is to unravel the coping mechanisms of rubber smallholders by focusing on two issues: diversification and community development. The main empirical analysis is based on a survey of 53 smallholders in a village in Nakhon si Thammarat Province. Besides rubber these smallholders also grow fruits in particular mangosteen for the domestic market. This is complemented with a smaller survey in another village which is much more dependent on rubber as well as several semi-structured interviews with community leaders in two best practices villages in Rayong Province in central Thailand. This paper highlights the vulnerability of rubber smallholders. Although household activities have become substantially diversified, volatility in the international rubber price still causes households to zigzag back and forth between the categories of ordinary farmers and accomplished middle class earners within a time span of a few years. It also highlights the challenges of achieving successful rural community development across Thailand.

Key words:

Rubber smallholders; boom and bust cycles; diversification; community development; Thailand

Cost of Cultivation and Farm Income of the Tribal Households: An Analysis of Hilly and Plain Regions of Rajasthan (India)

Meena AJAY

Department of Geography, Government College, Tonk (Rajasthan, India), aj.meena@gmail.com

Abstract

Agriculture is the most important source of livelihood of the tribal households of Rajasthan (India) and the level of earnings from this source is an important determinant of their well being. In this Paper, attempts have been made to explain the economic characteristics of agriculture in terms of cropping pattern, cost of cultivation, cost structure and net farm income of the households. It is an analysis of the tribes living in two different geographical settings (hilly and plain regions) of Rajasthan. The source of data is the field survey which has been carried out in December 2011 and April 2012. The methodology adopted for estimating the cost of cultivation is that followed by the Comprehensive Scheme for Studying Cost of Cultivation/ Production of Principal Crops in India. The cropping pattern of the hilly region is subsistence type whereas it is diversified towards the commercial crops in the plain region. The relatively greater share of the modern inputs in the total cost of cultivation reflects the elements of modern agriculture in the plain region. Both the physical productivity and the gross value of output for most of the crops are comparatively low in the hilly region. The net farm income (net of Cost C_2) is negative for almost all crops in the hilly region whereas it is positive for majority of the crops in the plain region.

Key words:

Tribes; Cropping Pattern; Cost A_2 & Cost C_2 ; Cost Structure; Gross Value of Output; Net Farm Income

Development and Livelihood Sustainability: Pangri Tribal Region of Western Himalaya, India

Chand Khyal

Assistant Professor Department of Geography St. Bede's College Shimla 171002, khyal.hpu@gmail.com

Abstract

The Pangwala tribal community lives in close proximity of nature with typical mountainous specificities. By and large, the inhabitants of Pangri region depended on subsistence agriculture, livestock rearing and allied activities to support their livelihoods. Therefore; the present paper explores the impact of development programmes on the sources of livelihoods of people of the study area. The livelihoods of people have been examined in terms of their means of living including types of crops grown, food, income and assets. The study reveals notable changes in the livelihood options in remote tribal region of Himachal Himalayas. The traditional foodgrain crops a major source of sustainable livelihood, cultivated in the study area have been replaced by cash crops which are more market driven and less sustainable. The study shows that food habits of the scheduled tribes have changed considerably during the study period. The impacts of developmental activities on the livelihood options and strategies are largely determined by expanding connectivity of villages through surfaced road and growing social media in the study area. These factors along with topographic controls are responsible for spatial variations in the livelihood options and strategies in this tribal area. The changing livelihood arrangements among the scheduled tribes of Pangri region also raise issues of different facets of sustainability.

Key words:

Pangri Region; Scheduled Tribe; Development; Livelihood; Sustainability

Economic Development and Cultural Change in rural *Guangzhou*

Yasuo Kojima

Kyoto University, Kyoto, Japan, kojima.yasuo.4w@kyoto-u.ac.jp

Abstract

Zhujiang Delta has been one of the most developed areas in contemporary China. Analyzing data from the field survey that we conducted in two villages, near *Guangzhou* city, this presentation discusses the process of rural change. Industrialization in the field was launched in the late 1980's and now the landscape of modern factories besieges old villages. Migrant workers for factories live in densely built-up area in the village. The rent of houses and factories has increased villagers' income, so there are few villagers working for factories or working away from home. Another rural change is observed in cultural dimensions. *Longzhou*, dragon boat is essential to traditional festival in the area, some village has bought *Longzhou* according to the improvement of living standards. *Citang*, ancestral hall which characterize the religion of southeast coast also has repaired in these years. The aim of this presentation is not causal inference of economy and culture, but describing the place where economic development under globalization and cultural revival in local context has gone side by side as the regionality of rural *Guangzhou*.

Key words:

rural change; industrialization; traditional culture; regionality; *Guangzhou*; *China*

Forced Displacement and Socio-cultural Adaptability among the Tribal Population: A Study of Sardar Sarovar Dam in India

Sushil

UGC-Research Awardee, Jawaharlal Nehru University, New Delhi, India, sushil_dalal@yahoo.com

Abstract

The building of large dams invariably results into forced displacement of human population which causes social, political, demographic, economic and environmental repercussions. The displaced people try to adapt themselves to the alien social and cultural environment for their survival. The life in tribal communities particularly in and around the reservoir area of Sardar Sarovar Project in India largely partakes of prevailing socio-cultural systems in the adopted environment. For instance many social and ritual practices in tribal communities revolve around worship of supernatural power. Due to the construction of Sardar Sarovar Dam on river Narmada, the tribal people are forced to settle down in the plain areas with communities practicing alien cultures as a consequence of which these resettled tribes are forced to adapt to the socio-cultural practices of the alien milieu.

The present paper attempts to find out the socio-cultural adaptability of the displaced population for their survival in an alien environment due to the construction of the dam. The study is mainly based on primary source of information and the data has been generated from ten resettled sites selected through stratified random sampling method from different physiographic regions. The study reveals that there is significant change in social and cultural life of the affected families as a result of which the practices of traditional social and cultural rituals show signs of transformation. In nutshell, people have adopted alien social and cultural practices while the relation with environment and ecology has been negatively affected due to the process of displacement.

Key words:

Forced Displacement; Sardar Sarovar Dam; Survival

Impact of Urbanization on Rural West Bengal in India

Dey FALGUNI

Senior Research Fellow, Department of Geography, University of Calcutta, Kolkata – 700019, India,
falguni.dey2008@gmail.com

Abstract

Urbanization in west Bengal has been a long but slow process. Since colonial days West Bengal experienced early advent of urbanization process mainly in the capital city Kolkata, erstwhile Calcutta. On the other hand vast areas of west Bengal remained under deprived rural areas even after independence where agriculture has been the main stay since generations with no alternate mode of earnings. Much change did not take place in last fifty years because almost 70 percent people of west Bengal still lives in rural areas. Census of India on the other hand has strong evidence of decreasing number of villages due to sprawling and outgrowth of urban areas. The balance between rural and urban development did not run hand in hand rather an imbalance could well be visible. Kolkata being the capital city enjoyed highest primacy of ranking of urban areas as no alternate city came up except a little effect of Asansol, Durgapur and Siliguri. It could easily be said that entire west Bengal is oriented unidirectional towards Kolkata. The authors in this paper attempt to introspect into the changing agricultural, demographic and socio-economic scenario of west Bengal in recent times and to find out the role of urbanization process to accelerate it. The result shows that southern part of Bengal is well influenced by the Kolkata, whereas northern part is controlled by Siliguri town. National and state highways and alongside urban areas are transforming into a promising agglomeration. Land values are well affected by distance decay effect.

Key words:

Agricultural development; Urbanization process; Rural Development; Demographic Change; Land Value

Livelihood Strategies of Ethnic Minority in the Borderlands: Case Study of the Bru-Van Kieu in Northern Central Vietnam

Kim DC, Nguyen A, Ubukata F

Okayama University, Okayama, 700-8530, Japan, kim@okayama-u.ac.jp

Abstract

The Bru-Van Kieu, one of ethnic minorities in Vietnam, have lived in the mountainous area along the border with Laos for centuries. Approximately by the end of the Second Indochina War, the Bru-Van Kieu were still a kinship-based and non-stratified societal group relying mainly on subsistence economy. Their traditional physical geography, nonetheless, has been transformed vigorously during the last few decades as a result of state-formation processes and changes in macro-economic policies. The paper aims to examine how ethnic minority adapt their livelihood to challenges instigated by macro political and economic processes. By examining livelihood adaptation of the Bru-Van Kieu, the study also identifies strategies that ethnic minorities use to negotiate with more powerful political and economic forces. The authors argue that the Bru-Van Kieu have deployed a strategy combining everyday resistance to maintain their limited social and cultural agencies and utilizing of these agencies in economic adaptation with other cross-ethnic non-state actors, enabling them to tap into new type of resources and opportunities.

Key words:

livelihood strategy; ethnic minority; state formation; borderlands; Vietnam

Market Failure in Global Production Networks and the Emerge of New Market Opportunities for Small-Scale Dairy Producers in Slovenia

DELLMANN N., HASSLER M.

Phillips-University, Marburg, 35037, Germany, nicolai.dellmann@geo.uni-marburg.de

Abstract

The Slovenian dairy industry is determined by processes of consolidation which lead to a dramatic decrease in the amount of small-scale producers. Contemporary GPN literature allows for an understanding of the underlying links between globalization and the restructuring of regional production systems. A blindspot/, however, remains on processes caused by the exclusion of actors from such systems, notwithstanding the concomitant implications on the local production system. Based on a qualitative research, this paper analyses the various sets of activities small-scale producers develop in order to cope with the changing economical environment. Interviews with different Slovenian actors of the dairy industry revealed alternative forms of direct marketing as opposed to the distribution through intermediaries, such as cooperatives. These forms of direct sales empowered the actors to overcome income uncertainty induced by volatile milk prices instead of realizing economies of scale through enlarging the herd.

This contribution enhances the benefits of locally organized, disintegrated distribution systems as well as its limits, predominantly driven by the consumer's choice. It furthermore offers a wider and deeper understanding of how the GPN framework can be used to portray market failures in selected sectors.

Key words:

GPN; dairy sector; small-scale producers; alternative distribution

Metabolizing the Rural, Fermenting the Landscape: Considering Wine as a Driver of Social and Environmental Change along the Rural-Urban Interface

Hiner, C

Texas State University, San Marcos, TX, USA, cchiner@txstate.edu

Abstract

The study of “fermented landscapes” involves examining how shifting patterns in the production and consumption of beer, wine, cider, and spirits impacts physical-environmental and socio-cultural landscapes. Specifically, the concept hones in on the production, distribution, and consumption of fermented beverages as a focal point in the complex study of rural-urban exchanges or metabolisms over time and space. In this paper, I investigate how differing forms of production/consumption influence material and symbolic landscapes at a variety of scales. Drawing on qualitative fieldwork and secondary data analysis in California, Arizona, and Texas in the United States, this paper describes the crucial role fermentation places in the politics of placemaking and associated processes of ecological change in “emerging” wine regions in the United States. Using the wine industry from “grape to glass” as a lens through which to examine landscape production and consumption, I outline the impetus and justification for a comprehensive conceptualization and political ecology of “fermented landscapes” that examines the environmental, economic, and sociocultural implications of fermentation in both expected and unexpected places and ways. Further, I explore how the pursuit of a “wine country” identity does or does not improve local and regional attempts at sustainability.

Keywords:

wine; fermentation; production vs. consumption; landscape; political ecology; rural-urban interface

Multifunctionality, Resilience, and Globalization: building a Theoretical Perspective from Brazil in the context of Rural Change

Machado, F.S.

Human Geography, Plymouth University, Plymouth, United Kingdom, felipe.dasilvamachado@plymouth.ac.uk

Abstract

With deepening industrialization Brazil has gone from being the 14th largest global economy in 1970 to 10th in 1990 and to the 7th largest economy in recent years (Becker and Egler, 1992; Cohn, 2012). As the economy globalized away from metropolitan areas, profound changes have occurred in the rural areas. The research question relates to how rural areas in transition economies such as Brazil will be affected by socio-economic, political and environmental changes expected in this country over the next decades.

Using transition theory, to discuss a temporal and spatial model for transition in different dimensions, the aim of this study is to bring together a transition theory approach with the areas of investigation of rural multifunctionality and rural community resilience. The argument is based on the contemporary debates concerning rural change in the context of economic globalization and should be seen as a theoretical perspective of interconnections between globalization and rural community resilience in a rapidly changing world.

Wilson (2010, 2013) has discussed the complex interlinkages between community resilience and policy challenges, linked especially to the notion of policy corridors and who should be in charge of the global resilience transition. This approach relates to attempts to understand how transitions in community resilience pathways are linked to various capitals and how these interact with exogenous policy processes. According to Wilson (2012), human geography is particularly well placed to provide insights into the spatial discontinuities and heterogeneities of community resilience across a range of various community types and globalization processes.

multifunctionality; rural community resilience; globalization; rural change; transition economies; Brazil

New Age of Agrarian Transformation in Sumatra, Indonesia: The Expansion of Oil Palm Cultivation and Its Impact

Yusuke Koizumi

The University of Tokyo, Tokyo, Japan, koizumi@humgeo.c.u-tokyo.ac.jp

Abstract

As the demand for edible and vegetable oils has increased on the world market, the area dedicated to oil palm cultivation in Indonesia has dramatically expanded. As one of the unique characteristics of oil palm cultivation in Indonesia, the number of smallholders is increasing and their economic position is improving to an unprecedented extent. This situation has drastically changed livelihood strategies and the landscape of rural societies in the outer islands of Indonesia, especially in Sumatra Island. Several studies have already noted that differentiation was brought into rural societies in Sumatra as the consequences of the expansion of oil palm. Others have admitted that the regional economy was substantially improved because the income of smallholders is higher than other jobs. In addition, new job opportunities were provided by plantation companies as well. However, it is still unclear how the new social and economic system has been created and maintained after oil palm has prevailed in rural areas. Therefore, this study tries to figure out the recent chronological changes of rural societies in Riau Province, which is located in the middle of Sumatra where oil palm cultivation by smallholders is most expanding. As for the research method, this study firstly analyses the meso-scale dynamics of social changes with census data, and secondly conducts intensive interviews with local people. In Riau Province, there are many in-migrants from other provinces and they are playing a key role both as labour in plantations and small scale cultivators.

Key words:

Indonesia; oil palm cultivation; smallholders; rural economy

Peasants and Agribusiness in the Middle-income Trap: The Case of “Safe and Traceable” Asparagus Production in Thailand

Ubukata F., Datai H., Kim D-C.

Okayama University, Okayama, 700-8530, Japan, ubukat-f@okayama-u.ac.jp

Abstract

It is widely known that Southeast Asian peasants have been actively involved in commercial agricultural production since the colonial time. However, due to the recent development of downstream agroindustry and the introduction of strict quality control measures by developed countries (major importers), many agricultural commodity chains have been rearranged toward larger integration into global agribusiness. Coordination between peasant-based production system and global agribusiness can thus be one emerging issues in Southeast Asian agricultural sectors. Taking example of “Safe and Traceable” asparagus production in Thailand, this study therefore examined how Thai peasants have become integrated into such a rearrangement of commodity chains.

After the series of surveys during 2012-2015, the study found following results. First, development process of the commodity chain could be divided into three phases: 1) early phase, 2) matured phase and 3) transition phase due to severe international competition. A Japanese packer played leading roles throughout the process, while the state sector played coordinating roles. Second, many peasants had started to enter the contract scheme during the second phase and gradually developed their technical, organizational and negotiation capacities. And third, both private and state roles for industrial upgrading were limited. The R&D activities were inadequate in both sectors, thereby caused initial failure to tackle diseases damage in the third phase. As a result, many peasants have exited from production. These findings indicate that Thai peasants are facing an agribusiness system which falls into the middle-income trap.

Key words:

Peasants; agribusiness; integration; upgrading; asparagus; Thailand

Roles of Rural Communities and Smallholders in REDD+ and Community-Based Forest Management: A Case of Vietnam

Bayrak, MM

Harbin Institute of Technology, Shenzhen Graduate School, P.R. China, mmbayrak@link.cuhk.edu.hk

Abstract

The Reducing Emissions from Deforestation and Forest Degradation (REDD+) programme is offering developing countries financial incentives by creating financial values for the carbon stored in forests. The main aim of this initiative is to combat climate change, deforestation and forest degradation. It also includes forest conservation, sustainable management of forests and enhancement of forest carbon stocks. In a decade in which community forest management initiatives are rising, the REDD+ programme could reverse this process in putting forest governance on national level again. This could have severe consequences for local forest-dependent communities. REDD+ could recentralize forest governance if it is not sufficiently integrated in the local context, and therefore exclude rural communities and stakeholders who depend on their forests for their livelihoods and food security.

This paper examines how REDD+ can be compatible with local forest-dependent communities, smallholders and community-based forest management (CBFM) in Vietnam. The results of this paper are based on household-surveys (n=187) in Thua Thien-Hue, Quang Tri, Lam Dong and Kon Tum province. The communities in these sites are involved in CBFM, REDD+ or benefit sharing mechanisms in forest protection (BSM) in various degrees. The central question of this paper reads as: What roles do community-based forest management (CBFM) and communities play in BSM/REDD+, and in what way does CBFM align with the programmes' respective objectives? We aim to summarize this paper through a renewed typology of community-based forest management within the context of Vietnam and beyond.

Key words:

REDD+; community-based forest management; Vietnam; forest governance; indigenous peoples; climate change mitigation

Roraima: The Latest Soybean Growing Frontier of BrazilDiniz, Alexandre M A¹, Lacerda, Elisangela G²¹Geography Graduate Program – Pontifical Catholic University of Minas Gerais – Belo Horizonte- Brazil

alexandremadiniz@gmail.com

²Geography Department – Federal University of Roraima – Boa Vista - Brazil**Abstract**

Roraima is the northernmost Brazilian state, located along the borders with Venezuela and Guiana. Deeply rooted within the Amazon rainforest, the state also encompasses large tracts of savanna. Roraima has a short history of occupation and economic exploration. It was not until the 1980s when a more liable terrestrial link with the rest of Brazil was materialized. Since then Roraima has experienced tremendous population growth with thousands of migrants arriving in search of mineral riches, land in colonization projects, and employment in the tertiary sector of Boa Vista, the capital city. Roraima still represents one of the last resorts for the Brazilian landless, displaying active agriculture frontier areas; vast tracts of pristine lands; national parks; and native people's reservations. Despite its strategic location Roraima has established only feeble and indirect links with global markets until recently. Responding directly to the international appetite for commodities and mimicking processes undergone by the southern fringes of the Amazon, Roraima witnessed the progressive arrival of soybean during the 2000s given its low land markets values; favorable climate; and its location. Roraima is much closer to major consumers markets, and soybean can be easily shipped abroad through Venezuela and Guiana. Russia and Holland are major importers, and in 2014 soybean surpassed Roraima's historical leading exporting good: wood. This study explores the recent historical and geographical expansion of soybean plantations in Roraima examining some of its social, economic, cultural and environmental impacts based on secondary data and fieldwork.

Key words:

Globalization; Soybean; Amazon; Roraima; Socioeconomic Impacts

Rural Resilience in Response to the Decline of Rural China

Yuheng Li

Associate Professor, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China, liyuheng@igsnrr.ac.cn

Abstract

When urbanization in the developing world still mainly occurs at the expense of the countryside, the hollowing out of the countryside has become a widespread concept in many developing countries. China witnessed rapid urbanization development in the past decades, however, this development has been accompanied by the ever decaying countryside when huge amounts of peasants have migrated to cities. As a result, the once self-sufficient villages of China become hollowed and declined, and face challenges like labor shortage, industry recession, infrastructure backward, cultural loss and social conflicts.

What are the villages' capability to prepare for, respond to, and recover from significant socioeconomic threats in rural China? How to understand rural resilience? What are the implications for policy making? Bearing these questions in mind, we tend to investigate the villages' resilience capability in response to the decline of rural China. Firstly, the paper makes theoretical interpretation of rural resilience towards the decline. Secondly, historical review of how villages start to decline and the driving forces will be made. Then, the paper tries to analyze ways of improving villages' resilience capability in China, which is followed by policy implications towards sustainable rural development in the future.

Key words:

Rural resilience; Socioeconomic decline; Urbanization; Sustainability; China

Rural Space and Concept of Social Representation. Case of Poland

Wójcik M

University of Lodz, Lodz, Poland, wojcik.moskwa@gmail.com

Abstract

The proposed project applies to space realized in specific forms of cultural landscape (forms of human settlement). The main aim of the research is to determine the diversity of spatial representation of rural settlements in Poland, based on the model developed using the concept of "production of space" (H. Lefevbre, D. Harvey, K. Halfacree). Representations of space are the ways of cultural creation of life environment and they include various material (forms of its spatial organization) and mental structures (such as images of spaces). In other words, spatial representations are specific forms of space (landscape) appearance - being visible (real structure) and images of space (mental structures). Three objectives were formulated according to this model, namely: 1) Multifaceted determination of the forms of rural spatial practices. The aim is to analyze the forms of cultural landscape (settlement landscape - spatial structure (arrangement) and settlement physiognomy) interpreted as a material effect of social and economic practices 2) Identification of methods of representations of rural space. The aim of the research in this area is the analysis of various types of documents - historical and contemporary 3) Determination of spaces of representation. The aim of the research in this area is to present proposals for the analysis and classification of "freehand sketches", which could be used in studies of subjective rural spaces (structure of "human spatial images").

Key words:

rural geography; rural settlements; social representations; imaginations

Socio-Economic Analysis of Informal Activities: A Case Study of Women Participation in Local Embroidery (Dinkin Zargo) in Wudil Town

Bichi, A.M., Maimuna, H.H., Muhammad, A.D.

Kano University of Science and Technology, Wudil, Kano Nigeria adobichi@yahoo.co.uk

Abstract

The research explores the socio-economic benefits of local embroidery among women in Wudil town. A questionnaire survey was used on two hundred and thirty five households' carefully selected using stratified random sampling technique. The households were drawn from the old Wudil town and the new residential area popularly known as Sabon Gari. The result shows that the production and marketing of locally embroidered textile products is one of the major occupations in Wudil town generally. The findings reveal that the benefits from embroidery improve women's standard of living and their economic status. It shows most of the income generated by women through this activity is spent on contributions to friends and family towards wedding and naming ceremonies as it accounts for 43.3%. This is compared to all the other benefits that jointly account for the remaining 57.7%. A Chi-square test was conducted to determine whether there is any relationship between the marital status of the respondents and the type of benefit derived from their engagement in local embroidery, the result shows a p- value of 32.910 has a probability value ($p < 0.05$). The study recommends that for the informal economic activities to proffer, the government should as a matter of serious intervention provides funding to the rural women in order to promote their artisan skills. Women should be encouraged to form community based organizations to help their informal economic activities.

Tea Plantations and Socio-Cultural Transformation: The Case of Assam (India)

Kar, BIMAL KUMAR, Magar, CHANDRA KALA

Department of Geography, Gauhati University, Guwahati, 781014, India, bimalkar@gauhati.ac.in

Abstract

The tea plantations of Assam in India, which constitute country's 53 per cent tea area, 49 per cent tea worker population, and 51 per cent tea production, occupy an important place in the economy, culture and polity of the state. The onset of tea plantations during British colonial rule has not only changed the landscape of the upper Brahmaputra valley through green tea bushes being nourished by tea tribes from east-central India, but also evolved a distinct tea culture. Although formation of small tea growers has added a new dimension to the growth of tea industry of Assam in recent times, the culture that emerged due to the long continued interaction of British planters, tea worker tribes and indigenous Assamese is well reflected in the language, way of life, work culture, food habit and many other socio-cultural practices in most of the large tea estates in the state. In fact, the impact of tea culture is so penetrative that it has been able to bring about development in the form of tea festival, tea tourism, tea folk songs and dances, etc in the state. An attempt is made in this paper to explore the role of tea plantation and the people associated with it to the socio-cultural transformation of Assam based on both secondary data and primary data through field study. The primary data have been collected from selected tea estates, tea garden worker colonies, tea-tribe villages and urban dwellers.

Key Words:

tea plantation; Assam; tea tribes; tea culture; socio-cultural transformation

The Allocation and Management of Critical Resources in Rural China under Restructuring: Problems and Prospects

LONG H, TU S, GE D, LI T, LIU Y

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, longhl@igsrr.ac.cn

Abstract

Rapid and far-reaching development transition has triggered corresponding restructuring in rural China especially since the turn of the new millennium. Recently, there has been an increasing trend emphasizing regional resources in formulating rural development policy and restructuring rural areas. This paper analyzes the rural restructuring in China affected by the allocation and management of critical resources including human resource, land resource and capital, by establishing a theoretical framework of “elements-structure-function” of rural territorial system. It is argued that rural restructuring is a process of optimizing the allocation and management of the material and non-material elements affecting the development of rural areas and accomplishing the structure optimization and the function maximum of rural development system. Due to the constraints from the maintained urban–rural dualism of land ownership and household registration, the rapid rural restructuring under both globalization and the implementation of the national strategies on industrialization, urbanization, informatization and agricultural modernization, the changes of the allocation of critical resources have brought about many problems and challenges for the future development of rural China, such as the nonagriculturalization, non-grain preference and abandonment of farmland use together with the derelict and idle rural housing land, the weakening mainbody of rural development, the unfair urban–rural allocation of capital and its structural imbalance, and so on. Aiming at how to resolve the problems and adapt to the challenges, it is pivotal to restructure the rural development space, rural industry, and rural social organization and management mainbody.

Key words:

spatial restructuring; industrial reshaping; social restructuring; urban–rural development

The Impacts of Globalization on the Sustainability of Rural Areas Communities

Adjacent the Sues Canal Corridor, Egypt

Prof. EISA, S.A.

Department of Geography, Faculty of Arts, Menofia University. Egypt. d_salah_eisa@hotmail.com

Abstract

This paper focuses on the sustainability challenges of rural communities in the age of globalization, which is a deeply complex phenomenon. The impact of globalization activities on rural areas does exist within changing agricultural and food systems through new technologies for huge production, which may decrease labor input, then, may enforce rural people to emigrate.

The Suez Canal is a global navigation passage in Egypt between the Mediterranean and the Red Sea. A new achievement for upgrading and enlargement has been carried out in order to allow big ships to cross the canal. The Suez Canal Corridor Project (SCCP) has been designed to transform Port Said and Suez ports, beside others, into global warehouses, and to build industrial projects and traffic businesses served by logistics.

The eastern strip of Nile Delta, covering some districts of Ismailia and Sharqia governorates, and keeping territorial, economic, and social access, is the nearest neighbor rural area to the west bank of Suez Canal Corridor.

The present study aims at enhancing solutions for the sustainability of the mentioned rural area that faces the challenges of globalization related to the ascendant (SCCP). This will be approached in four steps: 1) mapping features of the rural area and tracts of access to Suez Canal corridor, 2) understanding the traces of globalization on study area before (SCCP) implementation, 3) expecting the impacts of globalization on study area relating to the intended targets of (SCCP), 4) trying for promoting the capacity of study area to preserve its rural sustainability.

The Spatial Patterns and Influential Factors of the Development of SVAT in China

Qiao J J, Lee J, Shao L C, Ma Y L

College of Environment and Planning, Henan University, Kaifeng, 475004, P. R. China, jjqiao@henu.edu.cn

Abstract

Under the banner of One Village, One Product (OVOP), many villages and towns in China had developed into specialized villages and towns (SVAT). Each of them had its specialty enterprises or engaged activities that dominated local economy. Based on the analysis of data collected for 1,605 specialized villages and towns in China we found that special villages and towns distributed spatially unevenly and their economic performance showed spatial inequality. We also found that the majority of these villages and towns focused on agriculture-related economic activities. The major spatial cluster of specialized villages and towns was in Beijing-Tianjin region. The secondary clusters were in Jiangsu, Zhejiang, and Shanghai areas. Using spatial statistical methods, we also found that promotions and assistance program by local governments as well as resource endowments were the major influencing factors to the development of specialty villages and towns in China.

The Study on Formation Mechanism of Market Town System in Southwest Mountain of China - A Case Study of Xuanwei City

Zhang Chao, Wu Yingmei

School of Tourism and geographical Sciences, Yunnan Normal University, Kunming, Yunnan, 650500, P. R. China,

zhangchao_geo@163.com

Abstract

The new urbanization in the southwestern region is different from the countries in the eastern plain, which is because of the mountain environment. Based on the comprehensive view and time-space view of geography, and the urban and rural settlements in southwestern mountain region were regarded as an organic integrity of continuous development, and the important role of the market town in the development of the southwest mountainous settlements was emphasized. At the present stage, and the Temporal-Spatial coordination and scope dimension were adapted as the theoretical basis points to explore the formation mechanism of the southwest mountain market town system. The results indicated that: the market town was the main carrier and hub to link the urban and rural settlements in southwest mountain region. Meanwhile, the spatio-temporal synchronization and scope maintain were the main driving force mechanism of the formation and evolution of the market town system, and the geographical environment, population distribution, traffic conditions and macro-policy were the factors to influence the size, rank and spatial form of the mountain market town system. Therefore, following the development laws of the mountain market town system, and regulating it scientifically, which is directly related to the directions and characteristics of the new urbanization in the southwestern mountain region.

Key words:

Southwest Mountain; urban and rural settlements; market town system; formation mechanism

Beyond Soybean Fields: Rural Diversity and Resilience in Grande Dourados Region, Central Western Brazil

Machado, F.S.

Human Geography, Plymouth University, Plymouth, United Kingdom, felipe.dasilvamachado@plymouth.ac.uk

Abstract

At present, great enthusiasm is expressed by the media and government concerning development and economic growth directly related to the spread of agribusiness-scale soybean production in the Cerrado savanna bush lands of the Brazilian Central Plateau. In contrast, academics have explored agroindustrial food networks through a critical perspective, placing agribusiness-scale soybean production within a mass production model which includes volume and standardization (Bernardes, 2015; Bernardes and Freire Filho, 2005; Hosono *et al.*, 2016). Questions about social and environmental impact, conflict of land use, and toxicity pose recurring problems to this agro-industrial dynamic. In these cases, the study of globalization in a rural context has commonly focused on transnational commodity chains and its contradictions.

According to Wilson (2010, 2012) and Woods (2007), for the majority of rural communities, globalization is experienced in more complex pathways. Against linear thinking concerning soybeans and regional development, the paper debates rural diversity and social resilience in Grande Dourados Region and discusses how the rural in agribusiness area such as Central Western Brazil will be affected by socio-economic, political and environmental changes expected in this region over the coming decades. The research was conducted on small and mid-scale farms, Jaguapiru indigenous community and at the Regional Documentation Center of the Federal University of Grande Dourados (UFGD) over a one month period. In summary, the research is based on debates concerning contemporary rural space with an emphasis on the territorial dimension and multifunctionality.

rural diversity; resilience; multifunctionality; Grande Dourados Region; Central Western Brazil; Brazil

From Mechanical to Organic——Research on the Change Characteristics of Village Collective Consciousness in Industrial Transformation

Yuan Fang, Wangming Li, Lixiong Zhu, Mingyu Zhang

College of Civil Engineering and Architecture, Zhejiang University, China, 120361565@qq.com

Abstract

Village collective consciousness is the villagers' identity attitude towards the collective. In the traditional villages where the labor division is at low level, collective consciousness assumes mechanical solidary collective unconsciousness, due to the villages' strong sense of belonging and consistency. With the development of emerging industries and the transformation of village, the village collective consciousness inclines to individual consciousness. The division of mechanical solidarity and the imperfection of labor division make the villagers more willing to act selfishly regardless of collective interest, which results difficulties in collective action. Under this circumstance, the rational ideology and the rural elites with social capital are the key factors in getting out of the dilemma, recreating the organic solidarity, promoting the healthy development of industries and the smooth transition of villages. The research is performed based on spot investigation and questionnaire survey in some distinctive pension villages of Hangzhou. With the help of the Social Solidarity Theory and Collective Action Theory, the change characteristics of village collective consciousness and the internal rules of village development are revealed.

Key words:

village collective consciousness; change characteristics; distinctive pension village; Social Solidarity Theory; Collective Action Theory

Research on Dynamic Model of Urban-rural Interface

Ma YL, Qiao JJ

Key Research Institute of Yellow River Civilization and Sustainable Development & Collaborative Innovation Center on Yellow River Civilization of Henan Province, College of Environment & Planning, Henan University, Kaifeng, 450000, P. R. China, jjqiao@henu.edu.cn

Abstract

In space location, urban-rural interface locates at the junction of Urban and rural areas. In function, it plays a role of spatial carrier for communication of urban and rural elements. Its development has great significance for the coordination of urban and rural areas. From the angle of element flow, this research established the theoretical framework of urban-rural interface based on system dynamics, built the quantitative model to characterize dynamic evolution mechanism of urban-rural interface by the method of quantitative geography, and drew the following conclusions by solving the model: (1) In different stages of development, urban-rural interface is effected to different degree by endogenous and exogenous dynamic power. (2) With the development of urban-rural interface, the effect transited from the negative effect to the positive effect, and the value of effect depends on the cycle accumulation capacity of urban-rural interface. (3) The balance condition of urban-rural interface is mutually affected by urban-rural elements exchange rate, its internal power and cycle accumulation ability. The equilibrium of an urban-rural interface is constant, but that of different spatial scales is not equal. (4) The switch model depicts the function of gate, and the interface equilibrium is the critical point to decide whether to open and close the switch. According to the above conclusions, the paper put forward policy recommendations respectively from the time scale and spatial scale.

Key words:

Urban-rural interface; Dynamic model; Switch model; Gate

Accidental Participation: Post-Disaster Reconstruction and the Emergence of Participatory Planning in Southwest China

Y. Li, X. Zhong, J. Ding

University of Wisconsin-Madison, Madison, WI 53706, USA, yifeili@ssc.wisc.edu

Abstract

Be they rocks, roads, or rivers, spatial objects are of pivotal interest to planners. Much of urban and regional planning seeks to create and maintain a spatial order that enhances the aesthetics of these objects. In the planning process, visual attributes of space often times overpower human attributes. The human user of space is typically presented in the generic or aggregate form. In the context of China, where a democratic accountability system is lacking, this problem is most pronounced. Despite more than a decade of efforts to “humanize” (yirenweiben) planning, participatory planning remains a marginal practice in the People’s Republic. This article provides an ethnographic account of participatory planning in the Southwest city of Dujiangyan during its recovery from the devastating 2008 earthquake. The earthquake not only disrupted the spatial order of the region, but also brought havocs to the social fabric of communities. Under such circumstances, the planner had to attend to both spatial and social aspects of reconstruction. In fact, much of the post-disaster planning process revolved around household surveys, town hall meetings, and consultations. As it organically evolved, post-earthquake planning in Dujiangyan prioritized community interests over spatial attributes. Planners and officials came to appreciate the “soft” concerns of individuals, households, and communities, deviating from their standard commitment to “hard” concerns of zones, parks, and roads. The emergence of participatory planning in Dujiangyan, which was in large part an unintended by-product of post-earthquake reconstruction, offers a unique opportunity to examine challenges and opportunities for “humanizing” planning in China.

Between the Rural and the Urban: Translocal Social Networks as a Source of Resilience to Climate Related Risks in Rural Northeastern Thailand?

Rockenbauch, T., Sakdapolrak, P.

Department of Geography, University of Bonn, Meckenheimer Allee 176, 53115 Bonn, Germany.

till.rockenbauch@uni-bonn.de

Abstract

Migration is a major livelihood strategy of rural households in Thailand (Rigg 2012). Both internal migration to urban centers and international migration to countries such as Korea, Singapore or Germany have fostered the emergence of social networks that span various places and scales thereby replacing traditional kinship based networks at the village level. There is growing evidence that these translocal networks have the potential to strengthen the resilience of households and communities in rural areas by facilitating the exchange of people, resources, ideas and practices between the areas of origin and destination of migration (Scheffran et al. 2012, Sakdapolrak 2014). However, there is little knowledge about which structure and which resource flows actually facilitate or even impede resilience. In this paper we investigate the role of translocal support and innovation networks for the resilience of rural households to climate-related risks, such as drought and floods, in three study sites in Northeastern Thailand. Drawing on resilience research and social network analysis (SNA) we provide a conceptual framework and methodology for systematically assessing and evaluating the role of social networks for different resilience capacities. We reveal that translocal connectedness varies with socio-economic background and migration patterns between different study sites. We hence conceptualize translocal networks as being a context-specific source of resilience embedded in the process of rural transformation. We further suggest that our approach, through combining quantitative and qualitative data, holds potential for closing the gap between intensive and extensive vulnerability and adaptation research (Birkenholtz 2011).

Agricultural transformation; climate related risks; migration; Northeastern Thailand; resilience; social network analysis; translocality

Changing Occupation with Changing Climate in India: A Case study

V. Nirmala, Sajad Ahmad Bhat

Chair, Department of Economics, Pondicherry University, Pondicherry, 605014, U. T. Pondicherry,

nirmalavelan@gmail.com

Abstract

The neighbouring States of Jammu and Kashmir (J&K), India, are affected by climatic changes like drought, heat-waves, and flood, besides unemployment and poverty. Such spells of times, induce especially the rural poor families to move to J&K in search of employment in brick kiln. The proposed study examines the nature and background of the migrant families; factors determining their migration; and the benefits and problems of having migrated. It would be based on primary data collected from 113 respondent families engaged in brick kilns in two districts of the State during June 2012. The study revealed majority of the migrants to be of younger age groups, illiterates, having poor economic background with low living standards, no land assets or proper employment in their native lands. They mainly migrate seasonally during March-November, when the brick kilns work in J&K. Their main reasons reported for mobility are climatic change, poverty, and to repay debts in home land. The analysis of determinants of migration indicates climate to be the most significant factor inducing mobility, followed by higher earnings in J&K. Whereas, better living standards in native land significantly discouraged it. The benefits of migration were free fuel for cooking, easy access to drinking water, employment and better income. Whereas, the problems reported were debt bondage, job insecurity and their migrant status. The study recommends job and social security measures to protect the migrants from exploitation by contractors who hire these workers, discriminations and employment insecurities, besides education and health facilities for their children.

Key words:

climatic change; migrant families; brick kilns; benefits and problems of migration

Climate Change and Rural-Out Migration: A Farmers' Perspective from Rural

Pakistan

Muhammad Abid^{1,2}, Jürgen Scheffran¹

¹Research Group Climate Change and Security (CLISEC), Institute of Geography, University of Hamburg, Grindelberg 7, 20144 Hamburg, Germany

²School of Integrated Climate System Sciences (SICSS), University of Hamburg, Grindelberg 5, 20144 Hamburg, Germany (muhammad.abid@uni-hamburg.de)

Abstract

In the last few decades, the agriculture sector and related rural livelihoods in Pakistan have become highly vulnerable to climate change. Along with other measures, farm households could potentially consider rural-out migration (either completely or partially) as an effective adaptation measure to climate change. This study investigate the farmers' perspective on rural-out migration using a survey of 450 farm households collected through face-to-face interviews from 76 villages in three agro-ecological zones of Punjab, Pakistan in 2014. Particularly, we analyze the farm households' perception of village level rural-out migration trends. In addition, we examine the rented-in and -out trends using local land tenure data. Furthermore, we analyze the farm households' rural-out migration intentions and possible reasons for not adopting it as an adaptation measure. The findings of the study suggest that mainly farm households perceived an increase in the rural-out migration trend since 2009 which was mainly due to reduced agricultural productivity and income due to climatic-related risks such as floods, excessive rainfall, and crop diseases. Further, the analysis of the land tenure data also shows an increase in rented-in trends which also confirms local perceptions of increasing rural-out migration trend. Furthermore, one-tenth of the farm households intend to migrate due to farm level vulnerability to climate change, however only one-third of them actually adopted it. The major reasons for not adopting migration as an adaptation option were the perceived lack of opportunities and required skills for jobs in urban areas. Intentions to migrate were shown mainly by small farmers but actually adopted more by large farmers.

Key words:

Climate change; Rural-out migration; Farm households; Agriculture; Pakistan

Conceptual Explaining of Effective Factors on Economical Security in Rural Area and Its Effect on Rural Migration

Tahereh sadeghloo

Assistant Professor of Geography, Ferdowsi University of Mashhad, Iran, tsadeghloo@yahoo.com

Abstract

Nowadays, desire to emigrate from rural to urban and decreasing of rural population is a common perspective in so many of countries especially, in developing countries that have so many driver causes and dimensions. In so many of cases, leakage of cultural and infrastructural services, Reduced quality of life or supply in excess of demand for manpower in rural areas can be considered as most important factor of such movements. But, among all of these factors, economical dimensions as a main and basic reasons, play important role in forming these population spatial movement. Lack of employment and economic revenue, non-diversified rural employment opportunities, and most importantly, low economic security of economic activities in rural areas, is important reason for the formation of temporary or permanent migration ideas and permanent evacuation of so many rural settlements. Climatic changes, drought, lack of adequate water resources, unplanned agriculture, ambiguity of the sales price and profit from agricultural activities as well as the loss of environmental capabilities in many rural areas could be mentioned as most important dimensions and indicators of lost economic security in rural area. In such circumstances, seasonal or permanent migration to rely on or employing in the false but lasting activities in urban areas such as services and itinerant peddlers, day laborers, to ensure cost and annual expenditures could be accounted as accessible solution for rural populations. Meanwhile, absence of governmental supportive policies for farmers, lack of insurance, farmer's limited knowledge or ability to pay for their own insurance against the risks, and etc, increase the economical insecurity and improve migration of rural area. Thus, this article had been tries to category and conceptual explaining of effective factors and impacts of economic insecurity in rural area.

Key words:

economic security; agriculture; migration; rural area; rural development

Does Migration Increases Resilience of Households in Environmental Disasters?**Leanings from the Gorkha Earthquake of Nepal**

Maharjan, A., Prakash, A, Goodrich, C.G.

International Center for Integrated Mountain Development, Lalitpur, Nepal, amina.maharjan@icimod.org

Abstract

Migration is considered to be a self-insurance strategy adopted by households. The literature points at the crucial role often played by remittance in times of crises, and specifically in the aftermath of environmental disasters. This hypothesis was tested using the Gorkha earthquake in Nepal, where a 7.6 magnitude earthquake hit central Nepal, followed by more than 300 aftershocks including one of 6.8 magnitude, causing massive damage to life, livelihoods and infrastructure. The study, which was conducted in two of the most heavily earthquake-affected districts, show that the out migration of youth from the villages had both positive and negative impacts at different stages after the disaster. During the rescue phase, migrant households were more vulnerable than non-migrant households as they had fewer able-bodied members to rescue people and other assets. In the relief phase, migrant households were slightly more vulnerable than non-migrant households in accessing relief. To access government support, lack of legal documents was a major obstacle, whereas to access non-government support lack of male members to carry relief stuff was a bottleneck for the migrant households. However, high migration communities managed to overcome some of these challenges by taking a group approach. Social remittances/social network were found to play an important role in accessing relief. With regards to post disaster recovery, migration and remittances is expected to support in quicker recovery as remittance income is not affected by the local destruction. Thus, the resilience of the migrant households differed at various stages post disaster.

Key words:

Migration and disaster response; remittance and resilience; mountains and disasters

Environmental Change and Migration in China: Process, Pattern and Trends

Yang, L., Scheffran, J., Song, X.

The University of Kiel, Leibnizstr. 3, 24118 Kiel, Germany, lyang@gshdl.uni-kiel.de

Abstract

Climate change and its adverse effects lead to increasing environment vulnerabilities and disaster risks both globally and regionally. It is therefore a major source of concern regarding degrading human livelihood, ecosystem services and social security that is likely driving present and potential human migration. This study is based in large part on literature data in Ningxia, Chongqing and Guangdong in China, representing respectively the ecological migration, disaster migration and economic migration in the climate change context. Results show that, though human migration is often caused by combined many factors, climate change related environment degradation and livelihood difficulties are indeed part of the concerns. Planned and well organized migration plays a significant role in improving the livelihood of migrants. However, migration is still an option of last resort after the vulnerable populations attempting to cope with new and challenging circumstances have exhausted other options such as harvesting less, suffering disasters, or continuing poor. Actually, local people acted diverse adaptation measures with aids from government and external sources, which at a certain level mitigated climate stresses and reduced the necessity of migration. The study concluded that it is necessary to classify the causes of migration and propose specific migration plans which consider both instant settlement and long-term development. Further, an integrative framework of top-down and bottom-up approaches would optimize the utilization of various resources from, e.g., individuals, governments, enterprises and international aids.

Key words:

Climate change; migration; vulnerability; disaster; China

Gender-wise Workers' Mobility to the Textiles and Apparels Industrial Tirupur City, Tamilnadu, India: A Coping Strategy under Climatic Change

Vijay Prakash, V. Nirmala

Assistant Professor, Department of Commerce-CA, Kongunadu Arts and Science College, Coimbatore – 641029. India,
vijayprakashvip@gmail.com

Abstract

The textiles and apparels industrial Tirupur city of Tamilnadu, India, attracts migrant workers from all over the country. It provides employment to both male and female workers, who seek alternative employment to their climate change affected villages. Majority of the workers move into the city from rural areas of the country, owing to droughts affecting agricultural employments and shrinking cultivable land. This paper attempts to investigate the factors influencing mobility of workers into the city. A gender-wise treatment of the issue is crucial, due to varying factors affecting male and female decisions to migrate differently. This also warrants a decomposition analysis of their migration decision. This study is based on primary data collected from a random sample of 340 male and female workers (170 each) engaged in textiles and apparel industries in Tirupur city, during May-August 2010. The study uses simple averages, percentages, ratios and regression. The findings reveal climate change and poverty to be the driving force behind workers' mobility to the city, mainly as an income coping strategy. They are largely the poor, less educated/skilled, and young, lacking assets, and job security and social security. The women migrants are more vulnerable than their male counterparts, as they are treated as reserve workers and easily targeted during crisis. The determinants of migration shows income to be the most significant factor drawing the unskilled rural workers to the city. The study recommends awareness generation on their rights as a worker and provisions of social security measures for the migrant workers.

Key words:

textiles and apparel industries; migrant workers; exploitation and discrimination; climate change

Influence of a Logging Ban on the Development and Transformation of Forest-Dependent Districts in China: The Case of the Wangqing Forest Region

Zhichao Hu¹, Hualou Long², Yanglin Wang¹, Jian Peng¹, Zhiqing Song¹, Guang Xu³

¹Peking University, China, hzc_070@126.com

²Chinese Academy of Sciences, China

³Wangqing forest department, China

Abstract

Forest-dependent districts provide substantial wood resources for economic development, playing an irreplaceable role in the national strategy. However, some forest-dependent districts are facing challenges related to industry restructuring and urban transformation, as well as an intense trend of degradation. The Chinese government implemented a series of policies and measures, such as the Natural Forest Protection Program (NFPP) and the Returning Farmland to Forest Project (RFFP), to address those challenges; in 2014, the government decided to stop commercial logging completely and conducted a pilot study. We constructed a theory of coordinated evolutionary framework based on “forest ecosystem – forest economic system – society system” for a forest-dependent district. We examined the Wangqing forestry department to analyze its development status and identify the prominent problems based on the three-system theory. We discuss the potential influence that the forest logging ban will have on the Wangqing forestry department based on our framework, and we provide suggestions to promote the transformation and development of forest-dependent districts if the logging ban is implemented in these areas.

Key words:

logging ban; forest-dependent district; wangqing forest region; development and transformation

Livelihood Vulnerability of Post-disaster Resettlers: Case Studies in the 2008

Wenchuan Earthquake Resettlement Areas, China

Yong Chen¹, Yan Tan², Graeme Hugo², Yong Luo¹

¹Institute of Population Research, Sichuan University, Chengdu, Sichuan, China, 610064, yongchen@scu.edu.cn

²Australian Population and Migration Research Centre, University of Adelaide, Adelaide, Australia, 5005

Abstract

China has been frequently struck by natural disasters so it is an expedient alternative to resettle people out of disaster-prone areas. There is not much means to survive for those devastated by natural disasters unless they are resettled away from their original places. However post-disaster resettlers still face numerous challenges although they are well supported with preferential policies in their new resettlement communities. The paper takes two resettlement villages in Nanbao township of Sichuan province where long-distance (trans-prefectural) post-disaster migrants were resettled after the Wenchuan Earthquake in 2008, as case study areas. The study constructed an empirical framework for analyzing and assessing livelihood vulnerability of these resettlers. Findings show that post-disaster migrants have fewer livelihood assets than before displacement and that they face higher livelihood risks and vulnerability than local host people. Resettlement policy and programs need to address the needs of resettler households to improve their livelihood capability.

Key words:

post-disaster resettlement; livelihood vulnerability; livelihood asset; risk to livelihood; Wenchuan earthquake; China

On Relationship between Winter Fallow Field and Outflow Population

Li Hongsheng

State Key Laboratory of Resources and Environmental Information System, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, P. R. China, lihongsheng@igsrr.ac.cn

Abstract

There are many studies focusing on interaction between floating population and regional economic development, social integration of migrant people etc. However, the research on relationship between winter fallow fields and floating population in outflow places remains blank. In recent 20 years, more and more farmers have given up autumn sowing, which contribute to lots of land unused from harvest in last autumn until next year sowing. Thus, the assessment of impact of rural labour migration on farmland vacancy is significant in optimizing winter fallow fields development and food security.

Taking Guizhou province as an example, the study extracts the winter fallow fields and summarizes regionally in 2010 through cloud removing, HANTS and NDVI dynamic threshold methods, based on Guizhou land use data and SPOT-VEGETATION NDVI data. According to the ordinary least squared regression method, the size of winter fallow fields is related to outflow population which is significant at $P \leq 0.000001$ level. But the adjusted R-squared is 0.26 which means the outflow population can explain 26% of winter fallow fields. Moran's Index of the winter fallow field size and outflow population is 0.5821 and 0.4905 respectively which indicates strong spatial dependence. Thus, the spatial error model is used here. The result shows that adjusted R-squared is 0.65 which means the outflow population can explain 65% of the size difference of winter fallow fields. These results indicate that outflow population has strong impact on cultivated land use pattern. If more and more population floats out to other developed regions for better revenue, more cultivated land will be left unused which in turn affects the food production.

Key words:

Winter fallow field; floating population; spatial error model; SPOT Vegetation; Guizhou

Policy Options to Support Climate-Induced Migration: An Perspective of Disaster Relief in China

Hongjian ZHOU, Xi WANG

National Disaster Reduction Center of China, Beijing, 100124, P.R. China, zhouhj_bnu@hotmail.com

Abstract

Attention to climate-induced migration has grown considerably in recent years, reinforced by high frequency of droughts, storms and flooding. Focusing on migrations induced by flash floods in Zhouqu and droughts in central Ningxia, China this study illustrates key factors in the process of policy options to support climate induced migration. The study is based on stakeholder interviews and secondary data processing. The findings show that integrating sudden and slow-onset hazards, combining top-down and bottom-up methodology and encouraging private sectors to establish Public-Private Partnership, are the main policy options from disaster relief perspective. Otherwise, two prospective transformations are proposed in policy options, transferring from re-active migration to pro-active migration, and from move & stay to hope & development in the aspect of migrants' livelihood improvement.

Key words:

Migration; Climate change; Policy response; Sudden disaster; Slow-onset disaster

Research on Spatial Pattern Evolution Mechanism of Rural Settlements in Peri-Urban Areas: A Case Study of the Kangdu Village from South-University Town in Xi'an

Ma E P, Li T S, Wei Q R, Li M X, Xie Y L, Li J L, Chen Y S

College of Urban and Environmental Science, Northwest University, Xi'an, 710127, P. R. China, leetang@nwu.edu.cn

Abstract

Peri-urban areas has been widely discussed by scholars from multiple disciplines including geography, urban planning, ecology and sociology due to its transitivity, diversity and dynamism in socio-economical structure and landscape features. The study aims to find the fluctuation rule of urban and rural settlements in peri-urban areas during the process of urbanization, and discuss the spatial pattern evolution characteristics of retained villages. Based on the review of theoretical research on rural settlements in peri-urban areas, this paper takes the Kangdu village in South-University Town of Xi'an as a case study area, and explores its spatial pattern as well as evolution mechanism by comprehensive application of remote sensing imagery interpretation, field investigation and statistical analysis. Results indicate that a total four times building boom and two significant employment changes emerged in 15 years from 2001 to 2015, and most of local residents' house lease appeared in 2006. We found a high consistence between the villagers' employment change and the main node of urbanization; and the system evolution characteristics of "stimulus-feedback" is found between the change of employment and building boom. This study shows that external drive of urbanization pushed by near domain and local residents' self-adaptation is the main dynamic mechanism of rural settlements' spatial pattern evolution in peri-urban areas.

Rural Depopulation and its effects on settlement in North China Plain

Jieyong Wang

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China;

Abstract

Economic reforms since the late 1970s have brought about significant changes in rural China. Academic and policy debate has primarily focused on farmland loss and construction land expansion in rural areas caused by rapid economic development and increasing urban population. Meanwhile, the changes of rural depopulation and its effects to settlements have received less attention. Because of high migration rate of rural to urban and low fertility rate resulted by one-child policy, rural areas have been undergone a process of rapid depopulation since the middle of 20th century. Rural depopulation changed the pattern of man-land relationship in rural areas, which caused some problems such as shortage of agricultural labors, domestic vacancy, abandoned farmland, and degraded rural inhabitable environment. In this article, using series data of six national censuses and land use survey, the process of rural depopulation and its pattern in North China Plain were analyzed, and land use changes of rural settlements was evaluated. Rural depopulation has changed the settlement patterns which formed by traditional cultivation culture in the past several thousand years. What patterns of settlements will be formed after rapid depopulation in rural areas? Then, Zhaozhuang Village is selected as samples. Based on historical aerial photographs and participatory rural survey, the land use maps of the village in different decade were rebuilt, the rural depopulation process and its effects to settlements were explained. In the end, the way to rural restructure of settlements were discussed, and some suggestions for improving rural land system were given.

Rural-Urban Interactions in Kenya with Focus on Environmental Change, Migration and Conflict in the Informal Settlement of Kibera, Nairobi

Janpeter Schilling

Climate Change and Security, University of Hamburg, Institute of Geography, Grindelberg 7, 20144 Hamburg, Germany, janpeter.schilling@uni-hamburg.de

Abstract

In Kenya, less than a quarter of the population lives in urban areas which is changing rapidly. The annual rate of urbanization between 2010 and 2015 was 4.4%. The capital Nairobi has a current population of about 3.1 million which is expected to almost double by 2025. Kenya and particularly Nairobi offer opportunities to study how climate change, resulting in increasing temperatures and rainfall variability, affects income, water and food security which in turn drive rural-urban interactions. These will be most visible in informal settlements such as Kibera, an important destination for migrants and one of Africa's largest informal settlements. It is exposed to heavy rainfall events and seasonal flooding which aggravate the existing environmental problems of pollution and lack of access to basic services. In 2007 Kibera was a hotspot of the post-election violence in Kenya and insecurity continues to be a significant risk to local livelihoods. The presentation will highlight some of the key rural-urban interactions between Kibera and rural areas of Kenya. Particular attention is paid to migration, environmental changes and conflict implications. The study is based on qualitative research conducted in Kibera between November 2012 and February 2016. Preliminary results suggest that rural-urban interactions, mostly in the form of migration, contribute to both tensions and opportunities in Kibera.

Rural-Urban Migration and Agricultural Change: A Translocal Perspective on Herding and Farming Societies in Eastern and Southern Africa

Greiner, C.

Global South Studies Center, University of Cologne, Cologne, Germany, clemens.greiner@uni-koeln.de

Abstract

Circular rural-urban migration and social and economic transfer relations between cities and their rural hinterlands are fundamental to African social life. They are deeply embedded in historically processes of land dispossession, colonial endeavours to exploit and control native labour, and post-colonial economic dynamics. Based on empirical cases from Eastern and Southern Africa, the paper explores the effects of rural-urban interactions in rural sending areas, particularly in wetlands and savannah environments. It focuses on groups, which are believed to be most vulnerable to changing environmental conditions: small-scale farmers and pastoralists. The conceptual framework of translocality is used to explore and compare patterns of migration, flows of social and economic remittances and the different effects on the rural sending areas, particularly their impact on land-tenure, agricultural investments, farming practices, knowledge and livestock husbandry. Based on empirical and secondary data, this paper demonstrates that a range of variables mediate the environmental impact of rural-urban relations, particularly socio-economic inequality, labor, gender dynamics, cultural factors and local environmental conditions. It argues that a comprehensive analysis of these variables and their dynamic interplay is essential to come to a more holistic understanding of the wider environment-migration nexus.

Key words:

small-scale farming; pastoralism; land-use; migration; rural-urban relations; translocality; Africa

Rural-Urban Migration as Adaptation to Environmental Change: The Move to Resilience

Melde, S., Laczko, F.

Global Migration Data Analysis Centre (GMDAC), International Organization for Migration (IOM), Berlin, Germany,
smelde@iom.int

Abstract

Urbanization, demographic growth and the impacts of environmental change and disasters are one of the key challenges of our time. More than 26 million people have been estimated to have been displaced by disasters annually since 2008 and many more move to reasons linked to environmental degradation affecting livelihoods. Research on the topic of environmental migration has increased over the past years, but a gap remains with regards to comparable data across countries.

This paper presents innovative research based on household surveys in 5 countries (Dominican Republic, Haiti, Kenya, Mauritius and Viet Nam) comparing how rural-urban migration has enabled households to adapt to environmental change and disasters as well as undermined potential adaptation strategies. Findings indicate that households with migrants are better able to respond to environmental challenges but still have less resources available than the richest quintile of the population that can adapt in the place of origin. Confirming previous research, the poor cannot move due to a lack of resources and are the most vulnerable in light of natural hazards. Policies should therefore aim at making internal migration an accessible adaptation strategy, while at the same time increasing disaster risk reduction and resilience strategies to adapt *in-situ*.

Migration; urbanization; adaptation; resilience; displacement; environment; climate change

Spatial Analysis of Work-Related Floating Population in Rural Areas, Iran with Exploratory Spatial Data Analysis Approach

Rezvani, Mohammad Reza

Prof. in Geography and Rural Planning, university of Tehran, Tehran, Iran, rrezvani@ut.ac.ir

Abstract

The workers flows is one of the most important of rural- urban linkages. This flows in many cases is in form of work-related floating population. The work-related floating population in this paper is a group of people who reside in villages a county, but works in cities and thus they have a daily movement between villages and cities. The paper analyses the spatial distribution of floating population in Rural Areas of Iran using the data gained from the Population and Housing Census (2012) Statistical Centre of Iran (SCI). The employment population over 10 years in Iranian rural areas in 2011 was 6058902 people which about 12.93 % of them works in urban areas. In provinces levels, this ratio is changing from maximum 36.59 % in Qom province to minimum 6.27 % in *Sistan and Baluchistan*. In counties level, this ratio is changing from maximum 43.77 % in *Baharestan County (Tehran province)* to minimum .22 % in *Rudbar Jonub County (Kerman Province)*. Results of exploratory spatial data analysis indicate clustering (positive spatial autocorrelation) and spatial heterogeneous in spatial distribution of work-related floating population in rural areas in Iran's counties.

Strategy to Address Environmental Induced Migration in India

Ojha Nabaghan

Policy Reforms Expert, IPE Global Pvt Ltd, New Delhi, MSc Student (Distance Learning), Bangor University, UK,
nojhabbsr@gmail.com

Abstract

In the 1990s, as the agrarian crisis in India intensified, migration of rural populations for work rapidly emerged as a major source of rural livelihood. Odisha, a State in eastern India, has emerged as a key labour sending region. With declining agricultural incomes and inability of rural households to cope with the current environmental shocks due to climate change, about 1.53 million people use to migrate each year to adjoining cities in search of livelihoods. Among them the case of distress migration is quite high which are seen mostly in western Odisha. To address it, a strategy has been deployed by government of Odisha and a programme supported by DFID UK. The strategy which has been operational since 2013, aims at creating climate resilient assets through convergence of different government schemes and programmes. Water conservation and water harvesting structures, land development and afforestation activities etc have been taken up under the strategy which provide local services such as ground-water recharge, enhanced soil fertility and increased biomass. These assets have also ensured at least 100 days of employment provision for each migrant households in every financial year with a stipulated wage rate defined by Government of India. The strategy has also introduced different climate resilient livelihoods models for the migrant households. It is proved that when employment created locally, the migrant people prefer to stay back. The strategy is being revised now to use it as an adaptation strategy to climate change.

Migration; adaptation strategy; climate change

Sustainable Food Production Practices in Victoria: The Emergence of a Breed of New Farmers Engaged in the 'Beyond-Farm-To-Table' Agrarian Concept

Zainuddin, Z

RMIT University, Melbourne, Australia, zainil.zainuddin@rmit.edu.au

Abstract

The paper will explore the emergence of a breed of new farmers in Victoria and Tasmania. These are farmers by choice, often professional with no background in farming but who have decided to engage in sustainable and ethical farming as a full-time occupation. It will interrogate the socio-demographic characteristics of these new farmers and more importantly their motivation for taking up ethical and sustainable farming, their farming practices and the values and ethos for these choices.

The paper focuses on one small aspect of the food system — farming and food production. It is about who, why and what, of this “new” approach to farming and food production in Victoria. These are farmers and food producers by choice, often with no prior background in farming or food production.

They tend to be small-scale family oriented, exclusively organic with diverse income streams from the one farm. They are ethically minded in their farming practices with emphasis on sustainability.

The research interrogates how this approach is framed often as sustainable and ethical farming practices. In doing so it will investigate the following characteristics:

- socio-demographic profile
- individual motivations
- values and ethos

It will also investigate the socio-technical aspect of the modern farmer communities use of digital platforms to enhance their community of practice. It will explore the relational dynamic between these farmers of ethical and sustainable produce with their consumers by exploring their usage of digital medium in their business engagement, social activism and online networking.

Key words:

Ethical and sustainable farming practices; civic agriculture; farmer-hipster (farmster)

The Adaptation-Gender-Migration nexus: the case of the Mahanadi delta, India

Prati, G.

Geography and Environment, University of Southampton, Southampton SO17 1BJ, United Kingdom.

giorgia.prati@soton.ac.uk

Abstract

There is a growing interest in understanding changes in migration patterns as response to climate hazards. However, the feedback process of migration on the families left-behind is rarely explored and even less is known about its gendered implications for adaptive capacity. Adaptation strategies, including migration, could reinforce inequality and vulnerability of some social groups with differentiated effects on the socio-cultural barriers to adaptation. Migration and adaptation are not gender neutral processes. Still, gender remains an often neglected dimension of the climate change-migration debate. This research seeks to investigate how migration shapes gender and power relations with consequences on women's adaptive capacity in the sending areas. The study draws on field research conducted in the Mahanadi delta as part of the 'Deltas, Vulnerability and Climate Change: Migration and Adaptation' project. In the delta migration remains a male dominant phenomenon that leaves women behind with social, economic and physical consequences. In contrast to traditional binary approaches, this study employs different qualitative tools to explore gender through the lens of *intersectionality* so as to disentangle the multiple dimensions of power and vulnerability. The findings show that migration can play a significant role in shaping women's adaptive capacity in the migrants' places of origin with differentiated impacts across the spectrum of caste, class, gender and other social identities. To fully understand migration in the framework of adaptation, there is a need to investigate its implications for the adaptive capacity of those who remain behind through gender analyses that break down intersectional inequalities.

Key words:

Adaptive capacity; Vulnerability; Gender; Migration; Intersectionality; Adaptation; Resilience

The Impact of Climate Change on Rural-Urban Interactions

The Case Study: Iran

Reihaneh soltani Moqadas

Assistant Professor, Payam Noor university, Iran, Tehran, r.soltani@pnu.ac.ir.

Abstract

Nowadays many factors play a role in changes in interactions between the urban and rural regions. Several factors play an important role in the development of local rural networks. The shortcomings of local economics due to the reduction of environmental resources that have evolved as a result of climate changes have had a decisive role in regional migration of rural youth. This is because the basic rural economy that is the foundation of the production of rural products faces a decline in efficiency. The continuation of this trend does not answer rural income requirements. Drought, loss of vegetation growth and trees would result in a reduction of rural income and the marketing of rural products which result in a reduction of household income. Moreover, any additional income that may be obtained from food processing economic activities will also drop due to its dependence on the agricultural sector. This will result in a further drop in the sources of household income. It is under such conditions that villagers choose to migrate to cities and towns in order to engage in unproductive urban jobs. This will result in the destruction of positive and efficient interactions between the villagers and a one-sided interaction between the urban and rural regions. Therefore, local rural networks will get destroyed and rural economic growth will be hampered. This will result in rural residential instability and an imbalance of regional networks. On the whole, this trend will yield a reduction in national food security and increased dependence on food imports which negatively affects rural residence and regional networks.

Analysis on the Effect of New Urbanization on Population Deloading in Three Gorges Ecological Protective Zone

Zhang H.Z, He J.J, Fan L.S

ChangJiang Project Supervision & Consultancy Co. Ltd, WuHan, 430010, P. R. China, 150223620@qq.com

Abstract

The Three Gorges Reservoir is a national strategic Fresh Water Resource Reservoir. According to The Three Gorges Follow-up Work Plan approved by the National State Council, the Ecological Protective Zone has been prioritized as an important task for protecting the Three Gorges Fresh Water Reservoir as well as ensuring its longterm safe run. The major problems are the highly intensive population and improper land utilizing structure. In this sense, population deloading has become a must for activating the ecological functions. This thesis researches on comparative analysis on ecological migration, land requisition and resettlement, new migrations including population transfer by new urbanization and its the necessity, the promoting effect of urban infrastructure and public services on the population deloading of Three Georges Reservoir, the significance of constructing ecological protective zones in over 4000 big or middle water reservoirs.

Abstract

Agro-Small and Medium Enterprises (agro-SMES) are engines of economic growth and catalysts of socio-economic transformation in many countries. Their contribution to socio-economic development includes employment creation, income generation, GDP contributions, export earnings, women empowerment and provision of basic goods and services. In a country like Zimbabwe where agricultural land use is the mainstay of the economy, land use sustainability becomes indispensable. The land users operating a business model, called agro-SMES, form the central cog of the economy. As such their resilience, the backbone of land use and rural sustainability, is important to the national economy at large and land use and rural development in particular. It is acknowledged that flexibility, adaptability and responsiveness make agro-SMEs resilient in challenging operating environments. These resilience capabilities are, however, a result of the interplay of particular agro-SME characteristics. This paper outlines agro-SME characteristics that make them resilient in challenging operating environments using results from an investigation carried out in Kwekwe District, Zimbabwe. All the agro-SMEs established before 2005 and survived the 2000-2010 challenging operating environment constituted the study population. Total population sampling was used. A questionnaire was administered to collect data that was used to characterise agro-SMEs that were still operational in 2013. Frequency distribution analysis, measures of central tendency and content analysis were used to characterize the agro-SMEs. Results revealed that socio-demographic characteristics of agro-entrepreneurs and operational characteristics of agro-SMEs have a significant influence in enhancing agro-SMEs' resilience under such circumstances. This set of characteristics enhanced their establishment, growth and survival during the challenging environment.

resilient; survival; characteristics; entrepreneur; agro-SME

Change in Socio-economic Behavior in Urban Rural Interface Area in North India: A Geographical Analysis

Khan Nizamuddin

Department of Geography, A.M.U. Aligarh, India, nizamuddin_khan@rediffmail.com

Abstract

The urban rural interface area is dynamic in nature, moving in response to horizontal expansion or urban sprawl. It is passing through transitional stage of modification slowly under mutual exchange of socio economic interaction. Rurality of area is threatened and urban influence is imposed and consequently remarkable transformation is observed. The study is based on primary and secondary sources of data. Dynamics of urban rural interface region is also identified by GIS and remote sensing technique. Four villages were selected for detailed survey in the interface area of Aligarh city. Study revealed that the interface area witnessed change in house type, food habits, and means of livelihoods as well as socio cultural transformation to a considerable level. Environmental challenges are also emerging on account of socio-economic transformation in the study area.

Key words:

Urban Rural interface; Rurality; Livelihood; Transformation

Combined Analysis of Land Cover Change and NDVI Trends and Its Implications for Regional Sustainable Development in the Loess Plateau, China

Cao Zhi^{1, 2}, Li Yurui¹, Liu Yansui^{1,*}

¹Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing 100101, China;

²University of Chinese Academy of Sciences, Beijing 10039, China

Abstract

China has witnessed accelerated industrialization and urbanization over the past three decades, which also happened in Loess Plateau. Loess Plateau in China also has implemented “Grain for Green” project since 1990s. All of the human activities above-mentioned and climate changes have influenced land cover and land use changes. Plenty of studies have addressed the land conversion and vegetation growth of Loess Plateau with land use data or NDVI data. But Land cover change is discrete change, ignoring the quantitative change with in one classification, and NDVI data can show continuous, gradual changes on the land surface, unable to identify land cover clearly. Using either land use data or NDVI data alone cannot uncover the impacts of human activities on ecosystem effectively. With land use data of 1990, 1995, 2000, 2005, 2010 and NDVI data from 1990 to 2010, this paper analyzes the land use and land cover change (LUCC) during 1990-2010 in Loess Plateau. The LUCC were mostly among farmland, forested land and grassland. And the NDVI changes can be divided into three stages: it kept stable during 1990-1998, decreased during 1998-2001 and increased during 2002-2010. The LUCC and NDVI changes also presented spatial difference. This paper also detected and compared land use types between the regions where NDVI rapidly changed, and create a combined analysis method of LUCC and NDVI changes, excluding the incorrect recognition that higher NDVI represents better ecology. Besides, this paper analyzes driving force of LUCC and NDVI changes with field investigation and statistical data analysis. The rapid industrialization and urbanization and “Grain for Green” project played an important role. Given the complexity of coupling human-environment system, more studies should be on LUCC change simulation and multiple scales analysis, supporting understanding the dynamics of eco-environment and decision making on ecosystem conservation.

Abstract

Crop Diversification is the multiple cropping system i.e. addition or replacement of more crops to the existing cropping system. Growing multiple crops pays wider scope and opportunities in socio-economic transformation backed by sustainable farming. District like Malda, having dominance of agriculture and occupied by different crops has maintained a tendency to diversify the crops symbiosis. In the study area agricultural sustainability is consequent outcome come of crop rotation crop diversification and use of organic fertilizers. The present paper is an attempt to find out the consensus relations between 'drivers of crop diversification' and sense of sustainable agriculture. Variations of crop diversification in response to fast changing physical in general but, socio-cultural conditions in particular are studied for 'rabi' and 'kharif' crops for 2015. The study is carried by both primary and secondary sources of data and prior, collected through households and institutional (contract farmer) survey. Simpson Index of crop diversification found both positive and negative relations with sustainable agriculture. Quantitative techniques and GIS approach used to shown the distribution of data. Result shows that the marginal farmers (<1 hectare of land) cultivate multiple crops but lack of institutional and infrastructural support they increasingly merge towards organic farming. Contract farmers and, large and medium land holders are in the race of diversification enhanced by larger investment away from sustainable farming.

The Impact of Cultivated Land Rental Markets on Sustainable Land Use: Evidence from China

Xu yuting^{1,2}, Huang xianjin¹

¹School of Geographic and Oceanographic Sciences, Nanjing University, Nanjing, 210023, P. R. China, 18900531575@163.com

²School of Territorial Resources and Tourism, Anhui Normal University, Wuhu, 241000, P. R. China

Abstract

The purpose of this paper is to empirically track the progress and consequences of the emergence of cultivated land markets in China since 2008. We draw on a set of nationwide, household-level pool data (for 2008 and 2014) and find that the markets for cultivated land rental have emerged robustly. According to our data, 28 of China's cultivated land was rented in farm operators in 2014. We also find that the nature of China's cultivated land rental contracts has become more formal and lengthened the period of time that the tenant is able to cultivate the rented-in plots. While there may be benefits for lessors and tenants, our data show that there are falling rates of investment in organic manure. The analysis, however, does not find that improved property rights in cultivated land rental affect investment largely because property rights have largely been established by 2008, the first year of our sample. Our results, however, also show that there are forces that appear to be mitigating the negative consequences of rising cultivated land rental. After holding constant initial rental rates and other factors, we find that the gap between investment in organic manure in own land and rented-in land is narrowing. One interpretation of our findings is that if policymakers can find ways to even further strengthen the rights of lessors and tenants as well as lengthen contract periods, farmers—even those that rent—will invest more in their land, because they will be able to capture the returns to their investments.

Effects of the Influence of Cultivated Land Transfer on Food Production: A Case Study of Henan Province

LI Yating, PAN Shao, MIAO Changhong

Key Research Institute of Yellow River Civilization and Sustainable Development & Collaborative Innovation Center on Yellow River Civilization of Henan Province, Henan University, Kaifeng, 475001, P. R. China, ytli81@126.com

Abstract

In recent years, the cultivated land transfer in China accelerates constantly and the scale continues to grow, the transfer area also extended from the coastal developed area to the traditional agriculture area. “Non-agriculturization”, “non-food”, reduced productivity of arable land and other issues arise in some regions in this process, this probably affect the national food security. What impact does the cultivated land transfer in the major grain-producing area have on regional food production? Whether it will threaten regional food security? Aimed at these problems, this article took the major grain producing area Henan province as the research case, through large-scale peasant household survey, analyzed the influence effect of the cultivated land transfer on the food production in the province; calculated the critical value of cultivated land transfer which may threaten regional food security and the capability of grain export in Henan province under certain conditions. This study will be helpful to provide decision-making basis for stabilizing grain production in major grain-producing area and ensuring national food security.

Key words:

cultivated land transfer; food production; Henan province

Farmland Degradation in Heilongjiang Province, China: Human factors and Land-Use Policy

²Haerbin Normal University, Haerbin, 150025, P. R. China, zsf7415@163.com

Abstract

There are a lot of land-use problem in Heilongjiang Province due to the rapid urbanization. These land-use problem including land degradation, land pollution, food security problems, and ecological issues. Taking the case of Daqing City and Suihua City for study, this paper presenting the farmland degradation reality, such as soil erosion, soil deterioration, pollution, nutrient loss, and salinization in Heilongjiang Province. Analyzing the human factors and land-use policy that impact on farmland degradation, some countermeasure, such as formula fertilization by soil testing technology, grazing exclusion, grain for green, and using organic fertilizer was proposed. We belied that the farmland degradation will be curbed with these countermeasures.

Key words:

Farmland degradation; human factors; land-use policy; Heilongjiang province

Feasibility of Presenting a Model of "Rural Collective Management" in Mountainous Region of the Southwest of the Caspian Sea

Abstract

Regarding the different needs of people in rural areas according to variations in facilities and resources, rural management acts differently, and a fixed management pattern cannot be considered for all villages. Establishing Islamic council and village management office for villages fewer than 20 families and 50 families, respectively is impossible, and the problems faced by villages in mountainous and piedmont regions have caused migration which in turn results in low number of families, and no residency, at the end. The present article aiming at measuring the feasibility and presenting a model of rural collective management by merging villages that lack managers with villages enjoying managers has presented a new definition of scales in order for villagers lacking managers to enjoy manage. Utilizing a descriptive-analytic research method and collecting data and needed information by library and documentary search, especially, field study through 138 questionnaires distributed in 13 towns located in piedmont and mountainous areas of 26 districts, 10 counties, and 12 villages. Findings indicate that villages with management offices and Islamic councils believed in the establishment of rural collective management and their roles with regard to the implications and positive consequences. Providing the accessible road between villagers with and villagers without management, providing vehicles, and reducing the threshold level of establishing village management office and Islamic council for villages fewer than 20 and 50 families, respectively, are the main findings of the present study.

Functional Changes of Land Use in Hubei Province

Jiaxing Cui, Mengli Hua, Xuesong Kong

Wuhan University, China, cuijiaxing@whu.edu.cn

Abstract

Land cover has always been the primary study section of land use due to the possibilities to map and characterize land cover based on observations and remote sensing. However, the communication of land cover change cannot fully reflect the land use change because there is no one to one relation between land cover and land functionality. This paper attempts to investigate the functional structure of land use by decomposing the land function into five functions: agricultural production, non-agricultural production, social security, cultural heritage and ecological service. A comprehensive framework for integrated assessment of the functional development of land use was presented. The framework was applied to assess the functional changes of land use within Hubei province during 2000 and 2010. Results showed that, the land function of agricultural production went steadily up due to the improved planting technology and breeding technique. There has been enormous growth in non-agricultural production because of the rapid economic development. The land function of social security was improved modestly due to the improvement of public service facilities. The high value region of cultural heritage transferred from the central region to the eastern region because of the cultural development in the Wuhan metropolitan area. The ecological service of west part of the province has been improved due to "the grain for green" policy. In the contrast, the ecological service of eastern part of the province declined due to the sprawl of the urban area. In addition, land areas with each prevailing land function were identified.

Impact of Rural Road Construction on Agriculture Sector in Jaipur District of Rajasthan, India

Kalia, Sarina; Singh, Richa; Mishra, K.K.

University of Rajasthan, Jaipur, 302004, Rajasthan, India, richaajm@gmail.com

Abstract

Rural roads act as catalysts, linking villages and providing opportunities for villagers to reap the benefits of the development. Efficient rural road connectivity puts strong impact on development of agriculture, health, education, forestry, fisheries, small scale industries, trade, commerce etc. Rural roads provide the access to basic amenities and means of transporting agricultural products to the nearest market centres. Realizing the role of rural road connectivity, Government of India, launched its ambitious programme Pradhan Mantri Gram Sadak Yojana (PMGSY), in the year 2000, to provide connectivity to all habitations up to a population of 500 and more in general areas and a population up to 250 in hilly, desert and tribal areas. This paper, studies the changes occurred in agriculture sector after construction of all-weather roads under the scheme. Analysis of the primary survey and Land Use Land Cover maps of Dudu and Phagi blocks of Jaipur district of Rajasthan indicates major changes have occurred in the land use pattern and farming techniques. Farmers have started employing modern methods of farming and are shifting to agro based ancillary productions. Villages situated within 50 kms to the city centre have started growing perishable agriculture products. Various spatial analysis tools have been used to find out the impact of rural roads on agriculture sector in Jaipur district.

Land Consolidation and the Sustainability of Rural Community: A Case Study in Traditional Agricultural Areas of China

Li Yurui, Cao Zhi, Chen Yufu, Long Hualou

IGSNRR, CAS, China, liyr@igsnrr.ac.cn

Abstract

Under the background of economic globalization, rapid industrialization and urbanization, the man-land relationship has changed dramatically in traditional agricultural areas (TAAs). Hundreds of millions of rural labors left home and work in cities every year. And more problems have been driven by vast and increasing out-migration of rural labors under urban-rural dual-track system, such as rural hollowing, farmland abandon, and infrastructure shortage, and those have imposed huge obstacles on improving land use efficiency and coordinating urban-rural development in China. Therefore, it's necessary to implementing land consolidation in rural China. With its wide ranges and complexity, rural land consolidation may have a far-reaching influence on the sustainability of rural community. This paper established a framework and index system for evaluating the sustainability of rural community. Then, takes three typical rural communities in TAAs as an example, this paper analyzes the impacts of three typical land consolidation (rural residential land consolidation and allocation, gully land consolidation and high quality farmland construction) on the sustainability of rural communities, using the data gotten by questionnaire survey and depth interview. On considering the sustainability of rural community, suggestions for future rural consolidation in China have been put forward.

Key words:

rural community sustainability; rural residential land consolidation and allocation; gully land consolidation; high quality farmland construction; case study

Land Cover Change and Diversified Rural Development – A Croatian Case Study

Lukić, A., Cvitanović, M., Radeljak Kaufmann, P. and Valožić, L.

University of Zagreb, Faculty of Science, Department of Geography, Zagreb, Croatia, alukic@geog.pmf.hr

Abstract

The environmental and land cover change is influenced by demographic, cultural and economic factors, physical characteristics of the environment itself, and their complex interactions. The question this paper focuses on is the connection between land cover change and dynamics of rural development in Croatia. The presented research is a part of a broader study which aims to produce a set of alternative future scenarios for Croatian rural areas in 2030 with the goal of encouraging informed and evidence-based public debate on rural futures. Land cover change trajectories are analysed using object-based analysis of LANDSAT and SPOT multi-spectral imagery for 1991, 2001 and 2011 using ArcGIS 10.0 and eCognition 9.0. By comparing the 1991, 2001 and 2011 datasets major environmental change trends are detected and quantified, which helps in discovering direct causes of environmental change. The results of land cover change analysis are compared with different developmental types of rural areas in Croatia, recognized by aggregative approach and techniques of multivariate analysis (factor and cluster analysis). The recognized types of rural areas confirm strong diversification of Croatian countryside (e.g. dynamic, demographically stronger areas, market oriented agricultural areas, economically diversified, mainly tourist areas, rural periphery etc.). Preliminary results confirm the hypothesis about the correlation between intensity and type of land cover change on the one side, and developmental dynamics of rural areas on the other.

Land Use and Sustainable Agriculture under Climate Change in China

Yansui Liu

Academy of Land and Urban-Rural Development, Beijing Normal University, Beijing 100875, China; Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China, liuys@igsnr.ac.cn

Abstract

Food is the fundamental of people's livelihood, but also an important strategic material of national economic security. As a major grain producer and most populous country, China's food security issues have aroused widespread concern in the community. Food security in China is undoubtedly under threat as limited arable land availability, deteriorated soil quality, water scarcity, climate change and intensive reliance on fertilizers and pesticides, which will all begin to limit or reduce agricultural production. In this study, we investigated the relationship between climate change, grain production pattern and potential agriculture crisis in China. We found that warming has induced staple crop cultivation boundary moving northward over the past decades and made it possible to increase marginal land reclamation in northern China. Accompanied by rapid urbanization, cultivated land occupation by construction and abandoning as well as arable land using for non-food production purposes in south China has accelerated the northward migration of gravity centre of national grain output. The deep reason for the migration lies in the inequality of economic development between north and south China, land policy being out of control and comparative advantages driven. Confronted with the reality of water shortage, ecologically fragile, low land productivity and more marginal farmland in north China, some major national policies and measures, e.g., the south-to-north water diversion, requisition-compensation balance of arable land, and wasteland reclamation, will likely bring water resources, ecological and agro-climatic security. Although China's crop output has continuously increased in the past twelve years, this increment is mainly sourced from agricultural structure adjustment. Under the climate cooling scenarios in the future, the grain production in north China, especially in the northeastern region, would suffer more low temperature and cold damage, which will result in hundreds of millions of acres of land out of agricultural production. China's food security and agricultural development would face supply shortage crisis.

Climate change; land use; food security; sustainable agriculture; China

Land Use Transition and Land Management

LONG H

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, longhl@igsnrr.ac.cn

Abstract

Land use transition refers to the changes in land use morphology including dominant morphology and recessive morphology of a certain region over a certain period of time driven by socio-economic change and innovation. In general, dominant land use morphology refers to the quantity, structure and spatial pattern of land use, and recessive land use morphology includes land use features in terms of aspects of quality, price, property rights, management mode, input and productive ability, and function. This paper puts forward the theoretical model of regional land use transition as the following: with the socio-economic development, the transformations between different land use types during a certain period of time arise the changes of regional land use morphology pattern from strong conflict to weak conflict, i.e., coordination, which enable a new balance between different land use morphology patterns reflecting the development trend of different economic departments, and then realize the transformation of urban-rural land use system from quantitative change to qualitative change. Then, the mechanism of mutual feedback between land use transition and land management was probed based on a three-fold framework of natural system-economic system-managerial institution system. Generally, land use transition is affected by land management via economic measures, land resources engineering, policy and institution. Land use transition can also contribute to the adjustment of land management measures via socio-ecological feedback. Therefore, policy-makers need to adjust their land management policies taking into account the continuous change of land use morphology and different phases of regional land use transition.

National Agritourism Parks in China: Distribution Characteristics, Types and Spatial Optimization

Wang Fuyuan, Wang Kaiyong, Chen Tian

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, wangfy.15b@igsnrr.ac.cn

Abstract

Leisure agriculture is an important starting point to promote agricultural modernization and upgrading, and the research on agritourism from a geographical perspective become a important topic for rural and tourism geography. The construction of national agritourism parks (NAPs) plays the leading role for the development of leisure agriculture, which may have significant implications for the future development of agriculture and tourism industry. The paper focused on the NAPs development characteristics and spatial distribution in China, and the basic data about 960 Chinese NAPs was collected as the basic data through the internet. Then, the GIS spatial analysis method was adopted to describe the spatial distribution patterns of NAPs at national, and the eastern, central, western and northeastern regional levels respectively. Inductive method and statistical methods (i.e. chi-square test and cross-table analysis) was used to analyze the type constitution of NAPs both in national and regional levels. The results shows that: firstly, the spatial distribution pattern of NAPs appears agglomerative both in nation and regions; secondly, the location of NAPs formed obvious agglomerate area within four regions, furthermore, these agglomerations tend to develop into a large agritourism belt (area) across regions; Thirdly, the type proportion in terms of dominant function and developing entities of NAPs had no obvious difference, but there are statistical differences between regions in terms of location and resource-dependent type. According to the results of the research, several optimization strategies were proposed from two levels in terms of overall space arrangement and regional NAPs' development.

agritourism; national agritourism park; spatial distribution; optimizing strategy

Planning for NGO's at Districts Level along the River side of Jamuna, Bangladesh: Using GIS and Remote Sensing Technology

Tanjinul Hoque MOLLAH, Kun XIAO, Sharmin SHISHIR, Takaaki NIHEI

Graduate School of Letters, Hokkaido University, Sapporo, Japan, thmollah@gmail.com

Abstract

This paper emphasis on planning and spatial distribution of NGO's provided services as education, agricultural sector, micro credit, health and sanitation to the rural poor people at districts level along the river side of Jamuna, Bangladesh. This study used satellite images from 1975 to 2015 years to identify the spatial and temporal dynamics of alluvial char as well as making the plan for the NGOs distribution to ensure the proper services for the rural poor. Every year the char land shifts due to multi-channel river flow, local topography, flood, erosion and sedimentation into the river bed as well as braided characteristics of the Jamuna River as a consequences severe damage to the agriculture, infrastructure, vegetation cover and so on. The rural poor along the river side of Jamuna suffers a lot as because they are not stable in a char land and consequently shifting one char land to another so that it requires a long term policy for the betterment of the char lands people's livelihood. The rural poor people live in remote areas that are often huge distances from centers of commerce and social services areas as a result difficulties in accessing market opportunities rural people don't get proper health facilities as well as increase high levels of illiteracy. The poor suffer from hunger, ill health, a lack of education and other environmental vulnerabilities. For all of these reasons, this paper makes a plan for sustainable development for the poor along the river side of Jamuna, Bangladesh.

The spatial and temporal dynamics; accessing market opportunities; sustainable development

Research on the Quantitative Evaluation Model of the Restriction Effect of Farming Radius on Rural Settlements Relocation

Tao Zhuolin^{1,2}, Liang Jinshe³, Zheng Qingjing³, Dai Teqi³

¹College of Urban and Environmental Sciences, Peking University, Beijing 100871, China, taozhuolin@pku.edu.cn

²School of Urban Planning and Design, Peking University, Shenzhen 518055, Guangdong, China

³School of Geography, Beijing Normal University, Beijing 100875, China

Abstract

Farming radius plays an important role in the relocation of rural settlements, especially in underdeveloped regions. However, no efficient method has been developed to evaluate this impact. This study not only introduced but also improved the location set covering problem (LSCP) model in facility location-allocation models, thus proposed a quantitative model to evaluate the restriction effect of farming radius on rural settlements relocation. The model was empirically implemented in a case study of Chongkan Town in Chongqing, China. Several conclusions have been drawn as following: 1) the quantitative model proposed by this study for evaluating the restriction effect of farming radius is an important supplement for existing relevant studies; 2) this model can be used for modeling the evolving process of rural settlements relocation as farming radius increases, by quantitatively evaluating the restriction effects of various farming radiuses on rural settlements relocation, thus providing efficient instrument for the knowledge-based planning and guidance of rural settlements relocation. 3) the covering-sorting algorithm proposed by this study can efficiently support the application and promotion of the model; 4) the results of the case study can provide knowledge-based guidance for the relocation of rural settlements in Chongkan Town.

Resource Utilization Vs Sustainable Development in India

Dr. Sarda Prasad

Post Doctoral Fellow, CSRD, Jawaharlal Nehru University, New Delhi-110067, India, sardaprasadk@gmail.com

Abstract

Availability and accessibility of resources (either natural or human) for sustainable development are influencing by social, economic and political factors. Some of us using resources more than optimum need and some are facing shortage of resources. This imbalance in using resources have created socio-economic inequality and led political activities. Inequality in using resources between haves and have not and over use of existing resources by upper economic strata of society create problems in environment. Population is increasing with decreasing growth rate since 1971. Objectives of this paper are- to measure the changes in demographic trends; to examine economic status of the population; and to find out the imbalances in using resources such as food, water, power, and space by using secondary sources of data from Censuses and NSSO. In one hand urban TFR is lower than that of rural and on the other hand urban population is increasing. Resultant of the rural out-migration widening gap between supply and demand in rural areas that has changed wage rate and bargaining power of labour for both agricultural work and non agricultural work. This change in rural labour market affects agricultural products by quantitatively as well as qualitatively. Similarly, soil fertility and input use in agriculture have affected. In one side rich are using all the resources more than requirement and in other side rest are suffering for resources for survival. That would create inequality in society and it also not good for sustainable development.

Key words:

Resources; sustainability; labour market; migration; demographic change

Rural Households' Perception of Rural Residential Land Consolidation and Their Satisfaction with The Processes and Results——A Case Study of Yuanqiao and Baihui Rural Communities of Dezhou Country, Shandong Province

Xiaoyu Zheng¹, Yang Zhou¹, Zhi Cao¹, Yansui Liu²

¹Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences; University of Chinese Academy of Sciences, China, 1039870375@qq.com

²College of Land and Urban-rural Development, Beijing Normal University, China

Abstract

In recent years, with the rapid development of urbanization and industrialization, the contradiction between urban and rural land becomes obvious in China. In order to improve the rural residential land use efficiency, the rural economy and to meet the demand for land of rapid urbanization development, China Land and Natural Resources launched some pilot works of rural residential land consolidation(RRLC) at the end of 2005. From the perspective of practice, RRLC progress well on the whole, and plays a great role in improving the rural ecological environment, easing land conflicts and balancing the increase and decrease of arable land. However, some areas' government ignores the wishes of farmers in the implementation process of RRLC, merging villages and constructing center village blindly, forcing farmers to high rises, which runs contrary to the goal of promoting the sustainable development of farmers and countryside.

Taking YuanQiao community and BaiHui community of Dezhou city in Shandong province as examples, through questionnaires and in-depth interviews, using exploratory factor analysis and building satisfaction structural equation modeling, the paper explores the perception of rural households on the RRLC, which reflects actual impact of RRLC on rural households, and further probes into which factors influence rural households' satisfaction with RRLC. The results show that, firstly, after RRLC, social security function of land is still paid more attention than the functional production of land, but some residents view land as a burden, and hope to transfer the land. Secondly, though having experienced RRLC and allocation, rural households still lack of understanding of the RRLC policy, and some residents even hold the negative perception of it, this result may have a certain relationship with the singleness of land policies' dissemination channels. Thirdly, RRLC changes the rural households' production and lifestyle thus shifting the attitude of residents who do not support the RRLC initially. However, affected by the facilities construction, village collective strength, personal development and other factors, the changing degree and trends of production and lifestyle vary between people and communities. Fourthly, rural households' satisfaction evaluation of RRLC consists of four dimensions, from big to small are facilities, living conditions, housing conditions, policy fairness, among which

housing conditions and policies fairness have a significant positive correlation with rural households' satisfaction. In addition, rural households' socio-economic attributes such as gender, age are positively related to satisfaction, while there was a significant negative correlation between the number of family farmland and rural households' satisfaction. Fifthly, rural households are willing to recommend to others to carry out RRLC on the basis of their satisfaction with RRLC. Nonetheless, they are not necessarily likely to make positive comments on RRLC. The Paper provides a microcosmic perspective of RRLC research, improves RRLC study system, and broadens the study object of resident satisfaction. The recommendations for RRLC's continuous improvement exert an important guiding significance on the protection of rural households' interests and the smooth implementation of RRLC.

Rural Settlement Land Use of China: Evolution, Research Status and Research

Prospects

Zhenzhen Zhao¹, Pu Lijie^{1,2,*}

¹School of geographic and Oceanographic Sciences, Nanjing University, Nanjing 210023, China

²The Key Laboratory of the Coastal Zone Exploitation and Protection, Ministry of Land and Resources, Nanjing 210023, China, ljpu@nju.edu.cn

Abstract

Since China's reform and opening up, with its process of marketization, industrialization and urbanization, rural settlement land use has been expanded massively, accounting for 2/3 of land for urban and rural settlement plus industrial and mining area, which is posing a great challenge for China's farmland protection and land intensive and economical use. The goal of this paper is to provide research prospects for more targeted and instructive research of rural settlement land use in the future through a review on the evolution and research status of China's rural settlement. Firstly, the development of rural settlement characteristics and its land use structure and function was summarized under some macro factors, including economy, land system and national policy, as well as some micro factors, including rural population, farmer's livelihood and income, farmer's traditional view. Secondly, a summary of the research contents, idea, methods for research of rural settlement under different scales was conducted, including nation, region, county, town and village. Finally, considering current integrated urban-rural development, new-type urbanization, a few perspectives are proposed for future research.

Rural Transformation from the Perspective of Regime Shifts of Socio-Ecological Systems in the Loess Plateau

Yang Xin-jun, Wang Zi-qiao

College of Urban and Environmental Sciences, Northwest University, Xi'an, 710127, P.R. China, yangxj@nwu.edu.cn

Abstract

Socio-ecological system theory offers a conceptual model that has not been previously applied in the analysis of the process and evolution of rural transformation in China. Drawing on a theoretical framework of system transformation, we selected the town of Hongjia in Changwu County as a case study to explore the context of local rural transformation and its associated environmental factors. We examined village-level socio-ecological system dynamics, with a particular emphasis on influential factors associated with regime shifts and the robustness of rural socio-ecological systems. Our findings are as follows. First, the local rural socio-ecological regime has evolved through the transformation of the traditional agricultural regime, with some of the household regimes shifting to a non-agricultural system. Second, family characteristics constitute the objective conditions for the transformation of household regimes. Internal factors driving the transformation process include the quantity of the household's cultivated land as well as labor quantity and quality. Furthermore, householders' ages, degree of education, and social networks are major determinants of the transformation direction of the household regime. Third, the shift in household regimes presents a scattered and aggregated pattern, with obvious differences in the robustness of households. Rural households are classified according to the planting structure and households' incomes. Differences in the robustness of different types of rural households can, in turn, be expressed as follows: apple + non-agricultural production > non-agricultural production > grain + non-agricultural production > apple production > agricultural production. Lastly, the findings of rural transformation in the Loess Plateau are presented and discussed.

Rural Transformation Model through Integrating Improved Bee, Coffee and Goat Farming with Agro-Forestry in Kamwenge District-Uganda

TUMWINE F, MUGAGGA F, TUNANUKYE G, TUMUSHABE J T

Department of Geography, Geo-informatics & Climatic Sciences, Makerere University, Box 7062 Kampala Uganda, tumwrug@gmail.com

Abstract

Kamwenge is one of the districts in Uganda with one of the highest population growth rates in the country (3.91% compared to the national average of 3.03%) (UBOS, 2014). The department of Geography, Geo-informatics and Climatic Sciences (DGGCS) of Makerere University in collaboration with Kamwenge Bee Keepers Cooperative Society (KABECOS) and Kyabwanswa Rural Integrated Farming Systems (KRIFS) intend to reduce poverty through integrating improved bee, coffee and goat farming with agro-forestry in the district. The data for this paper was derived from a survey that was conducted in Kamwenge district in December 2014, records of KABECOS and KRIFS and other secondary data sources. Results show rural transformation of Kamwenge district. Improved bee farming has increased hive products. Increase in the number of bees, the best pollinators is expected to increase yields of crops. Agro-forestry shall increase the nectar and pollen for the bees by reducing the distance covered in collecting raw materials for the hive products. The trees will also provide shade for the coffee while at the same time increasing forage for the huge highly prolific zero-grazed boer goats. The goats will supply the highly required organic manure from their urine and droppings thereby sustaining soil fertility and increasing crop yields. Increase in production and productivity are expected to improve the livelihoods of the community.

Spatial Allocative Efficiency of Construction Land Expansion and Its Optimum Control Strategy in China

Yang Zhou, Yansui Liu

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China, zhouyang@igsnrr.ac.cn

Abstract

Construction land and high-quality cultivated land is high degree of overlap in the spatial distribution in China. Over the past three decades, rapid expansion of construction land has further exacerbated the decrease in arable land resources, posing a serious threat to food security in the whole society. The question on how to further improve the allocative efficiency of construction land and to alleviate the contradiction between economic development and resources protection has become an urgent problem to solve under China's new normal. Here, based on a balanced provincial panel dataset in China over the period 1985-2012, we used an extended Cobb-Douglas production function to investigate the spatial allocative efficiency of construction land at the national and provincial scales. Empirical results showed that physical capital stock, construction land and labor force input have contributed to non-agricultural GDP growth in China. Investment in physical capital has a greater positive and significant impact on non-agricultural GDP growth in China as a whole and in its provincial levels than that in the labor force and construction land. The effects of construction land expansion to non-agricultural GDP growth were heterogeneous across the provinces. Further investigation demonstrated that the output elasticity of construction land has not corresponded to the level of economic development, indicating that there exists a greater room for improving the utilization efficiency of construction land in China. These findings indicated that, as the arable gradually approaching the red line, some economically developed provinces where the available cultivated land resources occupied by construction land are tightening needs to further improve spatial allocative efficiency of land use.

Key words:

Allocative efficiency; construction land; Cobb-Douglas production function; optimum control strategy

Spatial-Temporal Change of County-level Inequality and Social Deprivation During the Continuous Growth of Grain Production in Henan Province, China

Gao Junbo^{1,2}, Liu Yansui¹, Li Yurui¹, Qiao Weifeng³

³School of Geography Science, Nanjing Normal University, Nanjing 210046, China

Abstract

This paper examines the spatial-temporal dynamics of inequality from the prospective of social deprivation using the national census data of 2000 and 2010 in Henan province, China in the context of continuous growth of grain production. Our analytical results show an overall high level of social deprivation and a widening gap of county-level social deprivation. The county-level social deprivation was also significantly autocorrelated spatially, the spatial cluster pattern has changed from a low-low northwest and high-high south in 2000 to a core-periphery semi annular spatial structure in 2010. Similar to the spatial pattern of grain production in Henan, the county-level social deprivation also showed an overall "west high and east low" pattern. The social development in most counties in Yudong plain and south Henan was low despite the high level of grain production, meaning that high grain output did not result in expected high social development in traditional agricultural areas.

Spatiotemporal Evolution and Driving Mechanism of Rural Settlements in the Poverty Belt Around Beijing and Tianjin, in China

Sun P, Xu Y, Liu Q, Liu C, Wang H

China Agricultural University, Beijing 100193, P. R. China, lcu05yabo@gmail.com

Abstract

Being the core of rural settlement geography, research on rural settlements has always been one of the key issues in regional system of human-environmental relationship research. Zhangjiakou city, located in the poverty belt around Beijing and Tianjin, was taken as example to analyze the evolution of rural settlements during 1985-2010 with mathematical statistics and spatial methods. The results demonstrated the following. (1) The area of rural settlements expanded from 665.76 km² to 928.14 km² during 1985-2010. The spatial distributions of rural settlements in terrain niche presented approximately normal distribution over the period studied. The rural settlements were usually distributed within in regions where the terrain niche indicated that an elevation of between 900 and 1500 m, and a slope from 5 to 20 degree. (2) The rural settlements in Zhangjiakou were characterized by obvious concentration with evident spatial variability. A clustered distribution appeared frequently in the administrative districts and their surrounding regions as well as the central plain area of Yuxian. The hot spots for the sizes of rural settlements were tended to be clustering in 2010, while the cold spots decreased significantly as compared to 1985. (3) Rural economic development, investment in agricultural technology and infrastructure improvement played important roles in the evolution of rural settlements. And there were spatial differences of the relationship between rural settlement distribution and socio-economic factors in Zhangjiakou. This study can provide practical significance for the achievement of urban and rural integration development and the promotion of new countryside construction.

Sustainability of Commercialisation of Agriculture in Tribal areas of the North-East India: The Case of Meghalaya

Nayak Debendra Kumar, Behera Rabi Narayan

Department of Geography, North Eastern Hill University, Shillong-793022, India. dknak@rediffmail.com

Abstract

The paper investigates how diets and food security are altered by cash crops in previously shifting cultivation areas in Meghalaya plateau of India dominantly inhabited by the Khasi—Jaintia and the Garo Tribes practicing until recently slash and burn type of cultivation locally known as jhum. Phenomenal increase in land-man ratio in the past century has considerably reduced traditional agricultural land-use through increasing commercialisation in many parts of the plateau. With the help of agricultural census data and intensive field surveys conducted in six villages distributed over the plateau and representing diverse farming systems, the study analyses the magnitude and implications of the introduction of cash cropping in areas and among communities hitherto practicing traditional farming. The sample includes two villages under the jhum farming system, three other villages shifting to cash crops of the traditional type and one that has accepted modern cash crop introduced recently. It is argued that the drastic land use change have many food security implications including the alternation in local food systems. The study finds that the land-use change has brought major alterations in hill agricultural practices, enhanced cash-cropping and promoted mono-cropping, changed food consumption patterns, underpinned the emergence of a new food system, and exposed farmers and consumers to the vagaries of the market, all of which have both long and short-term food security implications.

Cash Cropping; Farming System

Territorial Changes in Municipal Limits of Statutory Towns in Haryana: An Overview of Causes and Consequences

Dr. Randhir Singh Sangwan

Professor & Chairperson, Department of Geography, Indira Gandhi University, Meerpur, Rewari (Haryana), India,

randhirsangwan56@gmail.com

The Geographical Society of China, Beijing, 100101, P. R. China

Abstract

The change in municipal limits of statutory towns is done to bring geographical growth of towns under administrative limits in order to regulate the haphazard urban growth on the periphery of towns, to increase the municipal income by imposition of taxes on enterprises that come up outside the legal limits of urban centres and to smoothen the future growth of towns. With a rise in the number of municipal towns from 58 in 1961 to 79 in 2011 in Haryana, the area under them has increased from 319.39 km² to 1499.84 km², an increase of about 5 times. This represents an urban conversion of about 1180.45 km² of rural land. The present study is based on census data and attempts to analyse statistically the explanatory variables of territorial expansion and consequences of change in municipal limits of statutory towns in Haryana. It has been hypothesized that changes in the municipal limits of statutory towns is associated with their population growth, administrative status, non-agricultural workforce and location in respect of major roads. The statistical analysis confirmed close association of the variable 'change in territorial jurisdiction' of a town with the variables of 'connectivity' and 'administrative status'. Permanent loss of fertile agricultural land, rural-urban conflicts and the inability to revise municipal limits frequently and preferably much beyond the present urban built up land leading to chaotic land use are some of the consequences of changes in the municipal limits of statutory towns.

Key words:

municipal limits; statutory towns; geographical growth; haphazard urban growth; urban conversion; population growth; administrative status; connectivity; rural-urban conflicts

The Evaluation of Land Consolidation Policy in Improving Agricultural Productivity in China

Abstract

China's recent rapid economic development has resulted in rampant urbanization and substantial reduction in farmland, which makes food security a great concern not only to China but also to the whole globe. To stabilize and improve the quantity and the quality of national farmland, Chinese government has been implementing large-scale consolidation programs since 1998. However, no formal evaluation has been conducted on empirical projects at national wide. Thus, effectiveness of land consolidation policy remains uncertain. We got detail information of 3891 land consolidation projects implemented between 2006 and 2010, and used MODIS NDVI data from 2001 to 2013 to assess effectiveness of China's land consolidation policy in improving agricultural productivity. Different from optimistic estimates derived from regional statistical analyses and/or theoretical approaches, here we show that the overall effectiveness of land consolidation in improving agricultural productivity appeared to be low. Productivity in 36.44% of study projects did not increase as expected and 50.97% actually declined compared to control sites. Furthermore, we found effectiveness of land consolidation projects is of observable regional difference and influence factors are inconsistent with policy design. Based on the above analysis, we suggest Chinese government improving implementation methods and pay more attention to long-term mechanisms of land consolidation.

Land consolidation; agricultural productivity; effectiveness; NDVI; China

The Evolution and Regulation of Rural Settlements

Zhou GUOHUA, He YANHUA, Tang CHENGLI, Tan XUELAN, Wang MEIXIA, Chen ZHENG

Department of Resources and Environment Science, Hunan Normal University, Changsha, 410008, P. R. China,

uuy828@163.com

Abstract

Now there are more than 600 million rural population in China, 43.9% of the total population, and the rural settlement is still the main form for live. Rural settlements are diversity, regional and dynamic, and the research on the differentiation characteristics, evolution tendency and influence mechanism is the key to alleviate “country disease” of China, to promote rural transformation and development, to achieve urban-rural integration. Based on synthesis-coherence analysis of geography, sociology, economy, and ecology, with the central China as the study area, we studied the rural settlement types and regional differences, evolution mechanism and development trend, development stage, space optimization and so on. The study suggests that: space differentiation characteristic of rural settlements of size and shape, facilities and living conditions, subjects and social structure are obvious; Evolution of rural settlements are influenced by various factors, which are classified into base factors, new-type factors and mutation factors, working by “three-wheel” driving mechanism and three typical driver path; The general process of rural settlements evolution is divided into four stages, which includes initial stage, transitional stage, development stage and mature stage, with the tendency of system networking, scale rationalization, form intensification, function diversification, location to facilities, and so on; Organization of space function and control of scale is key to space optimization of rural settlements, so we talked about “Rural Road-Oriented Development Model”, referred to as “RROD”. We also believe the proposed approach will have significant implications for similar rural settlement research, especially oriented by life quality.

Key words:

rural settlement; rural settlement evolution; driving mechanism; RROD

The Logical Framework of Rural Land Comprehensive Consolidation during New Period

Qiao L Y, Liu Y S

China urban-rural development institute, Shanxi University, Taiyuan, 030006, P. R. China, qiaoly.12b@igsnr.ac.cn

Abstract

Currently, the new countryside construction and agricultural modernization lack of a major hand-grip. Under this situation, there is an unprecedented strategic opportunity period for rural land comprehensive consolidation (RLCC). Therefore, the basic theory and top-level design of RLCC should be studied deeply. This paper has defined the concept firstly and then constructed the logical framework of RLCC, including five aspects such as guiding idea, aim system, macro strategy key points, project arrangement spatial system and function of RLCC. The conclusions are that **(1)** RLCC is complex system engineering, and its process should use several disciplines' basic theories, especially geography, land engineering and land management, therefore, the guiding concept must be inter-disciplinary and comprehensive; **(2)** RLCC should has a hierarchical aim system which include four levels such as actual target, basic target, middle target and strategic target; **(3)** the macro strategy of RLCC should clarify the key points and main aspects in the future, the arable land consolidation should be the base content, the rural construction land consolidation should be the emphasis, and the degraded and polluted land consolidation should be strengthened; **(4)** land consolidation project arrangement should follow a logic thinking, which is formed by strategy function areas, dominated type areas, main potential areas and consolidation project areas, to build the spatial hierarchical system of land consolidation projects from national level, regional level, sub-regional level and project level; and **(5)** RLCC could promote rural transformation development and push on urban-rural integration proceeding through space reconstruction, elements integration and mechanism innovation. We hope the study could be useful for practical work.

land comprehensive consolidation; logical framework; strategy emphasis; spatial hierarchy; rural transformation development; China

A Comparison of the Means and Ends of Rural Construction Land Consolidation: Case Studies of Villagers' Attitudes and Behaviours in Changchun City, Jilin Province, China

Fang Yan-gang*, Shi Ke-jian, Niu Cai-cheng

School of Geographical Sciences, Changchun, P.R.China, fangyg578@nenu.edu.cn

Abstract

Rural construction land consolidation (RCLC) is an innovative approach to coordinating the outmigration of a rural population and the increase in rural housing land, thereby protecting farmland and ensuring food security, adding to urban construction land quotas, and improving the rural habitat environment in China. Since 2005, several different models or approaches to RCLC have been practiced by local governments. Its implementation is not successful without the cooperation of relevant villagers whose attitudes and behaviours in response to RCLC have thus far been given only minimal academic attention. Focusing on one of the approaches of RCLC, viz. the homestead exchange apartment approach (HEA), this paper analyses the means and ends of its practices and villagers' attitudes and behaviours in response to them based on a comparison of a failed case (Village A) and a successful case (Village B) in Changchun City, which is located in the northeast of China. The results show that the geographical location and associated socio-economic background of villages endow them with different potentials, strengths, and weaknesses in implementing HEA, the higher adaptability to urban living usually accompany with lower consolidation potential of rural construction land, and vice versa; The different means of HEA result in different ends, both absolute private property-based means and absolute population-based means are dogmatic and impractical; Under constrained socio-economic, biophysical, and institutional situations, the main factors influencing villagers' attitudes and behaviours in response to the various means of HEA include household population size, original housing conditions, livelihood, life course, and Guanxi.

Key words:

Rural housing; Land consolidation; Homestead exchange apartment approach (HEA); Rural households; Attitudes and behaviours; China

Assessment of Peasant Household' Sustainable Livelihoods on the Poyang Lake

Region

LI S P, MA D G

Jiangxi Normal University, Nanchang, 330022, P. R. China, dgm7799@163.com

Abstract

Poyang Lake region is located in the the middle and lower reaches of Yangtze river, which are belonging to Poyang Lake Ecological Economic Zone Lakefront. It is an important grain, cotton, oil, aquatic production base of Jiangxi province and even the whole country. The frequent floods and droughts seriously restricting the sustainable development of the regional agriculture and peasant household livelihoods which has become the main reason for the poverty of peasant household here. Taking Lakes farmers Floods and Droughts vulnerability analysis as the background, through the Poyang Lake region 754 household survey, Using DFID sustainable livelihoods analysis framework, combined with the feature of regional characteristics in poyang lakeregion and farmers, selected the 18 evaluation index of sustainable livelihoods, with analytic hierarchy process (ahp) to determine the weight of each index, fuzzy evaluation model was constructed, Build sustainable livelihoods fuzzy evaluation model, and then discusses the The level of sustainable livelihood. The results show that: in 754peasant household, the Sustainable livelihoods composite index between 0 to 0.2 , accounting for 8.09%, Accounting for 51.86% of all surveyed households between 0.2 to 0.4, Sustainable livelihoods composite index between 0.4 to 0.6 was 37.00%, Higher than 0.6, accounts for only 3.05% of all households surveyed. In general, The low level of peasant household sustainable livelihoods of poyang lake region. Therefore, the ability to expand farmers' livelihood strategies to improve sustainable livelihoods of farmers is very important.

Comparative Analysis of Village Infrastructure Planning and Construction—The Example of Quzhou City

Lixiong Zhu, Wangming Li, Yuan Fang

Institute of urban and rural planning and design, Zhejiang University, zhulixiong2004@126.com

Abstract

In this paper, the situation of rural infrastructure planning and construction in Quzhou city is closely studied in the field. In the process of village renewal, there are problems of the lack of combination in planning and construction. For examples, Planning lags behind in the construction and planning and construction does not match the situation. Through interviews with village managers, engineering design units and design staff, and the research on the planning process, the engineering design process and the construction management of the three major processes. The village infrastructure planning should be improved through real-time update of technical specifications, multi-disciplinary integration and other measures to improve the science of planning. Meanwhile, improve the village construction management system also important to promote the planning and construction of village infrastructure. The construction and planning of village infrastructure should be based on the principle of multi disciplines, and set up a flexible planning technical specification and management system.

Abstract

Since the implementation of Modern Urban Agriculture (UA) Development Strategy in 2003, Beijing have gone through the initial and strategic adjustment stage. Now it is in a critical period for Beijing to plan the 13th Five-Year UA Plan. Based on the comprehensive data in recent years, this paper firstly summaries Beijing UA's current state from the aspect of economic benefits, function change and spatial distribution, then points out the problems needed to be solved in macro planning and implementation strategies. Finally, several suggestions, such as the ordination of Beijing's UA plan with the integration of Beijing, Tianjin and Hebei, and the relevant administration policies, are proposed.

Erosion Gully Information Extraction Based On Remote Sensing Images with Different Resolution

PU Luoman, ZHANG Shuwen, WANG Ranghu, CHANG Liping, YANG Jiuchun

Northeast Institute of Geography and Agroecology, Chinese Academy of Science, Changchun 130102, China,

puluoman@sina.com

Abstract

In this study, based on multi-resource remote sensing images, combined with DEM data, using qualitative method, characteristics of erosion gully extracted from each remote sensing image are analyzed comprehensively, and two investigation units are selected in survey area for field verification. The results obtained are compared with the results of visual interpretation of remote sensing images. The results show that: (1) Although Pleiades remote sensing image with the highest spatial resolution and DMC image can express the information of gully erosion clearly, the increasing of spatial resolution of remote sensing images will increase internal details of erosion gully, which can cause interference for extracting information. (2) Different types of erosion gully can be extracted from different remote sensing images. Compared with Pleiades remote sensing image and Alos remote GF-1 satellite images, as the ideal images, can express the information of dissected gully and gulch that need to be researched mainly. (3) When resources satellite three and GF-1 images extract the information of quantity, length and width of dissected gully and gulch, which need to be investigated mainly, the results close to the field verification results, so they are more appropriate images.

Key words:

remote sensing images; erosion gully; information extraction; field verification

Examining the Causes and Consequences of the Expansion of Second Homes in Rural Areas and Suburban in Iran (1990-2015)

Izady H.

Department of Urban Planning, Shiraz University, Shiraz, Iran, izady@shirazu.ac.ir

Abstract

The expansion of second homes has been an important feature of land use and landscape change in some of the rural and suburban areas in Iran. Although the creation of second homes has a long history in Iran, but it has been grown substantially over the past two decades, especially in the coastal areas of the Caspian Sea, around metropolitan cities and some rural areas. This paper investigates the causes and the economic, social and environmental consequences of the expansion of second homes in rural areas and suburban in Iran through content analysis method. Our findings show that the main causes of the expansion of second homes include: increased leisure time, rising household incomes, investment in housing in order to create added value and increasing household assets. Moreover, the results show that the expansion of second homes have had both positive and negative consequences. Some of the positive consequences include creating new job opportunities and increasing income in rural areas, improving the quality of life among local communities, improving local infrastructure and enhancing the quality of rural housing construction. Among the negative consequences the illogical increase in the price of land and housing, deep changes in traditional social values in rural areas, and the emergence of cultural conflicts between the local people and new settlers or the second homeowners, degradation of natural resources and changes in traditional land use can be mentioned. These findings suggest that negative consequences have resulted due to the lack of program and overseeing the building of second homes. Therefore, effective monitoring and control is essential over the construction of second homes and implementation of housing programs in rural areas and suburbs in Iran.

Key words:

Causes; Consequences; Expansion; Second Homes; Rural Areas; Suburban; Iran

Exploring the Factors Influencing Land Use Conflict Based On Multilevel Model: A Case Study in the Poor Belt around Beijing-Tianjin, in China

Yu Z, Sun P, Zhang H, Liang J

School of Geography, Beijing Normal University, Beijing, 100875, P. R. China, yzlei87@163.com

Abstract

Land use conflicts often result from the spatial arrangement of incompatible land uses representing different stakeholders' interests. In order to improve ecological environment, the policy of returning farmland to forest has been implemented in China, which requires the land with large slope must be used as forestland to protect public interests of ecological service. But there are still many sloping land are used for cultivating, which exacerbates soil erosion and threatens ecosystem services. Comparing the public ecological benefit carried by forest in sloping land, the sloping cultivated land carries the households' private interests. Thus, we can define the land with conflict as the sloping cultivated land which should be used as forest. This paper selects Chicheng County in Poor Belt around Beijing-Tianjin as study area, which is one of the important sections of Green Wall of China, and with the function of soil and water conservation, wind-preventing and sand-fixing. We use the multi-level model to identify the influencing factors of land use conflict based on natural, socio-economic data and remote sensing images. The results show that land use conflict is driven by the factors at both town and raster level. At the town level, average cultivated land and population have negative relation with land conflict, while agricultural economic development plays a positive role. At the raster level, land use conflict is mainly driven by soil fertility and land relief, while restricted by elevation and distance to the nearest road and settlement. These can make a lot for land management decision.

Key words:

Land use conflict; influencing factors; multi-level model; Poor Belt around Beijing-Tianjin in China

Geographical Feature Recognition and Classification of Ecological Restricted Development Zones

—Using the Case of Lianhua of Jiangxi Province as an Example

Ma J, Ma D G

Jiangxi Normal University, Nanchang, 330022, P. R. China, dgm7799@163.com

Abstract

In the rapid economic development, under the natural ecological environment overload condition of reality, completes the ecological restricted development zone regional function identification and classification is helpful to maintain the country's ecological security, to solve the contradiction between ecological protection and economic development, reflects regional differentiation in the development and the ecological civilization. Using the case of Lianhua of Jiangxi province as an example, based on GIS technology, through the natural background conditions, protection of incremental demand present situation, the development and construction to carry out the single factor and integrated assessment analysis, Lianhua County is divided into ecological improvement, agricultural, urban development and prohibited development four types of functional areas. The results show that: (1) The county town covers an area of 53.32 km² accounted for 4.97% of the county area, mainly distributed in the flat plain of the southeastern; (2) For 22.08% of the total agricultural production area, it scatters in the Lianhua county of eastern lowland, and in the western minority villages and towns; (3) Ecological improvement areas up to 72.95% of the total area of 782.04 km², and covered in the county in the west, north, east mountain region. According to the characteristics of the various functional areas put forward its developing orientation and countermeasures and Suggestions to promote the regional development.

Identifying Disparities during the Implementation of Land Consolidation in China By Coordinated Evaluation

Xiaomin Xiang, Xiaobin Jin, Xindong Du, Xuhong Yang, Yeting Fan, Yinkang Zhou

School of Geographic and Oceanographic Sciences, Nanjing University, Nanjing, 210023, P. R. China, xxmju@163.com

Abstract

China's recent rapid economic development has resulted in rampant urbanization and a substantial reduction in farmland, making food security a major policy concern not only in China but worldwide. Since 1998, land consolidation (LC) has been implemented in China in an attempt to stabilize and retain valuable farmland, improve farmland quality and promote adequate agricultural production capacity. Although the Chinese government fully controls LC, it remains unknown whether these LC implementation efforts have been successful. This study attempts to develop a factor-combination method that can be used to evaluate the coordination of LC implementation and its conformity to current land management plans, to explore any spatial disparities, and to especially identify any potential problem areas. The study period, 2006–2012, was based on data acquired from a LC project management dataset developed at the county scale. The study found that (a) by analyzing the intensity of, potential for and difficulties involved in LC, the coordinated evaluation method used here that is based on a mechanical balance model can effectively identify disparities that occur during the implementation of LC; (b) only 22.15% of all units are in the state of coordination, and incidents of uncoordinated implementation are mainly ascribed to a mismatch between the intensity and potential for regional LC; (c) six categories of problem areas can be identified in China where improvements are urgently needed related to the coordinated implementation of LC so that it conforms to planned goals.

Key words:

China; coordinated evaluation; land consolidation; intensity; potential; difficulty

Landscape Planning and Design Based on Ecosystem Services Evaluation and Tradeoff Analysis: A Case Study in Ansai Watershed

Wenwu Zhao, Xuening Fang

Beijing Normal University, Beijing, 100875, P. R. China, zhaoww@bnu.edu.cn

Abstract

The concept of ecosystem services facilitates the valuation of the multiple services from ecosystems and landscapes, the identification of tradeoffs between different land use scenarios, and also informs decision-making in land use planning. Unfortunately, ecosystem services evaluation and trade-off analysis has been mostly neglected within the landscape planning and design framework. In this study, we focused on analyzing three kinds of ecosystem services and their trade-off relationships based on field survey of the Ansai watershed, Yanan, Shannxi province. Our results show that (1) the three types of ecosystem services are not evenly distributed in Ansai watershed, the southeast region owns high soil erosion control services, high soil carbon sequestration services and low soil moisture conservation services capacity, while in northwest region the soil erosion services and soil carbon sequestration services are low, soil moisture conservation services is high. (2) Ecosystem services are significant different in various land use types, forest and shrub land own high soil erosion control services and soil moisture conservation services, farmland owns high soil carbon sequestration services, while in grassland the tree ecosystem services types are all at mediate level. (3) Significant tradeoff relationships exist in different ecosystem services types. Different land use types own different ecosystem services tradeoff relationships. (4) Detailed landscape planning and design strategy has been suggested based on ecosystem services assessment and trade-off analysis. This study explored a new method of landscape planning and design; it is of important practical significance for landscape sustainability management.

Key words:

Ecosystem services evaluation; ecosystem trade-off; landscape planning

Research of Fallow Scale in the Yangtze River Ecological Barrier—A Case Study of Chongqing, China

CHEN Zhan-tu^{1,2,3}, YANG Qing-yuan¹, YANG Ren-hao¹, CHEN Yi-duo¹, ZENG Li¹, TONG Xiao-rong¹

³Guangxi Research Society of Urbanization Development, Nanning, 530022, P. R. China

Abstract

The upper reaches of the Yangtze is an important ecological barrier of China, which related to the middle and lower reaches of the region's ecological security directly. Under the concept of green development and ecological civilization, China's arable land use transition gradually, from the predatory development to protective development. At the end of 2015, the central government put forward the implementation of arable land fallow pilot in official documents, but as far as we know, there is little research about this subject at home, especially a system survey. Chongqing on the upper reaches of the Yangtze river, fallow is an effective way of protect cultivated land production capacity and regional ecological environment, fallow scale is the key problem needed to solve before implementation of fallow. The paper take Chongqing, China as an example, from the perspective of both food security and ecological security, selected the population, per capita consumption of grain, multiple crop index, self-sufficiency rate of grain, slope cropland, rocky desertification land and other indicators, to research the fallow scale of Chongqing. The result shows that about 170 thousand hectares arable land could be fallow in Chongqing if the self-sufficiency rate of grain is 80%, and in the ecological security perspective, the fallow scale should reach to 300 thousand hectares. Therefore, the fallow scale of Chongqing should be between 170 and 300 thousand hectares, which accounting for 7% to 12% of the regional arable land.

Spatial Organization Mechanism of Rural-urban Integration in Urban Agglomeration Area

HE Yanhua, ZHOU Guohua, TANG Chengli, TAN Xuelan, CHEN Zheng

Department of Resources and Environment Science, Hunan Normal University, Changsha, 410008, P. R.

China,hyhychx@163.com

Abstract

Spatial organization is always the core study field of geography, which is correlating with spatial pattern and spatial process. It is key to improve spatial welfare and construct spatial order. Spatial organization of rural-urban integration refers to configuration of rural and urban factors, action of spatial construction and following spatial correlation, which is to fulfil the goal of rural-urban integrating development. Taking Changsha-Zhuzhou-Xiangtan urban agglomeration in central China as the study area, we studies the connotation, characteristic and mechanism of spatial organization of rural-urban integration in urban agglomeration area. It can provide principal bases for quality urbanization and overall urban-rural development. The core research contents of spatial organization of rural-urban integration include optimizing the material morphology, improving the function structure, constructing the elements system and establishing behavioural paradigm. The characteristics of spatial organization of rural-urban integration is being networking, complex, overall, multi-directional and gradient, and it highlights integration across scales and progress by stages. At the macro level, the key points is sustainable for urban-rural ecosystem and efficient for operation of urban-rural economic system, and its core mechanism are agglomeration and diffusion of elements, while complex network model can indicate it well. On the contrary, at the micro level, it is focused on upgrading urban-rural living environment and social harmony, and spatial competition and interests pursued are the core mechanism, while multi-agent model is preferable in expressing it. We believe the proposed approach will have important implications for the optimization strategy research on spatial organization of rural-urban integration.

spatial organization; rural-urban integration; urban agglomeration; Spatial Organization mechanism

Study on Influence Factors of Farmers' Willingness in Rural Residential Land Consolidation: A Empirical Study of Zhongdu village, Tongnan county

Li PE, Yang QY, Fan Y, Zhang RW

School of Geographical Sciences, Southwest University, Chongqing, 400715, P. R. China,

enpeili@sina.cn

Abstract

Rural residential land consolidation is an important way to coordinate urban-rural development in the new era in China. Analyze the main influence factors of famers can help to understand the famers' true thoughts and provide a reference comments for advancing rural residential land consolidation. This paper based on the survey data of famers in Zhongdu village, Baizi town, Tongnan county, Chongqing, which concludes the information of person and family, living conditions, policy awareness as well as the willingness of rural residential land consolidation and its reasons. Structural equation model are implemented in this research in order to analyze the influence factors and the influence direction of famers' willingness in rural residential land consolidation. The results showed that: Firstly, 43.51% of the famers are willing to join the rural residential land consolidation, 47.08% of them do not want to do, 9.21% of them think it doesn't matter. Loving their homeland, being difficult to change the mode of production and life and worrying about the cost of living increasing are the main reasons why famers do not want to join rural residential land consolidation. Secondly, in the numerous factors, the key influence factors are the non-farm payrolls in family, non-farm income, the awareness of policy, the use of homestead and the structure of house. Combining the rural residential land consolidation with job training, industry development and good living, strengthening the propaganda of related policy and improving the social-security system of rural residential land consolidation are the effective way to enhance famers' willingness.

Key words:

rural residential land consolidation; structural equation model; famers' willingness; influence factors; Zhongdu village

Study on Spatial Distribution Optimization of Rural Settlements Land Use in Hilly Area: A Case of Gulu Town, Chongqing in China

Kuang YY, Yang QY, Liu S

School of Geographical Sciences, Southwest University, Chongqing 400715, P. R. China, 403239979@qq.com

Abstract

Suitability evaluation on rural settlements' land is the basis for dividing rural optimization modes. This paper chooses Gulu Town in Chongqing as a case and builds a suitability evaluation index system of rural settlements' land based on spatial analysis and statistical analysis functions of GIS, and uses weighted average method to calculate the suitability scores of rural settlements. Accordingly, by superimposing construction land regulation region from general land use planning of Yubei District, the rural settlements' land is divided into five modes of optimization. And based on limited ranks of rural settlements land extension, the optimization strategies should give preference to the low restriction lands, and the adjacent areas are transformed gradually into construction areas. The results of the optimization are, firstly, the area of rural settlements in two modes of urban transformation and migration have a more substantial decrease to 222.47 hectares; secondly, settlements in key extension mode extend out to absorb the surrounding small settlements; thirdly, settlements in potentiality exploitation mode focus on economical and intensive land use through reclaiming unused settlements; lastly, settlements in merging mode focus on scale-up development by choosing the settlements with well location as the centers for integration.

rural settlements; suitability evaluation; distribution optimization mode; Gulu Town

Study on the Spatial Reconstruction of Rural Settlement in Western China—A Case Study of Xianyang City in Shaanxi Province

Simin Zhao

Northwest University, Shaanxi, 710127, P. R. China, 412907082@qq.com

Abstract

With the rapid development of urbanization in China, the public facilities and infrastructures in rural settlements are not sufficient for the minimum threshold of population in China. The construction and operating costs of that are increasing continuously, and the normal operation and the improvement of facilities are also difficult. The improvement of living quality for residents and the amelioration of environment are hindered seriously.

Three typical rural settlements were examined to obtain information through interviews, surveys and field reconnaissance of Xianyang City in Shaanxi Province which located in a transition zone of the Guanzhong Plain and the Loess Plateau. The article reveals that firstly, the topography, the traffic conditions, the farming radius, the income constitute of farmers, the service scope of facilities and the social factors are the influencing factors of the spatial layout in rural settlements. And the traffic conditions and the service scope of facilities are the key factors. Secondly, the three orders of hierarchy including key towns, central communities and general communities are put forward according to the orders of public facilities. And the spatial layout of rural settlements should be reconstructed under the consideration of farming radius and the service scope of public facilities, which are different in every order of the hierarchy. Thirdly, according to the characteristic that the central place of a higher order has the functions of the central place of a lower order, the spatial layout of rural settlements is reconstructed based on the service scope of facilities in different orders.

Key words:

rural settlements; spatial reconstruction; Western China

Study on the Compensation Standard of Fallow in Ecological Barrier area of the Upper Yangtze River

——The Case of Chongqing

ZENG Li, YANG Qingyuan, CHEN ZHantu

School of geographical sciences, Southwest University, Chongqing 400715, P.R. China, zengxuli@163.com

Abstract

With the concept of Green Development, it is certain that changes in the protection of land capacity and function will take place in Chongqing, because it is an important part of ecological barrier of the upper Yangtze River. Fallow is a way to protect the land capacity and function. Compensation standard for fallow is the heart of fallow compensation mechanism. Based on the economy-society-ecology profit and loss of fallow in Chongqing, this paper measures the economic value, social value and ecological value of the cultivated land, using the theory of land value to build a quantitative evaluation model. It is measured that the total value of cultivated land in Chongqing is 63495.60 yuan per hectare, of which the economic value is 16705.50 yuan per hectare, the social value is 27331.05 yuan per hectare, and the ecological value is 19459.05 yuan per hectare, respectively, 26%, 43% and 31% of the total value. According to the principle of full compensation, the fallow compensation is between the economic value and the total value. In the current social and economic conditions, fallow compensation in Chongqing is presumably between 30% and 50% of the total value. And there are some suggestions:(1) The compensation standard vary by the cultivated land quality, the higher quality, the more output, then the standard is higher; (2) The compensation standard vary by fallow period, the longer the fallow period, the more cost the fallow management, then the standard is higher;(3) Taking the incentive mechanism to encourage fallow in ecological degradation area.

Key words:

The compensation standard of fallow; The cultivated land value theory; The calculation the cultivated land value; The ecological barrier area of the upper Yangtze River; Chongqing

Study on Water Supply Project Planning of Villages Based on the difference of Water Use Behavior

Lixiong Zhu, Wangming Li, Yuan Fang

Institute of urban and rural planning and design, Zhejiang University, zhulixiong2004@126.com

Abstract

The scale of water supply facilities in the village of the old age pension is much higher than that of the average village. Through the field survey, we found there are many channels, multi water sources and independent water use behavior of the villagers. Traditional village water supply facilities planning could not adapt to this kind of behavior pattern. Based on the case study, this paper proposes a water supply project planning method based on the difference of water use behavior. Reasonably predict the scale of centralized water supply, and guide the standardization of the construction of independent water intake facilities. Scientifically construct water supply facilities for the actual life of the villagers.

Key words:

water supply facilities; water use behavior; water supply facilities planning

The Changes of Spatial Pattern of China's Grain Output and Its Impact on Resources and Environment

Jieyong Wang¹, Ziwen Zhang^{1,2}, Yansui Liu^{1,*}

¹Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing 100101, China

²University of Chinese Academy of Sciences, Beijing 10039, China

Abstract

Grain output is of irreplaceable importance in China's agriculture, social stability and national economy. This paper aims to investigate the spatial pattern of grain output in China and its changes in the period 1990-2014. The research findings show that the Northern China plays a major role in grain output though the hydrothermal conditions of Southern China are better. The gravity center of China's grain output has moved from the south to the north of the Huanghe River and reached the southern part of Hebei Province in 2014. Also, changes of grain producing structure could be seen in micro scale. What is more, we made a discussion on whether these changes are sustainable to the environment and agriculture development in the long run. Under the assistance of virtual water and virtual land measurement, it could be concluded that the northward movement of grain output away from the superior area for grain output in south China causes rising cost of resource utilization. With further analysis, intensive grain farming leads to hidden risk of environmental degradation. Besides of climate warming and construction of water conservancy facilities, economic benefit is another reason that directly leads the changes of grain planting pattern. To rectify the market failure in environment protection of grain production, however, regional grain producing policies need to be made scientifically and reasonably.

Key words:

Grain Output; Spatial Pattern; China

The Realization Mechanisms of Urban-Rural Integration of Shaanxi

Renyi

North-West university, Xian, 710127, P. R. China, 29855482@qq.com

Abstract

Urban-rural Integration is a higher stage of the relationship between urban and rural, it is also the primary approach to promote social harmony and justice. This paper have reviewed the literatures about urban-rural integration, researching the connotation and realization mechanisms of urban-rural integration. Finally, put forward the development strategy of Urban-rural integration According to the actual development of Shaanxi. The connotation of the Urban-rural Integration is to achieve the urban and rural residents' income equivalent, to achieve equalization of urban and rural public services and the development opportunities, urban space and orderly use of resources. First, rural incomes will be increased through the developing of modern agriculture and promoting the county urbanization. Second, we could commit to achieve equalization of public services under rural residential area system readjust background. Third, we can carry out to improve urban and rural development in the external environment, including extend the use of infrastructure to rural space and controlling generally the use of urban and rural space.

Key words:

Urban-rural Integration; realization mechanisms; Shaanxi

Zoning of Rural Residential Land Consolidation in LiangJiang New Area in Chongqing based on the Urban-rural Integrated Development

Bi GH, Yang QY

School of Geographical Sciences, Southwest University, Chongqing, 400715, P. R. China, 895559691@qq.com

Abstract

China's urban-rural integrated development is not only about the integration of land use, but also concerning the harmony of human settlement environment and the equalization of basic public services between urban and rural area. With multiple targets of rural residential land consolidation under the perspective urban-rural integrated development, this paper, taking LiangJiang New Area as an example, investigated the scheduling and layout of the rural residential land consolidation based on the evaluation of rural human settlement quality, the evaluation of rural basic public services and the potential measurement of rural residential land consolidation. The results show that the schedule of rural residential land consolidation in LiangJiang New Area can be divided into 4 regions, including the key region, the sub key region, the general region, the reservation and optimization region. Based on the results of evaluation on rural settlements suitability, combined with the characteristics of rural residential land, we formulated 4 types about rural residential land consolidation, including the model of urban-rural combination, eco-development, foster transformation, optimization and potential tapping. To improve the comprehensive benefit of rural residential land consolidation, we should investigate the scheduling and layout of the rural residential land consolidation firstly. Than we can formulate the suitable and targeted models for rural residential land consolidation.

Key words:

Rural residential land consolidation; Spatial-Temporal Collocation; Urban-rural integrated development; LiangJiang New Area

Catchphrases as Instruments of Social/Identity Recovery in Nigeria: A Sociolinguistic Study

Idowu Odebode

Redeemer's University, Ede, Nigeria, odebodei@run.edu.ng

Abstract

Nigeria is located in West Africa. It is a country of almost 450 diverse ethnic groups and about 200 million people. It has three major linguistic groups: Hausa (North), Igbo (East) and Yoruba (West). It also has 36 states which have been (re)named by the colonial masters and the military in the pre and post independence era respectively. The name, Nigeria (*Niger Area*) was given by Flora Shaw, a European. *Niger* denotes the River of the Blacks according to Leo Africanus. This system of naming (after rivers) influenced the military in the post-independence era such that some states in Nigeria were named after one river or the other. But as power shifted through independence and ballots, Nigerians began to see inadequacies in some of the place-names, hence, the need for better description of such places through catchphrases. As a corollary to the initial historical emblems represented by the previous names, each catchphrase reflects the socio-cultural milieu of the people vis-à-vis occupation, religion, education and politics among others. Similarly, certain catchphrases have to be modified through negotiations because they generated conflicts among the diverse socio-ethnic groups in the country. Thus, Sokoto has to metamorphose from *born to rule* to *seat of the Caliphate*, and Osun has to drop its initial *state of the living-spring for the virtuous state*. This paper examines selected states' catchphrases in Nigeria with a view to unraveling the social constructs involved in (re)naming of such places.

Communicative Community as the Core Criterion for the Endonymic Status of Toponyms. An Addendum to P. Jordan's Definition of Endonym

Wojciech Włoskiewicz

Institute of Slavic Studies, Polish Academy of Sciences, Warsaw, Poland, wloskowicz@gmail.com

Abstract

Besides the UNGEGN-approved definition of endonym there are several new academic definitions and theoretical approaches that were proposed in recent years. They are generally based either on the language criterion or on the community criterion. The 2012 definition by Peter Jordan binds the endonymic status of a name with the toponymic usus of the community closest to the named feature (principle of subsidiarity). The aim of this paper is to elaborate on the very nature of such community and to redefine it as a communicative community according to the theory proposed by the Polish linguist Ludwik Zabrocki. This approach combines both sociological and linguistic aspects of the use of geographical names as the concept of communicative community is not limited by the concept of language and language community.

endonym; definition; communicative community; community; toponym; geographical name; exonym;

UNGEGN

Constructing a Waterfowl Common: Toponyms, Monuments, and the Ecological Sciences

Hatvany, M.

Université Laval, Québec, Canada Matthew.Hatvany@ggr.ulaval.ca

Abstract

Unusual toponyms and memorials mark the geography of Western Canada. Across the Prairie Provinces are numerous lakes and memorials reflecting the names of American cities, states and conservationists. This extrinsic place naming dates to the 1940s when one of America's most successful conservation organisations launched "The Lake that Waits" project. Emerging from the Dust Bowl, disappearing wetlands, and declining waterfowl, this project married ecological data, toponyms and other cultural symbols, and geographical imagination to encourage American waterfowlers to invest in the rehabilitation of Canadian duck breeding areas. Tina Loo remarks in *States of Nature* that this "was not simply re-engineering the landscape, it also re-colonized it in the name of conservation." But, is this an example of one national group using nature conservation as a means to colonize the resources of another? Or, is this problem more multi-layered? An historical geography relying upon a critical analysis of archival documents illustrates that this toponymic renaming and commemoration, rather than symbolic of the power of colonization, is an early example of using toponyms and memorials as tools in applied ecosystem management to encourage recognition of the shared responsibilities of national groups who, despite large distances and political and cultural differences, needed to reenvision the Canadian-American map not in political or nationalistic terms, but rather as a continental waterfowl common.

Key words:

Toponyms; Place Naming; Colonization; Ecological Common; Nature Conservation

Cultural Interpretation of Place Name Brand in the Process of Marketization—As an Example of “ChenMai BaiLian Goose”

Zhaoliang, Zhangzhengsheng

School of Geography, South China Normal University, China, zlookbook@163.com

Abstract

The place name brand contains rich and diverse cultural connotation. Therefore, this article chooses the trademark disputes as a research case, in regard to the trademark “Chengmai Bailian goose”. Next, the author studies the cultural meaning and market value of the place brand systematically. Furthermore, the author explores the place culture’s supporting effect on brands as well as the inheriting relationship between place culture and the wide spread of the brand, so as to prepare for the references about making the brand developing strategy and the enhancement of the brand awareness.

Key words:

place name brand; geographical indication; trademark; culture; BaiLian goose

Diachronic Analysis of the Godonymic (street name) Space of Astana City

Zharkynbekova Sh., Konyratbayeva Zh., Kairova M., Tussupbekova M., Kozhayeva A.,
Abduali B., Kulmanov K.

L.N. Gumilyov Eurasian National University, Astana, 010008, Kazakhstan, Tusupbekova_mzh@mail.ru

Abstract

This paper explores the principles of forming onomastic space in the city of Astana using “godonyms” (street names). Using an analysis of historical archival documents, resource books, and theoretical and empirical research in onomastics, the formation of the modern “godonymic” space of Astana was examined, and the principles of naming policies in different periods of the city's existence were revealed. Directing the focus of research toward naming policy issues in the city is fully justified because of a number of problems regarding the naming and renaming of cities and streets that demand an immediate solution. In this respect, Astana, as the young capital of Kazakhstan, is of particular interest. The godonymy of Astana is a holistic historical and cultural phenomenon, in which each era has left a noticeable mark, which characterizes not only the semantics, but also its structure. As analysis of the research material shows, the street-naming system of the city has undergone tremendous changes. The reason for this is huge transformations, dictated by geopolitical, cultural, social and economic priorities.

Key words:

city space; demonstrative; godonym; onomastic research; memorative; onyms; state and language policy

Evaluating Toponymic Brand Equity: A Case Study of 'Gwanghwamun' and 'Gangnam' in Seoul, Korea

Kim, H., Choo, S.

Kyung Hee University, Seoul, 26 Kyungheedaero-ro, 02447, Republic of Korea, nicoleheesu@gmail.com

Abstract

This study, as an exploration of this economic value of place names by employing the concept of customer-based brand equity, developed in the debates of the business management attempts to evaluate the brand equity of place names. A framework to evaluate the brand equity of place names has been designed, which is composed of four elements; awareness of place names; evaluation of the quality of place names; association with place names; and loyalty to place names. Researchable variables have been drawn to concretize these elements. Some factors which may influence the brand equity are also suggested, such as demographic factors, social background, and more importantly, perception of the geographical boundary associated with the place names. A case study conducted on two place names, 'Gwanghwamun' and 'Gangnam' in Seoul, Korea. Results of the survey shows that the brand equity of place names is an effective tool to evaluate their economic value: 'Gwanghwamun' is positively evaluated in the respect of its historical value and 'Gangnam' in the respect of peoples' awareness. Research topics are suggested, including the process of becoming a place name as brand with economic value; the evaluation of each elements of the brand equity; and fundamentally the relationship between place and place name.

Key words:

place name; toponym; economic value; brand; brand equity; toponymic brand equity; customer-based brand equity; Gwanghwamun; Gangnam

Expressing 'Far-Away-Ness' In Exaggerations: 'He Has an Ego from Here to Tokyo'

Riemer REINSMA

Amsterdam. The Netherlands, rr@riemerreinsma.nl

Abstract

Metaphorical sayings which contain a toponym are a popular phenomenon in the Netherlands and some other countries. The toponyms concerned refer mostly to towns and cities, in the Netherlands as well as abroad.

The sayings express exaggeration, and are equivalents of

- 'huge/ large' (He has a criminal record from here to Maastricht)
- 'extremely' (I feel sentimental from here to Tokyo)
- 'intense, loud' and the like (I heard shouting from here to Jerusalem)
- 'many' (We heard stories from here to Malaga).

The earliest attestation in the Dutch language dates from 1528 (a fart from here to Jerusalem). Since then, over time tens of toponyms occurred once or repeatedly in these sayings. According to LexisNexis, a newspaper database, the name of Tokyo emerged in 1969 and has gradually become the most used toponym in this type of expressions. This paper will pay special attention to this name variant and propose an explanation for its rise in the last decades.

Key words:

Metaphorical saying; toponym; Tokyo; exaggeration

Geographers' Approach to Naming the Physical Geographical Regions of Hungary (1945–2015)

Gercsák, G.

Eötvös Loránd University, Budapest, Hungary, gercsak@map.elte.hu

Abstract

The professional geographers' approach to giving names to physical geographical regions often confronts the accepted, traditional or local usage. Hungarian geographers consider it important to name the various levels of geomorphologic regions (macroregion, mezoregion, subregion and micro region) so that the name should reflect the geographic character (mainly the morphology) of the specific area. Even so, certain place names are changed almost periodically for various reasons. First, there may be different professional views of the same land area, which leads either to slight differences in the names or produces new names according to the opinion of authors. Second, with the development of research, scientists may realize that certain accepted place names do not describe the features of the area precisely any longer. Third, when the geographical borders or extent of the regions are revised, new regional divisions are set up with names newly introduced and others dropped. Further, political-administrative influences can result in new place names. This practice has brought about confusion in the usage of names mainly in schoolbooks, in the press and in everyday communication. These artificial names (professional constructs) often contain technical terms and strange word combinations the correct spelling of which challenges not only the common people.

The author has collected the name changes of the major physical geographical (landscape) regions of Hungary introduced by the scientists either from the academic institutions or the private sphere in the past seventy years, and analyzes the motives of these changes.

geographical regions; geographers; place names; Hungary

How Egyptian Geographical Names Represent Identity and Cultural Heritage?

Orieby, Eman

Central Agency for Public Mobilization and Statistics, Cairo, Egypt, emanorieby@gmail.com

Abstract

This paper represents how place names are considered as a witness of history and memory of nations. I explain why we consider the geographical names as a part of the cultural heritage, how to express geographical names for identity, and the variables that affect the interaction and feelings of geographical names, what are the factors affecting our perception of place as an identity. I outlined the stages of the historical development of the Egyptian geographical names and the impact of foreign languages at the Egyptian geographical names pronunciation, the impact of the local dialects and Egyptian Literary languages on changes happened to Egyptian geographical names. The history of Egypt is categorized into several successive historical Eras. They are Pharaonic Era, Greek Era, Roman Era, Coptic Era, Islamic Era, Modern Era¹. Through those eras The Egyptian spoken language has developed from Old Egyptian, Middle Egyptian, Late Egyptian, Greek, Demotic, Coptic, Arabic And Also Egyptian Literary language from Egyptian Hieroglyphs, Hieratic, Demotic, Greek, Coptic, Arabic.

Finally, I give a brief note about how changes of place names are happened according to social, political, commercial impacts.

Key words:

Toponymy; GIS; Standardizing geographical names, Cultural Heritage

La Toponymie Des Pays Du Sahel Et Du Maghreb : Une Homogenite Toponymique Et Spatiale

Brahim ATOUI

CRASC, Algeria, atoui.brahim@hotmail.fr

Résumé

Si les études de la toponymie des pays d'Afrique du nord et plus particulièrement ceux du Maghreb sont plus ou moins abondantes, celle des pays dit du Sahel ou sub-sahariens l'est très peu. Encore moins la relation qui pourrait exister entre ces deux parties de ce continent !

En effet, pour la toponymie des pays du Sahel, considérée, d'ailleurs en partie, à tort, comme une toponymie issue de langues orales, non écrites, nous nous enregistrons très peu d'études si ce n'est quelques tentatives de quelques érudits notamment européens, qui ont rédigés quelques notes éparses sur quelques toponymes des ces pays, souvent peu documentées ou peu objectifs car menées parfois avec une approche colonialiste.

Dans le papier proposé, nous essayerons de montrer que la toponymie du nord des ces pays, contrairement à ce qui a été écrits par certains, est issue de langues écrites et surtout qu'ils ont avec ceux du Maghreb, non seulement une continuité spatiale mais aussi une continuité toponymique.

On effet, si on observe la carte linguistique de la région dont il s'agit, on remarque qu'une partie de ces pays qui la composent, ont en partage la langue amazigh (berbère), la langue arabe à côté d'autres dialectes et par conséquent l'espace couvert par ces langues, porte une toponymie issue soit de la langue berbère ou soit de la langue arabe toutes deux sont des langues écrites ! la langue arabe est d'ailleurs soit officielle comme au Tchad et au Mali soit nationale comme au Niger.

Dans ce papier proposé, nous essayerons de montrer la relation toponymique spécifique qui existe entre les pays du Nord de l'Afrique et ceux des pays dits du Sahel et d'en proposer une nouvelle approche pour des études futures de la toponymie de cet ensemble spécifiquement dite saharienne qui n'est ni rurale ni urbaine ! et qui exprime une mode de vie propre à ces pays.

Mots-clés:

toponymie; langue écrite; langues parlées; toponymie Saharienne

Metamorphic Toponymic Identities: Case Study of Urban Villages of NCT of Delhi

KANAUJIA, K

Ph. D Research Scholar, Department of Geography, Delhi School of Economics, University of Delhi, New Delhi, 110007, Republic of India, sak2lucy@gmail.com

Abstract

Of the myriad characteristics that may define or identify a certain entity; animate or inanimate, name is perhaps one of the most significant portals providing access and passage to the inner most sanctum sanctorum of a specific entity and this becomes even more prominent when one observes the names of places. Toponymy gains prominence as identities traceable on maps as a place name is the primary identifier of locating a place in myriad spaces and places. But since change is the only constant in this world, toponymy as well is subjected to it. Numerous reasons may be attributed to toponymic erasures, erased-preservations and even unchanged existence. The urbanscape of Delhi, with its myriad urban villages is an exemplifier of diverse, inter-related and interactive toponymic identities as microcosmic reflections of the macrocosm of Delhi in context of nature, people, functions and patterns.

This toponymy does not exhibit a simple, generalized or coherent facade rather is entwined in class, caste, spatial location, resistance and acceptance to stereotypical norms of development, changing times and reality. The toponymy of these urban villages began in rurality, in social structures and stratification, entwined in socio- cultural topographical space and which is now subjected to the influences of politics, power and urban development.

Key words:

Toponymy; urban villages; Delhi; urban development

Place Naming Between Words and Numbers and its Impacts on Place Identity

Rassem Khamaisi

Department of Geography and Environmental Studies, University of Haifa, Israel, Khamaisir@gmail.com

Abstract

The process of place naming is not neutral; it is derived from socio-cultural identity and articulated as belonging to an ethno-national community. It contributes to shaping the identity of individuals in the society. In addition, the process of naming produces a differentiation between societies and communities, and presents diversity. Naming is part of the soft symbolic resources which have an impact on community awareness and place affiliation. Place names have an impact on defining and differentiating through words or numbers. In modern states and societies, every person has a name (words), and number such as identity or passport number. Geographic objects such as places, roads, mountains, valleys and caves often have names to define it by words or numbers or both. The topic of this paper is the roots of transformation of place naming by words and numbers, and its implications for identity of place belonging and affiliation. The paper will compare the context of place naming by words or numbers and its meanings and advantages, particularly regarding the situation of geopolitical and socio-cultural conflict in Israel between Arab Palestinians citizens and the State of Israel.

Key words:

Place naming; words; numbers; identity; Arab Palestinian; Israel

Post-Colonial Urbanization and the Changes of Vernacular Toponyms around Bupyeong-gu, Incheon: A Critical Perspective

Ryu, Je-Hun

Korea National University of Education, Cheongju City, South Korea, jhryu@knue.ac.kr

Abstract

The present patterns of naming around Bupyeong-gu of Incheon reflect the long and contentious history of Japanese colonialism, the significance of reinstating Korean toponyms after liberation, and the contemporary politics of culture, identity, and belonging. The vernacular toponyms of Bupyeong have played an important role in the construction of identity among the people who identify themselves with the imagined community named Bupyeong. It is speculated that local Korean residents were still using these autochthonyms, or vernacular toponyms, as substitutes for the Japanese names during the Japanese colonial period. Since the 1980s, indigenous toponyms have disappeared in everyday conversations, while being replaced by the names of apartment complexes. Wontei Gogae, by contrast, is an old vernacular toponym that is still in use along with the creation of humorous nicknames. The toponym Datagumi can be classified as a kind of resistant toponym in that it has no alternative toponym. Since the 1940s, Samneung, the Korean pronunciation of a Japanese toponym, has been used as an alternative toponym to the official toponym Bupyeong 2-dong.

Key words:

Bupyeong-gu; vernacular toponyms; indigenous toponyms; resistant toponym; alternative toponym

Probing the Place Identify via the Naming of Bus Stops

Dong-Po Deng¹, Peter Kang²

¹Institute of Information Science, Academia Sinica, Taipei, Taiwan (ROC), China, dongpo@iis.sinica.edu.tw

²Department of Taiwan and Regional Studies, Donghwa University, Hualien, Taiwan (ROC), China,
kang@mail.ndhu.edu.tw

Abstract

The name of bus stop is not arbitrary-given. The naming process actually considers the social and spatial context of the designated spot. It involves the locative memories and experiences of the people who live in the service areas of bus stop. The name of bus stop, nevertheless, reveals the different meanings for the people outside of the service areas. The shared experience of using and referring the bus stop name promotes the local people to constitute a social and spatial identity. This paper attempts to explore the naming of bus stops as a platform for the construction of place identity. We collect 3,794 bus stops of the greater Taipei area (both Taipei City and New Taipei City) and divide the nature of bus stop names into three themes: landmarks (points), transportations (lines), and places (areas). By way of geo-visualization, we may see the spatial distribution of the three themes reflecting the different naming genres from urban to suburban areas, which in turns demonstrates how we perceive the place identity in different areas.

Southern African Place Names as Social Constructs

Peter Raper

Research Fellow, University of the Free State, South Africa, raperpe2@gmail.com

Abstract

Place names, or geographical names, are social constructs, as are languages themselves. The natural geographical features to which names refer, and which they identify, presumably existed prior to the emergence of society, and are thus independent of social construction. Features made or adapted by human agency, on the other hand, are social constructs, as are the names allocated to them. The wide variety of languages from which place names are derived has necessitated, and resulted in, divergent constructs, reflecting language contact that incorporates adaptation, translation, hybridization and replacement of names. Evolutionary onymic formation involving the shift from appellative to proper name, and the shift from evolutionary to illocutionary formatives, also reflect social construction. In Bushman society the application of the name was dependent on the relevance of the feature to society, and geographical features and their component parts were thus named accordingly, resulting in toponyms incorporating different generics, from different languages, all being social constructs. The syntactic structures of toponyms are the result of social structuring, the generic term frequently designating the feature type, the specific term serving to distinguish the particular feature from others of the same class within the given context. This paper considers social variations reflected in toponyms coined by Bushman hunter-gatherers as compared to those of later inhabitants of Southern Africa.

Key words:

Place names; Geographical names; Language contact; Social constructs; Bushman languages

Spatial Patterns of Manchu Place Names in Northeast China

Zhu ZH, Zhang HY

Northeast Normal University, Changchun, 10024, P. R. China, zhuzh569@nenu.edu.cn

Abstract

Place names (toponyms) represent a wealth of information, which is closely related to the local civilization, language, environment, history and habit. UNESCO classified Manchu, Ewenki, Dagur and Manchurian Krirghiz in Northeast China's as critically endangered languages. It means the disappearance of the multiethnic heritage besides the reduction of linguistic diversity. While place names action as carriers of languages which can be preserved for a long time. For that Manchu known as "Mandarin" has significance in Qing dynasty, there are a large number of Manchu place names in Northeast China as "living fossils" storing local cultures. We study Manchu together with other ethnic place names in Northeast China, integrating spatio-statistical measures by GIS, in order to focus on the temporal and spatial distribution of place names in Northeast China. The objective is to explore the geographical factors in minority-inhabited areas with the relevant historical background, as well as the influences upon the original culture by Han Chinese immigrants. Through the evolution of place names to indicate the ethnic acculturation and assimilation during historical migration process. This article integrates the approaches to linguistics, geography, history and related disciplines, so as to promote the conservation of endangered languages.

Manchu toponym; GIS; spatial analysis

Spatial Politics of Street Names between Taipei and Shanghai

Huang wenchuan

Dong Hwa university, Taiwan, China, sunnyhuang@mail.ndhu.edu.tw

Abstract

The naming of streets after historical figures and events is an important part of modern culture policy; it not only provides spatial and semiotic orientation to the city but also serves to naturalize and legitimize a selective vision of the past. Street naming thus can become a contest about who has the power to determine how the landscape is represented and whose history will be told.

According to the history of China, after the Chinese Civil War, the ROC government led by the Kuomintang (KMT) retreated to Taipei in 1949, while the CPC proclaimed the PRC government in Beijing. Since then, the relations between mainland China and Taiwan are in conflict with each other. However, unfolding the map of Taipei and Shanghai, we will find the street names have a high degree of correlation in these two cities. Both are all filled with place names of mainland China. The first street named after Chinese cities and provinces appeared in the British and American Settlements of Shanghai from 1863. Even Shanghai has undergone different political regimes and street names changed, but the principle of naming streets after Chinese cities and provinces become the main rule of street-naming, finally. On the other side, after the 228 accident in 1947, the KMT government decided to rename all the streets of Taipei with the place names of mainland China. From then on, the place names of Mainland China were inscribed on the streets of Taipei city. Although the place names of mainland China dominant the street names of Taipei and Shanghai city, but we still concerned about which place names were chosen to show the difference political ideology.

The paper will borrow the concepts of critical theories to argue street names as the illustration of state power on its spatial politics by examining the scale and location of the streets named after Chinese cities and provinces between Taipei and shanghai where base on their political difference on the two sides across the Taiwan Strait to compare and analyze the difference responses between PRC and ROC governments.

The Ancient Names of Cities in Mesopotamia and Their Changes over Time

Palagiano C.

Sapienza Università di Roma, Città Universitaria Roma 00178 Italy cosimo.palagiano@uniroma1.it

Abstract

The great interest of both mass media and public opinion on the current situation of territories and their cities of ancient Mesopotamia have highlighted names and sorry business of cities that were largely unknown by the majority of the people. Many of these cities have discovered thanks to intensive archeological digs especially conducted in the last fifty years. In the ancient times the names of these cities were well known because they have flourished for many centuries some millennia B.C. under different governments. For this reason, the names could have changed, because the new powers could speak different languages, Semitic and Indo-European.

The aim of this study is to trace briefly the history of the names of these ancient cities and to classify the different types of city names according the different historical periods.

There are: (i) cities which have changed their name only with slight linguistic variation; (ii) cities that have changed the name but not the place; (iii) cities rebuilt with the same name in nearby locations; (iv) names of cities disappeared or destroyed totally or partially; (v) names of cities of undoubted location.

In conclusion I will try to draw up a table with the different name of cities in different historical times.

Key words:

Mesopotamia; Syrian city names; Iraqi city names; City names changes

The Change of Specific Term of Marine Geographical Names in Old Sea Charts

Sung, H.H., Kim, H., Ahn, S., Suh, J.W., Lee, W.Y., Kim, J., Jeon, S.

Ewha Womans University, Seoul, Republic of Korea, hhsung@ewha.ac.kr

Abstract

This study aims to analyse the change of specific terms of marine geographical names in Korea which are inscribed in old sea charts. At first, about 300 marine geographical names were collected from 105 old sea charts around the seas of Korean peninsula published from 1800s to 1960 by U.S.A, Japan, U.K, France, Russia and Korea. In addition, those names were compared to the ones used in current charts to identify the changes of the geographical names. The history and origin of the specific term were analysed through <The Chronicle of Korea Fishery (1908)>, <Korea Pilots (2014)>, and <Oceans and Marine Geographical Names (2015)> published by KHOA.

The result of analysis shows the change of marine geographical names with the times. From 1800s to right before Japanese occupation period, specific terms of marine geographical names were named differently by each country. In many cases, the names were identical with the name of people or ship of several countries which came to survey Korea. The specific terms, used in charts published in Japanese occupation period, were similar to the currently used names. After the liberation of Korea, sea charts were newly published, adding survey data based on charts published by Japan. In this process, some of the foreign specific terms were changed to Korean alphabet and showed on the charts. Few of those names are still shown in current charts. This study will contribute to preservation of Korea's inherent marine geographical names and shed new light on the history and origin of those terms in Korea. Also, they can be used in changing foreign specific terms in sea charts to Korea's own.

Key words:

marine geographical name; sea chart; specific term

The Definition of Toponyms Mentioned in Secret History of Mongols

Dash D., Mandakh N.

The Institute of Geography and Geoecology, Ulaanbaatar, 15170, Mongolia, maaggi@yahoo.com

Abstract

Geographical names are the main socio-cultural artifacts to identify territorial extent, lingual belonging, and settlement patterns. Without knowing and understanding the hidden meanings of the geographic names the real features of the spatial objects cannot be defined.

The earliest publication in Mongolia which reflects the geographic names is the Secret history of Mongols. In other hands, this book replicates historic names of geographic objects not only for Mongolia but also other adjacent regions. This paper includes description of more than 70 toponyms and geographic names, which can be found in the Secret History of Mongols.

Key words:

Secret history of Mongols; geography; toponym

The Meaning of Space Perception for the Standardisation of Geographical Names – Poland's Perspective

WITES Tomasz

Commission on Standardization of Geographical Names Outside Republic of Poland.

Warsaw, 00-926, Poland, t.wites@uw.edu.pl

Abstract

Geographical names are settled and approved in a concrete social reality and hence often constitute the result of a compromise that takes into consideration a multitude of conditions. There are many factors that significantly affect the process of standardisation of names considered the most appropriate for objects. One of the stages on the path to standardisation of names is referring to the geographical space perspective. The basis for these analysis is the reference to two classic studies on geographical perception (LYNCH 1960, SAARINEN 1969). Perception develops in three stages, starting with the identification of elements of the environment and differentiating them from their surrounding. Next, you determine the spatial relations between elements of the environment, and in the end you define the meaning of the individual elements, which is tantamount to a practical evaluation thereof. Space perception is a complex cognitive process occurring under the influence of environmental and cultural stimuli, consisting in the establishment in one's mind of structures that reflect the space surrounding man. This presentation will show the specifics of standardisation of geographical names in Poland, taking into account ambiguous criteria of determining names. In order to make the applied exonyms correct it is required to keep those Polish names that should be protected and to abolish those that have been introduced rashly or which are no longer in use. The paper also presents how the determining and the approval of geographical names changed in Poland over time.

Key words:

space perception; standardisation; place names; Poland

The Other Side of Place Names: Understanding and Investigating Their Economic Value

Choo, S., Kim, H.

Kyung Hee University, Seoul, 26 Kyungheedaero-ro, 02447, Republic of Korea, sjchoo@khu.ac.kr

Abstract

This study investigates the economic value of place names, especially focusing on providing research issues and framework. Motivated by the finding that place names are highly capable of acting as one of the most conspicuous brands in the economy, this study has explored the essential nature of the brand value of place names and has suggested possible methodology to evaluate this value. As the place name brand has multi-dimensional elements mirroring the attributes of place, its understanding should be framed in terms both of users of place names as a subject and of place as an object. In order to evaluate the brand value of place names, the possibility of adopting the concept of customer-based brand equity, which is centered on the perception and assessment of customers, has been reviewed and more detailed items of evaluation have been addressed. A few future research topics are suggested: the nature of brand value; its relevance to place identity; the influence of place marketing; the significance of exposing place names to the public; the effect of geographic indication on brand value; delineating the spatial boundary of geographic indication items.

Key words:

place name; toponym; economic value; brand; brand equity; customer-based brand equity; geographical indication

The Partisan Odonymy as a Local Political Instrument of Franco-Algerian

Disagreement

Ammara BEKKOUCHE

Centre de Recherche en Anthropologie Sociale et Culturelle, Oran, Algérie, ammarabekkouche@gmail.com

Abstract

During the French colonial period in Algeria (1830-1962), the toponymic system generally glorified characters of Christian holiness or military known for their warrior feat against the indigenous population. The names of public places, however, show that some of them were distinguished by their Algerian origin. This award was a recognition sign of the "natives" personalities' collaboration with the colonizing country. After the independence of Algeria, place names are changed glorifying in part, the revolution martyrs died for their country. This change involved the decolonization process of Algerians in structuring their existence and ownership of their usurped intangible heritage.

On the French side, after 1962, selected names honor the rebellion's leaders and some Muslims favorable to France. As a resurgence sign of a grueling past, this symbolic act refers deliberately to the far right supporters of "French Algeria" proclamation. As such situation, it is interesting to question the characteristics of this social urban medium relating to this particular political use of choosing a place name. It implies the representations and the meanings denomination study which reflect different qualifications of the both countries' common history. Beyond designations that maintain rivalries by promoting the ex-colonial empire's events, their evocation is significant of stakes that restore them.

Key words:

Toponymy; local urban policy; place-name symbolic choice; social urban medium

The Ups and Downs of German Exonym Use. Use of Exonyms as an Indicator of the User Community's Prestige

JORDAN, Peter

Austrian Academy of Sciences, Vienna, Austria, peter.jordan@oeaw.ac.at

Abstract

Exonyms in the sense of place names used by a community for features outside its territory and differing from the place names used by the local community have the essential function of integrating foreign geographical features important enough for a certain receiver community into its cultural sphere, to facilitate domestic communication about them. What makes them politically delicate, however, is the fact that they are also sometimes regarded and used as expressions of political claims and that they are indicating the relative prestige of linguistic communities as well as power relations between them. It is, e.g., obvious that German-speaking communities use relatively few exonyms for geographical features in the Anglophone and Francophone world, while it is quite the opposite with features in the eastern part of Europe. Since the political, economic and cultural prestige of German-speaking communities, especially of Germans and Austrians, has undergone significant changes since the late 19th century, affected by the two World Wars, the Nazi regime, the Holocaust, Germany's political division and re-unification, Germany's and Austria's economic success and Germany's leading position among European Union countries, by the example of these communities also diachronic change in the relation between a community's prestige and its exonym use can be studied very well. This will be done by investigating into the use of exonyms in a representative selection of German and Austrian school atlases between the late 19th century and present.

Key words:

Exonyms; toponyms; German; cultural prestige; critical toponomastics; cultural geography

Tunisian toponyms as Social constructs. A case study from Sfax, Tunisia

Mohsen DHIEB¹, Tahar YANGUI²

¹King Abdulaziz University, Saudi Arabia, mohsendhieb2003@yahoo.fr

²University of Sfax, Tunisia

Abstract

Departing from questionnaires related to a PhD research study on spatial dynamics in the Greater Sfax City, Tunisia, we discovered noticeable differences between official or institutional labels and the ways people designate place names.

This fact appears surprising to some extent. However, if we take into account the fact that names are living bodies that evolve through history as social constructs, more or less influenced by the manners people integrate place names and identify places, we may understand the reasons and the origins of these differences in perceiving and telling place names. Moreover, responses of people are not similar: another set of differences were observed in the place denominations with regards to the users depending on their social classes, their sex, their age and some other parameters that should be investigated.

Besides social aspects, there are individual reactions to place names. These latter demonstrate the influence of social and constructions much more than official or academic productions.

In this paper, we intend to measure and portray these differences, their origins, and probably give some insights to Officials, planners and deciders when adopting one toponymic policy.

Key words:

Tunisian toponyms; Sfax; social labels

An Appraisal of the Trends, Patterns, and Determinants of Million Plus City Growth in India

HAQUE Ismail

Centre for the Study of Regional Development (CSRD) / School of Social Sciences (SSS), Jawaharlal Nehru University (JNU), New Delhi 110067, Presenting Author's email: ismail19_ssf@jnu.ac.in

Abstract

The Metropolitan Cities are the Million Plus cities or often called as 'Mother City', generally recognized through its urban way of life or urbanism and diverseness of population. The pattern of urban growth in these metro cities enjoyed extreme significance, as metropolitanisation has been a striking peculiarity of India's urbanization amid post-independence era, due to escalating growth in number as well as percent share of urban populace in these cities. Present study examines the trends, patterns, and determinants of growth of Million Plus Cities/UAs in India since 1901. Examination of census data revealed that post economic reforms period marks the beginning of a rapid pace of metropolitan development in India witnessing dispersed pattern of metropolitan growth during recent two decades. Result from multivariate regression analysis inferred that NSDP per capita, percent Urban literate, share of male main worker engaged in non-farm activities, railway connectivity and existing metro cities of a state/UTs seems to have statistically significant positive impact on metro city growth. It has too been discerned that cities having earlier birth have not grown at a rapid pace while many of them flagged negative demographic growth suggesting a tendency of population drift towards periphery from the core city leading to an 'agglomerated trend' of metropolitan development in India.

Urbanization; Million Plus City; City Growth; Periphery; India

Analysis of the Zhoukou Pingfen Scandal from the perspective of landscape politics

YANG Rong

School of Geography and Planning, Sun Yat-sen University, Guangzhou 510275, China

Abstract

The modernity has become the dominant logic in social space operation by means of conquering and integrating space. Space is the site of reproduction of productive relations as well as the site of conflict between different social groups. However, there is few research on modernity view of urban development under the perspective of landscape politics in China. In this paper, the connotations of cultural landscape (especially deathscapes) from social & cultural geography is illustrated firstly. Then the intensive development of ceremony in the process of modernization in China is discussed. Taking the Zhoukou Pingfen Scandal in Henan province in 2012 as the study case, we analyze and capture the discourse practice as well as the space practice in order to summarize the consensus viewpoint together with cognition of each social group. In this research, the data and materials for analyzing come from text documents and statistics of government, speeches of leaders, mainstream media reports, thematic reports on the web as well as the corresponding comments, and semi-structured interviews on the part of the stakeholders. The results indicate that: landscape aesthetics, capital logic, concentration of power play a more important role in the urban development notion in modern China rather than the sacred needs, family identity, personal emotion and memory as the core of traditional deathscapes. In addition, conflicts and negotiations based on the landscapes have emerged during the current process of modernization and urbanization.

Key words:

Zhoukou Pingfen Scandal; modernity; deathscapes; urban development notion; landscape politics

Extraction of Urban Residential Buildings Based on Object-oriented and Space Analysis

LIU BO

School of Geography and Planning, Sun Yat-Sen University, Guangzhou 510275, China, lovise0926@163.com

Abstract

The object-oriented ideas was many times integrated into the “top-down” multi-scale image segmentation, then combining space method to extract residential buildings in high resolution images. First, calculating each object segmentation feature information such as spectrum, space, texture, etc. According to the characteristics of different objects a different member function was selected for raster data spatial analysis, which preliminary realizes buildings edge extraction. And then the specific spatial clustering analysis and spatial convolution filtering operator were used for the building image microprocessor, which have better precision extraction results. Finally, the results are compared with the traditional information extraction method. The experimental results show that it has better accuracy and high adaptive when applying the idea of object-oriented multi-scale segmentation and integration of a variety of image space analysis method is targeted to extract residential buildings. For high resolution images accurately and rapidly extracting large areas of urban residential buildings is a good exploration.

Key words:

High resolution image; Residential buildings; Object-oriented; Spatial analysis

Pollution in Mexico City Metro Area; Public Policy Analysis 2000 - 2015

Reséndiz, Tonatiuh

National Autonomous University of Mexico, Mexico City, Mexico. in.teotl.in.yolotl@gmail.com

Abstract

Mexico City is the largest city in the Western Hemisphere with a population ranging 23 million people in its metropolitan area. This overflowing urban mass is the political, economic and industrial center of the country; from the 1970s federal government have been applied an ambitious economic and development model, focused on the industrialization of the Mexican capital, a fact that has impacted the levels of contaminants in air, water, waste management and even auditive pollution. During the first decade of the XXI century, has been implemented program like vehicle restrictions, trying to reduce air pollution; however, these measures have not been entirely effective, plus they are very unpopular among the population. Environmental viability of the city is at high risk, if the state should not apply urgent public policies to save the health of its inhabitants.

Key words:

Pollution; Latin America; environment risk; Public policies; vehicle restrictions

The Emergence of City-Regionalism under Changing Central-Local Relations:

Regional Cooperation in the Yangtze River Delta

Yi Li, Fulong Wu

School of Geographic and Oceanographic Science, Research Centre of Human Geography, Nanjing University, Nanjing 210023, P.R. China, emilyliyi@hotmail.com

Abstract

China has recently witnessed the emergence of city-regionalism, and two different regional-scale mechanisms have influenced this integration and cooperation: the top-down state-mandated process and the bottom-up process initiated by local governments. Scale building in China is determined by changing central-local relations and the politics surrounding this change. This paper focuses on regional cooperation in the Yangtze River Delta and finds that top-down regional plan making has been undermined by economic decentralization, while the administrative and political hierarchies hinder bottom-up regional building. This paper argues that central-local dynamics are at the core of regional governance and state rescaling in China.

Key words:

central-local relations; city-regionalism; governance; state rescaling; China

The Interaction Mechanism between Urban Planning, Land Supply and Tertiary Industry Spatial Structure in Hong Kong

Cao Zhejing

Tsinghua University, Beijing, 100084, P. R. China, caozhejing1120@163.com

Abstract

Hong Kong is among the mostly dense big cities and has blossomed from the fishing village all the way to the financial hub in Asia. Hong Kong government has taken the “little intervention” policy to facilitate free market economy and applied “high land price” strategy for sufficient land revenue. This paper established the economic-social model to examine the interaction mechanism between urban planning, land supply and tertiary industry spatial structure in Hong Kong. Firstly, the model is based on the assumption that (1) urban planning influences the primary land supply by strategic plan, OZP (outline zoning plan) and planning application system; (2) the secondary land supply is influenced by urban design guidelines, construction cost other than primary land supply; (3) the secondary land supply impacts the tertiary industry spatial structure which includes residential land, grade A office land, general business land and special industry land; (4) the spatial structure includes two dimensions of spatial economic structure and spatial concentration structure; (5) the spatial economic structure is determined both by secondary land supply and buying demand; (6) the buying demand is impacted by spatial concentration structure of the tertiary industry; (7) the spatial economic structure would regulate the primary land supply through feedback mechanism of land revenue. Secondly, the spatial economic structure and spatial concentration structure are analysed through GIS based on the data of 300,000 POIs (point of interest) of 2016, Hong Kong population census, annual digest of economic statistics, employment statistics. Thirdly, the relationship between urban planning and primary land supply is further judged in three aspects: the making of OZP under Hong Kong strategic planning (Hong Kong 2030, new town development policies); high land revenue, land bank and oligopoly; planning application system in controlling urban development. Fourthly, the relationship between secondary land supply and tertiary industry spatial structure is also studied in three aspects: spatial shaping mechanism of OZP and urban design guidelines; spatial economic structure impacted by secondary land supply and buying demand determined not only by individual economic situation but also geographic location; spatial economic structure’s feedback on primary land supply through land revenue. Finally, the urban space shaping mechanism of market and urban planning is briefly concluded.

Key words:

Urban Planning; Land Supply; Tertiary Industry; Spatial Structure; Hong Kong

Key Laboratory for Geographical Process Analysis & Simulation Hubei province, Central China Normal University, 430079, Wuhan, P.R. China, gujiang_ccnu@163.com

Abstract

Since comprehensive reform and the Opening-up began in the first half of the 1990s, a remarkable level of urban development has taken place in Beijing. With the disintegration of the unit-yard system, and the introduction of new land distribution policies, a remarkable demolition-reconstruction process can be seen in the inner area.

In this study, we developed a new method of land use classification using remote sensing analysis --- based on the shadows of buildings and green space. Based on this method, we have confirmed that in Beijing city, a remarkable development process has occurred since the reform and opening up. The main driving force behind this urban transformation process was the expansion of high residential building areas. The construction of high-rise buildings began around the second ring road, gradually expanded to the outer part, and was distributed to the whole area within fifth ring road in the 2000s.

On the other hand, the Beijing CBD area is becoming one of the most important business centers, many offices of domestic and multinational companies have agglomerated in the CBD. However, most of the developers who obtained right of development in the CBD core area were state-owner insurance companies. The offices in CBD vary in size, activity, main customers, and length of establishment. It was the prestige of the CBD that many companies valued most in choosing the location of their office. Following this, high availability of offices, high quality of infrastructure and agglomeration of supporting services were evaluated as important advantages.

Key words:

Beijing city; Reform and opening up; CBD development; urban transformation

Informality as a Strategy: Urban Redevelopment in the Pearl River Delta, China

Yingmin Huang, Desheng Xue

School of Geography and Planning, Sun Yat-sen University, Guangzhou, 510275, P. R. China, huangyingmin693@163.com

Abstract

Urban informality is a one of important agenda in global South study, it is also considered as a new urban theory in the future. Since 1978, the reform and opening up policy in China is the process of transformation of socio-economic institution with the characteristic of pragmatism and gradualism. During this process, the Chinese cities growth fast, and informal urban have been taken place. Some researchers think the source of the informal urban development is form “below”, or because of the market mechanism. Most of the informal urban research lack of focus on institution. This paper analyses the informal urban development and restructuring in the Chinese Pearl River Delta (PRD) in the field of urbanized village (UV) redevelopment—— Xiaobian Village in Chang’an Town of Donggun City. By introducing the notion of “conceded informality”, and emphasis will be put on restructuring processes of this village. Conceding informality can be seen as a coping strategy the Chinese governments are using as an experimental mode of governance in order to deal with new phenomena of urbanization and critical situations in times of permanent change and legal uncertainty.

Key words:

Informal institutional change; Urban redevelopment; Informality; PRD

Urban Informality in The Internet+ Era

Deng, HH

School of Geography and Planning of Sun Yat-Sen University, Guangzhou, 510000, P. R. China, 378068361@qq.com

Abstract

Urban informality refers to the informal forms of development in the process of urbanization. As the economy globalization and the advance of the era of Internet +, the urban informality enters the line of sight with new forms, Airbnb and Uber are the typical products of it. The concepts of disruptive innovation are used to consider Airbnb and Uber's business model, which is built around modern internet technologies and sharing economy, and their distinct appeal, which centres on cost-savings and convenience. Despite their growing popularity, many of them are actually illegal. These legality issues and their corresponding tax concerns are discussed, with an overview of the current state of regulatory flux and a possible path for resolution. We also discuss the government and non-governmental organizations how to manage with this informality and manage its development.

Key words:

Urban informality; sharing economy; Internet; Airbnb; Uber

Acculturation under Globalization in the World City: Self-Adjustment of Turkish

Culinary Culture in Berlin

LIU Huaikuan¹, XUE Desheng¹, HUANG Gengzhi²

¹School of Geography and Planning, Sun Yat-sen University, Guangzhou 510275, P. R. China; ²Guangzhou Institute of Geography, Guangzhou 510070, P. R. China, eesxds@mail.sysu.edu.cn

Abstract

Acculturation of transnational immigrants is one of the essential topics on human mobility. The conservative pessimistic theory argues that immigration will fall into a negative cumulative causation and receive constant exclusion. The route dependency theory deems that immigrants are unable to acculturate into the host society unless they abandon their initial culture. Nevertheless, globalization erodes local differences and resistance against homogeneity emerges. Inheritance of initial authentic culture gradually becomes an effective acculturation route for immigrants especially from the global South. This study on Turkish ethnic food, Döner, in former Mitte, Berlin, elaborates an acculturation route with a three-stage process. At the first stage, Turkish ethnic food self-adjusts into a simplified package form so as to meet the Turkish labors' requirement for portability and affordability. Then at the second stage, the adjusted Turkish food receives not only Turkish migrants' but the native residents' acceptance. Some transnational immigrants with similar cultural background even perceive Döner restaurants as a social communication space, which contributes to the acculturation into local society. At the final stage, globalization brings growing number of international tourists. Thus Döner obtains more widely favors due to its pure authenticity as it inherits Turkish cuisine style and initially adjusted in Berlin. This empirical study discovers a new type of acculturation through inheritance and self-adjustment. It also confirms that with rational guidance and incentive, the exotic culture from global South could contribute to the formation of a multi-cultural society in world cities through a down-up route of cultural self-adjustment.

Key words:

acculturation; self-adjustment; globalization; transnational immigrant; culinary culture

Kolkata's Informal Economy: Processes of Change

Shaw, A.

Indian Institute of Management Calcutta, India, ashaw@iimcal.ac.in

Abstract

In the last twenty-five years, the largest cities in India have been undergoing considerable change. Apart from growth both in spatial and demographic terms, they are also experiencing the effects of economic liberalization and globalization as India officially opened up in 1991. While changes in the organized and formal built environment are easily observable, their ramifications on the informal economy of the city remain less noticeable and their specifics less highlighted. Through a re-study, on-going, two decades after the first study in 1995-6, this paper attempts to shed light on this aspect of urban change. Going back to two areas in the city of Kolkata that were studied in 1995-6 for their concentration of small motor vehicle repair workshops and related services, the paper looks at the impact of post liberal economic policies on livelihoods. Early findings reveal that only about half the enterprises are traceable after twenty years and this is no longer a viable occupation. Increasing constriction in the availability of roadside space, the shift from indigenously made cars to foreign brands, growing numbers of formal repair workshops of such brands and the rising price of land on which these informal establishments are located have been some of the reasons. Through interviews of both enterprise owners and workers, the paper examines the pathways by which the 'creative destruction' of livelihoods is unfolding and its impacts both on people and the built environment.

Key words:

informal economy; Kolkata; livelihoods; motor vehicle repair workshops

Labour Market Arrangements in the Organised Garment Industry in India

Lahiri Baishali

Senior Research Fellow, Jawaharlal Nehru University, New Delhi, 110067, India and also Guest Lecturer at Dyal Singh College, University of Delhi, Lodhi Road, New Delhi -110003, India, baishalilahiri@gmail.com

Abstract

The effect of globalization on labour market has been debated. Low-income countries often compete through lowering costs which is obtained partially through downward pressure on wages. In India, low costs of production are achieved by utilizing cheap sources of labor such as women, children, people belonging to disadvantaged castes and religious groups. Existing research shows that India's unique social structures of gender, caste and religion creates an uneven plane for these disadvantaged sections in the labour market, especially in terms of wages. However, whether certain enterprise conditions based on the size and nature of firms overcome discriminatory labour practices or takes advantage of existing societal discriminatory labour norms is missing in the literature. Therefore, this paper aims to examine whether such societal effects of wages are overcome by the large globalised export orientated firms or rather do they take advantages of the discrimination to keep low on wages as in case of small and medium domestic market oriented firms. The study is based on a sample of over 300 workers and 20 firms in the garment industry in Delhi National Capital Region which has a global value chain and export processing clusters. Being a global industry it offers an added insight into the effects of global recession on employment. These results have important implications for policy makers in India in terms of increasing educational opportunities for various social groups, reducing social discrimination and increasing post-implementation accountability.

Key words:

globalization; societal discriminatory labour norms; firm characteristics and worker's conditions; uneven plane

Spatial Diffusion of China's Mega-Urban Regions—Pattern and Mechanisms

Zheng Yanting

School of Economics and Resource Management, Beijing Normal University, Beijing, 100875, P.R. China,

zhengyt@bnu.edu.cn

Abstract

Since 1978, China's mega-urban regions, especially the Pearl River Delta and Yangtze River Delta, draw people's attention owing to their large scale and scope of rapid urban transformation and development. Based on the latest population census data, it is found that diffusion effects have demonstrated in the prefectures near these two mega-urban regions in a dispersed way. Further analysis shows that the increase of labor prices, decreases of transport cost, and related policies contribute to this dispersed spatial pattern of diffusion.

Key words:

Mega-urban regions; Urbanization; Diffusion effects; Mechanisms

Urban Informality in the Internet+ Era

Deng, HH

School of Geography and Planning of Sun Yat-Sen University, Guangzhou, 510000, P. R. China, 378068361@qq.com

Abstract

Urban informality refers to the informal forms of development in the process of urbanization. As the economy globalizes and the advance of the era of Internet +, urban informality enters the line of sight with new forms. Airbnb and Uber are the typical products of it. The concepts of disruptive innovation are used to consider Airbnb and Uber's business model, which is built around modern internet technologies and sharing economy, and their distinct appeal, which centres on cost-savings and convenience. Despite their growing popularity, many of them are actually illegal. These legality issues and their corresponding tax concerns are discussed, with an overview of the current state of regulatory flux and a possible path for resolution. We also discuss the government and non-governmental organizations how to manage with this informality and manage its development.

Key words:

Urban informality; sharing economy; Internet; Airbnb; Uber

Abstract

BRICS are representatives of the emerging economies and developing countries, whose economy has experienced rapid growth in recent years. Meanwhile, their airline networks are in a rapid development period. However, the studies about the comparison of the structure of BRICS's airline networks are rare. This research aims to analyse the topology properties and spatial patterns of the airline network using the data of the five airline networks with the routes, flights and traffic. We try to explore the difference of the five countries' airline networks throughout the whole paper. Firstly, this paper tries to analysis the evolution of five countries' airline networks combined with their respective national conditions. Secondly, this paper tries to explore the topology properties of the airline network using the methods of complex network theory and graph theory mode. Thirdly, this paper tries to examine the spatial patterns of the airline network.

BRICS; airline network; topology properties; spatial patterns

A Comparative Study between Chinese and American Air Transportation

Kim, C., Ma, K.

Department of Geography, University of Cincinnati, Cincinnati, USA, changjoo.kim@uc.edu

Abstract

This research compared air transportation between China and America with respect to hub and spoke networks. The development of Chinese air transportation network is analyzed based on the number of air passengers and is compared to American case. In particular, factors that lead to develop hub and spoke network in China such as hierarchy of airports and geographical factors are explored. For an empirical analysis, theoretical optimal hub and spoke networks are constructed and compared to the current hub and spoke networks structure.

Key words:

air transportation; air passenger; hub-and-spoke

A Comparison of Wave-System Structures in Chinese Hub Airports: 2010 vs. 2015

Jie Huang, Jiaoe Wang

Institute of Geographic Sciences and Natural Resources Research, CAS, China, huangjie@igsrnn.ac.cn

Abstract

From 2010 to 2015, the number of passengers served by four hub airports in Beijing, Shanghai and Guangzhou experienced a significant increase, for example, the traffic volume at Shanghai Pudong International Airport grew by 48%. To deal with traffic growth, Chinese airlines concentrated their networks by adopting or intensifying wave-system structures in their flight schedules. Following the definition of wave-system structure, we identify the daily flight wave center for every 5 minutes to understand reasons behind the absence or presence of wave center. Meanwhile, as the aviation market has gradually experienced deregulation since 1980s, airline alliances appeared. Hence, we consider the effect of airline alliance in the investigation of wave-system structures and discuss how Chinese airlines can implement wave-system structures better. Through a comparison of Chinese hub airports between 2010 and 2015, the paper examines the correlation between the concentration of traffic volume and flight waves. Moreover, this paper studies top three airlines in Chinese market with features of temporal configuration at four different airports so that we could explain their market positions in different regions. In brief, the wave-system structure identified in Chinese hub airports is not intensive but tends to have high level of peak in flight waves.

Key words:

Hub airport; flight schedule; wave-system; airlines

Mapping Intercity Air Transport Networks: Connections, Prices, and Options

Liu X.¹, Derudder, B.², Wang J.³

²Department of Geography, Ghent University, Belgium

³Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, China

Abstract

This paper aims to chart an alternative geography of intercity air transport network with emerging new data sources. While most studies focus on the frequency of scheduled flights, this study characterizes intercity air transport connections with additional measures, including the availability of direct flights, the number of flight service providers, flight time, and (cheapest/media) prices. This new wealth of information about intercity air connections is gathered from online booking website Skyscanner.com. Data are collected for air connections among 175 airports in 138 world cities in 2014. A comparative analysis identifies world cities that are well served by direct flights, enjoy a relatively large selection of service, and/or could be accessed economically. These findings shed additional light on the unevenness in the air connectivity among world cities.

Abstract

A great amount of research on competition between HSR and airlines have been conducted in the context of western countries, while the research in China is rather limited. There are three research gaps in the academia: First, the research of HSR's impacts on airlines is rather crude in the application of HSR relevant variables. Variables such as frequency, travel time, fare and access time to/from transport terminals are not taken into account in the econometric model. Second, a few of restricted overlapping routes between HSR and airlines raised the issue of representativeness. Third, focus on the longitudinal impacts of HSR on airlines in China is rather limited.

We explore the relationships between the operation of HSR services and the change on airline passenger flow from 2007-2014 for 277 city pairs. This paper will first carry out a descriptive analysis to find the general pattern between the operation of HSR services and the change trend of the airline passenger flows for three situations: (1). the cancellation of airlines; (2) the reduced demand for air travel; (3) No influence. Then, an econometric analysis will be conducted to identify the extent to which those variables influence the airline passenger flows. Exogenous variables will be input into the econometric model, such as HSR transport variables (frequency, ticket fare, and line haul time), geographic variables (HSR opening time, access/egress time to HSR terminals) and socio-economic variables (GDP, income per capita and population).

Key words:

High-speed rail; airline; competition; longitudinal impact; China

Newly Established Airlines Developing Process and Changing Patterns of Its Air

Route in China

Chuntao Wu¹. Lei Peng²

¹School of tourism, Sichuan University, P.R. China, chuntao@scu.edu.cn

²Air China, China

Abstract

In line with the central government's "non-public economy 36" document, the Civil Aviation Administration of China (CAAC) started to open commercial airlines sector to private, collective and foreign capitals in 2004. For various reasons, CAAC suspended to give certification in 2007. From 2004 to 2007, 14 airlines were given approval to operate domestic passenger flights, which brought researchers a vital chance to investigate the performances of various capitals or local state-owned enterprises in aviation sector. The study purposes of this paper are (1) to review the development process of these newly established airlines, and (2) to examine the changes in spatial patterns of its air route networks in term of geographical locations airlines' main hub located respectively. The results show that, over those 10 years, the airlines have been re-constructing its network generally in four trends. CAAC traffic rights and slots allocation policies, and the effects of high-speed rail (HSR) development are two elements used to explain the change patterns. The study results are useful for aviation policy makers, airlines stockholders, and capitals interested in Chinese aviation markets.

Key words:

aviation deregulation; new airlines; China; route network; high-speed rail

Study on Industrial Structure Adjustment and Spatial Differentiation of Hub-orientation Industry in Airport Economic Zones: An Empirical Study in Yangtze River Delta from 1999 to 2013

Zhang Lei

JiangSu Second Normal University, Nanjing, 210000, P. R. China, zhangleinj_1983@163.com

Abstract

Hub-orientation industry development is the core drive of airport economy. This paper constructs a theoretical framework of its industrial adjustment and spatial differentiation, and follows an empirical study in Yangtze River Delta. Conclusions are as follows: 1) With the development of airport economic zones, both hub-orientation industry and none hub-orientation industry have a rapid growth, while the general hub-orientation industry agglomerates the fastest. Besides, the urbanization level of airport surroundings rather than the airport scale has a stronger influence on the hub-orientation level of industries in the airport economic zone. Compared with mature foreign airport areas, airports in Yangtze River Delta now have set up a relatively comprehensive hub-orientation industrial system primarily. In the meanwhile, the manufacture industry takes a much higher proportion than high-end manufacture and service industry. 2) the comprehensive development level of airport economic zones determines whether the circles' differentiation is clear or not. Furthermore, strong hub-orientation industry often gathers around the airport while the none hub-orientation industry locates with fewer spatial consideration. A deeper industrial analysis shows that it is easier for relatively mature airport economic zone to form an industrial distribution pattern that the manufacturing gathers inward and the service industry expands outward. For the manufacturing industry, there is an obvious gap between the spatial differentiation of hub-orientation and none hub-orientation industry, which may be influenced by the industrial foundation, business soliciting policy and available lands etc. For the service industry, its layout in all the mature airport economic zones is basically same, namely the transportation service locates in the core, the producer services expand outside and the retail service obtains the largest agglomeration space.

Key words:

airport economic zones; hub-orientation industry; spatial differentiation

The Competitiveness of Chinese and U.S. carriers in Bilateral Air Transport Market

Zhuo Chen

Department of Geography, University of Illinois, Champaign, U.S.A. zchen136@illinois.edu

Abstract

As a part of the globalization trend, free-trade agreements between countries in air transport industry have big influence on the market. However, carriers from developed countries often benefit the most from the agreement, and carriers from developing countries become disadvantaged at least at the start. In this research, I study the competitiveness of Chinese and U.S. carriers' in bilateral passenger air transport market. I find Chinese carriers are too small to compete with U.S. carriers on the same stage. Besides, domestic network, passenger composition, ticket sales channel, national level industry policy and profit proportion rule of connecting flights all reduce Chinese carriers' competitiveness. This research suggests free-trade in service industries like air transport may harm domestic industry players in developing countries.

Key words:

air transport; China; U.S.; free-trade

The Geography of Low-Cost Airline Networks: Comparing China and Europe

Frédéric DOBRUSZKES, Jiaoe WANG

Free University of Brussels, (ULB), Brussels, Belgium, frederic.dobruszkes@ulb.ac.be

Abstract

Both China and Europe have experienced the advent of low-cost airlines (LCAs) in the aftermath of more freedom offered the airlines. In Europe, the dramatic development of the LCA networks is the main outcome of the extensive aviation liberalisation process involving the EU28 and some neighbouring countries. LCAs now account for more than one third of intra-European air services. In China, LCAs are emerging as a consequence of progressive aviation market opening. In this context, this paper will compare China's and Europe's LCA networks in terms of volumes supplied and of spatial patterns (that is, network structures). Special attention will be paid to spatial expansion including distance stages; to the kind of airport served (main, regional, secondary), including the choice of bases; to the kind of places served (city size, central vs peripheral areas, regional economic typology); and contribution to competition with incumbent airlines. Beyond these spatial analyses, we will consider the very different political, social and economic frameworks to interpret the results.

Key words:

Transport geography; air transport geography; low-cost airline network; aviation liberalisation

A Review of China's High-speed Rail Study in Perspective of Geography

Shunying Zeng

South China Normal University, Guangzhou, 510631, P. R. China, Email: 1113509457@qq.com

Abstract

The world is changed by transport, and High-speed rail(HSR) as latest technology of transit will have a huge impact of social development. So it is significant to carry out High-speed rail research. 289 papers were collected and arranged under the logic of “accessibility—factor mobility—effects”. Presently, the research contents of China's High-speed Rail study have included passenger transportation, freight transportation, station, tourism, environmental effects, the effects of city and region, and so on. But a large number of studies belong to the macro qualitative analysis and only describe the phenomenon. There are less research on the specific characteristics and differences. Generally, the deficiencies of present literature are lack of mature research framework, theoretical supporting, and regularity summary. Finally, combined with the reality of China, scholars should pay more attention to the impact of high speed rail on Chinese industrial transfer and industrial upgrading, regional and social equity, urbanization and rural development, etc.

Key words:

High-speed rail; mobility; transport; China

Accessibility Evolution and Impacts on Urban System in Guangdong Province During the Past Decades

Hu Weiping, Mao Chaorong

School of Geographical Sciences, South China Normal University, Guangzhou, P.R. China, 510631,

huweipingok@sina.com

Abstract

As one of the leading developed province in China, Guangdong improved its transportation system greatly in the past decades. The accessibility changed quickly during the high-speed transportation facilities construction years. We use four different calculation methods to analyze the accessibility and its evolution of highway and railway network in Guangdong province from 1985 to 2020. Furthermore, we analyze the coupling relationship between accessibility and urban system of Guangdong.

The results show that the highway and railway network have developed rapidly and transportation accessibility has been significantly improved since the opening of the first expressway in Guangdong Province. Overall, the accessibility value is imbalance on county-level, the spatial variation of accessibility value is significant. But the spatial pattern of accessibility keeps stable on macro-level, the "core - periphery" pattern has changed only a little during the past decades. To 2020, the accessibility of Guangdong province will be better. The accessibility will make great progress in some regions.

The coupling relationship between accessibility and urban system is also prominent. A quantitative index called Cd was used to measure relationship between accessibility and urban size. We calculate the Cd values using urban size data surveyed in 1985 and accessibility values before the first expressway of Guangdong opened. We also extracted urban area from ETM remotely sensed images dated in 2013. Most of regions have a high Cd value, but the spatial variation is dominate. The impacts of accessibility on urban system development discussed using normalized data.

Key words:

Accessibility evolution; Spatial pattern; Coupling relationship; Urban system; Guangdong Province

An Ongoing Faster Speed Rail Project - “KMRCL”: Effect on Socio-economic Change and Land Use Change; A Case Study of Kolkata City, West Bengal, India

Saha Biswajeet

Post Graduate Student, Department of Geography, Bhairab Ganguly College, West Bengal State University, Kolkata, India, biswajeet.suman@gmail.com

Abstract

In the year of 1969, the Metropolitan Transport Project had initiated in Kolkata City. Almost 97.50 km area consisted of three North-South corridors, which were Dumdum-Tollygunge; Bidhannagar-Ramrajatala and Dakshineswar-Thakurpukur. Over the respective years, more corridors have constructed and finally in the year of late 2010, the corridor extended up to New Garia. After the experience of India's first metro service and the success of Delhi metro network, sanction of East-West Metro corridor connection can be observed, which connects Howrah and Sealdah Station through under Hooghly River. Howrah and Sealdah Station, both are the busiest stations due to lot of local as well as express trains, which connect all over India. In Kolkata, this is the first time when river crossing metro tunnel will be made in the country. After the modification of the project, the length of the route became 14.58 km consisting of the Underground Corridor of length 8.84 km and Elevated Corridor of length 5.74 km. The project cost is about Rs.4874.58 crore, which was approved by Government of India on 20th February 2009. There are several objectives to point out the evolution of KMRCL (Kolkata Metro Rail Corporation Limited), to find out various reasons for extension of East-West corridors, to know the after effect of constructing the project, to state socio-economic change and land use change and to highlight various problems faced by the people of Kolkata followed by recommended suggestions. However, Kolkata has been experiencing the fastest technology of transport connectivity through radical change of development.

Key words:

corridors; success; underground corridor; socio-economic change; fastest technology

Applying a Spatial Planning Approach to Sustainable Transport Planning: Achieving Better Integration of Land Use and Transport Planning in Wuhan '1+8' City Cluster, China

N Li

University College London, London, WC1E 6BT, UK, nan.li.14@ucl.ac.uk

Abstract

Existing studies and research demonstrate that contiguous relationships between land use planning and transport management positively contribute towards achieving sustainable development goals. Thus, such integration is typically established as a policy goal for sustainable transport planning. In the UK, and the wider EU, spatial planning has been used as an approach to policy making and its delivery, especially at city-region levels; subsequently, this is connected to the delivery of sustainable transport. In China, land use planning and transport planning practices are weakly linked, and there is insufficient research exploring how they can be better integrated. Spatial planning, at the city-region level, has been adopted in China's recent development plans as an approach towards achieving its development objectives. However, there is no clear guidance on the implementation of this approach. Using the Wuhan '1+8' City Cluster, this research explores contrasting arguments concerning land use and transport planning integration. Additionally, this research uncovers potential methods that apply spatial planning approaches to transport policy making in city regions. Wuhan '1+8' City Cluster is a city-region that includes a group of nine cities, where this term was defined for economic development purposes; the planned construction of the inter-city railway network between these cities partially intends to pilot European spatial planning models in the delivery of practical transport policies. This research explores European models of spatial planning in the delivery of established transport systems, and identifies key strategic approaches applicable to better integrated land use and transport planning practices in Wuhan.

Key words:

land use; transport planning; transport policy; city-region; Wuhan

Economic Impact of High-speed Rail on Household Income in China

Feiyang Sun

Department of Urban Design and Planning, University of Washington, Seattle, 98105, United States, fs377@uw.edu

Abstract

Though developed only in the last 20 years, Chinese high-speed rail (HSR) has overtaken many of its forerunners in its unprecedented scale. However, such scale raises questions about its implications for regional economic development. Previous studies have discussed the HSR impact on region and city levels, but few have addressed its impact on individual level which is crucial for understanding the distribution of impact. To fill the gap, this study focuses on the economic impact of recent HSR development between 2009 and 2012 on Chinese household income and discusses its significance, magnitude and, most importantly, distribution. The paper utilizes the survey data from China Family Panel Survey and implements a quintile regression approach. Three measurements of inter-region accessibility, namely, weighted average travel time, weighted average travel cost and number of travel options, are tested in the model separately to investigate the direct impacts of HSR on different income groups. Probability of living proximate to HSR stations is also included in the model to examine the spillover impact of HSR. The study shows that the impacts for the low-income and high-income groups are either statistically insignificant or negligible in magnitude. For the impact on the middle-income group, spillover effect or the agglomeration effect contributes the most of the impact and favors more urbanized regions with stronger service sectors. Based on the analyses, the paper suggests that HSR projects need more comprehensive studies for the full spectrum of its impact to ensure both economic growth and regional balance and coordination.

Key words:

Interregional Accessibility; Regional Income Inequality; Agglomeration Economics; Regional Economic Growth

Estimating the Effects of High-Speed Railway(HSR) Operation on Reducing CO₂ Emission from Aviation Sector in China

Li Xi¹, Yi Dou², Chuntao Wu³

¹School of tourism, Sichuan University, Chengdu, 610041, P.R. China

²Graduate School of Environmental Studies, Nagoya University, C1-2(651), Furo-cho, Chikusa-ku, Nagoya City 464-8603, Japan

³School of tourism, Sichuan University, Chengdu, 610041, P.R. China, chuntao@scu.edu.cn

Abstract

This study aims to estimate CO₂ emission from domestic passenger aviation sector in China, and assess the effects of high-speed railway (HSR) operation on aviation emissions reduction. Firstly, ICAO method is used to respectively estimate the CO₂ emission from China domestic passenger aviation sector in 2008 and 2014. Secondly, GIS method is used to catch the spatial characteristics and patterns of emission distribution. And thirdly, the driving forces are assessed by LDMI decomposition. Particularly, the effect of HRS on aviation emission reductions is emphasized, and suitable Avoid-Shift-Improve (ASI) policy framework is proposed. 2007-2014 domestic airlines timetable provided by Travel Sky and ICAO database (emission factors by aircraft types) are two kinds of data used. The detailed results will be displayed at the meeting.

Getting Up to Speed: Assessing the Usable Knowledge from Global High-speed Rail Experience for the United States

Prof. Anthony Perl¹, Prof. Andrew Goetz²

¹Urban Studies Program, Simon Fraser University, 2124 - 515 West Hastings Street

Vancouver, BC V6B 5K3 Canada, aperl@sfu.ca

²Department of Geography & the Environment, University of Denver, Denver, Colorado 80208-0710

Abstract

As the United States has taken steps in recent years to invest significant funds to begin implementing high-speed rail (HSR), it is important to consider how HSR has developed elsewhere since its original deployment between Tokyo and Osaka in 1964. The three models of HSR development that have emerged over the last 50 years are: 1) the exclusive corridor strategy exemplified by Japan, 2) the hybrid corridor strategy found in France and Germany, and 3) the comprehensive national network strategy pioneered by China. The relevance of these three models to HSR development in the United States is conditioned by several factors, including previous attempts to develop HSR in the US, the institutional organization of the existing freight rail industry in the US, and external market dynamics.

While the U.S. railroad industry has evolved differently and moved apart from rail operations in many other countries, external market dynamics such as growing urban populations and increased demand for passenger rail transportation appear to be converging with the rest of the world. Accordingly, we draw several lessons for the U.S. from global HSR experience including: 1) a higher degree of relevance and higher ease in knowledge transfer would occur in following the exclusive corridor model, 2) less difficulty in knowledge transfer but less relevance would arise in adopting the hybrid corridor model, and 3) more relevance but more difficulty of knowledge transfer accompanies pursuit of the comprehensive national network model.

high-speed rail; development

High-speed Rail and Economic Geography: The “Shrinking China” and Agglomeration Economy

Maoqian LONG

Peking University, China, longmaoqianli@126.com

Abstract

High-speed rail (HSR) is bringing an unprecedented compression of time-space, which is reshaping the economic geography of the world. The construction and operation of HSR in China has made remarkable achievements, while the evaluation and review of the effect HSR on economic geography of China are still in its infancy. Based on the 2009 and 2015 national railway train schedules, we calculated the rail travel time for each city, and drew the map for railway space-time of China. Through the analysis of the space effect of HSR, we found an interesting and impressive picture of “shrinking China”. Afterwards, we constructed a new market potential function, combining with the calculation model about market potential and agglomeration economic benefits from Department for Transport, and calculated the size of the agglomeration of economic gains for 259 cities in China. Both the hierarchical and spatial differences were analyzed, and had come to an exact and uniform conclusion in the urban clusters scale. We also predicted the effect of the intercity rail network within the urban clusters which are to be finished in 2020. Our results showed that the HSR lines at the present stage and in the future will strengthen the existing urban spatial structure, by means of time-space compression effect, polarization effect and “funnel effect”. The future impact of HSR is worth further research.

High-speed Rail and Land Development in China

Pengyu Zhu

Boise State University, USA, pzh@masdar.ac.ae

Abstract

The construction of large-scale high-speed rail (HSR) network in China is altering the time-space relationships between cities. As a result, HSR is changing the traditional hierarchical urban system in China and regions with large-scale networks of cities are forming. At the city level, the construction of HSR new towns could contribute to rapid land use development. In this paper, we focus on the relation between HSR and land development at the city level and study how HSR is transforming cities in China through the land development process. We conduct empirical studies on all cities within the HSR-impact area, which is defined as provinces that are covered by at least one HSR line. Our sample will include cities with a HSR station and those without. The empirical model we apply will be a Difference-in-Difference model. Our first hypothesis to be tested is that HSR will facilitate the rapid land development in cities with HSR stations (i.e., through planned HSR new town surrounding the HSR station), to an extent that is faster than cities without HSR stations. Our second hypothesis is that, among cities with HSR stations, smaller cities tend to experience faster land development compared with larger cities. As evidenced in my forthcoming paper (Zhu et. al. 2015), large cities are able to carefully choose the locations of their HSR stations and thus their planned HSR new towns are often within their existing central cities. For medium to smaller cities, decentralization is often passively driven by HSR as the site selections of HSR stations are beyond their control. The long distance between the HSR new town and the existing urban center often result in leapfrog development.

This research helps to understand the relation between transportation infrastructure investment (i.e. HSR) and land use development in the Chinese context. With high-speed rail networks currently being proposed and designed to extend from Southeast China (the city of Kunming) to Southeast Asian countries such as Thailand, Vietnam, Malaysia, and Singapore, this research project will have important policy implications for the transportation planning and urban development in all countries of mainland Southeast Asia.

Impact of Guangzhou-Zhuhai Intercity Railway on Accessibility and Economic Development of Cities along the Railway

TU Zhifeng, MU Fengyun

Chongqing Jiaotong University, Chongqing, 400074, P. R. China, 1015113022@qq.com.

Abstract

The intercity rail transit between Guangzhou and Zhuhai is an intercity railway for passengers commuting the two cities in Guangdong province, China. In essence, it is a high-speed railway. This paper carried researches on cities along the Guangzhou-Zhuhai railway so as to extract qualified transportation network of these cities through a combination of remote-sensing image and vectorized digital map, analyze attainable changes of these cities through weighted mean traveling time, and figure out the economic linkage among these cities and its influences on the industrial structure of these cities through time-distance gravity model. As the results show, the Guangzhou-Zhuhai railway facilitated the attainable improvements of these cities, strengthened the economic linkage among these cities, reduced the negative influences of distance on the economic closeness among these cities, and lay positive influences on optimization of resource allocation and upgrading of the industrial structure.

Impacts of High Speed Rail on Economic Development in China

Jingjuan Jiao, Fengjun Jin

Institute of Geographic Sciences and Natural Resource Research, CAS, China, jiaojingjuan@163.com

Abstract

As the largest operating high-speed rail (HSR) network in the world, HSR network in China has largely influenced the accessibility, regional structure and economic development in national, regional and city level. Many scholars have studied the impacts on accessibility and regional structure, but the studies about the impact on economic development are rare. Therefore, this paper tries to explore the impacts of high-speed rail on economic development using the panel data of accessibility and the GDP. Firstly, this paper will examine the accessibility change caused by the development of high-speed rail using both the timetable-based analysis and the network analysis. Secondly, this paper will explore the impacts of high-speed rail on GDP by building the spatial panel regression analysis from the national and regional levels. Lastly, this paper will give some suggestions about the development of high-speed rail and economy in China.

MAGLEV – A Meaningful Transportation System? Impacts of High Speed Trains on Urban and Regional Development of Japan

Hekler, B. A.

University of Vienna, Universitaetsring 1, 1010 Vienna, Austria, tina.hekler@gmail.com

Abstract

Agglomerations that strive for success often seek to establish themselves as node points in the global economic system in order to compete against other cities in the strive to attract and allocate human and financial capital.

High speed maglev systems can offer a higher potential through their privileged infrastructure at transport node points in urban centers to promote the creation of valuable spatial structures. The more reliable, accessible and dedicated the systems are, the greater the potential for a positive effect for agglomerations. The utilization of high speed maglev systems could have significant impacts on future urban landscapes and new forms of urban living through creating new global and local spatial networks.

It is expected that improvements of accessibility by high speed trains will further increase, so that agglomerations with unattractive travel systems will lose out in the global competition.

What are eventual impacts of high speed maglev systems on urban and regional development? Who will benefit? And might there also be some limitations eventually – and who would probably suffer most from them?

The first results of some quite revolutionary Japanese Maglev (Tokyo – Nagoya, Osaka) – which will be built by JR-Rail by 2027 – might give some insights into their prospects with regard to agglomerations, which enjoy a significant benefit. In addition, some first impressions of their eventual impacts on urban and regional development will be given.

From a European perspective, the presentation will aim to explore relevant aspects of what might appear to be key issues of future perspectives of high speed maglev systems.

high speed transportation systems; urban development; spatial development; Maglev; Japan

Pattern and Efficiency of Railway Transit Network in Metropolitan Area Based on Compare between China and Western Countries

Sheng Kuang¹, Hu liang², Huang Shengwen³

China Architecture Design Group, Beijing, 100044, P. R. China, shkth@163.com

Abstract

The 35 years from 1980 to 2015 witness the urban regional development triggered by network of classified highway and common speed railway. Since the setout of 21st century, the speed upgrade of motor traffic technically has hit the limits. The growth of scale of metropolitan area weakens the motor connection in region. At the meantime, the innovation of rapid mobility, most typically the high speed railway, is likely to take the lead of regional urbanization. Predictably, networked rail transit, including national, rapid, suburban and urban railways, would take over the driving role of in metropolitan development from highways. This essay looks into the feature and operational efficiency of railway traffic of developed metropolis, such as Tokyo and Paris in aspects of network, transfer, station typology and distribution, and compares the outcome with developing metropolis of China (i.e. Beijing-Tianjin-Hebei). Three characters have been sought out. Firstly, application of new technology enriches typology of railway transit, improves accessibility, and then enlarges sprawl of metropolitan area. Secondly, railway patterns, such as stop density, departure frequency and interval speed, have a direct impact on efficiency of operational network. Thirdly, demand and power of public consumption as well as cost of new technological application determine pace of innovation and improvement of rail system.

Railway Stations into the Spanish High-Speed Network. Development and Transformation of Urban Areas

Soria Cáceres, C.H.

Universidad de Valladolid, Valladolid, Spain carloshugo.soria@uva.es

Abstract

The transformation of the territory and landscape in Spain is suffering a high profile since 1992 got underway the first high-speed rail line between Madrid and Seville. From that moment, it has been producing a profound change of space, land use, transport policies and the social vision of the railway. The new railway phenomenon can be seen especially in cities, where the needs rigged to high speed rail require the establishment of new stations with capacity of hosting a dynamic operating radically different to conventional rail. Therefore, one of the land on which the high-speed rail has the highest incidence focuses on urban areas, where in addition to a marked improvement in the accessibility and connectivity of cities, it runs parallel a new model of central concern in around the stations specially designed and equipped to the high-speed rail. This new fact has been particularly eloquent in medium-sized cities within a local visibility phenomenon but a pattern of national development based on the implementation of major urban renewal plans in the affected areas. The complexity and casuistry of these plans has been a recurring topic of study over the past decades, proposing solutions that can help minimize the impact of the railroad in both the city and the suburban.

Route Selection and Accessibility Impact of Chuo Shinkansen Maglev in Japan

TANAKA Koichi

Ibaraki University, Mito, 3108512, Japan, koichi.tanaka.gis@vc.ibaraki.ac.jp

Abstract

The purpose of the study are to discuss route selection of Chuo maglev Shinkansen in Japan from the viewpoint of geography and to clarify a prospective accessibility impact.

Spatio-temporal accessibility has improved greatly since the beginning of operation of Tokaido Shinkansen bullet train in 1964 in Japan. Tokaido Shinkansen connects Tokyo and Osaka in about 150 minutes with maximum speed of 270km per hour today. Shinkansen network was expanded with the opening new Shinkansen lines, such as Tohoku, Joetsu, Kyushu, and so on. It reached to Hakodate, located in southern end of Hokkaido Island, and Kagoshima, located in southern end of Kyushu Island. Total length of Shinkansen network is approximately 3,000km and while total passenger-kilometer is approximately 86 billion per year.

Shinkansen network will be expanded to Sapporo, Fukui, Nagasaki in near future. Moreover, a Chuo Shinkansen maglev is scheduled to open between Tokyo and Nagoya in 2027 and between Nagoya and Osaka in 2045. Route planning is fixed between Tokyo and Nagoya through southern end of Nagano Prefecture with extra-long tunnel. It will connect Tokyo and Nagoya over a distance of roughly 280 km in only 40 minutes, with a maximum speed of over 500 km/h; in comparison, the existing Shinkansen connects them in about 100 minutes. Four stations will be constructed between the Tokyo and Nagoya terminals.

On the other hand, route planning has not fixed between Nagoya and Osaka yet officially. Actually, the route via Nara has big advantage over it via Kyoto from the aspect of distance and construction cost. Kyoto Prefecture and Kyoto City are trying to entice maglev route under a disadvantageous condition.

The author measures accessibility change from 1960s to 2045 in Japan with simulating the future transport network by using GIS and discusses route selection of maglev between Nagoya and Osaka. Finally, prospective accessibility change by opening of Chuo Shinkansen maglev are clarified quantitatively.

Temporal Distance Map for Exploring, Analyzing and Visualizing China Railway

System

ZENG Jia-le, Li Wen-ling

School of Geographical Sciences, Guangzhou University, Guangzhou, 510006, P. R China, kalokzeng@qq.com

Abstract

According to Tobler's First Law, everything is related to everything else, near things are more related than distant things. In this paper, based on data of China's railway passenger service center, selecting 5 megacities of China: Beijing, Shanghai, Guangzhou, Chongqing and Wuhan as fundamental cities, using model-building, tries to transform spatial distance into temporal distance, calculated travel time from fundamental cities to provincial capitals in Rail and made time-space map of China railway system and map of connection degree of China provincial capitals in Arcgis. The result shows that: (1) The percentage of nonstop train in Beijing and Wuhan achieve 73%, Cities of the top three connection degree are Changsha, Zhengzhou, Wuhan. It benefits from Beijing-Guangzhou HSR line. (2) Yangtze River delta-Beijing-Tianjin-Hebei Region- Changsha-Zhuzhou-Xiangtan city group- city cluster surrounding Poyang Lake; along the Beijing-Guangzhou HSR line; basic pattern of "one day life cycle" have been formed by HSR line. (3) Cities of the last five connection degree are: Lhasa, Urumqi, Yinchuan, Kunming and Haikou. For instance, mean distance from Lhasa and Urumqi to fundamental cities are more than 3700km, mean time for more than 24h. To speed up the western inland region of HSR construction, strengthen the central cities of transfer function, Changsha, Wuhan, Zhengzhou and Shijiazhuang.

The Channel Tunnel as a Factor of the Regional Integration in the EU

Lomakina A.I.

Dr., research fellow, Laboratory of Geography of World Development, Institute of Geography Russian Academy of Sciences, Moscow, Russia, lomakina.lomakina@ya.ru

Abstract

The objective of the paper is the analysis of influence of Euro-Tunnel on the regional communication and as a result on regional integration. More than twenty years functioning of the Channel Tunnel showed that it serves a factor of consolidation of the integration structure of the EU. The Channel Tunnel has allowed to overcome the separation of the northern part of the European «blue banana» and consolidate the European Megalopolis. On the regional level the Tunnel being the factor of transborder integration united euroregion Kent-Nord-Pas-de-Calais.

Getting closer the global cities such London, Paris and Brussels the “Eurostar” promotes their as central places. At the same time, it gets the territory between these capitals more peripheral and contributes in increasing of the territorial inequality.

The influence of the Tunnel on the passenger traffic is not single-valued. High-speed connection has changed the structure of the passenger flows between the capitals. Firstly, Eurostar has «picked up» a significant part of the air traffic, providing more than 70% of the London-Paris and 60% of the London-Brussels carriage of passengers. As a result, the air traffic between the capitals dramatically decreased (more than 2 times).

At the same time, the structure and the geography of the passenger traffic in the Pas-de-Calais channel have gone through dramatic changes. Closing several ferry lines leads to the concentration of the ferry traffic on the line Dover-Calais. This direction is used by local people crossing the border for shopping and tourism.

Key words:

regional integration; high-speed rail; regional development

The Development of High-Speed Rail Station —A Comparison between Tianjin of China and the Randstad of the Netherlands

Wenxin Zhang¹, Xue Hou², Luca Bertolini³

¹School of Geography, Beijing Normal University, Beijing 100875, P. R. China, wzhang@bnu.edu.cn;

Abstract

The development of high-speed rail stations are becoming an increasingly important strategy to transform urban space. In the West countries, the high-speed rail(HSR) is viewed as a key factor to improve competitiveness, while in China, it is mainly used as a means to redevelop and upgrade urban space. What are the similarities and differences of the development of HSR station areas in countries with different urban conditions and what are the driving forces behind these differences? In this paper, two metropolitan areas were selected for comparison: Tianjin in China and the Randstad in the Netherlands. These two urban regions have some geographic similarities, they are both located near the capital, they also have similarities in terms of spatial structure and urban function, both being polycentric and having an important port function. Starting from these similarities, we focus on the micro scale of the stations and their neighborhood areas to gain more insight into the relationship between HSR and urban development and to explore the reasons behind the emergent differences between the two cases. Based on the stations' node and place characteristics, we have analyzed two HSR stations in these two regions and found that the HSR stations differ in development preferences and development types. Three main driving forces were found to influence the development of stations and also account for the differences among the stations: urban development patterns, urban economic growth, and the decision-making process.

The Spatio-temporal Structure of High-speed Traffic Network and Features of Its Stage-wise Evolution: A Case Study of Expressway Traffic Flow Network in Jiangsu Province of China

KE Wenqian

Institute of Geography, Fujian Normal University, Fuzhou, 350007, China, Key Laboratory of Humid Subtropical Eco-Geographical Process (Fujian Normal University), Ministry of Education, Fuzhou, 350007, China, wqke2005@163.com

Abstract

High-speed traffic network is a significant force in shaping the spatial structure of regional interaction and hence a key indicator for such spatial structure. In this paper, we constructed a three-dimensional matrix of "Origin-Destination-Time", which consists of time-evolving series network data of expressway traffic flows among 59 counties from January 2004 to December 2012 in Jiangsu, a coastal province in China. Supported by the data, we introduce the Non-Negative Tensor Factorization (NTF) method to analyze the spatio-temporal structure of high-speed traffic network and features of its stage-wise evolution in Jiangsu Province. The conclusions can be drawn as follows: (1) The reconstructed network has a good ability to reproduce and depict the spatio-temporal structure of original network in different evolutionary stages. (2) The temporal structure of Jiangsu expressway traffic flow network can be divided into three obvious evolutionary stages and multiple temporal patterns, namely the essentially immutable pattern in the period of January 2004 to April 2005; the essentially immutable pattern and the gradually rising pattern in the period of May 2005 to June 2008; and the essentially immutable pattern, the gradually rising gradual pattern and the rapidly rising mutational pattern in the period of July 2008 to December 2012. (3) The corresponding spatial structure consists of several local spatial systems with clear geographical connotations in each stage, i.e., the reversed "T" structure is consisting of the expressway network connecting the Shanghai-Nanjing expressway and the Jiangyin Yangtze River Highway Bridge along Beijing-Shanghai expressway in first stage; the reversed "T" structure in the second stage shaped the reversed "T" structure by adding the Runyang Yangtze River Highway Bridge along Yangzhou-Liyang expressway into; and the reversed "T" structure in the third stage further shaped the reversed "T" structure by adding the Sutong Yangtze River Highway Bridge along Shenyang-Haikou expressway into. (4) Each temporal pattern has its own coupling and corresponding spatial pattern respectively, and each system is a local mode of the whole spatio-temporal structure, which reflects the internal organization of spatio-temporal unity of expressway traffic flow network.

Transformation of Transport Accessibility in Ukraine as a Result of the Development of Intercity Trains

Putrenko V.¹, Pashynska N.²

¹World Data Center for Geoinformatics and Sustainable Development by NTUU "KPI", Kyiv, Ukraine, putrenko@ukr.net

²Institute of Geography NAS of Ukraine, Kyiv, Ukraine

Abstract

Rail transport is one of the most important sectors of the transport system of Ukraine.

In the last decades it has undergone significant changes. There are transformation of spatial organization, new structural elements, concentration of traffic, increasing mobility. These processes are largely reflected at the transport accessibility, which is the main product of the transport system and determine the geographic advantages of a region, city or territory from the placement and use of transport infrastructure in their territory.

Dynamics of transport accessibility on the example of changing the transport distance between Kyiv and regional centers of Ukraine during the 1989-2015 was studied. As a result of the introduction of InterCity trains accessibility between Kyiv and major regional centers (Lviv, Kharkiv, Dnipropetrovsk, Odessa) increased 1.6 times. At the same time accessibility between other regional centers almost unchanged. Time-space convergence between the capital and major regional centers was visualized using the time space cube.

The study used network analysis, spatial interaction models and models of transport accessibility, which are implemented using GIS. As a result, increasing the speed of rail traffic and service detected strengthen social and business ties and growth tourist flows.

Perspectives for implementing high-speed rail in Ukraine are analyzed.

Key words:

InterCity trains; Time-space convergence; Accessibility

A Study of the Northeastern China's Tourism Space Organization Based on the Influences of the High-Speed Railway

Meng AiYun

Department of Tourism Management, College of History and Culture, Northeast Normal University, Changchun, Jilin, 130024, P.R.China, meng76cn@163.com

Abstract

As an important Element of tourism system, Transportation is an indispensable prerequisite for developing tourism activities and expanding tourism market, every new breakthrough in traffic technology allows the tourists to travel at a faster speed to a remoter destination, also changes the spatial pattern of the tourism destination. High speed rail (HSR) is a significant symbol of the transportation revolution, thereby influencing the development of the regional tourism and the change of the tourism spatial pattern.

This paper tries to analyze the regional tourism spatial pattern under high-speed rail influence. First of all, the paper aims to establish the theoretical framework of high-speed railways' influences from the improvement of accessibility and the change of tourist traffic location, the mobility of tourism industrial factors and reconstruction of regional tourism space. Secondly, this paper analyzes the changes in travel status of city and the radiation effects of the tourism center city. In the end, to build 'core city driving, key scenic clustering, featured circle covering' spatial pattern linked by high-speed railway tourism axis from the integration of regional tourism resources and the restructuring of Tourism space etc.

Abstract

The paper studies and models the spatial accessibility and regional development interactions between 98 districts in the province of Guangdong, China. The idea behind this research is to investigate the spatial heterogeneity of regional development and infer some accessibility patterns, and to discuss and qualify the urban accessibility trends among the Guangdong districts, and their potential impact for regional sustainable development. The study first introduces spatial accessibility measures and the spatial interpolation methods within ArcGIS to illustrating the spatial distribution and heterogeneity of accessibility patterns in Guangdong. Furthermore, under the combination of influences derived from spatial impedances, this paper gives a novel potential-based accessibility measure with social and economic factors to discuss and explore the overall spatial pattern of regional accessibility and interactions between the cities in Guangdong. As a result, the potential accessibility patterns highlight substantial differences in the accessibility and regional development level in Guangdong. This study indicates that the key factors related to the emergence of spatial differences in regional accessibility involve geometrical properties, socio-economic factors and transportation opportunities, including high-speed rails. Moreover, this study reveals several issues in the industry restructuring and layout optimization by exploring the spatial patterns characteristics, variations and heterogeneity in the regional accessibility in Guangdong.

Key words:

accessibility; spatial heterogeneity; gravitational interaction; regional development

Economic Accessibility of Provincial Capital Cities in China Based on the Presence of High-Speed Rail

Huang Jie, Zhong Yexi, Li Jianxin, Wen Yuzhao

School of Geography and Environment, Jiangxi Normal University, Nanchang 330022, P. R. China, zhongyexi@126.com

Abstract

High-speed rail, is improving regional accessibility through time-space compression, and is promoting changes in regional economic patterns and spatial structures. Using traffic times between provincial capital cities, train trip prices derived from train schedule, and resident per capita incomes, this study explored the impact of high-speed rail on the economic accessibility from two important perspectives: rail service price, and rail service consumption capacity. There were three key findings. First, operating high-speed rail increases rail service prices to provincial capitals in different degrees. In addition, there are significant changes in rail service prices. Conventional rail service prices are distributed in approximate alignment with the core-edge model. The second key finding is when considering resident capacities to consume rail service, either conventional or high-speed, provincial capital cities with higher incomes have a higher capacity. Cities with lower incomes have lower rail consumption capacity. As such, the research concludes that urban resident income plays a decisive role in determining consumption capacity. Furthermore, the cost effectiveness of high-speed rail with increasing speed and price mainly depends on hourly economic limit. At the same time, resident income levels shape perceptions about cost effectiveness. Currently, the real cost effectiveness of most provincial capital cities are consistent with their perceptions. The third key finding is that high-speed rail reduces inequalities across all cities in terms of rail service price and consumption capacity, but expands inequalities for 22 cities with high-speed rail. In addition, the inequality of rail service consumption capacity is far higher than rail service price.

Key words:

high-speed rail network; economic accessibility; provincial capital cities; average price; hourly economic limit

Impacts of High Speed Rail on Economic Development in China

Abstract

Based on the enterprise database, we measure the evolution characteristics and investigate the dynamic mechanism of industry space in regions of HSR station before and after the opening in Nanjing. The research shows that, firstly, industry space has obvious circle structure in regions of HSR station. In the initial stage of the opening, concentric agglomeration as the center of HSR station is not obvious. On the contrary, the development intensity is not decrease from the site to the edge, that is to say, the core area is less than the affected area. Secondly, in addition to circle differentiation, layer agglomeration of industry space turned to be clear. Agglomeration level of business service industry, which is corresponding to the business affairs of passengers, is significantly higher than that of several other types of industry such as science and technology industry. Transportation and accommodation catering industry, as basic service industry in regions of HSR station, are between the above two categories. Lastly, this paper analyzed the dynamic mechanism of spatial structure evolution from both internal and external aspects. Besides traditional location factors such as traffic factor and agglomeration economy, industry property and land value have great influence on the change of industry space in regions of HSR station before and after the opening in Nanjing.

The Evaluation of the High-Speed Rail Sites Area Planning Based on Node-Place Model in Yangtze River Delta Area

Wenjie Song, Yujin Shi, Qing Zhu

Beijing Normal University, China, shiyujinbnu@163.com

Abstract

With the rapid development of high-speed rail construction in China, high-speed rail sites were regarded as the new growth pole of urban development, cities along the rail paid great attention to the planning and construction of high-speed rail sites area. The high-speed rail sites area planning of cities in Yangtze River Delta Area were similar in functions and industries, but the real construction and development of those areas were in huge differences. So it is important to evaluate the planning of high-speed rail sites area effectively. Based on the node-place model, we gave an empirical evaluation of the planning for 26 high-speed rail sites area in Yangtze River Delta Area by measuring node (traffic) value and place (function) value of each site. Results showed that Hangzhou east station, Nanjing south station, Yixing station and other five stations were in the sustainable development position, and most of the high-speed rail sites were in the unsustainable development position. So city governments should be aware of the risk of high-speed rail sites' construction, and in order to achieve a better development, proper strategies in planning should be taken.

Key words:

node-place model; high-speed rail sites; planning evaluation; Yangtze River Delta Area

Analysis of Road Traffic Accident in Vhembe District Municipality, South -Africa

Osidele, O.A, Nethengwe, N.S, Dondofema, F.

Department of Geography & GIS, University of Venda, Thohoyandou, South Africa, jimmyosidele@yahoo.com

Abstract

Road transport safety is challenging globally, most especially in developing countries where it affects both road users and governments of individual countries. The aim of road traffic safety is to ensure reduction or total eradication of road fatalities and other injuries that are related to road accidents resulting from public road usage. In South Africa, one of the major problems faced by the Department of Roads and Transport is the issue of road traffic accidents. The annual road traffic accidents have increased to over 500,000 and 28,000 or more are fatal which leads to serious injuries between 2004 and 2010 as reported by the Department. The study analysed the patterns and trends of road traffic injuries in Vhembe District from 2011 to 2015 and also mapping of road accident spots using GIS techniques. The research further establish the possibility of correlation/relationship between accidents spots and road geometry. The factors that are responsible for road traffic accidents leading to fatalities, injuries, death and loss of property were also identified. Likewise significant measures that assisted in the reduction of road accident occurrence rate within the last three years in Vhembe District were identified and evaluated since the commencement of World Health Organisation; Decade of Action for Road Safety 2011-2020. Comparative analysis was done to understand and compare road traffic injuries between local municipalities within the Vhembe District Municipalities and recommendation findings were geared towards contributing to road transport safety policy which can be integrated into the national enforced policies of the Department.

road accident hotspots; road design; road fatalities; road traffic injuries; safety policy; patterns and trends.

Assessing the Impacts of Large Transport Infrastructure Investment in terms of Transport and Social Justice: The Capabilities Approach Perspective

Cao. M and Hickman. R

Bartlett School of Planning, University College London, London, WC1H 0NN, UK, mengqiu.cao.13@ucl.ac.uk

Abstract

In the transport context, social justice has not previously been treated as a significant issue by most politicians and scholars, partly because the relationship between transport and social justice has not been fully understood. From a starting point of interest in social justice issues related to transport and mobility, researchers began to investigate the relationship between transport and social exclusion issues, focusing on aspects such as freedoms, capabilities, opportunities, income, reduced mobility, class, age, ethnicity, gender, social inclusion and exclusion, travel poverty, and unequal accessibility. According to most transport studies, the wider social and economic impacts of social exclusion in the transport context have primarily centred on the idea of reducing social inequity, and addressing the imbalance in the distributional effects of transport and mobility issues. Therefore, taking the aforementioned point as a basis, this research investigates and explores the relation between transport and social inequity, and its wider impacts on neighbourhoods within a city caused by large transport infrastructure investment projects (e.g. Jubilee Line Extension in London; Fangshan Subway Line in Beijing), particularly in terms of social patterns. It also aims to identify ways of trying to create a fairer society for members of the many different social groups within a city. The capabilities approach is adapted and applied within the transport context to design a travel equity sample questionnaire, as well as to assess reductions in poverty and social injustice, particularly in terms of functionings, capabilities, opportunities, values, freedom and choices.

Key words:

Transport and social inequity; transport investments; London and Beijing

Bridging Accessibility at the Neighborhood Level and Social Inequalities: The Case of Brussels

Lebrun K.

Saint-Louis University, Brussels, Belgium, kevin.lebrun@usaintlouis.be

Abstract

The development of public transport networks often combines (1) the need for carrying large number of passengers to city centres and employment districts and (2) social goals that encourage serving almost all areas. However, entrepreneurial urban policies have induced public expenditures in new development areas or in district to be gentrified while neo-liberal policies have restricted public transport's budgets. In several cases, investment in costly, heavy rail infrastructures designed for the middle class have contributed to lower means available for poorer inhabitants. All this suggests to revisit the concept of accessibility by public transport at the neighbourhood level by crossing it with social patterns.

Within this framework, Brussels has been considered as a relevant case study as the city has very contrasted sociospatial patterns.

For this purpose some accessibility indicators were first developed to analyse how easy/difficult it is to travel into the city by using public transport (mainly based on travel time and connections). Results show that accessibility is spatially heterogeneous, which offers the opportunity to measure how this contrast in correlated with social inequalities or not. In a second step, recent changes in the public transport network will be investigated too, so that I can tell to what extent the Brussels's situation is closed to those observed into some other cities.

Key words:

Accessibility; public transport; social equality; spatiotemporal analysis; Brussels

Distribution and Ownership of Means of Transport in Rural Kano Region, Nigeria

Dambazau A.M., Mukhtar A.B.

Department of Geography, Kano University of Science and Technology, Wudil, Nigeria, abalhafsah@yahoo.com

Abstract

This paper focused on the impact of accessibility on the ownership of means of transportation in the rural areas of Kano Region. A structured interview schedule was used which covers a total of 413 households selected from 28 survey villages from both Kano and Jigawa States. These villages were classified into three on the basis of their accessibility characteristics as Good, Moderate and Remote. A Chi-square test of independence was used to find out if the type of transportation owned by the rural household is independent of the accessibility characteristics. Also independent sample T- test was used to find out if there is a significant difference between the average transportation means owned by the household among the various villages in the region. The results of the chi square test shows that the type of means of transport owned by households is independent of the accessibility characteristics. While the results of the Independent sample tests shows there is no significant difference in the average transportation means owned by the rural households between Kano and Jigawa States. In all the survey villages, there is the dominance of non-motorized means of transport such as donkey, bicycle and animal cart as they account for more than 9 in 10. The study recommended the need for government and Non Governmental organizations to assist the rural people to acquire means of transport and also upgrade the surface over which transport take place in the rural areas.

Rural; Intermediate Means of Transport; Non-Governmental Organizations; Ownership

Efficiency and Spatial Equity Impacts of Trans-Strait Bridges in Pearl River Delta

Qitao WU^{1,2}, Hongou Zhang¹, Jie FAN²

¹Guangzhou Institute of Geography, Guangzhou, 510070, P. R. China, wuqt@igsnr.ac.cn

²Institute of Geographic Sciences and Natural Resources Research, Beijing, 100101, P. R. China.

Abstract

Cities separated by the strait experience the shrinking regional development advantage. While these areas benefit from significant improvements in accessibility when new trans-strait bridges are built. The improvements in efficiency due to the bridges produce locational advantages and increase the attractiveness of these cities, thereby possibly enhancing their competitiveness and economic growth. However, there may be equity issues at stake. The bridges may contribute to an increase in spatial imbalance and lead to more polarized patterns of spatial development. The main accessibility benefits are primarily concentrated in areas near the trans-strait bridge, whereas other locations obtain only limited benefits. Procedures for assessing the spatial impacts of trans-strait bridge must follow a twofold approach which addresses issues of both efficiency and equity. This analysis can be made by jointly assessing both the magnitude and distribution of the accessibility improvements deriving from multi-trans-strait bridges project in the same region.

This paper describes an assessment methodology for trans-strait bridges projects which follows this twofold approach. The procedure uses spatial impact analysis techniques and is based on the computation of accessibility indicators, supported by a Geographical Information System (GIS). Efficiency impacts are assessed in terms of the improvements in accessibility resulting from the trans-strait bridges project, and spatial equity implications are derived from changes in the distribution of accessibility values among these regions.

Key words:

accessibility; trans-strait bridges; Pearl River Delta

Examining Job Accessibility of the Affordable Housing Residents a Case Study of Beijing

Chun Zhang¹, Joyce Man²

¹Beijing Jiaotong University, China, zhangc@bjtu.edu.cn

²Indiana University Bloomington, United States

Abstract

Using data from Beijing, this paper evaluates job accessibility for people living in affordable housing to job centers. Results show an accessibility gap for different modes of transportation as travel by bus takes nearly double the amount of time as travel by car. While commuting time is closely linked to the location of the provided affordable housing, it is also dependent on the quality of local public transit service. Areas with substantial travel time differences between bus and car travel reveal the weaknesses of public transit provision. Furthermore, average commuting time by both bus and car from areas of affordable housing built after 2004 is much longer than that from previously built areas implying that low income groups are being driven to more disadvantaged locations with time changes. In contrast to the classical job housing mismatch hypothesis in Western cities, the mismatch model in Chinese cities is that while major job opportunities are still concentrated in the central city, affordable housing is being moved further afield into distant suburban areas. The paper will provide the implication for affordable housing and transportation planning in Chinese cities in the future. Improving job accessibility for this demographic will reduce car usage, promote the urban economy, and provide social welfare for the disadvantaged.

Accessibility; Job-housing balance; Low-income; Affordable housing; Beijing

Exploring Social-spatial Inequity of Commuting with Large-scale Transport and Population Data

Zhou M¹, Wang D¹, Li Q²

¹Department of Geography, Hong Kong Baptist University, Hong Kong, P. R. China, zhoumeng@life.hkbu.edu.hk

²Shenzhen Key Laboratory of Spatial Smart Sensing and Services, Shenzhen University, Shenzhen, 518060, P. R. China

Abstract

Connecting residential areas and workplaces, commuting trips contribute to a dominantly large proportion of urban travels. Issues in daily commuting have great implications to the transport-related equity and have drawn significant attention of scholars and decision makers. Jobs-housing relationship, land-use organization, and other factors might be related to the commuting and its equity or inequity over the urban space. Various studies have been focused on the social inequity of transportation provision and travel cost. This work proposes to explore the spatiality of commuting inequity in urban areas and combine the spatial and social aspects as a measure of the level of equity in daily commuting. Large-scale databases of residential population with detailed socio-demographics and employment information in the city of Shenzhen, China are utilized to extract patterns in the distribution of commuting and cost over different spatial regions and social classes at city-scale. Findings of this study would contribute to a more comprehensive understanding of the transport-related inequity issues in large urban areas and to providing useful supporting information to the planning sectors for the mitigation of the spatial-social inequity at large scale.

Impact of Production Factors Mobility on Firm Location Choice: Verification from an Agent-Based Model Approach

Feiyang Sun

Department of Urban Design and Planning, University of Washington, Seattle, 98105, United States, fs377@uw.edu

Abstract

In classical location theory, two driving forces jointly determine the location choice of firms, namely, local factor input cost and product transport cost to market. However, the theory is based on the assumption of localized factor supply and ignores the cost and benefit of using imported production factors from other region which could have a substantial impact on location choice. To fill the gap, this paper examined the impact of factor mobility on firm location choice in China by using agent-based modeling approach. In particular, this paper seeks to examine the relationship between unbalanced passenger-transport access, which is a crucial determinant for human factor mobility, and regional disparity. We first developed a dynamic production model that introduces a coefficient of factor mobility. We then applied the mathematical model to a simulation model based on the China GIS Map divided by 6 administrative regions to study the impact of factor mobility change on firm allocation in different historical scenarios. In conclusion, we found that factor mobility plays a more significant role in the early stage of economic growth when regional inequality has not been raised yet. On the other hand, with existing regional inequality, enhancing inter-regional factor mobility would rather exacerbate unbalanced growth since it allows the stronger nodes and more developed regions to absorb economic activities from the weaker nodes and under-developed regions in a faster pace.

Key words:

factor mobility; interregional accessibility; firm location choice; agent-based model

Investigating Travel Vulnerability in Greater London

Cao. M and Hickman. R

Bartlett School of Planning, University College London, London, WC1H 0NN, UK, mengqiu.cao.13@ucl.ac.uk

Abstract

This paper investigates the combined problem of high car dependency and housing affordability – in view of likely continued volatility in oil prices (and hence petrol and diesel prices) and also rising house prices. A travel vulnerability index is developed incorporating measures of car dependence and housing affordability (drawing on Dodson and Sipe, 2007; Lovelace and Philips, 2014; and Dodson et al., 2015). Greater London is used as the case study, with 2011 data analysed at the Lower Super Output Area (LSOA), and presented using Geographic Information System (GIS). The results obtained for Greater London reveal that there are high levels of vulnerability in households located in suburban areas, particularly where there are high levels of car dependence, but also those in the exclusive and, to many people, unaffordable inner urban areas, such as Kensington and Chelsea, and Westminster. If oil prices rise and use of petrol or diesel cars becomes much more expensive, and house prices continue to rise relative to average household incomes, then it can be assumed that many parts of Greater London would become more vulnerable, difficult to access for those on average or even relatively high incomes, and that those areas most affected may become much less popular to live in. The seemingly inexorable rise in London's population is not always guaranteed to continue, and perhaps the affordability issue is one reason mitigating against this. Not considering this possibility represents a major oversight in transport planning in London – there is much too little emphasis in improving public transport accessibility in suburban areas, and alongside housing affordability issues, this is placing quite a stress on household budgets and life in large parts of London – which is only likely to increase in severity in future years.

Key words:

Travel vulnerability; transport and social inequity; car dependence; London

Jobs-Housing Balance on Psychological Level and Transportation Social Equity

Yu Bai, Pengjun Zhao

The Centre for Urban Planning and Transport Studies, College of Urban and Environmental Sciences, Peking University, Beijing, 100101, P. R. China, sherrybai@pku.edu.cn

Abstract

Spatial separation of jobs and households in big cities extended individuals' commuting time. The problem of jobs-housing separation converting to jobs-housing balance equals to the problem of shortening individuals' commuting time. Previous studies mostly tried to search for ways of reducing spatial distance to shorten commuting time, however, the potential that improving efficiency and effectiveness of public transport system can shorten commuting time is ignored. In reality, taking factors like house prices and educational facilities into account, many people in big cities cannot avoid long-distance commuting under the influence of market. Neither urban-rural planning nor policies can solve spatial separation of jobs and households completely. Based on that, this paper aims to propose a new concept of jobs-housing balance on psychological level and holds the opinion that government should improve public transport system to shorten commuting time first. The key research question is if the city provides perfect public transport system for individuals of various traffic mode choices and achieves jobs-housing balance on psychological level which stands for traffic society equity to some extent or not. Indicators of accessibility and recent subway card data from Shanghai are used to estimate jobs-housing balance on psychological level empirically. After calculating individuals' jobs-housing balance degree, we discuss the relationships between transportation social equity and jobs-housing balance and put forward suggestions for improving the present transport system. The conclusions drawn in the paper would enhance our existing knowledge of jobs-housing balance, and contribute to public traffic infrastructure construction policies and transportation social equity vision.

Key words:

jobs-housing balance; psychological level; transportation social equity

Measuring Difference and Equity on Public Transportation Accessibility of Campus in Wuhan

Cheng SUN, Qian YANG, Aiwen LIN, Yuling PENG

School of Resource and Environmental Sciences, Wuhan University, Wuhan, 430072, P. R. China,

suncheng125@whu.edu.cn

Abstract

Accessibility is affected by status, power and social construction, which leads to equity issues. However, seldom equity studies on a specific group have been investigated in such developing countries as China. Thus, we focus on students in college and university in Wuhan, the biggest city in Central China, measure difference in their trip accessibility by public transportation (PTA), and assess the horizontal equity issue. We constructed a public transportation GIS database by collecting open data. Firstly, combining spatio-temporal behavior and cumulative-opportunity, an accessibility index (AI) was made to measure PTA. Then, features in spatial differentiation of AI was studied by local Moran's I, and horizontal equity was distinguished and measured by Lorenz Curve, Gini Coefficient, Coefficient of Variation, as well as Location Entropy. The result shows that PTA of campus presents as kernel-periphery, and there are four internal types. PTA in the kernel is better than periphery zones, and campuses located in kernel zone could get remarkable advantage from PTA than those in the periphery for their lower cost on trips by public transportation. Furthermore, it indicates that there exists horizontal inequity in the student group, which embodies in 2 types: diverse universities, and different campus owing by one university. To improve the situation, planning and building of public transportation infrastructure in periphery zones has to be enhanced by the decision maker. In addition, student PTA needs to be defined as a right to mobile so that equity can be protected by law.

Key words:

accessibility; campus; spatial differentiation; horizontal equity; Wuhan

Public Transit and Social Equity: An Examination of Transit Accessibility to Hospitals in Beijing

Shengxiao Li, Pengjun Zhao

Peking University, Beijing, 100871, P.R. China, pengjun.zhao@pku.edu.cn (corresponding author)

Abstract

Improving transit accessibility is believed to be an important transportation solution to create a more equitable society. Many empirical studies assess transit accessibility in terms of economic and operating efficiency. However, the impacts of social equity are often neglected in transit assessment criteria. In addition, social inequity issue is often neglected in literature about transport accessibility to hospitals. This study aims to fill up these gaps by looking at transit accessibility to hospitals in Beijing as a case. The key research question is how public transit network and services affect social equity in transit accessibility to hospitals? The spatial and social differences in transit accessibility to hospitals are examined. Firstly, transit accessibility to hospitals is calculated by an improved potential accessibility method, taking into account the public transit elements (travel interval, travel speed and traffic congestion) and different levels of the hospitals (neighborhood centers, municipal general centers and municipal senior centers). The competitiveness among the residents for various levels of hospitals is also considered. Secondly, the factors influencing social inequity in transit accessibility to hospitals are discussed. Institutional barriers to equitable transit accessibility to hospitals are addressed, such as public transit planning and management, housing price and residential segregation, health care system, danwei system and Hukou system. Finally, policy recommendations to improve social equity in transit accessibility to hospitals are introduced.

Key Words:

accessibility; public transit; hospital; social equity

Research on Matching Degree between Parking Space and Path Space

——A Case on the Underground Parking at Tianhe Sports Center in Guangzhou

Wenling LI, Yunshi LIANG

Guangzhou University, Guangzhou, 510006, P. R. China, lwling@gzhu.edu.cn

Abstract

The roads surrounding Tianhe Sports Center is one of the most congested areas in Guangzhou. The parking lots at the shopping malls surrounding are often hard to looking for a parking space. But rarely known by people, it also exist a very high vacancy rate at the underground parking at Tianhe Sports Center. Facing the problems of highly mismatching between the dynamic traffic and static traffic, exploring the origin and creating solutions become the research emphasis in the paper. With the field survey to the underground parking at Tianhe Sports Center, the characteristics of parking space design and parking situation, the behavioral characteristic of parking, and the motor vehicle traffic on surrounding roads were mastered. And then, a matching model was simulated to collocate the optimum parking space based on the path space and the characteristic of parking. Results show that the underground parking need more additional passageways; establish a gallery contact the shopping malls and the underground parking; set a temporary command system for the peripheral roads; build a parking guidance system; and displace the land utilization on parts of parking space; and etc.

Key words:

Parking Space; Path Space; Matching Model

Spatial Inequity in Public Transport Access and Implication for Urban Sustainability, a Case of Wuhan City

Peng M, Cheng J

School of Science and the Environment, Manchester Metropolitan University, Chester Street, Manchester, M1 5GD, United Kingdom, j.cheng@mmu.ac.uk

Abstract

Long-term rapid urbanization has facilitated and ensured the unprecedented growth of investment in China over the past decades. This process has facilitated massive changes in infrastructure and services, including large-scale metro and light-rail systems, advanced motorways and urban ring-roads, bridges and tunnels. However, the imbalanced investment and development in urban transport network has led to socio-spatial inequities between different groups working, studying and living in urban areas. These socio-spatial inequalities have undoubtedly fully excluded those disadvantaged/vulnerable groups from their participation in the required social, economic, and cultural activities, which contribute to their well-being. These issues have been extensively addressed and studied in the western world such as UK, but not in the global east. As the largest city in central China, Wuhan is characterized by high percentage of lower income residents and more dominant use of public transport systems. However, it is not clear if there is any social exclusion between the disadvantaged groups such as students and elderly people, caused by the spatial inequity in public transport access. In this paper, disaggregate demographic data (age groups) at building level and bus/metro system data are utilized for measuring these groups' access to the public transport systems and then exploring their spatial inequity across the study area. The social exclusion between the students and elderly groups will be examined and its implication for social sustainability will be analysed. The paper ends up with further comparison with those cases in the western world in order to develop unique theories for Chinese cities.

Key words:

socio-spatial inequity; public transport accessibility; social exclusion; GIS; Wuhan; sustainability

Sustainable Urban Transport – Does It Promote Social Equity?

Jørgensen, S. H.

Department of Geography, Norwegian University of Science and Technology (NTNU), 7491 Trondheim, Norway,
stig.h.jorgensen@svt.ntnu.no

Abstract

A sustainable urban transport strategy implies a modal shift from private motorization to public transport and active transport (cycling and walking). Considerable population growth accompanied by increasing private vehicle use in the cities emphasise the need for individual and structural changes. Social justice issues regarding modal shift consequences regarding road safety (casualties), efficient transport (accessibility) as well as environmental impact (air pollution, noise), have been formulated less explicitly or neglected. The paper aims to study social justice related to gender and age groups, with and sidelong regard to socioeconomic status. The study analyses transport plans and safety program documents (2012-2018) from the four biggest cities in Norway (Oslo, Bergen, Trondheim, Stavanger) and data on serious and killed casualties (1998-2012) with forecasts (towards 2025). There are some clues that a shift towards less private motorisation will reduce vulnerable casualties (younger and elder) and accidents in the inner areas, although cycle accidents may increase. The paper concludes that unequal distribution of health-damaging experiences related to inner parts of the cities will be mitigated by an intensified sustainable transport policy. Unfavourable groups will benefit over-proportionally by efforts to reduce accidents, air pollution and improvements of public transport. However contextual conditions in the cities (size, topography, land use) and profiles of transport strategies and measures matters. Physical private transport restrictions and regulations will have stronger impact, and appear as more inclusive for the total population, than toll road systems and taxes which high-income people may be able to pay and accept.

Key words:

Sustainable transport social equity; safety; urban; Norway

The Areas Potentially Exposed to a Transport-Related Social Exclusion in a Post-Communist Reality: A Case Study of Czechia

Jaroš V., Marada M.

Charles university in Prague, Faculty of Science, Department of Social Geography and regional development, Prague, Czech Republic, jaros2@natur.cuni.cz

Abstract

This contribution presents a summary of recent studies on a transport-related social equity issue as a specific form of social exclusion. It focuses on the relationship between transport accessibility and social exclusion set in the context of post-communist reality in Central Eastern Europe, specifically in Czechia. Public transportation in this area shows a relatively high level of both accessibility of transport opportunities and people's willingness to use it. This is a consequence of the centrally planned economy and the 'equalizing' regional policy approach used by the former political regime.

Several approaches to delimitating the potentially transport-excluded areas and the basic characteristics of these territories are discussed. The related question is how to measure or define the rate of this exclusion. The criteria defining the potential exposure of transport-related social exclusion are then categorized into three groups - area location, area accessibility and personal need of transportation. This approach to delimitation, based on secondary data, is subsequently applied to a case study of Czechia at the level of individual settlements. It is evident that unfavourable area location indicates higher risks of exclusion.

Key words:

Transport-related social exclusion; Accessibility; Personal mobility; Regional transport service; post-communist reality

The Effect of Built Environment on Spatio-Temporal Pattern of Bikesharing Use

Liang K¹, Huang¹, Xinyu (Jason) Cao^{1,2}

¹Northwest Land and Resources Research Center, Institute of Transport Geography and Spatial Planning, Shaanxi Normal University, Xi'an, 760119, China, hxiaoy@snnu.edu.cn

²School of Geography and Planning, Sun Yat-sen University, China

Abstract

Bikesharing system Program (BSP) as an alternative and complementary mode of transportation has been growing attention worldwide. Despite the rapid rise of this new transport opportunity, there has been limited research on the factors influence bikesharing flows due to lack of detailed data available to researcher. This paper using trip level data from Xi'an bikesharing system, the data provide an opportunity to present the spatio-temporal patterns of bikesharing flows, We examine the influence of built environment, public transport infrastructure, land use and meteorological data attributes on arrival and departure flows at the station level. The results show that bike sharing is principally used for commuting purposes, the factors of influence weekday and weekend usage has a great difference. The combination between bike sharing and bus is important to increase usage. Population density and jobs density are two main explicative factors for the bike sharing usage. The findings allow us to identify factors contributing to increased usage of bicycle-sharing in Xi'an and to provide recommendations pertaining to station size and location decisions. The present findings could be useful for others cities which want to adopt a bikesharing system and also for a better planning and operation of existing systems.

bikeshare; built environment; spatial analysis; sustainable

The Effect of Population Growth on Transportation of University of Ilorin Students

Ogunleye-Adetona, C.I., Banji-Onisile, Aderonke

Geography and Regional Planning, University of Cape Coast, Ghana, adeogunleye2005@yahoo.com

Geography and Environmental Management, University of Ilorin, Nigeria

Abstract

Population growth can either be a blessing, a curse/problem if it is not properly managed. This paper attempts to the effect of population increase on transportation among university students using university of Ilorin as a case study. This paper draws attention on various transport challenges the off-campus students of university of Ilorin experience and the coping strategies they employ. Questionnaire and focus group discussion were used to data collected from 270 students selected according to their level/year of study in a week at different occasions. Pearson moment correlation coefficient was used to **explain** the relationship between population growth and transport. From the result larger percentage (71.0%) of the Students agree that population increase affect Transport services because of long queues, long wait, rowdiness at the park and the students push themselves on long queue so as to enter vehicles going to the campus for lectures or other things all because of the inadequacy of the available transport facility. This has a great effect on the Students; falling sick and missing test and exams etc. The coping strategies includes leaving home/hostel early and stay back in school until the population at the park reduces, some go for lift 'tanke sir'. The paper recommends that more buses should be provided and private operators should also be allowed to build more affordable hostels within the school.

Key words:

off-campus students; transport challenges; coping strategies; population growth

The Social Equity Issues in Subway of China: Socioeconomic Variations in Responses to Subway Fare Increase in Beijing

Y. Zhang, P. Zhao

The Centre for Urban Planning and Transport Research, Peking University, Beijing, 100871, P. R. China,
pengjun.zhao@pku.edu.cn

Abstract

Public transportation plays an important role in promoting social equity and inclusion. To supply affordable transit is one of key issues in relation to sustainable public transport policies. Although the equity issue in public transportation has been widely discussed, the topic was largely overlooked in developing countries. The paper aims to bridge the gap in literature by looking Beijing as a case. In 2014, Beijing Municipal Government used a distance-based fare system to replace its flat fare system. In this paper, we apply before-after approach to investigate the impacts of the change of subway fare on different groups. The key research question is to explore whether the change of pricing policy affects the inequity between one or more groups of passengers over others. Our data is from a survey for Beijing subway, consisting of residents' travel characteristics and their socio-economic status. The results show that the increased subway fare would have larger influence on those are vulnerable to social exclusion, especially young office workers, people who don't have private cars, and people living in suburbs. It is also found that people living in public owned house (usually located in city centre) are better off after the subway fare increase, because of the flexible transportation access provided by city centre. There are many factors influencing socioeconomic variations in responses to subway fare increase. Spatial constraints in relation to the disadvantaged people's choice of job and housing location, and institutional barriers to affordable public transit are two of the most important factors. The study demonstrates that discriminative impacts will change residents' mobility in the future, and calls for policies focusing on social inclusion.

Key words:

Subway fare; travel behaviour; social equity; transport exclusion; mobility

Transport Accessibility and Level of Agricultural Development in Himachal Pradesh

Manjit Singh

Abstract

Transportation has long been recognized as a strategic factor in agricultural and rural development. It is a proven fact that improved access to all season roads enhances a positive influence in the development of rural areas. Transportation plays a key role in establishing intimate relationship between consumer and producer through agricultural market centers. Also, transport is regarded as a crucial factor in improving productivity and commercialization of agriculture. Thus, the provision of better transport accessibility is of great significance to overall regional development in general and agricultural sector in particular in rural areas. Different research works have been conducted on transportation and agricultural development, but very limited studies have been done on mountain regions in general and Himachal Pradesh in particular.

This paper is a humble attempt to answers these complex questions related to transport accessibility and agricultural development in Himachal Pradesh. Quantitative methodology has been used in the study and various forms of measurement of transport accessibility, delineation of service area of agricultural market centers and agricultural development has been conducted to derive relationships with sustainable rural economy. Also, various techniques like network analysis, overlay analysis, composite index, correlation and regression have been used with the help of ArcGIS and SPSS. The results highlight high positive correlation between expansion of road transport and agricultural development in Himachal Pradesh. Findings also highlight agricultural development as an important factor for sustainable rural economy in the region.

Urban Transport Inequity in Transition China: A Literature Review and Agenda for Future Research

Zhao, P

The College of Urban and Environmental Sciences, Peking University, Beijing, 100871, P. R. China,
pengjun.zhao@pku.edu.cn

Abstract

Urban transport inequity is increasingly attracting interests by researchers and politicians. It has become an important research theme in the field of urban studies or transport studies. However, our existing knowledge of urban transport inequity is mainly based on cases from Western World. Cases in developing countries could contribute to generalization of the knowledge since there are significant differences in transport and socioeconomic contexts between Western World and developing countries. China has been experiencing a transition from a centrally planned system to market system since the 1980s. The transitional socialist-style social equity is being broken by the increasing market power and a changing society. An increasing social inequity has been reported in many fields including transport. Although some studies have been done, findings and conclusions are still fragmented and ambiguous. A complete story of urban transport inequity in China is still missed. The paper aims to conduct a thorough review of literature about urban transport inequity in China. Firstly, a conceptual framework for studying urban transport inequity is proposed according to the theoretical arguments in the field. Secondly, literature about urban transport inequity in China is reviewed in terms of the evidences, determinants and impacts of urban transport inequity in China. Thirdly, critical discussions were conducted on the existing empirical studies in terms of research methods, data and theoretical contributions. Finally, an agenda for future research about urban transport inequity in China is proposed.

Key words:

urban transport inequity; literature review; transition; China

Urban Transportation Emission and Environmental Inequity in China -evidence from Beijing

Peilin Li, Pengjun Zhao

Abstract

In recent years, increasing air pollution in Chinese cities raises public concern on its adverse effect on health. Transportation exhaustion is increasingly attributed to urban hazardous air. It was reported that in some developed countries, there is transport-related environmental inequity since disadvantaged residents like minorities or in poverty suffer from higher level of negative environmental externalities due to housing, commuting or working close to detrimental infrastructures like busy road, whilst their opportunities accessing to enhance their health are lower than other groups. Is this a case in China? There is few literatures about transport-related environmental inequity in China's cities. The paper aims to examine the transport-related environmental inequity in China by looking at Beijing as case. This paper, using 11 million traffic congestion monitored data and housing price data in Beijing, analyzes the spatial distribution of traffic air pollution and its effect on city neighbourhoods. It shows similar trend that neighbourhoods with higher proportion of people in poverty and low education have higher proximity to traffic sourced air pollution. Moreover, locations of several infrastructure and public services spots like primary schools, parks, and libraries might leave physical vulnerable users like children or elders to heavily expose to air pollution from traffic. This paper also discusses the reasons and factors influencing transport-related environmental inequity. In particular, the institutional factors are addressed, such as Danwei system, housing policy, Hukou system, etc. Land use policies and transportation demand management are recommended for city governments to mitigate environmental injustice caused by transport sector.

Key words:

transportation emission; air pollution; environmental inequity; disadvantaged residents; Beijing

Dispersed Settlement Pattern in Slovenia as a Cause of Social Exclusion

Gabrovec M., Bole D., Razpotnik Visković N.

ZRC SAZU, Ljubljana, 1000, Slovenia, matej@zrc-sazu.si

Abstract

In Slovenia, as a post-Socialist country, the legislation is still effective that financially provides for school children and employees to commute to the place of their job or school. Monthly tickets for secondary-school and university students are substantially subsidized, and, in compliance with collective agreements, employers are obliged to reimburse their employees for their transport-to-work costs. As a rule, special school buses are organized for elementary-school children, while secondary-school students depend on public transportation. However, due to dispersed settlement pattern, numerous smaller villages are not provided with it, which means that the nearest stop or station of public passenger transportation is often several kilometres away. Thus, their parents or relatives often have to drive them to school or they have to go on their own by moped or bike, which is very inconvenient in winter and in bad weather conditions, especially in hilly areas. To make matters worse, these students cannot attend the extra-curricular activities, which can result in their social exclusion. The extent of this problem has not been studied before. For this purpose, we connected by means of the GIS the data from the Central Population Register with the data of transportation schedules and calculated the number of secondary-school students by individual municipalities who do not have adequate connections with public transportation. Proceeding from the results of these analyses we have proposed the adjustment of standards of accessibility to public transportation in Slovenia.

Key words:

public transport; social exclusion; settlement pattern; Slovenia

Is School Consolidation a Bad Policy in China: Implications from Decomposing Excess School Commuting at Yanqing, Beijing

Dai Teqi, Wang Liang

School of Geography, Beijing Normal University, 19 Xijiekouwai Avenue, Beijing, 100875, China, daiteqi@bnu.edu.cn

Abstract

School removal is a common policy option as a result of the decreasing in education demand and education finance, which tends to increase the distance from home to school, and even causes students dropping out of schools because of the long distance in some area. Thus, school removal encounters frequent criticism. But there's no specialised research suggesting to what degree of distance growth is caused by school removal. Many other reasons can cause the lengthen of the distance to school, only criticizing school removal may mislead policy evaluation. In order to evaluate and analyse the effect of layout adjustment, financial reduction, school planning and school district division change on the distance to school, we use p - media optimization model to make Scenario analysis in county yanqing. Through analysis we draw the following conclusions: (1) The increase of shool distance is also influenced by school layout adjustment, financial reduction and school district division change. Financial reduction has greater influence than school layout adjustment, and so does school layout adjustment compare to school district division change. (2) The influence of school removal has been exaggerated.

Spatial Characteristics and Dynamic Changes of Daily Communication Area Based on Time Accessibility in the Yangtze River Delta, China, 1985-2020

ZhangLi

Nanjing Normal University, Nanjing, 210046, P. R. China, zhangli@njnu.edu.cn

Abstract

With the arrival of economical globalization time, the concept of megalopolis, metropolitan area becomes more and more important. In the rapid development of traffic situation, Daily communication area as a kind of organization of city should be paid more attention to.

This paper develops a comprehensive research of daily communication area based on time accessibility of Yangtze River Delta with the help of GIS. Having reviewed briefly the previous metropolitan area and studies on accessibility, the paper defined the daily communication area and its boundary in the light of China's present situation. Taking the shortest time as indicator of time accessibility, the paper intends to construct overall coverage spatial analysis of regional accessibility based on land transportation network which is composed of highway and railway. Spatial diffusion, spatial interaction and daily communication area of regional spatial structure are studied from the view of spatial analysis of accessibility. Using MapX component and Delphi programming tool, regional accessibility calculation and analysis information system based on minimal seed algorithm is developed, with which mark diffusing figure and daily communication area of city could be generated. The studies focused on the Yangtze River Delta. It chooses the land traffic network of 1985, 1995, 2011 and 2020 and analyzes spatial characteristics and dynamic changes of daily communication area of 16 cities in the Yangtze River Delta. The conclusion was researched on the construction and influence factors and the developing trends of the daily communication area was discussed by the dynamic change analysis.

The Regulation Mechanism of Price Leverage's Influence on Residents' Taxi Travel Behavior and Its Spatial Effect Analysis

Yu Luo, Xin Dong

School of urban and Environmental Science, University of Northwest, No.1 University Xi 'an, 710127, China, 610143852@qq.com

Abstract

Taxi plays an important role in urban public transport system. It has been a common problem in metropolitan residents' life that it's hard to take taxis. Most cities have carried out multi-round price adjustments. Based on this, taking Xi'an as an example, the author divided the passengers into two classes—"the necessary" and "the nonessential" to do random sampling survey about the influential factors of their taxi travel behaviors, finding that price is the most important among them, then made an empirical analysis to the interaction mechanism of supply and demand with price leverage.

The study shows that the taxi price adjustment has little effect on "the necessary" while means a lot to "the nonessential". Simultaneously, the growth of low speed fee reduces the profit difference apparently.

For verification, the author randomly selected 2000 taxis' trajectory data before and after the price adjustment, used the Arc GIS software to compare the spatial changes of the focus, to overlay the density distributions of taxi and main population, and built function for the profit difference with the MATLAB software.

It proves that the problem can be relieved in fact, and the density distributions of taxis and the main population tend to overlap after the price adjustment.

This thesis provides reference for making policy of taxi price adjustment. Especially the problem of city transportation is prominent in China, using price leverage to optimize the urban traffic definitely has profound value.

Key words:

price leverage; the nonessential passengers; low speed fee; profit difference; the spatial analytic method

Transportation in Udaipur City: Problems and Prospects

Dr. Barkha Chaplot

Department of Geography, Mohanlal Sukhadia University, Udaipur, barkhachaplotjain@gmail.com

Abstract

Transportation plays a very significant role in determining the patterns of spatial growth and development of city. A well-developed transport infrastructure provides increased accessibility to various parts of a city and opens up remote areas on the periphery of the city, which is necessary from the point of future development and orderly growth of any town. Thus, present paper is an attempt to analyse the transportation system, its problems and prospects in Udaipur city. The entire study is based on primary as well as secondary sources of data, wherein primary data were obtained through the survey carried out during 2014 in the city and secondary data were collected from traffic and transportation master plan and city development plan. The study reveals that with the development transport, traffic related problems also increased in the city. The walled city and major junctions of the city (Surajpole, Delhigate, Udayapole, Hathipole and Pratapnagar) have maximum traffic and parking problems. Udaipur city needs the proper transportation facilities and services.

An Empirical Analysis of the Relationship between TOD and Rail Transit Station

Passenger Volume: A Case Study of Shanghai

Pan, Haixiao¹, Li, Jing¹, Qing Shen^{1,2}, Shi Cheng¹

¹Department of Urban Planning, Tongji University, China, hxpank@online.sh.cn

²Department of Urban Design and Planning, University of Washington, United States

Abstract

This paper is aimed at empirically examining the effect of rail transit station-based TOD on rail transit ridership. Using IC card data on metro passenger volumes and cellular signaling data on the spatial distribution of human activities in Shanghai, the research identifies variations in ridership among rail transit stations in different locations and with different starting dates. Then, regression analysis is performed using passenger volume in each station as the dependent variable. The numbers of jobs and residents in the station area, the distance between the station and the city centers and urban planning variables, such as the distribution of planned activity centers. The main findings are: (1) stations in different locations have metro ridership catchment areas that differ in geographic scale; (2) passenger volume in a metro station is significantly correlated with employment density nearby, distance from the city center, and distance from the nearest sub-center; (3) passenger volumes in metro stations that are better integrated with nearby developments tend to be higher than those in otherwise comparable stations. Several implications are drawn for TOD planning: (1) the geographic scale of TOD should be adjusted according to the location of the corresponding metro station; (2) more sub-centers should be developed and higher employment density in the metro station area should be encouraged to increase rail transit ridership; and (3) commercial development and rail transit facilities should be more strongly integrated when making TOD plans.

Key words:

TOD; rail transit; passenger volume; integrated rail transit and urban development; Shanghai

Correlation Analysis between Spatial Relation and Urban Expansion: An Urban Agglomeration View

JIAO Limin^{1,2}, TANG Xin¹

¹School of Resource and Environmental Sciences, Wuhan University, Wuhan 430079, China, lmjiao027@163.com

²Key Laboratory of Geographic Information System, Ministry of Education, Wuhan University, Wuhan 430079, China

Abstract

Urban expansion displays different characteristics in each period. Studying the spatial and temporal regularity of urban expansion, from the perspective of the urban agglomeration, plays an important role in understanding the complex correlation between urban expansion and network framework of urban agglomeration. We analyze urban expansion in the Yangtze River Delta Urban Agglomeration based on traffic network, gravity model and space syntax model. Construction land expansion was obtained from Landsat remote sensing data in 1980, 1990, 2000, and 2010 and then was used to calculate intensity and velocity of urban expansion. Urban location in traffic network of urban agglomeration is analyzed by accessibility to and spatial interaction intensity from core cities. Space syntax model is used to compute accessibility of urban traffic network and the status of a city in traffic network of urban agglomeration. Results show that, firstly, urban expansion intensity displays a positive relationship with accessibility to core cities, spatial interaction intensity from core cities, and space syntax indicators. Secondly, there is a positive relationship between urban expansion velocity and indicators mentioned above in the first (1980-1990) and second (1990-2000) period. However, it exhibits a negative relationship in the third period (2000-2010). Cities, with a relatively inconvenient traffic network and located in the periphery of urban agglomeration develop more quickly, displaying a trend of spatial convergence. This finding, on the one hand, embodies that accessibility to and spatial interaction intensity from core cities and traffic network link closely with urban expansion; on the other hand, it serves as a reference to the planning of Yangtze River Delta Urban Agglomeration and the regulation of urban expansion of other urban agglomerations.

Key words:

urban expansion; traffic network; space syntax; spatial interaction

Exploring User's Route Choice Preferences of Bicycle-Sharing System with the Smart Card Data: Empirical Evidence from Nanjing, China

Qiuyi Yin, Feng Zhen, Zhaxi Luosang, Suping Guo

School of Architecture and Urban Planning, Nanjing University, Nanjing, P. R. China, 512406866@qq.com

Abstract

Bicycle sharing systems (BSS) are becoming increasingly popular all over the world, lots of research have focused on BSS users. However, most of the existing research focuses on the origin and destination choice preferences through investigation and interview, little is known about how different kinds of users choose cycle routes using real trip information which demonstrably influences not only BSS itself, but also the economical activities and built environment along those routes or even the urban spatial pattern. Using the smart card data (SCD) collected in Nanjing from January to September, 2015, this paper simulates the real route network with SCD. According to the clusters of all the users with the indicators of age, gender, Recency-Frequency segmentation and travel time using Hierarchical Clustering Method, spatial-temporal characteristics of the cycle routes of classified user groups are identified and analyzed. We then find that females and elderly's routes show disperse spatial distribution, those streets offset the main roads, with lower traffic, decent environments and passing through the shopping centers are preferred. Meanwhile, male, young and middle-aged users prefer utilitarian trips with shortest routes which mostly allocated between transit stations and communities. Finally, optimizations concerning the bicycle infrastructure, the built environment along the routes and overall BSS planning and construction are proposed combining the findings and current population composition of research zone.

Key Words:

bicycle sharing system; route choice preference; smart card data

How Built Environment Influence Public Bicycle Usage: Evidence from the Bicycle Sharing System in Nanjing, China

Luo Sang Zhaxi

The school of Architecture and Urban planning, Nanjing University, Nanjing, 210095, P.R. China,

tashi_lobsang@163.com

Abstract

In recent years, there has been growing attention on Bicycle Sharing System(BSS) as an alternative to traditional modes of transport. Most previous studies about BSS focused on station planning layout, demand forecasting and trip characteristics, with small sample survey and simple statistical analysis, few studies focused on quantitatively exploring factors affecting public bicycle flows and usage employing real bicycle usage data. We examine the influence of temporal characteristics, bicycle infrastructure and built environment attributes on arrival and departure flows at station level using real bicycle usage data between April and September 2015 in Pukou and Qiaobei Area of Nanjing with linear regression method. The results show that the density of community and metro station are the most important factors affecting bike sharing flows and usage. Furthermore, during the morning peak period the density of subway station was positively and significantly related with bicycle usage rate, indicating bicycle sharing plays an important role in public transportation systems. While during non-commuting periods the numbers of commercial network, life service facilities, and the density of the bicycle sharing station, were positively related with bicycle sharing usage rate. These findings provide some useful information for city planners and BSS administrators who are designing or optimizing the bicycle sharing system, and also they are helpful for other cities with intentions of planning and developing the BSS.

bicycle sharing system; built environment; usage rate

Mapping Mobility Practices through Mobile Phone Data

Kharchi T

GRED Lab, Montpellier, France, taharkharchi@gmail.com

Abstract

Cities that have adopted the Transit Oriented Development – TOD concept mobilize a large amount of people mobility data. This paper proposes an analysis based on a kind of data, not usually used in studying citizens needs of urban transportation. These data come from a French telecommunication company: SFR (*Société Française du radiotéléphonie*).

The use of geographical information systems (GIS) to mapping out mobile phone data, allows us to understand everyday life organization of citizens as well as their routes patterns. A GIS modeling based on people mobility practices can therefore be established.

The results coming from daily activity programs of people will be confronted to the existing transport supply and the existing structures in our study area: Montpellier. This allows us to establish an applied study case and furthermore to analyze the adequacy between urban transport supply and displacement needs of citizens in Montpellier.

Key words:

Mobility data; mobile phone data; GIS modelling; Montpellier.

Media Cities, Transit Oriented Development and Transport Sustainability

Professor Richard Knowles

University of Salford, UK, r.d.knowles@salford.ac.uk

Abstract

Media Cities are an inter-organisational fusion of media, creative and knowledge industries. A contemporary urban development or regeneration strategy is to create new Media Cities of global significance in major regional or national centres, often as part of a transit-oriented development (TOD).

TOD is the process of focussing the development of employment, activities, services and housing around rapid transit stations. It is designed to create high density, compact and mixed urban form accessed by sustainable transport in the form of transit, cycling and walking.

This research explores the development of selected Media Cities which are part of TODs, and analyses the transport sustainability of MediaCityUK Salford and DR Byen (Media City), Copenhagen, Denmark.

Key words:

Transport Sustainability; Media Cities; Transit Oriented Development; Salford; Copenhagen

New Life for Old Tram Lines? Rehabilitation of Formerly Industrial Tram Lines in the Context of Transit Oriented Development

Jakub Taczanowski, Arkadiusz Kołoś

Jagiellonian University in Kraków, Institute of Geography and Spatial Management

Ul. Gronostajowa 7, 30-387 Kraków, Poland, iakub.taczanowski@uj.edu.pl

Abstract

The aim of the paper is to answer the question whether and to which extent the 'industrial' tram lines which have been inherited from the period which was characterised by completely different transport needs are able to play an important role in the present municipal transport networks. It would seem that this tram infrastructure could be a vital factor of urban development and revitalisation of post-industrial city districts as its existence makes zones of this type more attractive and accessible. The development of tram networks in Central and Eastern Europe between 1945 and 1989 was characterised by large-scale investments in new lines – and in some cases even entire networks - which were designed to connect multifamily housing estates with industrial plants. The role of the lines of this type was changed dramatically by the economic and political transformation of 1989 which resulted in scaling down and closures of several factories, in particular heavy industry plants. For this reason, the sense of further existence of these 'industrial' tram lines has often been questioned. However, after the EU accession of Central-Eastern European countries a large scale rehabilitation of municipal transport systems – including tram networks - has been started in almost all cities of the region. The potential of the existing infrastructure and EU grants seem to be an opportunity to the transit-oriented development which would enable to achieve synergy between transport and urban development in order to make Central-European cities – including their post-industrial districts – more sustainable and smart.

Key words:

Municipal transport; transit oriented development; light rail; sustainable transport

Potentials for Smart Transportation and Transit Oriented Development in Metropolitan Manila, Philippines

Boquet, Y.

Université de Bourgogne, 4 boulevard Gabriel, 21000 Dijon, France, yves.boquet@u-bourgogne.fr

Abstract

The capital city region of the Philippines is widely known as a basketcase of urban transport, combining high levels of congestion, pollution and inefficiency. Despite the the rapid growth of population and motorization, is it possible to adapt “best practices” of other cities to the MetroManila context? We will examine the potential for BRT corridors, urban rail and bicycling, as well as the efforts for greener transportation modes (e-jeepeys, e-tricycles). Several difficulties need to be overcome: the current structure of the transportation system governed by multiple competing operators, the lack of coordination between municipal governments, the high density of population and urban fabric making more difficult a densification of urban space, the lack of funding linked to the apparent lack of interest at the highest political level and the priority given in recent years to road projects. Should TOD be developed first on areas not yet reached by mass transit, on new routes, or should it be attempted in the most heavily traveled corridors? And what can be done to improve intermodality and a smooth connection for travelers?

Key words:

Manila; green transportation; TOD; jeepneys; BRT

Smart City Songdo between ambition and reality: Aspects from a European perspective

Hekler, B. A.

University of Vienna, Universitaetsring 1, 1010 Vienna, Austria, tina.hekler@gmail.com

Abstract

For several years already, several urban planning and development approaches have been exploring a new concept: The so-called Smart City. The concept tries to give 'sustainable' answers to the challenges that cities in industrialized countries worldwide seem to face: The number of people living in cities is growing rapidly and the contemporary infrastructure capacities cannot always cope with the needs that result from such growth. Quite often, there now seems to be an urgent demand for new sustainable solutions, in order to create new, modern infrastructures for transport, housing, working, education and urban services. Smart City Proponents are convinced: With Smart City Concepts new urban landscapes, new forms of urban living, new global and local spatial networks could be developed, that as a whole could better cope with the current problems of urban growth.

What makes life in a city in the future worth living? It is the history of cities, their urban identity or their urban perspectives? And to what extent do Smart City concepts appear to be useful for urban planning in the 21st century? Who will benefit? And might there also be some disadvantages eventually – and who would probably suffer most from them?

The first results of some quite revolutionary Smart City Project New Songdo City might give some insights into their real impacts and prospects.

From a European perspective, the presentation will aim to explore relevant aspects of what might appear to be key issues for designing the future of urban living in the 21st century.

Key words:

smart city; urban planning; urban development; urbanity; vitality; Songdo; South Korea

Study on Impact of ICT on Commuting Behavior in the Era of Internet

Chun Zhang, Luchen Cui

Beijing Jiaotong University, Beijing, 10044, P. R. China, zhangc@bjtu.edu.cn

Abstract

In the era of the Internet, information and communication technology (ICT) has not only changes the urban space deeply, but also change the commuting behavior fundamentally. Selecting Beijing as case study, this paper explores the influence of ICT on commuting behavior characteristics by small sampling questionnaire. It shows that the young, highly educated, high-income groups access to the internet of higher frequencies. It also finds that high frequently internet user group has longer commuting distance and time; they will use navigation APP more frequently and more likely to adjust their trip plan according to real time traffic. Commuters would like to accept longer commuting time if supported by smart phone and internet. Regression analysis indicates that both weekly frequency to internet and use smart phone would significantly increase their commuting distance. This paper aims to improve commuting quality, and make urban planning and transportation decisions under the trend of informatization and smart city.

Key words:

Commuting; Information and communication technology; Internet; Fragmentation; smart phone

The Potential Demands of Demand Responsive Customized Bus System in Dalian, China

Liu Kai, Zuo Zhi

Dalian University of Technology, Dalian, 116024, P.R. CHINA, liukai@dlut.edu.cn

Abstract

About 30 cities across China have developed successfully an innovative mode of public transport service, the demand responsive customized bus (DRCB) system, which combined the benefits of bus services and taxi services and served mainly for daily commuters in current systems. Unfortunately, while attractive in principle, a large amount of actual demands cannot be satisfied due to the current simple operating pattern and pricing pattern, on the other hand, the potential DRCB demands are not yet known for system operators and therefore impede this system. In order to improve the level of service of this newly developed transit system, it would be better to understand the time-spatial distribution of potential demands.

Dalian DRCB system is organized and operated by local transit agencies, while it was not subsidized by the local governments up to now. With the help of smart phone and booking APP, more and more commuters move from other travel modes to DRCB. The time-spatial distribution of DRCB demands of about 6000 registered DRCB users in Dalian is analyzed. The characteristics of DRCB users are employed to model their behavior choices. A questionnaire survey was conducted recently, which focus on commuters' aspirations of transferring from other travel modes to DRCB. Results will help estimate the potential demands of DRCB system.

Key words:

Potential demands; demand responsive customized bus (DRCB); time-spatial distribution; behavior choices; mode transfer; aspirations

The Progress of E-Development in China since 1998

Bo WANG, Becky P.Y. LOO

Department of Geography, The University of Hong Kong, Hong Kong, wangbo.nju@gmail.com

Abstract

Despite the increasing attention that e-development has received in the media, there is inadequate scholarly research on the process of e-development in China. Drawn from Loo's framework for tracing the development of an e-society, this paper aims to provide an empirical case study of China's e-development since 1998. Specifically, based on the official biannual survey reports on internet development in China and other related documents and statistics, the progress is analysed systematically by benchmarking various technological advancements in hardware and software, the composition of internet users, and the key dimensions of e-government, e-working, e-commerce, and e-networking. In addition, the questions of whether the geographical digital divide in the country has been reduced is examined. Our findings show that (1) China is on a fast track towards mobile informatization, with increasing number and adoption rates of mobile information and communication devices; (2) the use of the internet has quickly penetrated into the daily life of people from almost all walks of life, with high adaption rates for females, teenagers, and people with lower-level of education; (3) the use of the internet has gradually brought about fundamental changes in the political, commercial, and social spheres of people's daily life; and (4) the digital gaps have dramatically decreased along the mobile informatization and the Go West policy since 2000, while the disparities between urban and rural areas persist even after the implementation of 'Electrical Appliances Entering Rural Households' policy in 2009.

Key words:

E-development; Information and communication technology; internet users; e-activities; digital divide; government policy; China

Transit-oriented Development in Hong Kong: Opportunities beyond Public Transit

Loo B.P.Y., du Verle F.D.

The University of Hong Kong, Hong Kong, P. R. China, bpyloo@hku.hk

Abstract

Transport fuels and household usage of energy are identified as the main causes of carbon emission and consumption of resources (Brown et al., 2008). This research addresses the issue of comprehensive sustainability through understanding people's travel behaviour. In order to promote more sustainable mobility within Hong Kong, the characteristics of built environment around the metro stations in Hong Kong and the travel behaviour of residents living in these transit-oriented neighbourhoods are studied. Moreover, some key urban forms factors are measured and analysed with an integrated research approach to understand the benefits and opportunities of developing TOD as part of an integrated sustainable city strategy.

Key words:

Transit-Oriented Development; car dependence; carbon emissions; urban form; travel behaviour; walking

Transit-Oriented Developments and the Search for a Urban 'Sustainability Fix': The Case of Fastracks Rail Transit in Denver

Jonas, A.E.G., Goetz, A.

Department of Geography, Environment and Earth Sciences, University of Hull, United Kingdom, A.E.Jonas@hull.ac.uk

Abstract

Transit-oriented developments (TODs) are central to how many cities engage in the search for an urban 'sustainability fix'. Investments in mass transit systems, such as light rail and associated TODs, have become crucial components of such a fix and underpin smart-city strategies throughout the USA. Such strategies, in turn, have been associated with a proliferation of local funding arrangements, raising concerns about regional collaboration and equity. The extension of rail transit corridors often requires new and innovative funding arrangements in the form of public-private partnerships (PPPs), which in turn place new demands on local and regional resources. This paper examines the proliferation of TODs and PPPs in Denver associated with FasTracks, a long-term project to expand the Denver Regional Transportation District's light and commuter rail system. FasTracks represents a regionally coordinated effort to promote more sustainable transportation and smart urban development. However, financing the project has proven problematic, leading to tensions around Denver's hitherto successful model of regional collaboration.

Key words:

Transit-oriented development; sustainability; mass transit; public-private partnerships; Denver; USA

Correlation Analysis between Road Structure and Intensity of Commercial Land Use Based on Space Syntax

Jiao L.M., Han Y.Y., Xu G.

Wuhan University, Wuhan, 430079, P. R. China, hanyy@whu.edu.cn

Abstract

Urban road structure is one of the most important factors influencing the spatial distribution of commercial services of which density directly reflects intensity of commercial land use. Taking Wuhan urban area as an example, we explore the effects of urban road network on the intensity of commercial land use based on theories of space syntax combined with GIS. Road network and commercial point of interest (C-POI) of Wuhan in 2014 were collected. Four spatial syntactic variables, namely, connectivity value, control value, global integration value and total depth value, were calculated for each road. Values of each spatial syntactic variable are divided into seven classes using the natural breaks method and then buffers with 500m-radius are established for each class. The average values of four syntactic variables and C-POI density in each buffer are calculated to analyse their correlation. Bivariate correlation analysis between syntactic variables and C-POI density indicates that connectivity value and global integration value are significantly positively correlated with C-POI density. The trend of C-POI density increases at first and then decreases with the increasing of control value. Total depth value shows significant negative correlation with C-POI density. The results indicate that there is a strong correlation between road structure and intensity of commercial land use, which can provide guidance for urban land use planning.

Key words:

correlation; road structure; intensity of commercial land use; space syntax

Research of the Urban Periphery Park-And-Ride Facilities Space Organization: A Case Study of Guangzhou Metro Line 3

ZENG Jia-le, Li Wen-ling

School of Geographical Sciences, Guangzhou University, Guangzhou, 510006, P. R China, kalokzeng@qq.com

Abstract

Guangzhou Metro Line 3(include two section: Shiqiao Line and Airport Line) in turn connect from south to north, Panyu district, Tianhe district, Baiun District, Huadu District that it is one of the busiest metro line of Guangzhou. We select three park-and-ride facilities along Guangzhou Metro Line 3 as in peripheral area research object, we investigated parking organization, traffic organization, additional space of facilities, space activities and satisfaction of consumers, combined with user of consumer demand and regional overall plan to analyse interior space, exterior space, service condition and managing status of facilities. The survey show that convenient and parking fees for facilities influence is the largest. To establish special transfer channel and preferential transfer instruction can increase convenience of facilities. Supermarkets, convenience stores and other ancillary commercial facilities to meet consumers' daily needs. Lower parking fees or with metro and bus companies establish preferential price mechanism to attract consumers effectively. Finally, establishing evaluation system with comprehensive model for convenient degree, accessibility, ancillary facilities satisfaction, comprehensive satisfaction. According to the usage of different facilities and regional consumers' demand optimize external and internal space. Making park-and-ride facilities multi-functionalization to attract more consumers. We want to find out effective methods for alleviating urban traffic congestion and making park-and-ride facilities with efficient operation.

Keywords:

peripheral area; park-and-rid facility; Guangzhou Metro Line3; space organization

The Supporting Function of Taxi-Calling Apps' Data to Travel Demand Management: The Case of Nanjing

Yanhao GONG

Nanjing University, Nanjing, 210023, P. R. China, gongyanhao@gmail.com

Abstract

Travel demand management is currently an efficient way to solve urban traffic problems. Recently, many researchers used big data to describe transportation and support demand management policies with some powerful evidence. However, as the taxi-calling app is still an innovation in the Internet Plus era, related research is uncommon. Therefore, this paper uses the data of taxi-calling apps, a new data source, to explore its function to travel demand management. A spatiotemporal analysis method based on kernel density estimation and raster calculation is proposed to study the generation and distribution step of the “four-step model”. Taking Nanjing as an example, this paper first uses visualization method to depict and analyze the spatiotemporal pattern of residents' taxi-calling demand. Then, select four typical regions, namely “Xinjiekou”, “Confucius Temple”, “Southlake Community” and “Software Avenue”, to explore the relationship between travel demand and built environment. Finally, discover and summarize the data's supporting function to travel demand management. The study's result shows that the data of taxi-calling apps play an important role in supporting demand management policies, especially in the following three aspects: revealing the condition and pattern of traffic demand, managing travel demand combined with the built environment, and enhancing service ability in flawed public transportation planning.

Key words:

travel demand management; taxi-calling app; spatiotemporal analysis; kernel density estimation

A Case Study on the Land Use and Activity System of an Electronics Trading District, Huaqiangbei in Shenzhen, China

Lan, Tian

China Overseas Huayi Urban Planning & Design Co., Ltd (Beijing), School of Urban Planning and Design, Peking University Shenzhen Graduate School, P. R. China, 492737387@qq.com

Abstract

The nature of land use relates to activity taking place in its location. The formal land use could be easily identified, yet it fails to provide a comprehension of the city for better transport management or urban planning. Also, few research has seriously considered the functional land use rooted in the activity system. Based on a case study of a commercial district thriving on electronics trade, Huaqiangbei (华强北), a multidisciplinary perspective is employed to analyse the activity system and functional land use of the district in micro geographical scale. With information collecting from actors involved in electronic manufacturing and distribution and field observation for years, we develop a framework dedicated to examine activities and land use imprints within the district. Our study reveals that three type of functional land use in six architectural varieties (described in Fig. X.) have supported a complex activity system which determines the movement of people, good and information. We believe the study could not only illuminate the function or spatial form of a commercial district, but a strategic alternative for next step planning solution concerning liveability, safety and sustainability.

Key words:

land use; activity; commercial district; electronics trade

Consuming Air Transport: The Globalising Logistics of Airline Catering

Lin, Weiqiang

National University of Singapore, Singapore, Singapore, weiqiang@nus.edu.sg

Abstract

Geographical research has contributed much to understanding air transport as an end-product logistical service—either in ferrying passengers or goods—but seldom are the ancillary services supporting flights acknowledged for their equally important logistical role. I argue that this lacuna has resulted in an obfuscation of particular spaces of production and consumption *within* aviation that are in fact instrumental to enabling contemporary mobility and late-modern capitalism in the first place. The production of airline food is one area that warrants further examination, seeing how the catering industry has recently developed into a highly integral supply chain tethered to all flights. Likening its networks to those assembled in everyday commodities logistics, this paper analyses how the airline catering business has grown to become a highly globalised, and globally coordinated, trade that is organised, set in motion, and rendered efficient through familiar principles in logistical space-making. More specifically, what banally appears as a ‘packed lunch’ onboard an aeroplane is not some conjuration of magic, but the result of a calculated network of technologies, facilities, and managerial procedures, and international human value extractions that have increasingly spread across the globe. Reflecting on the airline catering industry in Singapore, this paper interrogates the diffused cartographies that have produced in-flight meals as an essential item of aerial sustenance, and an indispensable part of passenger air transport. It seeks to extend academic knowledges about the networked nature of airspaces, as well as the logistics of, rather than through, aeromobility.

Key words:

airline catering; logistics; air transport; aeromobility; globalisation; consumption network

Cross-Border E-Commerce (CBEC) as a New Means of Global Consumption Networks (GCN)

WANG, J. James

Department of Geography, University of Hong Kong, Hong Kong SAR, China. jwang@hku.hk

Abstract

Consumption networks have been there for long time. It consists of circulation systems that either 1) send products and goods to the (individual) consumers for (final) consumption, or 2) provide services, or move to or connect with (individual) people to consume services (such as tourism destination, gym) they demand for. GCN therefore are the consumption networks constructed for such processes at the global scale.

This paper elaborates on a new means of GCN - the cross-border e-commerce (CBEC) with focus on its development in and round China. Based on the surveys conducted in a few gateway cities in China, i.e. Tianjin, Guangzhou, Shenzhen, and Hong Kong, we argue that the new format of international trade due to the CBEC is reshaping the GCN substantially. Firms in this sector become more networked with rather than chained along other firms in the GCN. It results in both aspatial and spatial implications. The implications include but not limits to: (1) new business models of CBEC, (2) the reorganization of logistics systems due to the CBEC models, (3) the revitalization of global and local postal systems for a 'flatter' supply-demand pattern, (4) air-sea transport integration, which gives advantages to coastal cities with airport of good intercity connectivity, and (5) development of bonded warehouses at gateway cities.

Key words:

Cross-border e-commerce; global consumption networks; transportation; logistics; trade; China

Examining the Impacts of E-Retailing on Urban Logistics Parks: The Case of Shenzhen, China

XIAO Zuopeng, James J Wang

Dept of Geography, The University of Hong Kong, Hong Kong, 999077, P.R. China, tacxzp@gmail.com

Abstract

With the rise of e-retailing, the role of logistics park has been increasingly recognized as an elementary type of logistics infrastructure. The influx of huge market capitals is significantly changing the geography of logistics parks, which still have not been given sufficient academic attentions. With the case study of Shenzhen, China, the research question here is what changes e-retailing brings about on logistics park in Chinese cities. In reference to international literature, we first propose a conceptual framework about the travelling logistics park, including moving location, transitional function and the regionalism of market coverage. The sprawling distribution of logistics park from 2008 to 2013 are visualized on the basis of the dataset drawn from the Second Economic Census and open street map. Complemented by in-depth interviews with retailer, e-retailer and logistics companies, the underlying location decision of warehouse and logistics space are discerned to understand why logistics parks changes along with the e-retailing. Except for contributing to international compassion, the findings derived from this study would benefit government authorities in making new freight transport and logistics land planning.

Key words:

Logistics park; online retailing; supply chain reinvention; Shenzhen

Express Delivery Service, High Speed Transport, Spatial Friction and the Related Research Progress

LIN T

Shanghai Normal University, Shanghai, 200234, P.R. China, lin_tao@shnu.edu.cn

Abstract

With great expansion of the express companies' business volume and revenue growth, the express industry in China's logistics industry rise tremendously and become a new growth point of China's economic development in recent years. The author elaborates the the logistics and express industry development and the existing problems in China and argues that the transportation costs arising from the geographical distance has been still the main topic in the researches on the spatial friction at present. However, distance-related costs have changed across categories of production resource flows and across transport modes and /or media since 1960s. The new economics of distance is about the increasing role played by logistics management and the adjustment processes that are occurring as firms creatively seek to substitute between types of resource and between the transport modes and media for moving those resource. Therefore, the economic geographers have to expand the spatial friction researches to the supply chain complexity, transactional environment, physical environment, except from the traditional topic of transport/logistics costs. These four elements consist of logistical friction. Although the logistics friction elements could not be cut apart each other, but the element "physical environment", which includes infrastructure supply, road bottlenecks and congestion, urban density, urban adjustments, is just the topics for economic geography, transport geography and urban geography. Finally, the author reviews the related researches and put forward some scientific questions on the spatial friction mechanism for the express delivery service based on high-speed transportation network and makes a prospect for such kind of studies.

Key words:

express delivery; high-speed transportation; spatial friction

Go Beyond Port Regionalization: Co-Evolution of Gateway Ports and Intermediate Hubs

Wang, J.J, Li, J.Y

The Department of Geography, *Faculty of Social Sciences*, The University of Hong Kong, Hong Kong SAR., China,
jwang@hku.hk

Abstract

The development and changes in port hinterlands significantly influence the global freight distributions and thus reshape development paths of ports in various regions. 'Port regionalization' and 'foreland-based regionalization', as two concepts describing the evolving role of gateway ports and intermediate hubs respectively, have received considerable attention. They illustrate the emerging port hinterland and maritime hinterland dynamics in light of containerization, supply chain management, cluster of logistics firms and the setting of inland terminals. This paper expands the concepts by focusing on the shifting of intra - functional roles of a multi-gateway port system in an evolving economic and institutional system. It is argued that, going beyond the hinterland-based regionalization and the foreland-based regionalization, there is a multi-gateway ports regionalization where the gateway function and the transshipment function can be spread out among various ports. Key elements are Institutions (eg. free trade agreement, cabotage), industrial and market pattern of the hinterland, global trade and connectivity. Hong Kong, Shenzhen and Guangzhou, three key ports in the Pearl River Delta China, will be studied as an empirical illustration of the multi-gateway ports regionalization.

Key words:

Port regionalization; multi-gateway ports system; gateway port; intermediate hub

Pan-Eurasian Economic Integration Driven by Cross-Border Transport Infrastructure

Wang, J. J¹, Yau, Selina²

¹Department of Geography, Faculty of Social Sciences, The University of Hong Kong, Hong Kong SAR., China,
jwang@hku.hk

²Department of Industrial Engineering and Logistics Management, The Hong Kong University of Science and Technology,
Hong Kong SAR., China

Abstract

This paper discusses the prospect of the development framework and strategy of the One Belt One Road (The Silk Road Economic Belt and the 21st-century Maritime Silk Road) Initiatives (“OBOR Initiative”) recently advocated by People’s Republic of China. Against the backdrop of economic globalization, the OBOR Initiative aims at enhancing connectivity and cooperation primarily among Eurasian countries by focusing, inter alia, on cross-border transport infrastructure development. Given the enormous diversity of the Pan-Eurasian countries culturally, economically, politically and religiously, it is necessary and important to identify effective ways of how to push through these cross-border infrastructure-oriented programmes in order to fulfil their proposed catalytic role in boosting trade and economic growth, as well as economic integration of the region. In this paper, the critical success factors and lessons learned from failure stories of different development modes employed in the precedent cases worldwide will be analysed to help assess the opportunities and challenges of the OBOR Initiative.

Key words:

Cross-border transport infrastructure; regional economic integration

Spatial Accessibility and Heavy Goods Vehicle Traffic vs. Poland's Trade Linkages

Komornicki T.

Institute of Geography and Spatial Organization, Polish Academy of Sciences, Warsaw, Poland, t.komorn@twarda.pan.pl

Abstract

The presentation will include the results of research in regard to: a) differentiations of territorial accessibility in goods transport across Poland; b) a real and model distribution of heavy goods vehicles traffic. The analysis will be based on a modified methodology of Intermodal Transport Accessibility Index (using GIS), VISUM software, data from the latest General Traffic Census carried out in 2015, as well as data of Polish Border Guard concerning the traffic across the Polish eastern border. The study had a dynamic character, permitting to take into account effects of new infrastructure investments carried out in Poland in 2004-2015 period thanks to EU fund inflows. Against this backdrop, spatial distribution of Polish export activities by countries (trade partners) will be shown at the local level. This should allow for evaluation of relationship between infrastructure development, growth of traffic and intensification of goods exchange. Analysis will concern in the first place the trade exchange with countries located in Eastern Europe (Russia, Ukraine) as well as in Central Asia (e.g. Kazakhstan).

The findings presented above are the result of the study that was carried out within the framework of the project "Monitoring changes in traffic generating potentials and in determinant factors underpinning distribution of traffic of heavy goods vehicles transport in the road network over the 2005-2015 period". The project was financed with funds from the Polish National Science Centre, granted on the basis of decision no. 2014/13/B/HS4/03351.

The Global Network and The New Logistic System of Creative Fashion Industry on 21th century

MSc. Jeferson Rezende¹, MSc. Alexandre Pires¹, PhD Prof. Amália Lemos²

¹PhD Candidate at Department of Geography – University of São Paulo, Brazil, jeferson.rezende@usp.br

²Professor at Department of Geography – University of São Paulo, Brazil

Abstract

Nowadays the textile sector figure among the top five contemporary industrial activities, and what named creative fashion industry generates billions of euros annually within the global economy (IEMI, 2013).

According Frédéric Godart, from this point of view “Geography plays a crucial role in the fashion industry [currently], specifically when we regarding outsourcing” (2014). The effects of globalization process and technological advances not only decreased the distances as favored greater integration between flows and fixed in a complex network that connects local production realities and distribution to global consumption demands (CASTELLS, 1999; CARRERAS, 2003), which also brings it even closer to a production model based on the cycle “CONSUMPTION → PRODUCTION → CONSUMPTION” (REZENDE, 2014), which among other consequences added new “knots” in the Network of Creative Fashion Industry.

In contemporary times, under the aegis of globalization and influenced by the passage of an industrial economic model for the flexible accumulation (Financial System), we observed that the Creative Industry of Fashion, adherent to the Upper Circuit of the economy (SANTOS, 1979) has readjusted by adapting itself to the new realities and global requirements, inclusive of the logistical point of view and the transport systems required.

Our main objective is to identify and analyze what are the Challenges and impacts of globalization and outsourcing requires and offer the current distribution chain of creative fashion industry in its new productive ways, mapping the new realities of production, transport routes and distribution channels in creative fashion industry in the 21th century.

Key words:

Creative Fashion Industry; Global Network; Logistical System; Transports; Outsourcing; Consumption

Towards Short Supply Chains in the Global Food Consumption Network: A Comparative Study of China and Europe

Tiffany Tsui

PhD Candidate Wageningen University, Netherlands, tiffany.tsui@matrion.nl

Abstract

With continued economic growth and urbanisation, providing safe and high quality food holds the key to the 'new normal' of the Chinese economy in the coming decades. High quality food supply chain and logistics are the major areas to benefit from increasing global and domestic investments. Globally, the food distribution/consumption network is increasingly spanning greater distances, with higher demand for transport, and hence higher environmental pollution. The rising demand in China will no doubt have further significant impact on the geography of food at the global level. In order to foster sustainability and resilience in the urban food systems worldwide, there is an urgent need to shorten food supply chains. This would include maximizing the production of food in peri-urban areas, by developing green port polycentric systems that ensure innovative and sustainable production as well as developing sustainable trade alliances and policies at national and international level. This study compares the geography of agro-logistics clusters and networks of The Netherlands with China to shed light on how an integrated system of food clusters and transport networks connecting urban clusters can optimize supply chain efficiency, reduce burden on the environment, and foster urban resilience.

Key words:

Geography of logistics networks; Global Consumption Network; Urban Resilience

Trade and Low Temperature Logistics between Taiwan and Mainland

Zhuo Chen

Department of Geography of University of Illinois, Champaign, U.S.A, zchen136@illinois.edu

Abstract

International trade is often symbolized by container boxes and giant ships. Trade of tangible goods is an important part of international trade, but is only a primary stage. Trade of services is a higher stage, and trade of ideas is even one stage higher. In this article, I want to demonstrate that low temperature logistics take part in all three stages above. First low temperature logistics increase the trade of agricultural goods from Taiwan to mainland since 2009. Second logistic services themselves become an object of trade, and finally technological and managerial knowledge spreads by means of industrial cooperation. This process is illustrated through a case study of the Tianjin-Taiwan low temperature logistics cooperation plan. I draw a conclusion that all three stages of trade are beneficial to both Taiwan and mainland, and the last two stages are the most nutritious in driving upgrades for mainland logistics providers.

Key words:

Trade; Low temperature logistics; Taiwan

Urbanization and Access to Basic Amenities in Association with Development of Transport Network in Rajasthan

JANU. Anushree, GUHA. Pallabi

Research Scholars, Centre for the Study of Regional Development, School of Social Sciences, Jawaharlal Nehru University. New Delhi 110067, India, jnuanu@gmail.com

Abstract

Rajasthan is one of the backward states in terms of development and urbanisation. Ever since independence urbanisation pace has been slow and concentrated in pockets. Development in terms of human as well as economic has closely been associated with urban centres, while most of the rural part remains deprived. Geographical impediments such as isolation from the mainland, arid climate has also contributed to its uneven development.

Development in terms of access to basic amenities such as proper housing, electricity, drinking water, sanitation and cooking fuel are more closely associated with socio economic status and proximity to urban centres. In case of Rajasthan, access to basic amenities is better in large urban centres having good connectivity in comparison to small towns and cities or rural areas with poor connectivity.

In this paper attempt has been made to establish a relationship between transport network and access to basic amenities among the urban centres across various sizes over a period of time. An index of basic amenities is to be computed using indicators such as housing, sanitation, drinking water, electricity and cooking fuel. Another index indicating connectivity of the urban centre is to be computed and used for comparison to see how accesses to basic amenities have differed across the state with respect to connectivity. The spatial variation is to be mapped and compared over last decade. A comparison would be made as to how the relationship between transport network and access to basic amenities has differed across space.

Key words:

basic amenities; transport network; connectivity; urbanisation; development

Geography of International Trade, Maritime Transport and Climate Change in XXI Century: A Descriptive Basis for Multilateral Action

Tancredi, E

National University of Lujan, (6700) Lujan, Buenos Aires Argentina, eldatancredi1@gmail.com

Abstract

This presentation will describe the relationship among the main tendencies of the international trade of goods, the characteristics of seaborne trade and the challenges of climate change. In this XXI century, three economic characteristics can be pointed out: a significant expansion of global value chains as a new form of disintegration and de-localization of the production of goods and services; the deepening of the regional integration and cooperation South-South; and the resulting exponential growth of commercial exchanges. In this context, 80% of the world trade is carried out by maritime mean; supply places have been diversified due to technological improvements and transport efficiency; and marine routes have been enlarged and new ones opened. In terms of CO₂ emissions/ transported ton, marine transport is the more effective one. Nevertheless, due its enormous scale, it is estimated that ship emissions (especially from oil-tankers and container ships) represent 11,8% of the emissions of the transport sector and 1,6 to 4,1% of the CO₂ world emissions resulting from burning. As world seaborne trade increases, one of main challenges – from the perspective of a social and environmentally sustainable development, as well as from the point of view of the transport and trade facilitation – consist in reducing the GHG (mainly CO₂) emissions from international shipping and define mitigation and adaptation policies. In summary, the sector of marine transport needs to redefine strategies to adapt not only to the changes of the world economy and rules of the trade, but risks and current environmental uncertainties as well.

Key words:

Geography of trade; climate change challenges; seaborne trade patterns

The Prospects of the Iraqi Railways

MOHANAD HAMMAD

Laboratory ENeC UMR 8185 Paris-Sorbonne University, France, mohanad_france@yahoo.fr

Abstract

The rail transport is one of the most important and vital activities of the transport sector, whether it be for passengers or freight. The rail transport, especially for freight, has a high capacity for transportation over long distances and for relatively appropriate costs, compared to other means of transportation.

In 2015, Iraq had 2370 km of rail lengths, 1922 km (81%) of which are main railway lines, whereas the remaining is all sub-lines.

The Iraqi railways have always had an important role in the Iraqi economy since established by the British army. It has always been a principal means of transport of passengers and freight across Iraq; where it constituted approximately 30% of the volume of traffic in Iraq.

In the nineteen eighties, the rail activity deteriorated as a result of the war with Iran. In the nineties, the usage of railways diminished due to the economic blockade imposed on Iraq, especially for freight transport. After the war had ended, the Iraqi rail authorities attempted to rehabilitate the rail sector. Many problems remained.

Besides, the railway network does not crisscross all the Iraqi regions; it is limited to only some of them. Moreover, it is not connected to the neighboring countries. Thus, this research attempts to highlight all problems and obstacles facing the Iraqi rail sector.

The research aims at discussing the current status of the Iraqi railways and studying the prospects of the rail transport across all the Iraqi regions. Besides, it discusses the usage of high-speed railway lines with the aim of developing the road transport sector for its significant role in realizing the spatial development of the Iraqi economy. Moreover, it studies the means of connecting the Iraqi rail with the neighboring countries and its openness to the rest of the Middle East for its great significance for the future of Iraq.

Transport; Railway; Iraq; Development

Under "One Belt and One Road", Guangzhou'S Development Strategy Analysis of Transport and Logistics Industry

Luo Weijie

Guangzhou university, Guangzhou, 510000, P. R. China, 474828815@qq.com

Abstract

Combined with the latest policy "One Belt and One Road ", analysis Guangzhou's background in the development of transportation and logistics industry. Clearly the position and the role of the region of Guangzhou, and also clear its own geographical conditions, "One Belt and One Road "at the national level and the importance of the development potential in the future. Based on the "One Belt and One Road " policy environment and combined with the historical conditions and present situation of Guangzhou, analysis Guangzhou's development opportunities and issues of transport and logistics industry. Based on the above situation, combined with the policy advantages, and the geographical advantages, on the basis of strengthening the "hardware" and "software ", seeking the cooperation with more countries and regions. AS for the idea: "promote status by self-improvement, seek development by cooperation ", to build Guangzhou to become the world first-class transport hub and logistics center.

Abstract

Although there exist numerous urban growth models, most have significant data input requirements, limiting their utility in a developing world context. Yet, it is precisely in developing world where there is an urgent need for urban growth models since most expected urban growth in next two decades will occur in such countries and regions. Central Asia covers an area of 3,994,300 square kilometers which includes some of the most sparsely populated regions in the world. Its population of only 61 million people includes more than 100 different ethnic groups. In this study, urban area in Central Asia was analyzed using remote sensing and GIS. Utilizing binary urban/nonurban maps generated by MODIS and DMSP-OLS. Our model can inform urban planners and policy makers about the most probable locations and periods of future urban land cover change. Urban development was achieving momentum in Central Asia. The MODIS and nighttime light data have many advantages, such as high time resolution, continuity and low cost. It should be very useful to detect larger scale dynamics of environmental changes.

Capital Cities Role in Nation-Building: Genesis, Social Constructivism, Typology

Igor Okunev

Ph.D., Moscow State Institute of International Relations, Russia

Abstract

Two major territorial bases of stateness are traditionally singled out: nation-building and threats to security or, in other words, mental boundaries marking of “Us” community and actualization of “Others”. Contemporary political geography is turning to the study of the third mechanism – internal “Other”. Interregional differentiation within a state through establishing and maintaining mental boundaries between center and periphery is the mechanism to detect the territories needing the support for preserving the compliance with national norms and, thereafter, maintaining stateness.

Two strategies are possible to prove that interregional differentiation is a mechanism of nation-building. Analysis of different discursive and institutional practices marginalizing regions would be logical. However, such way leads us to the large number of cases differing from each other in the multitude of variables and, therefore, exclude generalization in the conclusions. Thereupon we consider it possible to address another strategy, such as the search for evidence that center is purposefully opposed to periphery and is given symbolic national and centrifugal functions as well as administrative ones. The existence of one dichotomic pole should confirm the existence of the opposite.

Our research makes an attempt to analyze an institute of capitals at functional as well as symbolic levels. In that case capitals serve not only as a place to dispose the governmental bodies, but their functions include national representation to themselves and the environment. Capitals are the idealized image of nation and national history, a sort of nation in miniature. That should verify the assumption that an additional mechanism of nation-building exists and is demonstrated by the creation of ideal national image and opposing it to peripheral marginality.

Key words:

capital city; nation-building; critical geopolitics

Centrality and Spatial Structure of China's Airline Network

Xiande Li

Department of Geography, Shanghai Normal University, Shanghai, 200234, P. R. China, lixiande2007@163.com

Abstract

Airline network is one of the cornerstones of urban network. This study uses the weekly flights between China's 156 cities to measure the centrality of China's urban system. The following is the finding of this study. (1) Beijing, Shanghai and Guangzhou are national hub of Chinese airline network. (2) Chengdu, Kunming and Urumqi city are the regional hub of Chinese airline network. (3) Beijing –Tianjin-Tang Region the Pearl River Delta Region and Yangtze River Delta Region have close air links between each other. (4) The administrative level, the level of economic development and the development level of tourism industry are the important factors that affect the structure of China's airline network.

²School of Architecture and Urban Planning, Huazhong University of Science & Technology, Wuhan 430074

³School of Geographical Sciences, Nanjing Normal University, Nanjing 210023

Abstract

By Mann-Kendall analysis, it is revealed that Chinese urbanization process has undergone two stages, each coinciding with a certain period of China's economic development. In the first stage, the dynamic mechanism of urbanization lay in the surplus labor force in the countryside and the ever-increasing demand of labor force driven by urban economic development in the urban areas; By contrast, the second stage saw some new driving forces, such as FDI, open policies and booming local development initiatives. Aiming to generate further insight into Chinese urbanization mechanism, this paper presents a dynamic framework, and based on it a new system dynamic model simulating Chinese urbanization process from 2015 to 2050. By comparing the simulated results against historical data of Chinese urbanisation, the SD model is proved stable and reliable. Through sensitivity analysis, it is found that Chinese urbanization is sensitive to the change of labor productivity in primary industry, birth rate of rural population, education level and growth rate of tertiary industry. In the scenario analysis section, different combinations of GDP growth rate and family plan are explored. The results show that China's urbanisation rate will reach at least 70% in 2035 and 75% in 2050, regardless of which economic development (6.5%-7.5% GDP growth rate) scheme and family plan (one or two children) policy are to be implemented. Even though the results indicate that population policy has more significant influence upon Chinese urbanization rate, it should not be overlooked that the dynamic mechanism of Chinese urbanization is always multi-dimensional at multiple levels.

City Network Structure of Chinese Urban Agglomeration: Perspective of Intro-connection within Top 500 MNCs in China

Xinzheng Zhao, Mengxue Li, Qiuping Li, Chang'an Feng, Tongsheng Li

College of Urban and Environmental Science, North West University, Xi'an, 710127, P. R. China, xzzhao@nwu.edu.cn

Abstract

Space of Flows as well as World City Network research attract more and more scholars' attention in City-Region study area, which leads to the shift of research paradigm from urban hierarchy analysis to urban network analysis. It is a frontier and hot research topic to analyze the City-Region spatial organization based on the enterprise network. Based on the Top 500 MNCs in China, we examined the network structure of three Chinese urban agglomerations in Yangtze River Delta region, Pearl River Delta region and Beijing-Tianjin-Hebei region. Finally, three typical network structure were found, including Monocentric and Multiple levels network structure in YRD, Double Centric and Bipolar network structure in BTH, as well as Polycentric and Multiple levels network structure in PRD. Moreover, significant Path Dependence and Domain Lock were concluded after the influence factor analysis of the city network evolution.

Key words:

City network structure; Urban agglomeration; Path Dependence; Domain Lock

Development of an Integrated Land-use Transport Model for Urban Activity

Distribution

NIU Fangqu

Key Laboratory of Regional Sustainable Development Modeling, CAS, Beijing 100101, China, Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing 100101, China. niufq@igsnrr.ac.cn

Abstract

A land use/transport interaction model (LUTI) is developed for Chinese city regions and used to model the evolution of urban activity distribution, and predict urban spatial development trends in the Beijing metropolitan area. The model consists of a transport sub-model, a residential location model, an employment location model, and an implicit real estate rent adjustment model. The model is used to predict the 2025 distribution of urban activities by type under current land use policies. Urban activities are combined into two groups (households and employment) and the distribution of these two activities is forecasted. The study shows more and more population and businesses are choosing to locate on the outskirts of Beijing, which is consistent with the objective to decentralize activities from the central urban area. The ways in which the model can be developed to provide a richer framework for analyses of the impact of planning strategies on the evolution of the spatial structure of urban areas is also considered, paying particular attention to the modelling of different socio-economic groups, different industries, and a variety of modes of transport. For these reasons this study is the first step in a program of work on the development of LUTI models and other mathematical models for examining urban spatial evolution and supporting the sustainable development of Chinese cities.

Evolution Process of Urban Spatial Pattern in Hubei Province Based on DMSP/OLS Nighttime Light Data

ZHENG Wensheng^{1, 2}, RUN Jiying³, ZHUO Rongrong^{1, 2}, JIANG Yupei^{1, 2}, WANG Xiaofang^{1, 2}

1Key Laboratory for Geographical Process Analysis & Simulation, Hubei Province, Central China Normal University, Wuhan 430079, China

2Academy of Wuhan Metropolitan Area, Hubei Development and Reform Commission & Central China Normal University, Wuhan 430079, China; 3. Chongqing Geomatics Center, Chongqing 401121, China

Abstract

This paper intends to investigate the urban spatial patterns of Hubei Province and its evolution from three different perspectives: urban nodes, urban connections and urban clusters. The research adopts nighttime light imagery of cities in Hubei Province, the viewpoint of “point-axis-area” in the “point-axis system” theory, and employs light index model, gravity model and social network analysis. The findings are as follows: 1) In terms of urban nodes, the urbanization process of Hubei has been carried out mainly on the basis of external expansion rather than internal increasing. The polarization trend of urban connection network is strengthening. 2) As for urban connections, the estimation of urban connections using light index model is capable of containing various actual flow, and the connections are getting increasingly closer. 3) In regard to urban groups, seven urban groups of varying sizes have formed. On that basis, three stable and relatively independent urban groups as the centers, namely Wuchang, Yichang and Xiangyang emerge as well. But the structures of “Wuhan metropolitan area”, “Yichang-Jingzhou-Jingmen city group” and “Xiangyang-Shiyan-Suizhou city group”, which are defined by local development strategy in Hubei Province, are different from the above three urban groups.

Extended Metropolitan Development in Southeast Asia: From Primate Cities to Territorial Urban Diffusion

Goldblum, C.¹, Wong, T-C.²

¹University of Paris 8, Saint Denis, 93526, France, charles.goldblum@wanadoo.fr

²Guizhou University of Finance and Economics, Guiyang, 550025, China

Abstract

Primate cities in Southeast Asia, primarily a Western colonization product have evolved from port cities to metropolitan development since World War II. Their growth was mainly attributable to high post-war population growth, massive rural-urban migration, and export-led industrialization and agglomeration effects accelerated by global linkages. Spatial effects of globalization impacts used to be more substantial in more internationally integrated market economies (Singapore, Malaysia, Thailand, Indonesia, Indonesia), but they have now penetrated also the transitional economies (Vietnam, Cambodia, Laos and Myanmar). Our aim in this paper is to revisit the theoretical debate whether primate city regions have grown “too big” as well as reassess the question of equilibrium city size in the context of decentralization and regional integration strategies - namely through extensive physical infrastructure networks - in the new ASEAN (Association of Southeast Asian Nations) framework. Other issues such as the characteristics of the Southeast Asian primate cities in the urbanization process, their major development trends in the twenty-first century and the ways in which they have responded to the territorial impacts of globalization are also addressed.

Key words:

Primate city; metropolitan development; Southeast Asia; urbanization; foreign investment; agglomeration effects

Factors of The Choice Behavior of Supporting Model for The Aged Based on The Living Arrangement in Urban China – The Case of Chengdu City

Yongchun Yang

College of resources and environment of Lanzhou University, The Environment, Key Laboratory of Education Ministry in West China, Lanzhou 730000, yangych@lzu.edu.cn

Abstract

The choice behavior of supporting model for the aged is more complex than Western countries, under the multiple effects of the unique market economy, the traditional distribution system and sociocultural factors, Particular model of “old-age supporting - living arrangement” emerged: ①One family live together; ②Two family but live together; ③One family but live separately; ④ Two family and live separately, and three old-age supporting models formed on this basis: ① relying on their offspring; ② relying on the elderly house; ③relying on themselves. Information of choice on supporting mode of the aged are gotten vial large depth interview and social investigation are used in this article, the method of discriminant analysis and binary logistic regression are used, attributes of the choice behavior of supporting model for the aged based on the living arrangement in urban China are discussed. The investigating finds that supporting the life after retirement relying on themselves predominates. Researches shows: ① attributes of the choice of relying on themselves are: have a spouse, either they or their spouse have the property of the house, higher education level, like private space, near their relatives and friends. ②attributes of the choice of relying on the elderly house are: only children, age, higher education level, either they or their spouse bear all the cost of living, habits and customs are different from children. ③attributes of the choice of relying on their offspring are: near from their children, have the willing to live together with their children, help children with caring kids, adapt to their present life, like the big family, near their friends and relatives.

How Are the Neo-Liberalism Urban Policies Affecting the Growth and Shrinkage of China's Cities since 2008?

YU Taofang

Dept. of Urban Planning, Tsinghua University, Beijing, 100084, P. R. China, yutaofang@tsinghua.edu.cn

Abstract

Since the late 20th century, China has undergone some called neo-liberalism turn in urban planning policies which deeply influenced the pattern and transformation of national urbanization. In this process, production factors were re-distributed across different regions, different scaled cities, etc, driven by increasing intertwined globalization, regionalization and industrialization. As a result, on the one hand, some areas were experiencing rapid growth as economic motors, which gradually emerging as competitive Mega Cities or Mega City-Regions. On the other hand, some areas have to face the realities of Decline or Shrinkage, with the loss of total population and employment at the same time. Although at the same time, the central government and the local government have adopted some policies for tackling with these issues. Since 2008, the world is undergoing a new round of large-scale economic crisis. As other countries, the Chinese government has also experienced many theoretical and practical attempts to fight with the global economic crisis and domestic economic overheating. How are the different urban planning policies affecting the Growth and Shrinkage of China's Cities since 2008? Based the reviews on urban growth and shrinkage research, this paper analyzes the shrinkage and growth of China's cities at the county-level national wide with the data from the 5th and 6th national census. And then, the changes processes of China's cities are analyzed since 2008, with highlights on typical areas and functional specialization. The final part is about the mechanisms of these new trends from the neo-liberalism urban planning policy models.

Key words:

Economics Crisis; Neo-liberal urban planning; Urban Growth; Urban Shrinkage

ITP Urban Systems: Cities' Evolution in The Worldwide Urban System: Combining Demographic and Economic Typology

Rozenblat C.

University of Lausanne, Switzerland, Celine.rozenblat@unil.ch

Abstract

Despite cities' evolutions in the world depend on uneven local contexts rendering difficult to specify a global new 'urban age', some universal urban processes can help to understand, compare and forecast urbanization features in different parts of the world (Scott & Storper, 2015). In fact, identifying dynamic processes in reaction to the globalization trends may situate the evolution of each city in the systems of cities to which it participates.

The paper assumes that the systemic approach of urban systems (Pred, 1977) enables going beyond difficulties in qualifying the 'urban age'. The paper will classify different trends in the contemporary worldwide urbanization processes by identifying the cities' evolution all along the hierarchical organization of their national and continental urban systems. The measurement of cities' similarities will be undertaken by combining two means:

- 1- the 1950-2015 relative trajectories of cities population (UN Urban prospect, 2014);
- 2- the evolution of each city's functions in the worldwide division of labor organized inside the 3,000 worldwide first multinational firms' subsidiaries networks between 2006 and 2016.

The resulting double typology allows qualifying generations of urban systems and evaluating the role of path dependence, economic development and urban policies in the contemporary urban issues that different parts of the world are facing. This approach brings a constructive answer to the large debate on the general theoretical nature of cities initiated by Brenner & Schmidt (2014).

Key words:

Urban systems; World; cities' trajectories; population; world division of labor

ITP Urban Systems: The Chinese Urban System

Liao Liao¹, Elfie Swerts²

¹Institut des Sciences Politiques d'Aix en Provence, l_liao@hotmail.com

²University of Lausanne, Switzerland

Abstract

The phenomenal speed of cities growth, their high density and their three-dimensional development characterize the Chinese on going urbanization process. This strong and recent urban growth leads the Chinese urbanization rate to 53.7% in 2013 (National Bureau of Statistics of China, 2013). The strong growth of Chinese small towns and the low trend of the hierarchization process of the system, which is unique in the World, show the weight of the political control on the evolution of the system. This is explained by the profound links between the evolution between the Chinese urban system and the administrative system. Particularly, the successive decentralization reforms have strongly influenced the development of the prefecture level cities and of the smallest ones, the district level cities. Moreover, due to the economic specialization of cities and the advantage of SEZ policies, the eastern and central cities have been steadily developed during the past decades, contrary to the Western and Northern cities, located close to minerals sites.

In this context, the main issue of our paper is to test if 40 years of strong political control has profoundly transformed the Chinese urban system. The approach will compare the theoretical corpus of universal processes and typical historical trajectories of urban systems with the Chinese urbanization processes. It will reveal in which extent some universal dynamic trends combine with specific Chinese features.

Key words:

Chinese urban system; urbanization

³French Institute of Pondicherry, India

Abstract

Despite a huge urban population of 380 million inhabitants and a very long urban history, India is still predominantly a rural country characterized by a slow rate of urbanization (31% in 2011) whilst hosting among the biggest metropolises of the World. The country experiments economic transition and political and territorial regionalization since the 1960 independence. In this context, the Indian system of cities questions the trends currently associated to the urban transition, in particular in term of hierarchical and spatial repartition of population and economic growth among the urban localities. We assume that the particular inherited shape of the Indian urban system combined with the regional policies developed since 1960, create some very specific evolutionary features of the cities' system.

The paper will assess how the urban transition impacts the demographic and economic evolution of the Indian urban System. It will show how, in a context of a slow urban transition, the demographic and economic growth is distributed among the Indian cities whatever their size, underlying that the million plus cities are not the only ones driving the Indian urbanization. Some very dynamic small towns appear on the frontline of the transition process as places, which accommodate a higher share of non-regular workers than larger cities. They constitute localities where people create non-farm activities and access to resources. While the cities' demographic trajectories are not very tiered, typologies made on the economic specialization of Indian cities reveal strong regional differentiation.

Key words:

India; urbanization

[ITP Urban Systems] The Sustainability of Urbanization in Africa's Great Lakes

Region: Trends and Policies Options

Sietchiping, R; Ngomsi, C; Kinyanjui, M; Omwamba, J and Velasquez, E

United Nations Human Settlements Programme (UN-Habitat), Nairobi Kenya, michael.kinyanjui@unhabitat.org

Abstract

Urban transition from 2014 to 2050 around the world would not be at the same rate and stage if the current situation remain constant. East African Countries, parts of the African Great Lakes region are among the least urbanized and most likely to keep their position in 2050. Their conditions for sustainable urban transition analyzed in this paper indicate inadequate connectivity, negatively affecting living conditions and limiting distribution of goods. Based on literature review and observations of recent urban policy statements and development discourses from governments, the paper attempts to demonstrate that there is need for effective and pragmatic political will at national and city levels and fair engagement of private investors and individuals to create an enabling environment for urbanization that will be beneficial to the current and future generations. The authors argue that to achieve sustainable urbanization in the region there is need for better policy frameworks for efficient corridors transportation network development and formulation of adequate development vision to ensure inclusive urban transition, incremental industrialization of economies with a focus on countries' specialization and management of proactive social and environmental investments for the benefit of all.

Key words:

African Great Lakes region; transport corridors; connectivity; migration; urban systems

Dilemma of Ageing in Cities Planning of Elderly Care (EC) Facilities Based on Multi-Level Needs of Older Urban Residents in Beijing

Xiaolu GAO¹, Bingqiu YAN^{1,2}, Zening XU^{1,3}, Xingchen Liu¹, Xizhe Wang⁴

¹Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, P. R. China, gaoxl@igsnr.ac.cn

³University of Chinese Academy of Sciences, Beijing 100049

⁴Longhua Institute of Technology, Taiwan, China

Abstract

How to respond to people's physical, social and emotional needs in the ageing process is the key to planning of elderly care (EC) facilities. At present, the EC facilities in Beijing have an average vacancy rate of 40% due to mismatch of service delivery and the true demand of people. The lack of appropriate knowledge on older people's needs and overlooking the important role of public planning partly correspond to this fact. Based on survey in eight different types of urban communities in Beijing, this study established a conjoint analysis model and investigated the preference of the elderly for EC facilities in terms of public or private operators, service level and environmental qualities, location, and charges. It clarified that, (1) about 40% of the old people preferred public facilities, and that 70% preferred a monthly expenditure of no more than 2000 RMB. Preferably, two-third of the beds at high-end private facilities should be in suburban areas and one-third in inner city areas. (2) In addition, the preference of the elderly significantly differed across communities, depending closely on the social, cultural and institutional context of various communities. Based on these results, we evaluate the spatial distribution of EC facilities in Beijing based on people's multi-level needs. From the perspective of spatial planning and the purpose of ensuring the optimal use of limited social resources, over-facilitated and under-facilitated areas are identified, and policy suggestions to bridge the gap of EC supply and actual needs are proposed, such as controls over the new provision of public and private facilities, appropriate standard, service delivery pattern, and spatial distribution.

Key words:

elderly care facility; community environment; spatial planning

Spatial Diversity and evolutionary character of Urban Logistic Along the “Silk Road Economic belt” (China)

LEI Jun, QI Shengda

Xinjiang Institute of Ecology and Geography, Chinese Academy of Sciences, Urumqi 830011, Xinjiang, China

Abstract

The “Silk Road Economic Belt” is not only a new strategy for China’s opening up to the Western world but also an initiative to the requirement of regional economic integration in Asia and Europe in addition to the globalization of the world economy. The developing level of urban logistics is an important sign to measure the level of regional development. This paper analyses the spatial organization and the evolution process of urban logistics by calculating the Gini coefficient, gravity and location quotient of node cities along the Silk-road Economic Belt (China). Through this research, we can find: ①The comprehensive competitiveness of regional logistics industry between provinces is getting gradually expanding with a pattern of multicenter hierarchical diffusion. ②The characteristics of the spatial distribution of regional logistics industry is significantly in different part of China. There is a positive correlation between the developing level of regional logistics industry and economic. ③The quantity of logistics parks appear gradient relationship, and establish its own system. ④Urban logistics distribution is relatively concentrated and agglomeration trends change from strong to weak. ⑤The one-area and two-group structure of urban logistics industry is further improved. And the differences of agglomeration degree between provinces are expanding. ⑥An integrated network of urban logistics has come into being.

Urban logistics industry; spatial organization; The Silk-road Economic Belt (China)

Spatiotemporal Analysis of Land Use Change and Green Spaces Index

Poonam Sharma

Bhagat Singh College, University of Delhi, Delhi, 110017, poonamsharma299@gmail.com

Abstract

Cities are complex and dynamic systems that constitute a significant challenge to urban planning. Urban environmental quality is influenced by several aspects, including its geographical configuration, the scale and nature of human activities occurring and environmental impacts generated. Cities have transformed into complex and dynamic systems that constitute a significant challenge to urban planning. Cities and their sustainability are often discussed together as the cities stand confronted with numerous sustainability issues with the world becoming increasingly urbanized as the cities are situated in the mesh of global networks in multiple senses. The increasing size of the built area up due to growing population pressure and economic growth have caused massive Landuse/Land cover change through encroaching the surrounding area which lead to loss of forest and agricultural land etc. To enhance the decision making process in urban planning, a detailed and real world depiction of these urban spaces is the need of the hour. Monitoring indicators of key processes in land use and economic development is essential for evaluating policy measures. a rapid transformed urban setting plays a crucial role to change the green area of natural habitats. To examine the pattern of urban growth and to measure the Landuse/Landcover change in Gurgaon in Haryana, India through integration of Geo-spatial technique is attempted in the research paper.

Key words:

Urban environmental quality; economic development; urban planning; green spaces index; geospatial techniques

Spatiotemporal Analysis of Quality of Life of Urban Residents in Haikou, Hainan

Province

MEI Lin, CHENG Ye-qing

College of Geography and Environmental Science, Hainan Normal University, Haikou, Hainan, 571158, P.R. China,
meil92@163.com

Abstract

To tackle the issues concerning urban-rural areas, the central government of China initiated a new strategy called 'the New-type Urbanization'. As an important indicator to measure the process of new type of urbanization, the quality of life (QOL) of the residents has attracted considerable attention from both the scholars and Chinese government. For better understanding its actual process and effect, this paper taking Haikou as an example, analyzes the spatiotemporal dynamic of the quality of life of the urban residents. Firstly, we establish a comprehensive index system including education, employment and social security to measure the QOL. Finally, we adopt exploratory spatial data analysis and multivariable linear regression model to examine the spatiotemporal dynamic and its driving factors of QOL of the urban residents in Haikou, Hainan province. Aiming at provide scientifically reference for policy made and the construction of new-type urbanization in Haikou, Hainan province.

Key words:

Haikou; QOL index; multi-linear regression model; driving factors

Spatiotemporal Analysis of the relationship between Urbanization and Urban Poverty in India: A New Perspective

Jha, Darshan Kumar and Tripathi, V.K.

Department of Geography, Banaras Hindu University, Varanasi, India, darshanjha@gmail.com

Abstract

This paper is an attempt to present a new perspective on relationship between urbanization and urban poverty using official data. The urban transition places cities and towns at the centre of India's development strategy. It has been argued that high rate of urbanization is closely associated with accelerated urban poverty. During the seventies and early eighties, the percentage of people below the poverty line (as estimated by the planning commission) was less in urban areas than their rural counterpart. The scenario, however, changed in late eighties as quick urbanization started to bring a larger part of the poverty into the cities. This urbanization of poverty is a structural trend embodied in the sprawling urban slums. But the argument is only partially true. Analysis of data presents an interesting result that more urbanized states have less share of urban poverty and vice-versa. The paper reveals that the regional variations in the distribution of urban poverty are significant. It also presents a new perspective that urbanization and urban poverty are inversely related. The paper also analyzes the trend and spatial pattern of urban poverty in India. Discussion starts with urbanization process and its trend in India as well as the trend of urban poverty. The paper also identifies future research scope related to complex relationship between urbanization and urban poverty.

Key Words:

The Brazilian Urban System

Ignazzi CA, Machado RP

University of Paris 1, CNRS-Paris France, University of São Paulo, antonio.ignazzi@parisgeo.cnrs.fr

Abstract

Recent trends in Brazilian regional development, particularly in relation to changes in the pattern of regional concentration of production activities and in regional economic specializations, have been the subject of debate among researchers.

This work investigates these trends, seeking to address together the issues of concentration and specialization, based on indicators of formal employment during the period 2000/2010. A large group of selected municipalities is analyzed: those with more than 10,000 inhabitants in 2010, corresponding to 2615 agglomerations between *municípios* and metropolitan areas in Brazil.

The methodology used for the analysis at the city level involves collecting and analyzing data on the number of regular employees in all selected cities. Database used for obtaining this information has been formulated using the Annual Report of Social Information (*RAIS*). The results are analyzed by means of different kinds of software in order to perform robust statistical investigation, mainly Principal Components Analysis and Ascending Hierarchical Clustering in order to give a broad overview of functional specialization of Brazilian agglomerations in five sectors of economic activity revealing the disparities present in an urban system distinguished by a huge territory.

Social and employment issues affecting differently the different parts of the country, have been examined in the light of the current policies adopted to redistribute resources and improve social conditions such as the conditional cash transfer program *Bolsa família* for reducing poverty and inequality and the initiative *minha casa minha vida* aiming to facilitating the access of Brazilian households in purchasing their first home.

The Clustering of Cities in China Based on Flows of Aggregated Massive Positioning Data

Dong LI, Menghe WU, Bingruo DUAN

Beijing Tsinghua Tongheng Urban Planning & Design Institute, Beijing, 100085, P. R. China, lidong@thupdi.com

Abstract

The world is becoming linked more and more. A shift of researching focus can be observed recently, from 'city as a system' to 'systems of cities', given the context of fast changing communicating technologies such as high-speed railways (physical) as well as social medias over internet (non-physical). Flows play essential role within the city network, describing the position and functions of each city and their changing trends. In this study, we adopted a new type of aggregated positioning data of massive internet users in China to explore the spatial patterns of cities measured by people's movements during the Spring Festival in 2015. By introducing new analyzing algorithm on spatially embodied network, models outputted hierarchic results with vary regional zones containing different number of cities. The higher layer of results with less members were not similar to the traditional simple delineation of China regions based on the distance to the eastern coast, nor the lower results with more members to the administrative boundaries like provinces. Nevertheless, the very differences suggested hidden forces driving cities connected intensely across the administrative boundaries such as sharing mutual regional cultures or employment markets. These facts grounded for a general picture for the study on polycentric urban regions over the whole national territory.

The Development and Locational Change of High-grade Supermarkets in Tokyo Metropolitan Area

KAMMURA, Hiroaki

Postdoctoral Research Fellow, the University of Tokyo, Tokyo, 153-8902, JAPAN. kanmura@humgeo.c.u-tokyo.ac.jp

Abstract

With the increase of the purchasing power of people through economic growth, the type of retail business has become varied. Among them, supermarket is one of the major retail businesses, and its development process and locational change have been discussed. But, as the customer needs become fragmented, new type of supermarkets, which is middle or small size and more specialized, expanded in recent years. This presentation focuses on the Japanese High-grade supermarkets (HGSs), and would discuss its development process and the locational change of them. Study area of this presentation is Tokyo Metropolitan Area. The HGSs in Tokyo originally operate one or a few stores near high-class residential areas. For corresponding to customer needs, these stores sell specialty food products, especially wines and cheeses, which are more expensive and rarer than that of other supermarkets. But recently, some of the HGSs rapidly expand its stores across Tokyo, not only near high class residential areas, but in commercial buildings near main stations or station buildings, department stores. This expansion is caused by three reasons. One is that Japanese major retail companies have acquired HGSs since 2000s. Second is the recent development of commercial buildings by railway companies. Third is the rise of customer needs that they want to buy specialty products, especially they are particular about its taste. It would be said that HGSs developed its stores along with the change of socio-economic conditions.

The Hinterworlds of the Main Cities in China Based on the City Interlocking

Network

Li Tao

Urban Development Institute of Fudan University, School of Social Development and Public Policy, Fudan University, Shanghai, 200433, P. R. China, 466695659@qq.com

Abstract

From the perspective of the city interlocking network, this paper uses approaches of the measurement of Connectivity and the measurement of relative Connectivity to examine the hinterworlds of the main cities in mainland China. It is found that the network structure could be revealed through the measurement of Connectivity but the relative weak connections would be omitted. Administrative economy and cross-border connections could be examined deeply through the measurement of relative Connectivity especially to those space units with smaller aggregated connectivity. This paper combines these two methods to reflect the connections between cities and spaciality in mainland China which has a positive practical significance. The conclusions and proposals could help to define the border of influence of the regional center cities. On the basis of hinterworld division, the directions, sectors and added value chain of connections could be involved to analyze the relationships between cities which provides a reference for the development of regional co-development policy. Empirical results enrich our understanding of the hinterworld in which both relatively strong and relatively weak connections both exist. New perspectives and ways are provided to describe and analyze the relationship between center city and its hinterworld.

The Spatial Distribution and Mechanism of Urban Shrinkage in the Pearl River Delta

LI Xun, DU Zhiwei, LI Xianfeng

Sun Yat-sen University, Guangzhou 510275, China, E-mail: jackso@qq.com

Abstract

Urban shrinkage emerged in European and American countries as early as the mid-20th century. The Pearl River Delta (PRD) is "miracle growth" area for urbanization, but cities and towns development also face population and economy shrinkage after the financial crisis in 2008. In this paper, we investigate spatial distribution of urban shrinkage in the PRD respectively from district/county level and town/street level, using permanent resident data of Population Census and the Statistical Yearbook. By the case of Chashan Town, an analytical framework is established in this paper for urban shrinkage from the perspective of industrial structure and labor structure. Moreover, we explore shrinkage characteristics and formation mechanism caused by supply and demand changes. The research reveals: 1) the spatial distribution of urban shrinkage displays partial in the core area as well as relative concentrated in the outer circle, developing three major shrinking agglomeration area; 2) economic continual decline and immigrant reduce are typical characteristics of urban shrinkage in the PRD; 3) the mismatching of industrial demand structure and labor supply structure causes urban shrinkage in the PRD together.

Urban Shrinkage; Industrial Demand; Labor Supply; Dongguan; PRD

Transnational Migration and Spatial Diversification of Koreatowns in Tokyo

Shin, J.

The University of Tokyo, Tokyo, 153-8902, Japan, shin@humgeo.c.u-tokyo.ac.jp

Abstract

This study aims to show how various types of international migration change migrant spaces in a global city. It particularly focuses on the appearance of highly mobile transmigrants who carry out multidirectional migration and their influence on the change of migrant spaces in the global cities. On-location studies were conducted in Koreatowns in the Tokyo metropolitan area through participant observation, landscape analysis, survey, and in-depth interviews.

The results suggest two conclusions. First, Korean migrants in Tokyo can be classified into three types: old comers, new comers, and new-new comers. While the old comers are the migrants (and their descendants) who settled during the Japanese colonial era (1910~1945), the new comers are permanent residents who arrived after the 1980s pursuing economic interests. The new-new comers are relatively young, well-educated, and high income transmigrants who have migrated recently. Second, Koreatowns in Tokyo are different from those of western global cities in aspects of location and function. Koreatowns for the old comers are invisible ethnic enclaves that are built in old and historical residential areas. On the other hand, the Koreatown in Shinokubo is a former multiethnic town which became Koreatown in the late 1990s with Korean cultural wave. The function of Shinokubo as a residential area or an ethnic community becoming less important is rather characteristic as an ethnic commercial area is specialized because the main visitors to the town are the new-new comers.

Koreatown; Transmigration; Global city; Ethnic enclave; Tokyo

Urban Land Use Change, Compactness and Fractal Measurement of Ulaanbaatar City

Myagmartseren P, Myagmarjav I, Zaya Ch, Munkhnaran S, Bazarkhand Ts, Gantulga G, Bolormaa B, Chinbat B, Erdenejargal, Enkhtuya N, Ganpurev D, Buyandelger M

Department of Geography, National University of Mongolia, Ulaanbaatar city, 210646, Mongolia,
land_management@num.edu.mn

Abstract

Through the example of some measurements in urban sprawl of Ulaanbaatar city footprint, this paper will illustrate how urban compactness metrics and new technology of the geographical information systems could be used for more effective visioning on urban planning strategy. Fractal dimension index and compactness ratio were identified, based on GIS map layers with had been extracted from a series of cadastral map, time series land use planning data's in National Land Information Database and Landsat TM imagery over the period from 2000 and 2010. Calculated indices analyzed by combining two terms of urban external shape/ urban morphology to be implicit thematic urban shape and structure changes. Despite the urban planner's effort to limit expansions and promote compact structure, city had been constructed far above irregular shapes. The main findings states here is that Ulaanbaatar is growing none systematically and incompactly, even though the geometrical growth hasn't been strictly planned and became most irregular shape of urban sprawl. Study has demonstrated that the GIS analysis with the compactness metrics have a good assistance to comprehend urban land use evolution study and obviously project future urban development plan.

Urbanization, Urban Poverty, Slum and Sustainable Urban Development in Nigerian Cities: Challenges and Prospects.

ROWLNAD NWEKESON

Queens Science Academy, Nigeria, chealrow29@gmail.com

Abstract

Urbanization, Urban Poverty and Slum are often intertwined, and constitute major challenges to developed and developing nations alike, but these challenges are more evident in developing nations among which Nigeria is not left out. Urbanization has been a major demographic trend in Nigeria and most especially in the major cities across the country in last half of twentieth century because of the relative increase in both social and economic development that is presently resulting in population explosion in major Nigerian cities, some of which are manifesting in the unnecessary pressures on available infrastructure, environmental degeneration, traffic congestion, housing shortages and high level of crimes. Urban Poverty equally posed a great challenge to urban sustainability in Nigeria because most of the poor in the cities suffer social exclusion, unemployment, homelessness, lack paid income and vulnerability to environmental risks and poor health, while the end result of these challenges and manifestations are the growth of slums, squatters settlements, shacks, dirty run down housing that are already becoming permanent structures in major cities of Nigeria. This paper embarks on comprehensive literature review on urbanization, urban poverty, slums and available statistical figures and relates these issues to Lagos, Kano, Port-Harcourt, Onitsha and some other cities in Nigeria, because these are the cities that faces these challenges the more, where there exist housing shortage in quantitative form, environmental pollution, traffic problems, huge pressure on existing infrastructure such as water supply, electricity supply, healthcare facilities, bad roads, high level of criminal activities, kidnapping, high level of unemployment among others and while at the same time, examined the factors responsible for these challenges in the urban centres. However, practicable recommendations are proffered as to the interrelation and opportunities that can be harnessed among these challenging issues, so as to ensure sustainable urban development in Nigeria as a nation.

Mechanism of Oasis Urbanization: A Theoretical Framework Based on Complexity

Theory

Haimeng Liu, Chuanglin Fang, Hanying Mao

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, haimengliu@163.com

Abstract

Oasis cities are the most concentrated zones of human activity and the most vulnerable places in the arid region of northwest China. Oasis urbanization is a typical complex giant system. Based on complexity theory, we analyzed the generation, evolution and transformation process of oasis urbanization, and built the theoretical framework of oasis urbanization evolution mainly from three dimensions of the emerging generation, coordinated sustenance and critical phase transition innovatively, by using proper concepts like emergence and synergism and the model of basin of attraction, according to which the Northam Curve was reinterpreted. The study indicated that: (1) Oasis city is an entire structural and functional emergence phenomenon of a human-centered oasis region system from the perspective of multiple spatial and time dimensions, and its formation conditions include generating subjects, self-organization and limited formation mechanism and environment policy. (2) Competitive and synergic mechanisms keep the vitality and evolution stability of the oasis urbanization system, which is the basic motive force of the system evolution. (3) Oasis urbanization process is also essentially a self-organized critical phase transition, which is the dialectical unity at the aspects of rheology and mutation, order and chaos, stability and non-stability. (4) The positive and negative feedback mechanisms in space and time improve the complexity and order of oasis urbanization, which approaches to the state of self-organized criticality; meanwhile, the vitality and diversity of urbanization system are reinforced in this process.

Research on Population Performance of Urban Construction Land Expansion Based on Perspective of Structure---Instance of Shandong Province

Wang Xiang-yu, Wang Cheng-xin, Wang Botao

College of Geography and Environment, Shandong Normal University, Ji'nan, China, 1365955738@qq.com

Abstract

Reviewing the development of rapid urbanization during the last two decades in China, the contradiction between the shortage of land supply and the high demand for urbanization has been sharp. Governments and experts have reached a consensus that land urbanization is faster than population urbanization. However, this is just a superficial phenomenon from the perspective of urban system and we should analyze its differences from the structural level. Taking Shandong Province as an example, from the perspective of regional structure, administrative level structure, land use structure and the city scale structure, this paper analyzes the population performance of expansion of construction land between 2000 and 2013 based on allometric mode. The results indicate that: ① From the perspective of spatial, land urbanization is faster than population urbanization in the whole province, and population performance of urban land is higher in northwest of Shandong, southwest of Shandong and peninsula area. The central and coastal areas become lower. ② From the perspective of land use structure, there are differences among types of construction land in different cities. population performance of urban land is higher in the residential land, industrial land and green land, and the storage land is lower. ③ From the perspective of city scale structure, the city with a population of less than 200,000, the urban population performance is the highest while the city with a population of 200,000-500,000 is lowest. the city with a population beyond 500,000 shows decreasing trend

Research on the Stuctural Relationship of Metro Accessibility, Pssenger Flows and Retail Business in Metro Sites: An Empirical Study of Nanchang in Jangxi Province

Zenghui, Dingguoma

Jiangxi Normal University, Nanchang, 330022, P. R. China, dgm7799@163.com

Abstract

Traffic network system on a city's economic development and the formation of the spatial structure plays a key role, the urban subway construction has had a profound impact on the development of internal business area, and the formation and evolution of regional structure of urban commercial there is great concern. For nanchang subway stations commercial retail business area of 24, the subway network data such as field investigation, using the grid method to different degree of the subway site accessibility analysis, using regression model for different subway station, passenger and commercial circle retail site accessibility spatial structure correlation analysis; Business center around the nanchang Red Valley beach, microscopic analysis of subway station passenger flow's influence on the business center of space structure. Research shows that: (1)The subway site accessibility of traffic, traffic and retail business area of strong affinity;(2) Metro passenger flow and higher level business bigger relevance, and little correlation with low levels of business and even negative correlation;(3) The increase of passenger flow promotes business evolution from the traditional retail business to a more advanced industry entity.

Accessibility; pssenger flows; retail business in metro sites; Nanchang

Research on the Spatio-Temporal Characteristics of the Influence of Population Urbanization on the Consumption of the Residents in China

Qiang Li¹, Haitao Ma²

¹College of Environment and Planning, Henan University, Kaifeng, China, 364406546@qq.com

²Institute of Geographic Sciences and Natural Resources Research, CAS, China

Abstract

This paper has established the complete decomposition model of population urbanization and living consumption on the 31 provinces population urbanization and living consumption from 2000 to 2014. We measure growth of living consumption and its 8 subsidiaries project. Conclusions are as follows: (1) China's consumption growth is the most main caused by the level of consumption per capita, population urbanization impetus in the secondary position. (2) Population urbanization contributions to the national consumption growth from 20.7% in 2001 to 7% in 2014. And it show that the eastern region of urbanization push for consumption growth more and more small, and the western region in volatility rises. (3) From the point of consumption structure, urbanization play a larger role in promoting consumption of food consumption, cultural, educational and entertainment, transportation, communications and clothing.

Key words:

Spatial Agglomeration Characteristics and Location Decision of Small and Medium Technology Based Firms in Beijing: Based on the Investigation of 22046 Samples

ZHENG Wei, ZHOU Fa, CHEN Wen, DONG Shuangqiang

School of Economics, Fujian Normal University, Fuzhou 350007, zw99028@163.com

Abstract

Using 22046 small and medium technology based firms in Beijing, this paper seeks to find the spatial distribution patterns, location decision and its evolution over time. Small and medium technology based firms in Beijing are mostly located between Sanhuan Road and Liuhuan Road, especially in these industrial parks. Spatial agglomeration shows obviously in town (sub-district) levels, while it shows relative diversification in some area. The spatial agglomeration is first appeared in basic industry and machinery industry, then turn to metallurgical, mechanical, electronic and chemical industry, finally to electronic industry, textile and clothing and other processing industry. The spatial distribution experienced the stages from centralization mainly in suburb to decentralization to centralization in Haidian, Chaoyang, Daxing and Tongzhou. The centre of economic gravity turns from south by west to south by east, while the imbalance is more obvious in west than east. Pearson correlation coefficient and Moran Index indicate that the small and medium technology based firms preferred to imitate or follow up leading enterprises behavior within the same industry before the 1990s, while they attaches great importance to large concentration of capital and labor which is brought by the construction of types of industrial parks as well as the location decision of related enterprises within the same industry or industry chain which has been entered in after the 1990s.

Key words:

small and medium technology based firms; spatial agglomeration; location decision; industrial network

Spatio-Temporal Coupling Relationships among Urbanization, Economic Growth and Electricity Change in Henan Province

Qiang Li, Jingyu Liu

Henan University, Kaifeng, Henan, China, henuliqiang@163.com

Abstract

In this paper, a complete decomposition model is used to analyze the data of population, economy and power consumption in 18 cities of Henan province. From the provincial and municipal scale to quantitatively reveal the contribution rate of Population Economic Urbanization to the change of power supply for providing the basis for the driving factors and mechanism of change. The conclusions are as follows: (1) population urbanization effects on the total electricity change greatly. (2) economy of urbanization effects on the total electricity change smally. (3) the total electricity of 18 cities of Henan Province is mainly affected by the size of the economy. (4) in urbanization mature area, the population and economy of urbanization contributes to total power lessly.

Key words:

urbanization; electricity change; complete decomposition model; Henan Province

The Efficiencies and Their Changes of Jiangxi's Cities Employing DEA and Malmquist Index Models

Zheng Lin, Hu Mengying, Liao Chuanqing

School of Geography and Environment, Jiangxi Normal University, Nanchang, Jiangxi, 330022, P. R. China,
zl6626@163.com

Abstract

Spatial pattern of cities has a typical effect on the cities' efficiencies. Jiangxi has experienced unprecedented urbanization over the past decades, resulting in a great change of its cities' scale. By employing the models of DEA and Malmquist Index, this paper estimates the efficiencies and their changes of Jiangxi cities from 2001a to 2010a. The conclusions can be drawn as follows: 1) while only three cities' efficiencies prove to be DEA efficient, the overall efficiency of Jiangxi Province proves to be DEA inefficient and moves towards the optimal production efficiency, and there is great room for improvement of urban management and development scale. 2) The city efficiency growth rate of Jiangxi Province slows down and there is still a huge gap between the city and town scale of Jiangxi Province and the optimal production efficiency. 3) Benefited from expansion of the city and town scale, allocation of the city and town development elements by city and town administrators and improvement of the administration level, the city efficiency growth rate in South Jiangxi is faster than that in North Jiangxi. 4) This research divides the 11 cities in Jiangxi Province into three types, namely cities and towns with increasing returns to scale, cities and towns with unchanged returns to scale and cities and towns with varying returns to scale, according to their returns to scale, and puts forward relevant improvement methods.

Key words:

DEA model; Malmquist Index; urban pattern; urban efficiency; Jiangxi

The Spatial Evolution of Urban and Rural Settlements' Hierarchical Size in Eastern Plain of Henan Province

Huimin Yang

Henan University, China, yanghuimin1989@126.com

Abstract

This paper uses the data of urban and rural settlements from 1975 to 2015 of Kaifeng city and Zhoukou city in the eastern plain of Henan province, to analysis the spatial evolution condition of the settlements' hierarchical size with the rapid urbanization and industrial growth. The method used in this paper is the Zipf's index, fractal dimension and the average nearest neighbor ratio, then analysis the characteristics of settlements' spatial distribution.

Key words:

urban and rural settlements; rank-size; spatial evolution; the eastern plain of Henan province

A New Approach to Analysing Transport CO₂ Emission from People's Daily Urban Travel in China

MA J¹, Zhou S²

¹ School of Geography, Beijing Normal University, Beijing, 100875, P.R. China, majingbnu@163.com

² School of Geography and Planning, Sun Yat-Sen University, Guangzhou, P.R. China

Abstract

Developing low carbon cities is a key goal of 21st century planning, and one that can be supported by a better understanding of the factors that shape travel behaviour, and resulting carbon emissions. Understanding travel based carbon emissions in mega-cities is vital, but city size, and often a lack of required data, limits the ability to apply linked land use, transport and tactical transport models to investigate the impact of policy and planning interventions on travel and emissions. Using Guangzhou as a case study, this paper develops a new bottom-up approach to provide improved transport CO₂ emission from people's daily urban travel in China. Drawing on an activity diary survey and demographic data from the 2010 population census, this study employs spatial microsimulation to simulate a realistic synthetic populations' daily travel behaviour and estimate their transport CO₂ emission at a fine geographical resolution (urban sub-district) in 2010 for Guangzhou, China. It combines spatial microsimulation approach from geography and activity travel research from the transport field and applies this in a developing country, where detailed data to undertake fine scale analysis of phenomena such as transport CO₂ emissions generated by travel behaviour is very scarce.

Key words:

spatial microsimulation; transport CO₂ emission; travel behaviour; population synthesis

A Novel Method for Identifying the Boundary of Urban Built-up Areas with POI Data

Xu Zening^{1,2}, Gao Xiaolu¹

¹Key Laboratory of Regional Sustainable Development Modeling, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, xuzn.13b@igsnrr.ac.cn

²University of Chinese Academy of Sciences, Beijing 100049

Abstract

The boundary of urban built-up area provides foundational information for urban studies which is also essential to implement urban spatial distribution. However, the traditional methods which obtain the boundary information, such as using night-light distribute data, land use or building coverage, are so imitated in data and research dimension that they usually fail to provide detailed explanations for urban social economic activities. As a new data source for urban analysis, POI (Point of Interest) data, obtained from online map reflects the agglomeration of urban activities and urban structure under certain conditions effectively and efficiently. Based on relativity of POI data, spatial structure and spatial distribution of city factors, a new method is proposed to identify the actual boundary of urban built-up areas by analyzing POI density distribution data. Therefore a so-called Densi-Graph method is developed based on analysis of the contour lines of the kernel density estimation of POI. On this basis theoretical analysis on how to identify the threshold value of the boundary is made and growth pattern of different urban structures such as mono-centric, poly-centric and linear cities is discussed, whereby the Densi-Graph method using POI data is validated. Compared with other urban built-up area boundary researches, Densi-Graph presents more intuitively and objectivity. Furthermore, the method is used to study the boundaries of urban built-up areas in China's prefecture level cities. The relationships between the Density-Graph thresholds and the population and location of the cities are revealed, and the corresponding thresholds of urban boundary for different kinds of cities are presented.

Key words:

boundary; urban built-up areas; POI; Densi-Graph; kernel analysis; urban-rural spatial structure

Anomaly

Abstract

Events happen all around. One of the main reasons we could say that something became an event is because of conflict. Conflict not in its definitive sense but any occurrence that happens because of an intervention that creates an event worth remembering. Unfolding of such events creates Cities and Urban spaces which exhibit their duality of spatial and trans-spatial by behaving as a discrete system. This system through its lawful internal working produces an output in the form of realized spatial order with its social logic and a social order with spatial logic. The components of this system form a collective through a shared relevance. This shared relevance creates meaning forming a group where all collectives share one identity. This group with its new social order and its spatial logic revives the already existing spatial order. These groups do so having a tendency to expand resulting in production of space in a situation of encounter where they have found relevance. But an encounter without a lawful internal working of discrete system results in anomaly because groups do not find relevance due to absence of collective identity. This paper makes an effort to explore one such event in the case of Babri Mosque and Ramjanmabhum, Ayodhya to explain the anomaly as transposition of social and spatial. Through the case study it makes an attempt to generate an equation explaining the two different situations of religious encounters, former reviving the social and spatial order and the other resulting in anomaly.

Key words:

Events; Social; Spatial; Order; Discrete; Anomaly; Collective; Conflict; Babri; Ayodhya

Can Planetary Urbanization Subvert the Jinx of Post-Colonialism?

Aditya Mohanty

PhD Student, University of Aberdeen, Aberdeen, UK, r08am15@abdn.ac.uk

Abstract

In the contemporary 'urban' condition, liberal democracy and transnational sovereignty offer us numerous avenues for the realization of a global human geography across space and time. But scholars like Ananya Roy (2015) caution us against the adoption of '... a universal grammar of cityness, modified by (exotic) empirical variation' by harping on the celebration of a contingent historicity. Howsoever the 'planetary urbanization' (Brenner 2013) analytic is soon making deep inroads into the postcolonial spatiality. The rise of a caste-class consociation and the growth of a hegemonic middle class (Heller and Fernandes 2006), for instance, seem to have had engendered an ossification of a neoliberal ethic that definitely dares to ruffle up the very ontology of a 'postcolonial aura' (Dirlik 1994) or the very 'ordinariness' (Robinson 2005) of the city. Apart from my current research work on the role of neighborhood associations in shaping the contours of urban politics in Delhi, the paper shall draw upon studies on the evolution and growth of two key themes viz., gentrification and urban renewal, in cities of both the Global North and South. In so doing, it argues that in order to understand subversive modes of representation amidst the growing 'specter of capital' (Chibber 2013), the ontology of a global human geography needs to go beyond the dichotomy of the 'civil' and the 'political' in everyday life. Further, we do need to unabashedly get prepared for capturing the ethos of what, I prefer to term as, 'symbiotic spaces of neo-populist sovereignty'.

Planetary Urbanisation; Civil Society; Neoliberalism; Postcolonialism

Case Study of Urban Renewal in the Jing'an District of Shanghai:

From a Small Area Analyses Perspective

Hai REN, Mitsuru SANO

Nihon University, College of humanities and Sciences, Tokyo, 1568550, Japan, nin.kai@nihon-u.ac.jp

Abstract

Urban renewal in Shanghai has been underway since the early 1990s. This study focuses on the effect of urban renewal within Shanghai's central district, Jing'an. The methods used in this study were first, investigations of land use in Jing'an district to map the actual situation in detail, and second, analysis of small area data to discuss the correlation between the change in land use caused by urban renewal and the change in population in the downtown area.

The analyses showed that the urban renewal of Jing'an district is in a process of "scrap and build," that is, condominiums are being built in place of lilong housing (traditional lanes of terraced homes). The downtown area has always been a residential area, and its urban function has not changed along with urban renewal. A number of previous studies of Shanghai's urban renewal, from a macroscopic view on the urban or district level, indicated that the population density has decreased as the number of high-rise buildings has increased. This study using small area data on a Residents' Committee level to analyze population redistribution in Jing'an district with urban renewal demonstrated that a population decline did not occur in all regions, but instead increased in some.

Key words:

Lilong housing; condominium; cluster analysis; population distribution; Jing'an district of Shanghai

City and State Relations in the Era of Globalization: The Perspective of the Politics of Scale

Zhang, Fulei

Assistant Professor, Center for Urban Development and Public Policy, School of Political Science and Public Administration, Southwest University, Chongqing, P.R. China, zhangfulei86@126.com

Abstract

Since the late 20th century, globalization has accelerated in breadth and depth, and economic, social, cultural and other aspects of the world have been challenged by this process. The nation-state has been encountering the most serious challenges, so that the nation-state is undergoing a profound rescaling of state power and transformation of state governance. The state has rescaled its power upwards towards supra-national levels of regulation as institutions such as the EU, the IMF and the World Bank and rescaled downwards towards sub-national levels of governance such as city-regions and cities, and devolves other power to civil society and individuals. Associated with the process of globalization and the transformation of state governance, cities are rising worldwide, in the process of which there is an unprecedented wave of large-scale global urbanization, the growth of urban economic power and the rise of global cities, global city-region and global city network. However, the awakening of city consciousness in national politics and global governance is an invisible and real "urban revolution." Under the rise of cities' political influence, cities not only obtain greater autonomy in their own governance, but also began extending their power to levels of nation-state and to the process of state governance. The city challenges the dominant position of nation-state and began to establish their own position in multi-levels of governance, so that the adjustment of the city and state relations in different governance processes gradually become one of key mechanisms.

This study aims to investigate city and state relations and its changing process, which is a very valuable view to understand processes of urban governance, national governance and global governance under globalization.

Comparative and historical methods are employed to conduct this study and investigate city and state relations under the processes of globalization. First of all, this study defines concepts of the city and the state, based on which a theoretical framework of city and state relations in the era of globalization is constructed. Secondly, this study employs a multi-scalar theoretical framework to explore the city and state relations in the process of urban governance, state governance and global governance. Finally, the study argues the nature of the city and state relations in the era of globalization, and point out the future of the city and state relations in theory and reality.

In the scale of urban governance, the city and its power system are embedded in the national state system. In the era of globalization, state foundational institutions define basic contents of city and state relations, and state basic institutions regulate the regime of city. The transformation of state institution causes changing roles of city and state, and induces the transition of city and state relations. Due to changes in state governance, the model of city and its governance has transformed to adapt to the process of globalization. And the adjustments of national urban policies are the most direct instruments of nation-state to intervene into urban affairs and regulation city and state relations.

In the scale of nation-state governance, the state is inextricably linked with cities. There is one side of conflicts as well as the other side of interdependences in city and state relations. The massive urbanization and the rise of global cities have brought challenges to nation-state governance, and the growth of city power has formed huge pressures for states. However, cities become increasingly important to state governance, since they provide political space for state governance and support the transformation of state governance and the production of new state space under the process of globalization.

In the scale of global governance, there is not an opposite relationship between city and state. They exist in both conflicts and interdependences. Nation-state could not dispel the roles and functions of global cities in the process of global governance. Global cities could not completely replace the role of nation-state in global governance.

The paper concludes that there is a tension between the city and the state, that is, the city and the state presents not a simple "zero-sum" relationship between life and death, but a dialectical relationship full with conflicts and interdependence. In this dialectical relationship, the city and the state relations will move towards a "politics of scale" in the future. Cities, states and their governance are permeated by much of the strengths from multi scales, while they are also involved in the governance of other scales.

The paper contributes to academic debates on urban governance, urban development and city power in the era of globalization. City/State relations is an important theoretical approach to promote the development of urban politics and urban governance studies, enlarge the view of state theory and state governance research and innovate the studies and theories of global governance.

Key words:

City/State Relations; Politics of Scale; Urban Governance

How Spatial Statistics and Multilevel Modelling Benefit Urban Studies—an Illustration of Modelling Neighbourhood Satisfaction in Beijing

DONG G, MA J, CHEN Y

Department of Geography and Planning, University of Liverpool, Gordon Stephenson Building, Liverpool, L69 7ZQ UK.
guanpengdong@gmail.com

Abstract

With the increasing availability of fine-grained geographical data (even geo-coded individual data) and their wide use in urban studies, analytical tools that can properly take into account both the spatial nature (correlations/interactions and heterogeneity across space) and the multiple-scale nature (e.g. individuals nesting into urban local contexts) underlying the data under investigation are in great need. Spatial statistics provides a valuable tool to accommodate spatial effects including correlations and heterogeneities across local contexts where individuals reside while multilevel modelling can suitably capture the multiple-scale structure and the subsequent correlations between individuals amongst the same neighbourhood. However, neither of these two approaches could model spatial effects and group dependence simultaneously. This study develops an innovative and flexible Bayesian spatial multilevel modelling approach by integrating spatial statistics and multilevel modelling, which can simultaneously model spatial correlations, heterogeneous regression coefficients and group dependence. This approach is applied to examining residents' satisfaction with neighbourhood environments, drawing on a large-scale household satisfaction survey in Beijing. In particular, we investigate the impact of a variety of homeownership types on neighbourhood satisfaction, finding that the impacts of homeownership on satisfaction vary significantly in different neighbourhood contexts and spatial locations.

Key words:

spatial statistics; multilevel modelling; heterogeneity; neighbourhood satisfaction; ownership

How to Draw a Neighborhood? The Potential of 'Big Data' for Understanding Urban Neighborhoods

Ate Poorthuis

Singapore University of Technology and Design, Singapore, ate_poorthuis@sutd.edu.sg

Abstract

How to draw and define neighborhoods, or spatial regions in general, has been a long-standing focus in the discipline of Geography, both from a more theoretical standpoint ('what is a neighborhood') as well as a methodological perspective ('how do you delineate neighborhoods'). This paper examines the latter perspective, often referred to as regionalization, with an empirical study of (perceived) urban neighborhoods in New York City. It reviews and contextualizes current approaches to regionalization by both tracing its historical foundations as well as assessing parallel-but-related approaches from the field of Social Network Analysis. I argue that methodological advances in both fields, combined with abundant computing resources and the affordances of Big Data (e.g. spatio-temporal granularity; relevance of data to spatial perception and mobility), allow for a less 'naïve' approach to regionalization. Such an approach acknowledges fuzziness, overlapping and nested regions, and the possibility of different sets of neighborhoods existing for different population groups. In short, this provides a quantitative approach to analyzing urban neighborhoods that is in line with social theories of space. This paper applies the map equation framework (Rosvall et al. 2010) to a dataset consisting of all geotagged tweets sent between July 2012 and July 2015 from the New York City metropolitan area. It shows how urban neighborhoods exist at different scales, at different times, and for different groups of people and argues that such an approach might provide more apt analytical units for subsequent spatial analyses than conventional-but-arbitrary administrative regions troubled by, for example, MAUP.

urban geography; neighborhoods; big data; network analysis; GIS

Integrated Approach for Smart City Index Development: From Concept to Indicator Weighting

Xiaolong Zou, Yan Li

Graduate School of Asia Pacific Studies, Ritsumeikan Asia Pacific University, Japan, zoufuchen@gmail.com

Abstract

Smart city (SC) initiatives are the new mega-trend in urban developments. Multifold concepts and frameworks have been proposed to interpret what constitutes smart cities, but have not yet reached a universal consensus. This study aims to propose a new conceptual framework for smart cities with an integrated index for better understanding and practical implementation of SC projects. The conceptual framework is proposed after reviewing SC literature under policy analytical method. Based on that, an index consisting of six domains, 18 aspects and 36 supporting indicators is proposed. The analytical hierarchy process (AHP) was applied for indicators weighting for prioritization or KPI selections. This study would contribute to more insights in understanding smart cities and their evaluation for policy makers, academia, urban managers and practitioners.

Smart city index; Smart city concept; Smart city framework; Indicators; Analytical hierarchy process

Power and Centrality in a Multiplex Network Perspective

Bellwald A, Chaperon P, Rozenblat C

University of Lausanne, Switzerland, antoine.bellwald@unil.ch

Abstract

So as to highlight the role of Global cities in global urban system, many previous studies distinguish between power and centrality (Taylor et al., 2001, 2013; Alderson & Beckfield 2004; Wall 2009; Bellwald & Rozenblat, 2016). However, they consider monoplex networks, with a single type of node, relation and spatial dimension. This presentation aims at going further, considering proximities between actors or communities of actors (firms, research institutes) in a three dimensions' network that takes into account three kinds of proximity: geographical, social, and cognitive (Boschma, 2005).

We propose to extend the analysis of centrality and power to this multidimensional network in order to clarify how these three dimensions shape urban networks evolution and redefine the role of cities in globalization.

The empirical analysis had been undertaken at the world scale on the network of the 3,000 first multinational firms and their 800,000 direct and indirect subsidiaries (ORBIS-IGD, 2013), combined with their co-patenting network (OECD-Regpat, 2013). Within this three-dimensional network, geographic distance comes into play via the localisation of firms, institutional and social distance occurs in financial relations and cooperations for patents between firms, whereas cognitive distance occurs at the level of the type of activities the firms develop. The confrontation of the three dimensions allows 1) evaluating the role of spatial proximity against the two other proximities and 2) giving new insights about the capacity of cities to concentrate different communities (social distance) and different knowledges and activities (cognitive distance).

System of cities; network centrality; multidimensional; multinational firms; patent

Queering Critical Urbanism: A Case Study of Habitat III

Kuecker, Glen

DePauw University, Greencastle, Indiana, USA, gkuecker@depauw

Abstract

Critical urban theorists have provided a rich framework for analysis of the city, especially the great challenges of 21st century urbanism. They have given new insights about slums, sustainability, security, and infrastructure. Critical urbanism also has enabled scholars to consider the power/knowledge frameworks within urban design and planning. The approaches to understanding the urban form provide an opportunity to critique an important moment within urbanism, which is the formation of the “New Urban Agenda” that will be launched in Quito, Ecuador in October 2016 by UN Habitat. The agenda will establish the general plan for world’s cities for a twenty-year period, until 2036. At this point nearly 2/3 of the global population will be urban. Critical urban they allow us to consider how inequities and inequalities are embedded within the New Urban Agenda. However, critical urbanism has a fascinating theoretical silence in that it does not include perspectives from feminist theory and queer theory. While scholars have engaged in queering the city by finding a place for queer actors in the city, it has yet to engage the critical (as in theory) perspectives generated by queer theory in the study of the city. This paper attempts that theory by using queer theory to undertake a critical analysis of the making of Habitat III.

Key words:

queer theory; critical urbanism; Habitat III; urban planning

Revealing Spatial and Temporal Scales in Landscape-based Design Approach for Fast Urbanizing Deltas: Pearl River Delta as a Case

Liang Xiong

Delft University of Technology, 2628 BL Delft, the Netherlands, l.xiong@tudelft.nl

Abstract

Urbanizing deltas are complex systems that influenced by both natural and artificial forces in various scales of space and time. However, the knowledge of the two dynamics lack a well connection in each scale. This study aimed to understand the mechanism of urbanizing delta with an inter scaler perspective. The study use mapping to illustrate the connection between the natural and human dynamic. It applied the method in the Pearl River Delta to identify spatial problems and potentials. The developed two series of maps indicated an unsustainable phenomenon during the past decades' urbanization process. Despite of the descreas of the flood risk in local scale, the shwift from a water-based landscape oriented pattern towards a land-based trasit oriented urban pattern has increased the flood risk in delta and regional scale. Such development mode would led to a more vulnerable urban pattern in the region from both flood and storm water. This study suggested that the potentials of solving scale disorder could be found across various levels of spatial scale with a focus on synchronizing the balance among the landscape, infrastructure and occupation subsystems. This study provided a graphic temporal- spatial scalar approach to organize, understand, analyse and design the different types of dynamic in urban region and its connected landscape. These insights would provide theoretical and methodological support in landscape based planning and design. It also would help to establish an effective communication for urban and regional planning among decision makers and specialists from different disciplines.

Key words:

The Evaluations of Vitality of the Commercial Centers in Shanghai Based on Big

Data

Li Tao, Zhang Yina

Urban Development Institute of Fudan University, School of Social Development and Public Policy, Fudan University, Shanghai, 200433, P. R. China, 466695659@qq.com

Abstract

Cities in China have transformed from production cities to consumption cities. The prosperity of retail embodies in the vigorous development of the city commercial centers. Based on the Big Data of mobile phones, rail transit, real estate price and pos machine, this paper evaluates the vitality of the city and regional commercial centers in Shanghai from four perspectives: people, real estate, service scope and consumption. It is found that traditional commercial centers are still strong while emerging commercial centers have risen rapid. The commercial centers which have superior geographical condition, good traffic service and higher Fars are more competitive. As many new commercial centers finish construction and are put into operation, the pattern of commercial centers in Shanghai would have new characteristics.

commercial centers; Big Data; Shanghai

The Spatiotemporal Pattern of Urban Expansion in the Colombo Metropolitan Area, Sri Lanka

Subasinghe S, Murayama Y

The Graduate School of Life and Environmental Sciences, University of Tsukuba, Ibaraki, 305-8572, Japan,
subasinghepgia@gmail.com

Abstract

The critical understanding of spatiotemporal pattern of urban expansion has become a key phenomenon to address a wide range of socioeconomic and environmental issues, related to the urban environment. In this study, the spatiotemporal pattern of urban expansion of the Colombo metropolitan area (CMA), the largest and only metropolitan area of Sri Lanka, was examined. A newly developed methodology based on remote sensing and Geographic Information System (GIS) tools and techniques, was employed for the conceptualising and quantification of urban expansion. Specifically, Landsat imageries and available maps were used to produce the urban land use (ULU) maps of three time-points (1992, 2001, and 2014). In doing so, the neighbourhood characteristics based morphological spatial pattern analysis (MSPA) and hybrid (pixel/object-based) image classification methods were integrated. The urban expansion was examined and compared during the initial urban expansion stage (1992-2001) and the secondary urban expansion stage (2001-2014) using the annual ULU change intensity concept. The spatiotemporal pattern of urban expansion was captured using three indicators, namely infill development, urban extension, and leapfrog development. The annual urban expansion intensity was calculated based on these indicators, in order to capture the urban expansion quantitatively. The results revealed that the ULU change intensity and urban expansion intensity of initial stage were lower than the secondary stage while the leapfrog development pattern is significant than the infill development and urban extension. Further, the present study improved the methodological and conceptual aspects of urban studies by expanding our knowledge and understanding of urban dynamics in the CMA.

Evaluate the Three-dimensional Urban Morphology Evolution by Fractal Dimension: a case study of Yangzhou City, China

Qin J

Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing 100101, China, qinj.11b@igsnr.ac.cn

Abstract

With rapid urban development in China in the recent two decades, the three-dimensional characteristic has been the essential feature of urban morphology. However, the research of urban fractal dimension still remains focused on the two-dimensional space, few studies have been conducted from a 3D perspective. In this paper, a three-dimensional box-counting method is proposed to estimate fractal dimension of urban form. Moreover, a method based on the second-order derivative of log-log curves is used to automatically identify the fractal scale-free range. The central urban area of Yangzhou city is selected as the case area. Three high resolution remote sensing images of 2003, 2008 and 2012 are used to acquire Yangzhou three-dimensional morphology data. Then based on the data, the detailed process of the three-dimensional box-counting method is described. The experimental results show that: the scaling range is the basis of calculating city fractals, the second-order derivative method can automatically identify fractal scale-free range accurately; The linear regression coefficients of scale-free range R^2 are all over 0.996 in the three years, which demonstrates that Yangzhou three-dimensional morphology is fractal; The fractal dimension of urban morphology has increased significantly in 2012 compared with that in 2003 and 2008, which indicates that the utilization of 3D spaces become more efficient and compact; The three-dimensional box-counting algorithm proposed in this paper not only provides a new methodology in quantifying the measurement of urban spatial structure and the evolution of urban morphology, but also extends the scope of urban studies to higher dimensions.

Key words:

Fractal Dimension; three-dimensional box counting method; scale-free region; urban morphology

Evaluation and Comparative Analysis of New-Type Urbanization Quality: from Chongqing, China's data

ZHANG Yin¹, YANG Qingyuan², YANG Mengyu³

¹College of Resources and Environment, School of Culture and Social Development Study, Southwest University, Chongqing, 400715, China, 66230422@qq.com

²School of Geography Sciences, Southwest University, Chongqing, 400715, China

³School of Economics, Renmin University of China, Beijing, 100872, China

Abstract

Based on the understanding of the essence of new-type urbanization, this paper has proposed an evaluation index system for new-type urbanization quality, which has consisted of development level and efficiency. The index system has contained 9 major primary indexes, including population urbanization, land urbanization, industrial urbanization, economic growth mode, resource utilization rate, social development quality, urban system layout, regional development relationship and ecological environment quality, as well as several secondary indexes. In order to verify the index system, this paper has also made use of the data in statistic yearbook during the past few years. By employing the analytic hierarchy process (AHP) to evaluate the development quality of the urbanization in Chongqing City, this paper has also conducted a horizontal comparison of urbanization development quality between Chongqing and other major cities and found that the new-type urbanization in Chongqing still need to be improved rapidly. Although Chongqing still far lags behind other major cities, it has already achieved a fair level of coordination between development elements of urbanization and resource urbanization mode and ecological environment. In order to further improve the development quality of urbanization in the future, more efforts in the form of constantly transforming development mode, optimizing element layout and urban system as well as promoting the coordination of urban and rural development should be made. On the whole, the path of new-type urbanization that is in line with the actual condition of regional development and featured by the local advantage should be laid down.

Key words:

Urbanization; New-type urbanization; Urbanization quality; Regional development

Evaluation and its Spatial and Temporal Evolution of Urban Competitiveness: A Case Study of Vice Provincial Cities

Wu ying, Wang chengxin

College of Geography and Environment, Shandong Normal University, Ji'nan, China, 1104403027@qq.com

Abstract

The research of urban competitiveness has been the focus and hot spot of domestic and foreign scholars and the 21st century is the century of the city. This paper takes 15 vice provincial cities as the research object and sets up the evaluation index system of urban competitiveness in 15 vice provincial cities based on economy, innovation, infrastructure, opening level, and environment. Based on entropy TOPSIS method, this essay analyzes in depth the spatial and temporal characteristics of the 15 vice provincial cities. According to the analysis result, the basic points of view are obtained as follows: From the perspective of the time alignment, the gap between cities has changed all the time and there is a shrinking trend among cities. The spatial distribution of competitiveness level presents the change pattern which descends from southeast coastal cities to the northeast. However, the development of the region gradually tends to be balanced.

Key words:

Urban competitiveness; spatial and temporal evolution; vice provincial cities

Green Space Accessibility Evaluation in Shenyang Based on the Gridding Cells Gaussian 2-Step Floating Catchment Area Method

Mengtong Li, Lingbin Yang, Ye Wei, Xiaojing Sun

northeast normal university, Changchun, 130024, P.R. China, yanglb862@nenu.edu.cn

Abstract

It is crucial important to configuration of public service facilities on a city's modernization. Space accessibility is one of the methods of reasonable measure of public service facilities configuration. In many research methods, the 2-step floating catchment area (2SFCA) method is relatively straightforward, whilst the greatest strength of the method is it overcomes the restriction of using only pre-defined regional boundaries. In this paper, we use the gridding cells Gaussian based 2-step floating catchment area method for green space accessibility assessment. Meanwhile, it offers an in-depth knowledge of green space of Shenyang. The results showed that: (1) As a whole, high accessibility of the inner city, low accessibility of outer suburbs in green space of Shenyang. (2) High accessibility value area are mainly distributed in the five boroughs meanwhile Low-value area are mainly distributed in the core city and the urban north and south of the country (3) According to the accessibility results, this study puts forward some suggestions about the optimization of spatial. The method of the real, objective reflects the accessibility of green space in Shenyang

Key words:

2-step floating catchment area method; GIS gridding cell; green space accessibility

Modeling the Range Anxieties on the EV Mode Choice Behavior

A field survey in Dalian

Liu Kai, Wang Jiang-bo, Sun Ye

Dalian University of Technology, Dalian, 116024, P.R. CHINA, liukai@dlut.edu.cn

Abstract

Although electric vehicles (EVs) should be able to meet most daily travel needs, the perception of limited mobility resources is still a barrier to EVs usage. How travellers trade off the uncertainty due to EV range anxiety and the uncomfortable trip by public transport mode?

How range anxiety prevents travellers from using EVs to various destinations, including workplace, recreation and visiting friends? The goal of this study is to provide a quantitative analysis on the range anxieties, that is, to what extent that travellers will have to give up private EVs under the assumption that only EVs and buses are available for choice. A questionnaire survey was conducted in Dalian, China. The binary logit model was used to examine how the EV conditions and driving environments contribute to travellers' green mode choice through totally 551 questionnaires. In addition, in order to investigate use behavior, remaining capacity, travel distance, range anxiety (theoretical remaining range divided by travel distance), whether vehicle can be charge during the remained trip, travel expenses and travel time are taken into considerations to compare the utility of travel between EVs and buses.

Key words:

Range anxieties; EV usage; charging uncertainties; SP survey; binary logit model

Simulation of the Yellow Sea Urban Pattern Based on BDI Decision MAS-CA Model: A Case Study for Dalian Jinshitan

YANG Jun^{1, 2}, PEI Ying¹, XI Jianchao², GE Quansheng², LI Xueming¹

¹Liaoning Key Laboratory of Physical Geography and Geomatics, Liaoning Normal University, Dalian 116029, Liaoning, China, pygis_lnu@163.com

²Key Laboratory of Land Surface Pattern and Simulation, Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing 100101, China

Abstract

Based on BDI decision MAS-CA model to simulate the Jinshitan of Dalian urban landscape pattern simulation forecast in the future. A BDI agent is a particular type of bounded rational software agent, imbued with particular mental attitudes, viz: Beliefs, Desires and Intentions (BDI). BDI decision MAS-CA model Simulation modeling is divided into three steps: (1) the CA part of the model (modeling of land use geographic distribution), (2) in the model of MAS (part of multi-agent and behavior modeling, the BDI decision affects the multi-agent behavior), (3) the combination of models (the agent behavior and the relationship between land use spatial distribution modeling between). MAS-CA model rely on the 1998, 2003, 1998 and 2013, four years of land use data to make predictions. In essence, the belief–desire–intention software model provides a mechanism for separating the activity of selecting a plan (from a plan library or an external planner application) from the execution of currently selection plans. Consequently, BDI agents are able to balance the accuracy spent on deliberating about plans (choosing what to do) and executing those plans (doing it). MAS-CA model in 2020 and 2030, urban area, the results Kappa coefficient reaches 0.635. From the simulation results can clearly show that:

(1) BDI decision making characteristics: guidelines for flexibility, fill the deficiency of MAS model. After joining BDI decision making MAS-CA model framework will be improved. Thus makes the results more accurate and current situation close, precision reaches 89.1%.

(2) The Jinshitan urban landscape pattern simulation results present the attached coastline and the pattern of traffic line. Urban landscape simulation pattern results to the coastline, urban land use and urban area in the central area were concentrated obvious expansion into the surrounding area. Convenient transportation, and so did the human activities, make traffic developed area and coast area gradually become the focus pattern of urban development. In the change pattern of urban where Putaogou village, Hejuzi village, Miaoshang village, Shizijie village, what change of urban transformation is the largest.

(3) From Jinshitan future urban landscape pattern transformation in the process of simulation and found that the coastline factors led urban landscape change of direction. We try not to make sure don't damaged the ecological environment. The government of Jinshitan should take long-term planning in developing economy looking for a point of balance the weight of the development and the environment.

¹School of Geographical Sciences, Northeast Normal University, Changchun 130024, China;

²Northeast Institute of Geography and Agricultural Ecology, CAS, Changchun 130012, China;

haofl587@nenu.edu.cn

Abstract

In the last decades, with the improvement of the public's awareness of shopping on line, development of economy, supported by the highly developed logistics and policy environment, the electronic commerce is developing rapidly in China, which is increasingly more and more important for social life and daily consumption of urban residents. Based on the data of E-commerce Development Index of 294 prefecture-level cities in China, which can reflect the level of e-commerce development, provided by AliResearch institute of Alibaba Group, this paper aims to reveal differences in the spatial distribution characteristics of the major cities and the factors influencing their development level, by means of using a comprehensive method of spatial analysis, Zipf theory and multiple regression. According to the research, three highlights are unveiled: (1) Overall the development of China's cities e-commerce is still at a low level, which shows the significant regional differences, with the eastern coastal cities higher than those in the western inlands. (2) The distribution of e-commerce level obeys to the Zipf principle at provincial level, showing obvious equilibrium distribution, while the fractal structure is more complicated at city level. The e-commerce level in provincial cities and municipalities is mostly in either low shopping and less enterprises or high shopping and more enterprises, showing a clear polarized situation. The cities' e-commerce level features significant spatial agglomeration globally and locally. (3) The results of multiple regression show that the e-commerce level is highly relevant to the population size, education, informatization degree and information infrastructure.

Key words:

e-commerce level; spatial distribution; influencing factor; China

The Construction of Space-behavior Interaction Theory

Yanwei Chai

College of Urban and Environmental Sciences, Peking University, Beijing 100871, P.R. China

Abstract

It is growing to be the significant mission for the behavioral schools of geography to construct a generalized theory explaining the interaction between space and behavior. It is also an urgent realistic demand for current urban development and transformation in China to summarize the conceptual model and explanatory model of space-behavior interaction combined with China's reality. Firstly, this study builds the theoretical foundation of space-behavior interaction research which takes social-space theory as epistemology, behavioral geography and time geography as methodology, activity-based approach as practical theory. Secondly, as for the research paradigm, the study argues the space-behavior interaction research needed to combine the place-based paradigm and people-based paradigm, facing current situation of China's urban development. Then this study makes an innovative attempt to construct a framework for space-behavior interaction theory. It needs to carry out research on spatial effects on behavior and behavioral effects on space to construct a generalized space-behavior interaction theory. On this basis, the diversity and similarity of space-behavior interaction in various cities, the trends and dynamics of spatial-behavioral interaction in different periods of time, the distinctiveness of various population segments, need be testified to improve the theory construction. This study provides foundation to space-behavior interaction theory, indicates directions to the summary and comparison of the space-behavior interaction patterns of different Chinese cities, and promotes the establishment of the Chinese urban space research paradigm based on behavior.

Key words:

space-behavior interaction theory; time geography; behavioral geography; urban space; space-time behavior

The Formation Mechanism of Urban Spatial Fragmentation

Peijuan Zhu

Hunan Normal University, Changsha, 410082 P. R. China, mrs-zhu@163.com

Abstract

The rapid development of China's urban constantly pushes the external expansion and internal restructuring of urban space. The spatial fragmentation of urban about ecology, economy and society has become an important characteristic of transition in big cities' space evolution, and along with it is a series of negative effects. Realizing the effects and formation mechanism of city spatial fragmentation is a critical issue for urban geography. This project aims to exploring the concept and connotation of urban spatial fragmentation with the general thought of "connotation-definition, phenomenon analysis, mechanism-exploration, and regulation-mechanism" with multidisciplinary integrate analysis prospective. With the methods of GIS technology in-depth analysis of Geo-informatic Tupu model and geoscience knowledge, which summed up the scientific laws. By combining the traditional evaluation method with the scenario analysis, the comprehensive evaluation of the fragmentation effect is realized by the fragmentation curve. Taking Changsha as a case study area, based on the empirical study, the level of urban spatial fragmentation and spatial effects are measured, and the formation mechanism is discussed from three aspects: the influence factor, the evolution rule and the driving mechanism.

Key words:

urban space; urban spatial fragmentation; formation mechanism

Urban Space Growth Based on GIS and Cellular Automation

Andong Guo

Liaoning Normal University, China, 1961551456@qq.com

Abstract

With the rapid progress of urbanization, the urban problems and phenomenon have a profound influence on economic, social and environment. Therefore, the complexity of urban space expansion process has been attached academics and government regulators widespread concern and attention. In this paper, we combined with geospatial data, statistical surveys, cellular automata and geographic information systems technology, take urban three-dimensional system as the research object, explore urban three-dimensional space characteristics and internal spatial effects, and build up a three-dimensional space urban growth model. Finally, we based on the urban growth trend and simulation results to predict the complexity of future urban space expansion and provide the quantitative analysis and suggestions for urban planning.

Key words:

urban three-dimensional space; expansion features; driving forces; simulation; urbanization

Advocating the Relevance of Open Source Smartphone GIS as an Emerging Technology in Managing Urban Solid Waste

Sengupta D, Das A.

Department of Geography, University of Mysore, Mysore 570017, India, dhritirajsen@gmail.com

Abstract

Mounting pressure on urban center with a large population gathering at a point base dwelling has become a serious matter in urban waste management. Especially when this per capita solid waste generated is going through an increasing trend. The city administrative bodies are out of gear to manage the disaggregated waste dumped in the nooks and corners of the urban centers. The issue in such type of urban maintenance is locating the extract point of waste dumps and channelizing the flow of its collection. Lack of data about waste dumping points can be overcome by open source GIS wherein each individual of the society will be a part of the management system without actually involving them directly either by time or physical strain. This paper showcases a systematic approach on why and how to implement mobile based open source mapping through which every citizen can be helpful to manage one such issue of solid waste management.

Key words:

Open source GIS; community participation; urban maintenance; mobile GIS; solid waste management

Chrono-Urbanism For Harmonious Cities

Luc GWIAZDZINSKI, Wenbo HU

Laboratoire PACTE, UMR 5194, 14 bis, avenue Marie Reynoard, 38100 Grenoble, France, luc.gwiazdzinski@ujf-grenoble.fr

Abstract

The temporal dimension of the cities has been neglected by planners and town councillors with inversely proportional intensity to its importance. It constitutes an essential aspect of urban activity, yet until now, urban planning has always focused on arranging space to use time better. Counter-efforts that consist of time-based planning with an effect on the occupation of space are few and far between.

Everything can change with the development of information technology and communication. The transformations of everydaylife compel too this development of tools for a chronologically-based urbanism. This paper proposes to integrate the concept of time in thinking about the smart city. From work carried out in several cities in Europe, we will examine the methods of collecting this information and spatio-temporal patterns of developed cartographic representations.

We examine the first design uses space-time. They require reflection on the dynamic character of a “malleable city”, in addition to the versatile nature of space and the built environment in relation to the time of day, the day of the week, or the year. This type of reflection on smart and sustainable cities attempts to limit the consumption of space, reduce energy use, and maintain urban intensity with its attendant social life.

Key words:

harmonious cities; chrono-urbanism; time-based planning; cartogramphic representations

Combination between Big Data and Small Data: A Case Study on Spatial Development and Influence Factors of Catering Industry in Nanjing Main City

Xiao Qin, Feng Zhen

The School of Architecture and Urban Planning of Nanjing University, Nanjing, 210093, P.R. China,

qinxiao1070@126.com

Abstract

The appearance of big data has led to hot topic in urban studies based on residential behaviour and activities and also promoted a reform of traditional methodology based small data in China. However, many faultinesses or limitations of big data (e.g., almost young individuals of Internet data, non-shared data in some critical areas, correlation preference) drive urban scholars to have to reconsider the role of small data. This paper believes that the small data will not lost its value in the big data era, on the contrary, should be fully combined with big data to solve gradually complicated urban problems and meet residential requirements in the future studies. Therefore, we need to explore the specific methods of combination between big data and small data, which are rarely seen in previous studies. Our paper will take Nanjing main city (China) as a case to analyze spatial development and influence factors of catering industry to discuss that combined methods. Firstly, we will collect the big data about restaurant comments of residents and locations from the website of Dianping.com, a third-party platform for restaurant comment. Second, we will build an index system to calculate the popularity of all restaurants to simulate their spatial distribution characteristics by using factor analysis and nuclear density analysis. Thirdly, we will sample a part of restaurants based on above analysis and use regress model to find the relationships between the restaurant popularity and some independent variables (e.g., price, dishes, environment, services, brand, location, transport).

Key words:

big data; small data; combination; restaurant popularity; Nanjing main city

Creative City Strategy: Externalities of Creative Industry Clusters on Urban Redevelopment and Branding in Shanghai

Jinliao He¹, Xianjin Huang²

¹corresponding author, PhD, Associate Research Fellow, Research Center of Human Geography, Nanjing University, 210046, China, Email: victor@geog.uni-heidelberg.de

²Professor, Research Center of Human Geography, Nanjing University, 210046, Nanjing, China

Abstract

While the creative economy plays an increasingly important role in today's globalized economic system, place-based strategies for attracting creative industries and talents are widely applied by cities within different socioeconomic contexts over the world. Though present creative city policy is more or less inappropriately implemented by such 'entrepreneurial governments', contributing limitedly to stimulating creativity in cultural production, there are significant externalities that creative industry districts have on urban redevelopment and branding. This is particularly applicable for Chinese cities where dramatic urban reconstructing is taking place; local city identities are getting even more indistinct because of a demolition-based urban redevelopment approach in China. This case study suggests that Shanghai's creative industry clusters (CICs) provide a sustainable mode for urban regeneration in China. First, it was found that creative industry clusters in Shanghai tend to reuse old constructions, and thereby reserve the architecture heritages which nearly become extinct in modern urban China. Moreover, creative industry clusters have a great positive impact on urban renewal and place branding by producing abundant unique urban landscapes and landmarks. Finally, it indicates that creative-city-image of Shanghai was generally perceived among external visitors and local residents within these creative industry districts owing to a beautification effect of creative industries.

Key words:

Creative industry clusters; city image; place-making; urban branding

Does Regional Technological Innovation Decrease or Increase Income Inequality?

Evidence from China

Quanen Guo, Bindong Sun

Center for Modern Chinese City Studies, East China Normal University, Shanghai, 200062, P.R. China, guoqedili@126.com

Abstract

Literatures on the relationship between innovation and income inequality mainly focused on USA and European regions, but it is also necessary to analyze that in China, which is the largest developing country, whether the innovation should be responsible for the striking income inequality. In this article, the authors examine the link between innovation and income inequality across Chinese city regions within 2004-2012 periods. A nonlinear relationship between innovation and income inequality is observed in our research. Also, these results are robust using the other measurement of income inequality, threshold effect models and investigations across regions. We then conclude that the innovation is one solution to decrease the income inequality. We propose that cultivating the low-skilled labor's innovative capabilities, increasing the inputs of innovation activities and overflowing innovative elements from the eastern region have moderated effects on the income inequality.

Key words:

innovation; income inequality; labor; nonlinear relationship; China

Evolution of Smart City Concept and Its Economic Performance: A Study of Cities in Telangana State, India

Lonavath Ashok Kumar, Karunakar.Virugu, V. Sathish Kumar

Department of Geography, Osmania University, Hyderabad, India 500007, ashokouprof@gmail.com

Abstract

Everyone is aware that modern cities are performing more and more of services necessary to the functioning of society. There is awareness that the vital services are not performed in the same proportions by all cities. Almost every geographer would identify Detroit as a manufacturing city, Glasgow as a port city, Manchester as Industrial city and Beijing as a Trading center there by indicating that one city does more than its share of manufacturing another provides trade and few facilitates the market for the finished goods.

Perhaps this classification is done more by faith or intuition than on the basis of exact knowledge. At what point does an economic activity become more important enough in the city to be of special significance? Can criteria be devised that will determine which city should be labeled manufacturing or trade cities and centers for market?

Telangana is the 29th state of Indian union with 3,50,03,674 population and 38.12% urban growth. Around 30% of the urban population is residing in the capital city of Hyderabad. The total number of cities during 2011 census was 160. The economic activity is the main cause for the city growth. Standard deviation procedure applied for city classification. These cities with strong economic potential have great scope for rapid development by using innovative technology and there by rising as creative centers have made them to emerge and transform as smart cities. It is the purpose that this paper presents a methodology that will form a basis for such classification.

Key words:

Modern Cities; Economic Activity; Smart Cities; Innovative Technology

Related Variety, Global-Local Linkages and Urban Innovation Performance

Wang Junsong

East China Normal University, Shanghai, 200062, China. wjsenjoy@126.com

Abstract

The paper intends to explore how related variety and global-local linkages related variety affect urban innovation abilities in China using prefecture level city-industry data from 2003 to 2010. The results show that urban innovation abilities benefited from spillovers of the related variety or complemented variety; it is related variety rather than unrelated variety that promote the urban innovation performance. The paper also explores the effect of relatedness of global-local linkages on urban innovation abilities, then we found that the city with external linkages, and in which the foreign sectors and local sectors have close linkages but not the totally the same have the best innovation performance, which demonstrates that the extra related knowledge linkages promote regional and collective learning.

Key Words:

Related variety; Global-local linkages; Innovation; Urban; China

Spatial Changes and Reconstruction of Taobao Villages in the Internet age: a case study of Lirendong Village

Chen Tingting¹, Yang Si¹, Zongcai Wei², Li Xun¹

¹Department of Urban and Regional Planning, Research Institute of Urbanization, Sun Yat-Sen University, tinting.chen@connect.polyu.hk

²Department of Urban Planning and Design, The University of Hong Kong, Hong Kong, China

Abstract

In the era of 'Internet+', E-commerce as a new economic activity, has profoundly changed the traditional way of life and production in the rural areas, and created rural e-commerce industry and spatial agglomeration - Taobao Village - with Chinese characteristics. Taobao Village promotes the reconstruction of spatial form and industrial pattern in the rural areas, and provides a possible new alternative of rural urbanization in the Internet age. This paper utilizes Lirendong Village as a case study to explore its spatial changes and restructuring as well as its mechanism for the 'Internet+' age. The findings show that Lirendong Village has experienced three stages of spatial changes: "Industrialization - Business Transformation - E-commerce upgrade". Moreover, the spatial transformation of Lirendong Village has experienced from a "core - periphery" trajectory that is original, single, and chaotic space to a more diversified, agglomerated, multidimensional space with new vertical and horizontal spatial characteristic. Last but not least, given the development of E-commerce, the forces of social network organization of hometown friends and the government-led transformation of spatial transformation have driven the spatial changes and reconstruction in the rural areas. The research provides some suggestions and strategies for realization of the new urbanization of villages.

Key words:

Spatial changes; Spatial reconstruction; Taobao village; Internet age; Lirendong Village

Temporal-Spatial Pattern Evolution of Knowledge Intensive Business Services in the Inner City: A Case Study of Baoding

Lin Zhou, Tiyan Shen

Peking University, Beijing, 100871, P. R. China, zhoulinup@pku.edu.cn

Abstract

Full implementation of innovation-driven development strategy has been regarded as the key point of industrial structure upgrading in many cities in China. By using multiple analysis methods such as standard deviational circle, kernel density estimate, nearest neighbor hierarchical spatial clustering and space syntax, this paper examines the spatial and temporal pattern of knowledge intensive business services (KIBS) in Baoding, the first demonstration city of innovation-driven development strategy in China based on the enterprise data of the second (in 2008) or third (in 2013) economic census. The results show that, first of all, as far as the overall development situation is concerned, the KIBS enterprises have become more spatially diffusion and distribute along northwest to southeast orientation from 2008 to 2013. While, the different types of enterprises show some differences in the range in diffusion and change in direction. Second, considering the block structure, the KIBS enterprises have significant characteristics of spatial concentration and remarkable differentiations on both side of Beijing-Guangzhou railway. Among them, financial service and sci-tech service enterprises shows the evolution patterns of fanned extension and fill-up agglomeration. Business service and information service enterprises' evolution patterns is intensive agglomeration. The third one is related to KIBS enterprises' linear structure. The whole KIBS enterprises and different types of them have similar hierarchical systems which are gradually converging from 2008 to 2013. At the same time, the enterprises' location choices are paying more attention to traffic network's "access" ability rather than "through".

Key words:

knowledge intensive business services; temporal-spatial pattern evolution; inner city; Baoding

The “Mobile Banking for Community” — Activation Paths for Neighborhood in Modern Cities

YE Yuanyuan, LIU Yuting

South China University of Technology, Guangzhou, 510641, China, 56981868@qq.com

Abstract

Neighborhood as a community based on geographical relation, has kept on changing to respond the demand of human being. Compared with ancient neighborhood with the characteristics of highly homogeneous, intimacy and stable relations, modern neighborhood turns to be more open, which has less social interaction and further triggers a variety of anti-social behaviors. This paper aims to investigate the nature and attributes of modern neighborhood, and to analyze its endogenous dynamic pattern. The paper advances multidimensional interpretation of implied “neighborhood attributes” by case study of “Mobile Banking for Community”, in which originated from community residents’ daily life, taking financial products as platform and media. The multiple participators from bank, real estate company, property management company, surrounding businesses, and local community form active interaction and a strong interest relationship, which leads to the neighborhood unit regaining its vitality and spirit. Finally, the paper puts forward some paths and measures to activate the neighborhood: 1) improve spatial proximity as the base of neighborhood relationship building, with the aid of modern scientific and technological methods such as internet, to promote neighborhood interaction; 2) multiple participators including local government, enterprises, and residents should be encouraged to join the action; benefits association should be established by combining community business and public services, so that an effective approach would identify to keep neighborhood working well with its social and economic base; 3) sequential goals and action plans should be set up to activate and cultivate the emotion and spirit of neighborhood.

Key words:

mobile banking; neighborhood nature; neighborhood attributes; activation paths

Urban Managers' Smart City Related Technological Innovations' Adoption and Utilization in Developing Country-Nigeria: An Exploratory Study

Asiyanbola R.A.

Osun State University, Osogbo, Nigeria

Abstract

The aim of the exploratory study is to evaluate smart city related technological innovations – Geographical Information Systems (GIS) and remote sensing - adoption issues among urban managers and examines the relationship between individual urban managers' GIS and remote sensing awareness/adoption and utilization issues. Among the research questions which the study addresses are: Do urban managers aware of GIS and remote sensing benefits and costs? Do urban managers have interest in GIS and remote sensing training/retraining programmes? Do urban managers have constraints in building their knowledge of GIS and remote sensing? Is there any relationship between the working experience and age of urban managers and their (i) interests, (ii) awareness/adoption, and, (iii) utilization of GIS and remote sensing? Is there significant difference in the urban managers (i) awareness, (ii) interests in GIS/Remote sensing training/retraining programmes, and, (iii) utilization of GIS/Remote sensing. The data for the study was obtained through primary and secondary sources. The primary data was collected through administration of questionnaires. A total of one hundred and one (101) questionnaires were administered to urban public servants in five local governments in Ibadan metropolitan area and at the Oyo State Government Secretariat in Ibadan between August and October, 2015. The data was analyzed using both descriptive and inferential statistics which include frequency analysis, Chi-Square test and correlation statistical methods. Policy implications of the findings towards enhancing human capacity building in relation to smart cities viabilities and technological innovations needs in Nigeria are discussed in the paper.

Key words:

Urban; urban manager; urban public servants; smart city; technological innovation; geographical information system; remote sensing; human capacity building; Nigeria

“Zhongchuang” Space in Urban China: Innovative or Entrepreneurial

Zhen Feng, Qinxiao

Nanjing University, China, zhenfeng@nju.edu.cn

Abstract

Recent years, some new kind of physical places in western countries such as co-working spaces, hackerspaces, maker spaces, FAB LAB and so on have got rapid spread all over the world. Although there is no standard definition for these kinds of space, lots of literatures emphasize the importance of innovation and community. As a big manufacturing country, China has also witnessed the growth of co-working/maker space from 2010. The first maker space emerges in Shanghai, and then expands to other Chinese cities. A new word is coined as “Zhongchuang” space which including co-working/maker space has got more and more attention in recent years by scholars, practitioners, enterprises and policy-makers in China. Practices of these spaces in the west countries are relatively mature. However, the theoretical research is still at the initial stage, which covers many fields include economy, management and urban studies. As a new model imported from the west, relevant theoretical research in China is also blank. Taking Beijing, Shanghai, Guangzhou and Nanjing as four cases, the paper discusses the development characteristics of “Zhongchuang” space in Chinese cities, compares the differences with the west. The paper tries to analyze the relationship between different actors, and explore the innovative/entrepreneurial model and the mechanism of collaborative process. Finally, the paper discusses the implication for policy-making in Chinese context, and gives some possible suggestions.

Key words:

“Zhongchuang” Space; innovative; entrepreneurial; China

Future Development of Urban Environment in Russia and Global Trends

Alekseeva N.N., Greenfeldt J.S., Klimanova O.A., Tretyachenko D.A.

Faculty of Geography, Lomonosov Moscow State University, Moscow, 119991, Russian Federation, nalex01@mail.ru

Abstract

The paper reveals key features and the results of long-term foresight of the development of urban environment in Russia. The foresight was undertaken at the moment when major changes occurred in Russian economy associated with transformation of scientific and innovation policy. The foresight represented a wide coverage of issues (global, regional and national challenges, growing markets, new emerging issues and barriers, assessment of urban environment development in Russia versus leading countries of the world, etc.) and methods (surveys, bibliometric and patent analysis, roadmapping, etc.). In total some 300 experts were invited to participate in the research. Windows of opportunity for Russia in the field of urban environment that may open in medium- and long-term perspective are as follows: development of technologies for environmentally safe recycling of waste and disposal of toxic substances; wide-range use of materials with new properties and technologies, development of green construction and green infrastructure; creating super-computing technologies and information infrastructure for smart cities; effective technologies for monitoring and evaluation of urban systems; development of environment-friendly transport. According to the experts, up to 2020 the most rapidly growing markets in the sector of urban environment are as follows: environmentally-friendly materials and products and systems of prediction of natural and man-made emergencies in cities. In the long term (2020-2030) the markets of water treatment and water reuse, environmentally safe waste management, as well as the markets of recycling and finished products based on the processing of waste and wastewater can significantly increase.

Key words:

urban environment; long-term foresight; waste management; green infrastructure

Internal Spatial Structure of Intercity Networks of Knowledge Flow in China

Haitao Ma

Institute of Geographical Sciences and Natural Resources Research, CAS, Beijing, 100101, P. R. China, maht@igsnrr.ac.cn

Abstract

The Chinese urban system is experiencing a fundamental shift from constituting a size-based hierarchy to becoming a network-based system. Most recent research on the Chinese city network has focused on flows of people, material, and information, paying little attention to the significance of flows of knowledge. Using data on co-authored papers and GIS and Ucinet software, this paper visualises and analyses the Chinese city network. Whilst the city network based on scientific collaboration demonstrated an apparent hierarchy, the level of the city's external network connectivity did not maintain a significant correlation with population size and economic strength. Further, the city networks were characterised by different hierarchical clusters, and network linkage intensity was found to be unevenly distributed in China. Aiming to promote inter-city collaborative innovation and the usage efficiency of national scientific and technological resources in the context of the knowledge economy, this study supports the building an innovative country.

Key words:

City network; knowledge flow; co-authored papers; spatial structure; China

Research and Practice on Qingdao Offshore Weather Forecast Service Platform

Sun Yong, Jin Fengxiang, Ji Min, Lin Hang, Wang Huimeng, Li Ting

Geomatics College, Shandong University of Science and Technology, Qingdao, 266590, P. R. China, gisskd@163.com

Abstract

Qingdao is an important regional economic central city of China. It's one of the first batch of open coastal cities. The gross ocean production of Qingdao was 209.34 billion in 2015, about 22.5 percent of GDP. In order to better serve the development of marine industry, and improve the service ability of offshore weather forecast, the Qingdao marine weather forecast platform was developed to supply accurate weather information to public in time. The platform is based on SOA architecture and WebGIS technology. It implements the unified storage and management of weather data and other information, such as the data of automatic weather station, the buoy station data, Doppler weather radar data, satellite cloud image, the Titan (Thunderstorm Identification Tracking Analysis and Nowcasting) data, the forecasting data, the fishing area and the marine chart data, etc. These data are shared and exchanged with other ocean administration departments. So it can offer the real-time observable data, the weather forecast and warning, the marine traffic navigation information and so on. It can push live weather warning message to the marine departments by analysing observational data and radar echo extrapolation overlay with user location based on GIS, which will help to avoid weather disasters. The platform can provide data support and analysis tools for the forecaster, and help to publish the forecast information rapidly to public and special users.

Key words:

Offshore Weather Forecast; Weather Warning; WebGIS; Radar Echo Extrapolation; Data Integration

Research on Creative Industry Parks' Spatial Evolution and Urban Space

Reconstruction in Shenzhen

DUAN Jie, ZHU Li-ping

School of Economics, Institute for Cultural Industries, Shenzhen University, Shenzhen, 518060, P. R. China, duanjie915@163.com.

Abstract

Since the new century, creative industry has become a new engine for the city development with the wave of globalization and the rapid development of knowledge economy to promote the economic, cultural and social transformation. Creative economy and Urban economy interacts each other, creative space and urban space promotes each other. Creative industry park evolution relevants to the transformation of urban spatial structure; how to optimizing the transformation of urban space with the help of creative industry park evolution and how to use urban spatial reconstruction to promote the development of creative industry have become hotspots in academic. Shenzhen is the first city in China that awarded the title of "the capital of design". The creative industry develops rapidly, the spatial agglomeration of creative industry parks becomes more and more obvious. In this paper, from the breakthrough point of the evolutionary economic geography theory, deeply discusses the interactive relationship between creative industry park evolution and the transformation of urban spatial structure. First of all, this paper describes the current development situation of creative industry in Shenzhen in terms of its development scale, the degree of concentration and environment, qualitatively analyzes the spatial evolution procession of creative industry parks; then with further analysis of the maps, it summarizes the features of space distribution, concludes models of creative industry parks' spatial expansion and organizational models; finally, it qualitatively analyzes the relationship between Shenzhen creative industry park evolution and the urban spatial reconstruction from the view of economic, social, cultural and transportation and offers some suggestions to promote the development of creative industry clusters.

Key words:

Creative Industry Park; Urban space; Spatial evolution; Spatial Reconstruction; Shenzhen

Research on Entrepreneurship Environment of University Students in Shanghai

ZHANG.Lu, WANG.ChengYun

Shanghai Normal University, Shanghai, 200234, P. R. China, 873672891@qq.com

Abstract

The Shanghai government has clearly put forward the construction of the global influence of science and technology innovation center as the future development of the strategic objectives, and further promote the public entrepreneurship, innovation, entrepreneurship and innovation to become the new engine of economic development. At present, compared with developed countries, the United States, the number of college students venture is still too small, entrepreneurial success rate is low, an important reason is entrepreneurship environment in our country are not perfect and sound, entrepreneurial culture didn't get the promotion. Shanghai as an important economic center, science and technology innovation center of China, have an obvious advantages of education resources and financing environment. This paper from the three dimensions of Shanghai government, universities and society as the entry point, making an investigation on College Students' entrepreneurial demand, entrepreneurial psychological, combining the Shanghai university students entrepreneurial situation and environment, further proposed relevant suggestions of Shanghai college students entrepreneurial environment and policies.

Key words:

Shanghai; entrepreneurship environment; university students

Research on Innovation Spillover Distance of Industry University Research Cooperation in Yangtze River Delta

CHEN.L. J, WANG.C. Y

Shanghai Normal University, Shanghai, 200234, P. R. China, chenlijun9212@163.com

Abstract

Industry university research is the main way and important source of regional innovation. Based on the invention patent data of the State Intellectual Property Office

for Industry university research cooperation. This paper studied the current situation of the Industry university research in Yangtze River Delta as well as the distance of knowledge spillover, the direction of knowledge flow and its evolution characteristics are compared and analyzed by using the Kernel density estimation and network structure analysis method. The results showed that: ①The number of the patent for Industry university research cooperation Continued growth. ②The patent of Industry university research cooperation is not necessarily a positive correlation with the number of knowledge spillovers. ③The regional spatial distribution of the patent of Industry university research cooperation and the distance of knowledge spillover are different in different industries.

Key words:

YRD; IURC; Innovation spillover distance; Invention patent

Spatial Pattern and Locational Model of Shanghai Innovative Industry: An Analysis Based On Enterprises and Postcode Areal Data

Yang Fan, Du Debin, Duan Dezhong, Lin Xiao

East China Normal University, Shanghai, 200062, P. R. China, yf_8845@hotmail.com

Abstract

In the background of innovation-driven and transitional development, it is meaningful to study industrial spaces and development models of postindustrial cities. Based on the data of enterprises, this article investigates spatial pattern from three different perspectives: geographic distribution, regional classification and spatial correlation, and also analyses the mechanism of spatial differentiation through negative binomial regression. The research shows that Shanghai innovative industries present the distribution characteristics of multi-axes and multi-cores, showing radiation and driving function to the whole city. The regional classification of Shanghai innovative industries presents a pyramid-like structure which Zhangjiang and Caohejing are the core areas. As a result, Shanghai develops two industry clusters with intergrowth and interaction. Development zones, universities and research institutes (URIs), old industry areas, traffic accessibility, suburbanization and path dependence have significant positive influence on enterprises location choice. With the mutual effects of factors, Shanghai emerges three different models of innovative industry districts: the first is the “anchor plus” model which is centered around universities and research institutes (URIs), the second is the “re-imagined” old industry areas, the last is development zones construction. There are differences among different types of enterprises including large-scale, small-scale, state-owned, urban industry and start-ups in the spatial pattern and mechanism of Shanghai innovative industries.

Key words:

Shanghai; Innovation; Industries; Enterprises; Postcode; Spatial pattern; Location

The Analysis of Spatial Convergence for High-tech Industry Innovation Performance in China

Zelei Xiao, Xinya Du

Hubei Institute of economic and social development, China, 42040074@qq.com

Abstract

Nowadays, there exist both regional scale differences and regional performance differences in China's high-tech industry development. Performance difference will directly affect resources allocation in regional high-tech industry and the upgrading of industrial structure. This paper conducts a systematic study on convergence issues about China's high-tech industry development performance by adopting spatial panel econometric method and related approaches.

Firstly, from the perspective of research and development efficiency and economic efficiency, it measures the comprehensive performance of China's high-tech industry development by applying Malmquist index and efficacy coefficient method; and then, by adopting Spatial Autoregressive (SAR) panel data model, it studies the absolute β convergence and convergence mechanism of China's provincial high-tech industry development performance from 2001 to 2013. The result indicates that distinct absolute β convergence exists in China's high-tech industry development performance since 21st century, which is mainly due to technology diffusion, and the convergence rate of central China is obviously faster than that of other regions.

Key words:

high-tech industry; performance; spatial convergence; SAR model

The Research on the Regional Difference, Evolution and Convergence of Innovation Capability of China — Based on the Level of Space and Factor

Zelei Xiao, Shao-hua WANG, Shao-peng ZHANG

Hubei Institute of economic and social development, China, 42040074@qq.com

Abstract

The article analyzes the innovation capability difference of China and its eastern, middle, western, and northeastern regions and their evolution law in the period of 1998-2012 with the Theil index and its decomposition formula from the perspectives of high-tech industries; and explains the main reason that causes the regional innovation capability difference from spatial and factorial level; then analyzes the innovation capability convergence of China and its four regions and the effect that innovation capital input, R&D input and innovation culture have on innovation capability convergence by implying the space panel β convergence model. The conclusion of the research shows that 2007 is the important inflexion point of China's regional innovation capability difference pattern. The convergence speed of regional innovation capability has been accelerated significantly since 2007, which shows a good posture of China's regional collaborative innovation construction and innovation capital and innovation labor is important in driving China's regional collaborative innovation.

Analysis of Effects of Transformation large Villages into Small Towns in

Contemporary Iran (1991-2015)

Izady H.

Department of Urban Planning, Shiraz University, Shiraz, Iran, izady@shirazu.ac.ir

Abstract

The rapid growth of small towns has been one of the main features of urbanization during the past decades in Iran, and remains as a major challenge for the managers, policymakers and urban planners. Changes in the regulations and criteria for separating villages from cities have resulted in increasing the number of cities from 520 in late 1991 to 1243 in 2015. Changing the large villages to small towns have variable effects on the economic, social and environmental aspects of people's life at the local, regional and national levels. This paper examines the impact of promoting villages to towns via content analysis method. The results show that there have been some positive effects such as increasing and improving service functions, creating some new job opportunities, especially in administrative and service sectors, improving quality of life, stabilization of population in rural areas and reduction of rural-urban migration. Some of the negative effects include: the loss of fertile agricultural lands around the towns, increasing the level of expectations and growing demands of the people of the state, increasing the price of land and housing and promotion of land speculation. Therefore, due to the rapid growth of small towns in the urban network of Iran, it is necessary to plan and formulate a national development strategy for small towns in order to direct them towards having an effective role in different aspect of development at the regional and national levels. This paper will examine these aspects and presents some solution to these obstacles.

Effects; transformation; large villages; small towns; Iran

Changing Demographic Face of Ukrainian Cities in the XXI Century: Challenges for Polycentric Development

Rudenko L., Lisovskyi S., Maruniak Eu., Mozgovyi A.

Institute of Geography of Ukraine NAS, Kyiv, 01030, Ukraine, emgeooffice@gmail.com

Abstract

After independence, Ukraine faces many challenges in the field of urban development, mostly conditioned by historical events of the twentieth century. Later, among significant factors of influence appeared globalization and complex economic processes, the decline of industrial production, population aging and decline. International and internal labour migrations led to significant polarization of Ukrainian urban space. As a result, in this polarized landscape we may see Kyiv (capital city), which gradually takes a shape of global city, few regional centres as well as rapid degradation of small and medium-sized cities within remote areas. There are also noticeable regional differences in urban space changes. Among main reasons are mentality and scenarios of cities' origination (mono-functional industrial centres, transportation hubs, centres of tourism, etc.). Extra problems are rising from the war in Donbas, Crimea annexation, which brought several million internally displaced people. So that answers on a numerous question are necessary. What are currently Ukrainian cities? What are the trends in demographic structure? How rapidly processes of marginalization are developing? What kind of policy do we need to ensure polycentric development?

In our studies we analysed the situation prevailing in the urban space of several model regions (respectively on the East, West, South, and North). The degree of polarization as well as factors of cities growth and decline was revealed. Special attention was given to changes of demographic structure in cities at the different levels and such important issues as health, education, age, gender and ethnic features of the local population.

Key words:

Urban development; urban space; cities; demographic changes; polarization; polycentrism

Characteristics and Formation Mechanisms of the Employment Centers in the Beijing Metropolitan Area

LU Minghua¹, YIN Zheng¹, SUN Tieshan²

¹School of Resource Environment and Tourism, Capital Normal University, Beijing, 100048, P. R. China,

lmhannie@vip.sina.com

²School of Government, Peking University, Beijing, 100871, P. R. China

Abstract

Based on the first, second and third economic unit census of Beijing, this paper identified the employment centers in the Beijing metropolitan area using spatial analysis methods, investigated the characteristics and formation mechanisms of the employment centers. We found that there existed 16, 13, and 13 employment centers in the Beijing metropolitan area in 2004, 2008 and 2013, which were mostly located in the central areas and the near suburbs. The number of employment centers in the central areas decreased, while the number of employment centers in the suburbs increased. From 2004 to 2013, the industrial specialization of employment centers enhanced and there was obvious industrial specialization division among centers. Through analyzing the determinants of the emergence of the employment centers, we found that agglomeration economies and transportation accessibility were the major explanations for the formation of centers in the Beijing metropolitan area. Meanwhile, the spatial scheme planned in the city's master plan could explain the formation of the centers, but not quite significantly.

Key words:

Polycentricity; Employment Centers; Urban Spatial Structure; Beijing Metropolitan Area

Landscapes of Development: The Urban Fringes

Valentina Anzoise¹, Weiliang Zhang²

¹Post-doctoral Research Associate, Ca' Foscari University of Venice, European Centre for Living Technology (Italy)

²Full-professor, Institute for Urban Studies, Hangzhou Normal University, Hangzhou, P. R. China, zwlia@163.com

Abstract

The paper will discuss the hypothesis and first outcomes of the EuropeAid project MEDIUM, focusing in particular on the important changes of Hangzhou city in the last 30 years, due to the implementation of different comprehensive master plans, which could be divided into three versions of 1981 – 2000, 1996 – 2010 and 2015 – 2020, but also to the presence of many non-state-owned industries. It will address the visions, narratives and discourses about urban development and modernization pursued in Hangzhou, and more specifically in Yuhang - presently a district in the urban fringe of Hangzhou in rapid development but planning to become another sub-center of the city - where one of the 4 pilots Future Sci-Tech city in China is been realized. Also, it will discuss the cascading effects - on landscape and environment, social organization and community identity, as well as on energy efficiency and food provisioning - triggered by such rapid changes in the area. Indeed, urban fringes are very dynamic (but critical) social and geographical entities – whether they are subjected to planning or not, where different populations, functions and opportunities (and threats!) might coexist. The urban fringes could link up to the central cities (and to their comprehensive planning) while ensuring that the spatial units have an organic fusion and relative independence. Moreover, the adoption/development of tools and processes pursuing urban sustainable development while ensuring high flexibility to future changes is also a major issue which the partners of MEDIUM project are addressing.

Key words:

landscapes; urban fringes

MEDIUM | Landscapes of Development: Hangzhou Urban Fringes

Valentina Anzoise¹, Weiliang Zhang²

v.anzoise@mediumcities-china.org

²Full-professor Institute for Urban Studies, Hangzhou Normal University, Hangzhou (P. R. China)

Abstract

The paper will focus on the urbanization-related changes faced by the city of Hangzhou, capital of Zhejiang Province and second largest metropolis in the Yangtze River Delta Region, in the last 30 years, due to the implementation of different comprehensive master plans (i.e. 1981 Ð 2000, 1996 Ð 2010 and 2015 Ð 2020) and to the presence of many non-state-owned industries. The visions, narratives and discourses about Hangzhou urban development and modernization will be analysed, focusing in particular on Yuhang district - until few years ago a county constituted mainly by farmlands, annexed to the city in 2001 and now part of Hangzhou urban fringe. Presently Yuhang is experiencing a rapid development, it is willing to become another center of the city and will host one of the 4 pilots Future Sci-Tech city in China (<http://www.zjfuture.gov.cn/english/>). The paper will discuss the cascading effects - on landscape and environment, social organization and community identity, as well as on energy efficiency and food provisioning - triggered by such a massive (and rapidly implemented) planning, dedicating particular attention to the way these transformations are perceived and framed by different stakeholders. Indeed, urban fringes are very dynamic but also critical social and geographical entities where different populations, functions and opportunities (and threats!) might coexist. For this reason, the adoption/development of evaluation and planning tools and approaches to pursue urban sustainable development while ensuring high flexibility to future changes, is another major issue the partners of MEDIUM project, this paper is one of the result of, are addressing.

Urban development; Medium size cities; Sustainability

MEDIUM: Medium Chinese Cities' Integration to The Global Economy

Ignazzi CA, Swerts E, Rozenblat C

University of Paris 1, CNRS-Paris France, University of Lausanne, France, antonio.ignazzi@parisgeo.cnrs.fr

Abstract

The Chinese urbanization is characterized by its rapid growth, particularly within coastal cities, and large and dense tridimensional cities. These coastal large cities concentrate most of the internationalization of economy, in particular foreign subsidiaries. However, a spatial deconcentration trends could have been encourage by the development of Special Economic Zones since the 1990's outside the coastal zones. On the other hand, the Chinese government promulgated successive decentralization reforms that facilitated the economic development of the prefecture level cities and of the smallest ones, the district level cities.

In the context of the fast integration of China in the global economy, our hypothesis is that policies fostering the development of both non-coastal cities and small and medium size cities, managed to diffuse rapidly the integration to the global economic networks

In the frame of the MEDIUM project our paper question (i) the evolution of the weight of medium size cities in the Chinese integration in global multinational firms' network and (ii) how their role and their position in these networks could transform their economic specialization.

In accordance with the MEDIUM project, we particularly focus on three cities: Hangzhou (Zhenjiang), Datong (Shanxi) and Zhuhai (Guangdong). The empirical analysis is based on the geo-location by Urban Areas of direct and indirect financial linkages between the 800.000 worldwide subsidiaries of the 3,000 largest multinational companies in the world in 2010, 2013 and 2016 (ORBIS database).

“MEDIUM” Planning the Smart City: Case Study of the Dream Town in Hangzhou

Argyriou I., Douay N.

UMR 8554 Géographie-Cités, CNRS, Paris, 75006, France, i.argyriou@mediumcities-china.org

Abstract

While smart city agendas are increasingly adopted in numerous cities, both in developed and developing countries, as a way of promoting sustainable development, research tends to pay little attention to the planning of the smart city. In order then to better understand the various ways through which this phenomenon is currently pursued there is a need for more empirical research on the types of planning frameworks and practices relevant to smart city development in diversified urban contexts. Aiming to contribute to this emerging scholarly debate, this article examines from a planning perspective how smart city development is designed and applied in the context of China’s urbanization process, a country which puts growing emphasis on the smart city as a mechanism to promote sustainability. In doing so, the article presents an empirical case-study, informed by interviews with diverse actors, for a recent innovation initiative of start-ups entrepreneurialism in the area of the digital economy, the so-called “Dream Town”, undertaken in Hangzhou, a provincial-level city located at the Southeastern part of the country, in the context of a governmental pilot scheme for urban innovation tested in four Chinese cities. By looking then more closely at the design and implementation of the “Dream Town” initiative from an urban perspective the article aims to gain understanding of the types of planning frameworks, institutional settings and actor perspectives central to smart city development in a particular Chinese urban context, as well as to identify issues which could inform broader efforts when planning the smart city.

planning; smart city development; urban China

MEDIUM - Transformation of Governance in Development Zones in China: A Study Case of Hangzhou Future Sci-Tech City

Liao LIAO

Institut des Sciences Politiques d'Aix en Provence, l_liao@hotmail.com

Abstract

During China's urbanization process, the development zone is an important and special zone, which has gradually experienced in different stages of development: the formation, the rapid growth, the stable development and the transformation, with a transition from the economic zone to the new model of urbanization. With China's economic development and urbanization, the development and governance in development zone has entered a new stage.

In this paper, according to research about Hangzhou Future Sci-Tech City in Zhejiang and its new characteristics, we can refer that the notion of governance or local governance seems to be more developed during the new era of development zones. Besides, the paper will analyze the characters that seem to those of local governance, such as "growth coalition" that excludes the participation of citizens and that "anti-growth" which was developed in an authoritarian country. Finally, we will discuss whether these new trends can be seen as a certain pluralization of public action in China and how the governance in development zones can be defined.

Key words:

development zones; transformation; growth coalition; local governance

Planning Polycentric Mega City-Regions in China: Evidence from Guangzhou's Outer Suburbs

Ms Cheng

Department of Geography and Planning, University of Liverpool, Liverpool, L69 7ZQ, UK, H.Cheng4@liverpool.ac.uk

Abstract

Since the 1990s, urban spatial restructuring in China has been driven mainly by price mechanisms induced by land reform. Correspondingly a number of metropolitan regions have been indeed transforming themselves from single centred, centralized structures into more polycentric spatial structures. Towards the end of 20th century, a terminology, *polycentricity*, was introduced as a new planning concept into China. Subsequently a number of mega city-regions began to apply polycentric development spatial planning strategies designed to better facilitate more sustainable and balanced development. This paper seeks to explore the key themes regarding polycentricity application in a Chinese context, and uncover both horizontal and vertical conflicts in effective delivering of polycentric development strategies from city-regional level to local development. The empirical basis of this paper is a case study of Nansha, which is considered as a sub-centre within Guangzhou mega city-region. Based on a detailed review of key planning documents and interviews with key actors from both city-regional and local scales, three key themes are raised including interpretations of the concept of polycentricity, multiple scales in application and multilevel governance under a polycentric framework. Nansha was originally a suburban town at the outer suburbs of Guangzhou, but it has experienced several shifts in repositioning and re-planning. In conclusion it is highlighted the inconsistencies between the emerging polycentric governance within China's mega city-region which leaves local capacity to enable independent actions and state's strong involvement and intervention in its development.

Key words:

polycentricity; mega city-regions; multilevel governance; Nansha

Polycentricity or Dispersal? Testing for the Effects of Polycentric Strategy in

Metropolitan Shanghai

Zhang T. L., Sun B. D.

The Center for Modern Chinese City Studies & School of Urban and Regional Science, East China Normal University, Shanghai, 200241, P. R. China, ztlbjy@126.com

Abstract

The employment suburbanization in western developed countries, especially in North America, has been widely recognized. However, attentions on how and where the employees dispersing in the metropolitan are not enough. In contrast, related empirical studies are much less in China. To achieve the balance of “fundamental trade-off” between agglomeration benefits and agglomeration costs, a number of large cities in China have implemented the polycentric spatial strategy, but it seems not as effective as anticipated. Based on the empirical analysis of the employment spatial structure in Shanghai, this study aims to answer the question: which structure does Shanghai tend to be, polycentricity or dispersal? The conclusion demonstrates that the employment in Shanghai is undergoing the decentralization process and spreading from the city center to the urban periphery. However, the influences of both the main center and sub-centers on the employment density of surrounding areas are decreasing, that means a process of generalized dispersion rather than polycentricity seemed well established for the period 2004 to 2008 in Shanghai. This study also shows that the administrative boundaries matters for the influences of employment centers, the density gradient associated with the distance to the nearest sub-center is steeper if the sample belongs to the same district as its nearest sub-center, although this segmentation effect is weakened as time goes on.

Key words:

urban spatial structure; polycentricity; dispersal; decentralization; Shanghai

Spatial Relations and Evolution of Urban System on Central Asia

Yeerken Wuzhati

Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing 100101, China, yeek.10s@igsnrr.ac.cn

Abstract

Since the dissolution of the Soviet Union, along with economic and social development, spatial framework of urban system in Central Asia has gradually changed. Spatial relations of urban system generally involve the exchange of matter, energy, people and information. But because the data about Central Asia are difficult to obtain and linkages among cities are complexity, this research attempts to use gravity model approach to analyze intensity of spatial relations among cities in Central Asia by quantitative calculations, and accordingly describe states of spatial relations and nodal region structure of urban system in Central Asia. The results show that, since 2000, urban network systems of Central Asia have gradually dispersed, evolving from two urban systems into four urban systems, and featuring with the basic form of "dual-nuclei, four-system, and four pairs of international twin cities".

Key words:

urban system; spatial structure; evolution; Central Asia

Territorial Arrangements of Small- And Medium-Sized Towns from a Functional-Spatial Perspective

Sykora L, Mulicek O

Charles University in Prague, Prague 2, Czech Republic, sykora@natur.cuni.cz

Abstract

This contribution applies a functional-spatial perspective to the study of small- and medium-sized towns. A methodology for functional analysis is developed and tested to identify towns, distinguish towns from cities, and detect town positionality within urban territorial arrangements, focusing on whether they are autonomous, networked with other towns or agglomerated with large cities. The methodology is used to compare settlement systems in two regions and two countries in Europe by looking at the existence and nature of networks between towns and cities and how towns perform in terms of population and jobs in respect of their belonging to different types of territorial arrangement.

Key words:

small- and medium-sized towns; settlement systems; territorial arrangements

The Belval Project: Towards More Polycentrism in Luxembourg?

Antoine DECOVILLE, Olivier Klein

Luxembourg Institute of Socio-Economic Research, Esch-sur-Alzette, Luxembourg, antoine.decoville@liser.lu

Abstract

The small State of Luxembourg faces very strong dynamics of economic and demographic growths, which are concentrated to a large extent in its capital city: Luxembourg-city. This spatial concentration of activities and people within the capital contrasts with the situation of the second-tier cities which face some problems of growing unemployment. This is why the Luxembourg government has put in place a polycentric strategy since 2002 which supports the development of the second-tier cities in the country in order to offset the dominance of the capital city. One of the key aspects of this strategy is to improve spatial equity by improving the accessibility at all places within the country. This spatial strategy finds its most obvious concretisation through the “Belval project”, which is a large-scale State-driven project of urban regeneration at the margins of the medium-city of Esch-sur-Alzette. In this paper, we use an accurate road accessibility model that we combine with a comprehensive database of public facilities at two dates (2005, before the development of the Belval project, and 2015) to assess the impact of the polycentric strategy (and of the development of the new city of Belval) on the general accessibility to public urban facilities. Beyond the case-study, we developed a single accessibility index which can allow to support decision-making concerning the relevance of the location of a new public facility with regards to the objectives of polycentrism.

Key words:

Polycentrism; small and medium city; accessibility; public facilities

The Role of Capital in China's Urbanization: The Case of a Small City in Yunnan, Qujing

Thierry Theurillat

LATTS, Paris-East University, France, thierry.theurillat@unine.ch

Abstract

This article addresses the issue of the role of capital in urban production in China by putting together three main strands of literature. It first backs on the land-driven literature that highlights the land revenues for local government as the main institutional and fiscal incentive to plan and build the city based on growth objectives. It then shows that this land model goes in hand with significant debt based on land mortgaging since local governments have to finance collective-purposes' projects and urban infrastructures which are the condition to the commodification of urban land. In this, the interrelations between land development and urbanization have been looked in terms of public finance and from the supply side. This article further goes beyond public finance by considering other financing circuits that enable to build housing and non-housing districts from the perspective of the property development industry. Based on a study case in the fourth tier city of Yunnan, Qujing, this article addresses the issue of the financing of urban production by showing the interrelations between land-property development, state and capital that has enabled the capital accumulation since late 1990s in China.

Key words :

China; capital; urban production; 4th tier city; land-driven model; property development

Trends of Urbanization and Regional Development in Rajasthan (India)

DR. SAWAN KUMAR JANGID

Lecturer in Geography, M.L.V.Govt. College, Bhilwara-311001, Rajasthan-India, sawan.jangid@yahoo.com

Abstract

Urbanization is a process of transition from a rural to a more urban society. Statistically, urbanization reflects an increasing proportion of the population living in settlement defined as urban, it is a long term process. Urbanization is a dynamic system in which development and changes are prominent features, which implies population growth and changes in primary, secondary and tertiary sectors in the economy. Rajasthan has a long history of urbanization, but dynamic urban system remained only a distant dream due to unstable political economy under the colonial rule. The modern urban system emerged with the new definition of urban centers and urban population in the 1961 census. A much more dynamic urban system is emerging now. Although the urban population constitutes only 33 per cent of the total population. The paper attempts to study various facts of urbanization and regional development in the framework of the present condition and future needs in Rajasthan. Urbanization is an important index of economic growth both at state and national level. V.C. Sinha has pointed out that, urbanization is the process by which villages turn into towns and towns develop into cities. This paper is a brief appraisal of growth and development of urban places in Rajasthan with the set objective to ascertain the patterns and trends in the state urbanization using Rajasthan census data during 1901-2011.

Assessment of Economic Resilience Capacity of Resource-based Cities in Northeast China

Juntao Tan^{1,2}, Pingyu Zhang¹

¹Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Jilin Changchun, 130002, P. R. China

²University of Chinese Academy of Sciences, Beijing, 100049, P. R. China, tanjuntao@iga.ac.cn

Abstract

Based on the theory of evolution resilience, the article presents the analytical framework of economic resilience of resource-based cities. Then building the economic resilience capacity evaluation index system according to persistence, adaptation and transformation aspects, using the method of principal component analysis, the article analyzes the economic resilience of 19 resource-based cities and its change characteristic. The results show that the economic resilience capacity of resource-based cities in Liaoning and Jilin province was higher than that in Heilongjiang province. Panjin, Benxi and Anshan in Jilin province were ranked as the top 3, but Shuangyashan and other coal cities in Heilongjiang province ranked last. The economic resilience of metal cities and petroleum cities were significantly higher than coal cities. Comparing with the rank of economic resilience, the economic persistence of Panjin, Dading and other petroleum cities were lower, but the adaptability was much higher. Heihe, Mudanjiang and other forestry cities have higher economic persistence but lower adaptability. The differences of economic persistence, adaptability, transformation and resilience among the resource-based cities have decreased since 2003. Comparing with the beginning of the Strategy of the Revitalization of Northeast China and Other Old Industrial Bases implement, the increment of economic resilience in Heihe, Fuxin and Liaoyuan were ranked as the top 3, and Daqing, Qitaihe, Shuangyashan and Huludao had the biggest drop. The forestry cities have the biggest increment of economic resilience, and then were metal cities and multi-resource cities; the coal cities decreased and the petroleum cities have the biggest drop.

Key words:

resource-based cities; economic resilience; old industrial base in Northeast China

Ecological Engineering for the Livability of Urban Projects

Delabarre Muriel

Faculty of Geosciences and Environment, UNIL Mouline, bureau 3419, CH – 1015 Lausanne, Switzerland,
muriel@unil.ch

Abstract

Some urban environmental conflicts and mobilizations express a new strategy to try to transform the public space. Beyond the purely aesthetic dimension, they also reflect an evolution of representations of habitability. Also a request for reconnection to the natural world, these conflicts and requests depict a growing awareness of environmental issues in the public arena and among those, that of nature in urban areas.

Sustainable city is an opportunity to bring out new compositions reflecting these urban environmental sensitivities and experiment with methods of work and urban project design in line with the renewed urban ecology. How, nature in urban projects participating in the definition and draw the contours of the contemporary urban livability? This paper launches a discussion about the implementation of a ecological engineering tool to support urban projects whose nature is an integral part. The development of this tool contains both elements of specific interventions in urban areas based on valuable choices from urban ecology and plural expertise (ecology, botany, hydrology, landscape, etc.) as well as normative thoughts extended to civil and decision-making spheres. A reference table has been developed to operationalize urban ecology and to objectify the minimum criteria to register a project in a transversal vision of habitability of urban spaces.

The development of the practice of original development of the metropolis of Lyon allows to approach these various knowledges and understand what directions in making public spaces were favored.

Examining the Impact of Collaborative Partnerships for Sustainable Outcomes in Urban Areas: The Case of Galway City, Ireland

Dr. Frances Fahy, Dr. Marie Mahon

School of Geography and Archeology, NUI Galway, frances.fahy@nuigalway.ie

Abstract

At the international scale difficulties associated with giving practical effect to the abstract concept of sustainable development have stimulated a good deal of research on the challenging task of assessing progress towards that goal. However, in the Irish context a number of urgent key challenges have been identified in trying to develop local processes for sustainability including the need for more wide ranging public participation, the need for practical tools to assess progress towards sustainability, as well as the need to collapse down the 'silos' produced by institutional divides within local government.

Focusing on Galway City and its municipal (local) authority, this paper presents the findings of a project conducted between 2005 and 2008 that engaged a range of actors, including community groups, local and national practitioners and academic researchers, in the design of a number of collaborative tools to progress a local process for sustainability. The paper initially reflects on the development of two locally derived sustainable development tools, community-derived quality of life indicators and a community map for Galway City, an urban centre of approximately 80,000 inhabitants on the west coast of Ireland. The paper then maps the trajectories of these two tools over the past decade, focussing specifically on (i) the integration of the tools within the case study local authority, (ii) the transferability of the tools and (iii) the relative 'impact' of the tools.

Food Security and Sustainability in Post-Conflict Freetown, Sierra Leone:

Examining the Role of Urban and Peri-Urban Agriculture

Professor Tony Binns

Department of Geography, University of Otago, Dunedin, New Zealand, jab@geography.otago.ac.nz

Abstract

Sierra Leone is one of the world's poorest countries and in the last two decades has suffered from both a brutal civil war and an Ebola epidemic. An estimated 45% of the country's 6 million people are food insecure and 34% of children under 5 years old are stunted. Freetown, the capital city, grew rapidly during the civil war (1991-2002) and is now approaching 2 million people. Urban agriculture plays a vital role in feeding the urban population but, as in many African cities, the scale and significance of urban agriculture in Freetown is not fully appreciated by urban authorities and planners. The paper presents the results of recent field-based research among urban farmers in Freetown, and reveals the significance of the practice in providing food, income and employment for urban households. It is suggested that future urban planning and development strategies should incorporate provision for urban agriculture as a key element in moving towards creating sustainable cities.

Local Environmental Governance and Individual Environmental Concern in Urban China: A Multi-Level Analysis

Liu, Z., Wang, J.

School of Public Policy and Management, Tsinghua University, Beijing 100084, China, wangjie15@mails.tsinghua.edu.cn

Abstract

As environmental sustainability becomes the biggest challenge for China's urbanization, profound institutional changes have taken place in China's environmental governance practices. Whereas existing literature has widely documented the local implementation gap in China's environmental policy, scholars also have observed regional disparity in local policy actions. Some cities have become the pioneers in pursuing more environmental-friendly urbanization while others have lagged behind. It is even less understood whether such pioneering actions by local government resonate with the rising environmental concern among urban citizens, which has been recognized as an important component of the changing environmental governance regime in China.

This paper seeks to answer two research questions. First, to what extent do cities vary in local sustainability actions – such as being designated by central government agencies as experimentation sites for various sustainability policy actions? Second, to what extent does local government's sustainability action resonates with the level of environmental concerns among urban citizens? We use data from the 2010 China General Social Survey (CGSS) and adopt a multi-level statistical model to empirically test whether citizens' level of environmental concern is higher in cities that have been more progressive in local sustainability actions – e.g. investing more public finance in environmental protection, and have been recognized by the central government as experimentation sites for sustainable development. Included control variables are individual socio-demographic variables – e.g. age, gender, education, household income, employment, and hukou status, as well as city-level variables that capture the level of economic development and citizens' exposure to environmental degradation.

Key words:

Environmental concern; environmental governance; urban governance; multi-level analysis; China

Optimizing Urban Water System Based on “Ecological Rehabilitation”

——The Regulatory Plan of Dali Innovation Industrial Park for Instance

Li He, Yang Peifeng

Faculty of Architecture and Urban Planning, Chongqing University, Chongqing 400045, China, 819680524@qq.com

Abstract

The health of urban water system is the important index of urban sustainable development, before urban is developed, the water system is natural ecologic water system, after developed, the system present natural system join together with engineering system coexistence state. At present, the problem of urban water system mainly reflects the degradation of the original natural water system, and the natural water system and water engineering system are separated and contrasted during the planning and construction process. Furthermore, Sorts of water problems appear. So the paper intends to use the “Rehabilitation” theory of restoration ecology during the whole process of planning, to optimize and adjust the original state of natural hydrological system, and using the positive stimulation of Engineering water system to reconstruct the whole water system and keep the function’s stability and efficiency. At the same time promoting transformation of hydrologic performance and making positive promotion to urban space. This paper uses the regulatory plan of Dali innovation industrial park for instance. At the early stage of the planning, this research adopts the regional water environment to evaluate and analyse the whole water system, after that applying the palnning methods to adjust and optimize the natural water system, then by the real-time evaluation to determine the most effective water system optimization way. At last, comparing the performance of the before and after water system during planning, to evaluate and further discuss the whole water system (Natural water system and Engineering water system) which takes a positive role in promoting the urban space structure. Conclusion summarizes the best way to adjust and optimize the original urban water system, and guides the construction of urban sustainability of the water system optimization.

Peri-Urbanization and Vulnerability to Disasters in Poor Settlements of Mexico City

Aguilar A. G and Lopez-Guerrero F.

Institute of Geography, Universidad Nacional Autónoma de México (UNAM), Mexico City, Mexico,
adrianguillermo1@gmail.com

Abstract

The peri-urbanization process has emerged as a new and extended form of urban occupation in peripheral areas of big cities in Mexico. In these urban-rural fringes city advances transforming land uses and socio-economic realities of the nearest rural areas. In Mexico City this process has created a discontinuous, dispersed and low density urban model that has become predominant in recent decades and continues to develop without a strict control. This is an important preoccupation as the peripheral fringes register the highest population growth rates.

One important dimension of urban expansion in peripheral zones is the presence of irregular settlements associated to poor population located in sites no suitable for urban occupation like slopes, ravines or old river beds that constitute zones of high ecological value. This situation not only contributes to the deterioration of local environment but also affects health and security of local population as they live in a high vulnerability condition exposed to events like flooding or land sliding.

Poor settlements have increased disasters potential in peri-urban zones. The more severe impacts on this population not necessarily respond to an increase in the intensity of events, but most importantly to low investment on infrastructure and rapid growth of irregular settlements in zones unsuitable for urbanization. There is a high association between high socio-economic vulnerability, frequency of disasters and high levels of poverty. Urban policy has to implement adaptation strategies that can highly contribute to urban sustainability, improve population quality of life and reduce disasters vulnerability.

Peri-urbanization; Mexico City; vulnerability; urban poverty; disasters; sustainable development

Preliminary Studies of Urban Wetland Changes in the Areas of Western

Zhu Weiping¹, Zhang Hui², Liu Guang², Tang Yao², Zhu Chaocheng², Ding Yuanyuan³

¹Institute of Ecological planning design and research, Hangzhou Normal University, China, zhwp66@163.com

²College of Life and Environmental Sciences, Hangzhou Normal University, China

³Zhejiang Provincial Key Laboratory of Urban Wetlands and Regional Change, China

Abstract

Hangzhou West wetland, the largest wetland group of Hangzhou, is located in the Hang Jiahhu plain. It mainly includes XiXi Wetland, Wuchang wetland and Hemu wetland as the core area. And it has very important geographical location and ecological system service function, for the healthy development of Hangzhou urban environment. Supported by GIS and RS Technology, the study extracts the data from 1955 and 1972 aerial images, 1984 topographic map and 2010 ALOS Image. By using qualitative and quantitative analysis method, deriving analysis of Hangzhou West wetland from 1955 to 2010 the temporal and spatial evolution and driving factors from the time gradient and spatial gradient angle. Research shows that the area, types and distribution of wetlands in the west of the city of Hangzhou has undergone tremendous changes. The general trend of West wetland change is: the total area of wetlands reduces 69.37km², river reduced 8.14km², marsh reduced 3.08km², pond reduced 8.23 km², artificial wetland change is particularly significant, the total reduction 53.89km², lakes and wetlands increased 3.96km². Compared to 1955, the main type of Hangzhou West wetland is still artificial wetland, but its types reduced largely. River network intensive degree not as before, large wetland is divided, forming small clear border, serious internal landscape fragmentation. But Nanhu Lake area increased. Spatially, Xihu and Yuhang district change is particularly evident. Artificial wetlands in Yuhang area reduced, leaving only a large area of paddy fields in the western region. The main driving factors of change include two aspects: natural and artificial, the interference of human activities is enhanced, and the influence of natural factors is weakened.

Regional Characteristics of Urban Parks in Dhaka City, Bangladesh

Saika U.

Tokyo Metropolitan University, Graduate School of Urban Environmental Sciences, Department of Tourism Science,
Tokyo, Japan, Ph.D. Student, usaikau@gmail.com

Abstract

Dhaka, which is one of the fastest growing mega cities in the world, already unplanned urbanization has caused serious ecological imbalances in the city. The case study site covers urban parks of Dhaka metropolitan area of Bangladesh. This study investigates the typology and uses of urban parks and also identify regional differentiate of parks of Dhaka city. Two aspects (Social and Living) were applied for this study. For social aspect methods were used questionnaire survey, observation, photographs, sketch and previous information about parks. And for living aspect used check table format, interview and case study. After calculated all data result showed by maps using GIS. According to physical size, parks of Dhaka city classified into four types: Small, Medium, Large and Extra Large parks. Small parks of Dhaka city situated beside the residential area and use as daily purpose. Medium parks located beside commercial area and its use for daily and weekly. Large parks placed at city center and only one extra large park found outer range of city area. In large parks people mainly visited monthly or occasionally. Again based on regional differentiation, in old Dhaka parks are well vegetated but have maintenance problem. Intersection zone of old and new Dhaka parks are used in national occasion more than daily recreation purpose. In New Dhaka parks are well organized and maintenance than other part of the city. The significance of the study to reveal that the utilization of park control by various factors and regional differentiation influence city parks.

Risk Assessment and Preparedness Plan for Earthquakes in Urban Delhi

Vishwa Raj Sharma

Shaheed Bhagat Singh College, University of Delhi, New Delhi, India, vrsharma2002@gmail.com

Abstract

An earthquake is a sudden shaking of the earth caused by the breaking and shifting of rock beneath the earth's surface and followed by a series of vibrations. Earthquakes can cause buildings and bridges to collapse, telephone and power lines to fall, and result in fires, explosions and landslides. Earthquakes are among the most devastating natural hazards and have tremendous damage potential in terms of casualty and destruction. Recent major urban earthquakes such as that in Nepal (2015) Haiti (2010), China (2008) and Iran (2003) have alarmed us that even moderate level of earthquakes can lead to large scale damage to structures and human casualties in a city like Delhi. In a mathematical form, this can be expressed as: Risk = Hazard x Vulnerability X Exposure. Consultations with government, city development authorities, ULBs, NGOs, training institutions, practicing engineers, architects, real estate firms, builders, contractors, etc. for city specific earthquake risk management and mitigation strategies. Identification and networking of nodal agencies and partners at different levels for implementation of the programme. Orientation for policy makers to enforce legislation for registration and regulation of builders, promoters, and real estate developers for creation of safe habitat. Orientation of officials in Urban Local Bodies - Development Authorities/ Municipalities/Town Planning Departments/Housing Societies/Housing Boards, etc. towards the earthquake hazard, risk evaluation and possible mitigation measures.

Key Words:

federico.martellozzo@uniroma1.it.

²Potsdam Institute for Climate Impact Research, Germany

Abstract

This research was developed within the EU-FP7 project TESS (Towards European Societal Sustainability). Its aim is to “illustrate the role of community based initiatives in creating a sustainable, low-carbon Europe”. In recent time societies’ interest for sustainability-oriented activism increased, fuelling the emergence of numerous Community Based Initiatives (CBI). Consequently, grassroots movements and associations dealing with socio-ecological issues have multiplied. These cultural hubs (very often) rely predominantly on participatory activism. However, thus far most empirical research grounds mainly on anecdotal evidence and little work has been done to quantitatively assess CBIs’ “environmental impacts” (EI). Furthermore, to the best of our knowledge, no research has attempted to investigate aggregate impacts and upscaling potential of CBIs’ activities. This research contributes to fill these gaps through an empirical analysis based on TESS database by exploring the potential aggregate impacts of upscaling CBIs’ activities in order to contribute to climate change mitigation. This research aims at discussing whether CBIs upscaling may not be in the realm of utopic visions but a viable and not-negligible possibility for policy makers. Secondly, results show that CBIs’ upscaling implies a change in their operational structure, which they may be reluctant in adopting, hence favouring other sort of diffusion of their practices. Third, this work debates about potential harmful and viable consequences of fostering global climate change mitigation through CBIs’ activity. Furthermore, an attempt to identify which activities/practices show the most promising potential in complementing sustainable top down policies is also given. While we are aware that several caveats still need to be further explored, this novel application and the discussion of the upscaling potential offer much to the existing literature on CBIs’ impact assessment.

The Efficient Size of Export-Oriented City Based on the City Network Theory -- A Case of Qingdao

Ji Ai-hua

Architecture institute, Qingdao Technological University, Qingdao 266033, China, jier916@163.com

Abstract

In view of the current city with a moderate scale of a single isolated though city static theory research more mature, but lack of regional contact or the world in the city of contact moderate scale of dynamic theory research of reality, this project is based on the theory of urban network, and urban as city in a node network system, this paper discusses the function of the city and network connection degree of the influence of the moderate scale, and with export-oriented city (Qingdao city) as an example case studies.

Through this topic research that can get the urban function and city network connection degree of city of moderate scale of export-oriented mechanism of the effect of law and a more comprehensive and thorough understanding, reveals the urban network factors on the influence of export-oriented city moderate scale of regularity, and has important theoretical significance and academic significance.

This topic is based on the function of the city and urban network connection degree of building up the city of moderate scale of export-oriented theoretical model for analysis and evaluation to the reality of export-oriented city scale whether reasonable provide scientific basis, to guide the further development of export-oriented city. Therefore, the research results to export-oriented city modest scale analysis and evaluation of important theoretical guidance function, and has a broad prospect of application.

What Is to Be Sustained? A Comparative Perspective on Generations, Consumption and Sustainability

Liu C, Diprose K, MacQuaid K, Valentine G, Vanderbeck R

Department of Geography, the University of Sheffield, S10 2TN, UK, chen.liu@sheffield.ac.uk

Abstract

This paper, based on multi-method research ongoing in three mid-sized cities in China, Uganda and the UK, explores the relationship between consumer cultures of different generations, everyday experiences and ordinary people's understanding of urban sustainable development. In particular, it is concerned with thinking comparatively about both environmental and socio-cultural sustainability across the Global North and South and de-centering debates about consumer culture and sustainable development, which has overwhelmingly been researched from the Western, in particular Anglophone, perspective. The paper will consider how changing consumption values and practices relate to and/or impede the production of intergenerational solidarities, and how generational discourses on consumption and sustainability are intersected by race, class, gender and other forms of socio-cultural difference. This research employs cross-disciplinary techniques including intergenerational theatre, discourse analysis and narrative and family interviews, to explore generational views on entitlement to consumption, how people in different socio-cultural contexts understand obligations to contemporary and future generations, how daily consumption is shaped and changed by people's concerns of sustainability, and how generational and lifestyle groupings influence attitudes towards both environmental and socio-cultural sustainability.

Which Kind of Urban Spatial Structure Benefits Sustainable Economic Development: Monocentric or Polycentric? Evidence from China

Sun B.D., Li W, Zhang T.L., Hua J.Y., He Z., Chen H

The Center for Modern Chinese City Studies & School of Urban and Regional Science, East China Normal University, Shanghai, 200241, P. R. China, bdsun@ecnu.edu.cn

Abstract

Aiming at relieving congestion and promoting economic growth the megacities in China have implemented polycentric spatial strategy and developed new towns and new zones. The effects are far from satisfactory, however. The central cities of most megacities continue to spread out and the monocentric urban form stays as before. Has the lower economic efficiency of polycentric urban structure than a mono-centric one hindered the progress of the polycentric strategy? This study explores the relationship between urban spatial structure and economic performance and compares the economic efficiency between polycentric and monocentric structure. In light of the scale sensitivity of spatial structure the study is conducted on two scales. The result on metropolitan scale indicates that a polycentric urban spatial structure has a better economic performance than a monocentric one probably due to lower diseconomy resulting from commute time and land price. The study on regional scale shows much higher productivity of monocentric urban spatial structure however. Further analysis on regional scale reveals the dependence of the economic performance of urban structure on city population size. The economic advantage of monocentric structure exists mainly in cities under one million. For those between one to three millions polycentric structure is a more efficient urban form. Nevertheless, when city size exceeds three millions monocentric structure is more productive again possibly due to the overcoming of diseconomy through those cities' strong economic and administrative power.

Key words:

urban spatial structure; economic development; monocentric; polycentric; China

Examining the Feasibility of Applying PV in a Community in Northern China

Tao WANG, Xin TONG, Wei WANG

Peking University, Beijing, 100871, P. R. China, wangtao9346@pku.edu.cn

Abstract

This study analyzes a plan to apply photovoltaics in Zhenggezhuang, a community in north suburb Beijing. We compared the electricity generation potential calculated by the NASA solar irradiance data and the real data collected from our demonstration system for c-silicon and thin-film modules. We provided LCA analysis for these two different technology regarding their contribution for CO₂ emissions reduction. A scenario analysis on the balance of electricity generation and consumption was conducted at the community level to address the potential of mixed land use to ensure reliability of the electric power grids.

The results show that, (1) theoretically, the PV electricity generation can satisfy the demand on electricity of the community at peak time by both thin-film and polysilicon PV technology. However, fluctuation exists due to weather conditions. (2) Significant reduction of carbon emission can be achieved by both technologies. (3) Potential could be explored for balancing the energy generation and consumption between the residential area and the workspace. The demand for coal-fired electricity reduces when we balance the supply and demand in the community level, comparing the case in which two areas are independent.

Key words:

low-carbon community; PV application; renewable energy; scenario analysis; LCA analysis

Research on the Development Process and Dynamic Mechanisms of

Suburbanization in Guangzhou

Chunshan Zhou, Juan Wang

Sun Yat-sen University, Guangzhou, 510275, P.R. China, zhoucs@mail.sysu.edu.cn

Abstract

The research indicates that, Guangzhou has basically contained a series of preconditions that suburbanization occurs since 2000, including the improvement of urbanization level, the rise of residents' income level, the development of traffic, the progress of communication technology, the improvement of people's ability to choose house as well as the growth of middle classes. The population suburbanization in Guangzhou has been in process since 2000, and the industrial suburbanization has been in process since 1990s. The commercial suburbanization in Guangzhou has not been in process yet, but the commerce has appeared to spread to the suburbs since 2000. The development of suburbanization in Guangzhou has experienced two stages in general yet. It's in the propulsion to suburbs stage before suburbanization from 1980s to 1990s, when the population mainly concentrated on the city central, and the industrial suburbanization began. Then it's in the stage when the suburbanization started and has been developing rapidly. In this stage, population suburbanization has started, residential suburbanization has quickened its step and brought the development of seasonal suburbanization, industry shows a trend of 'decentralization', and the phenomenon of commercial suburbanization is emerging. There are many factors combined to effect the occurring and developing of suburbanization in Guangzhou, including economic development, institutional change, urban sprawl and administrative division adjustment, the guide of urban planning and policies, the improvement of traffic, the development of real estate industry, more and more serious urban problems, social class differentiation and the change of people's living concept.

A Study on Living Environment and Life Satisfaction of Aged Population in Beijing

ZHANG Jingqiu¹, LIU Huan², QI Yingxi², LI Xueyan¹

¹College of Applied Arts and Science of Beijing Union University, Beijing 100191, China, jingqiu@buu.edu.cn

²College of Resource, Environment and Tourism of Capital University, Beijing 100048, China

Abstract

Taking the 60 years or older population in Beijing as the main research object and based on data from the sixth census and a sampling survey, this study analyzes the spatial characteristics of the living environment and life satisfaction of elderly in Beijing using statistical and spatial analysis methods. The results show that: (1) the distribution of aged population in Beijing concentrate in the inner city and the western suburbs, where the percentage of the aged population is generally greater than 10%; (2) the living form of the elderly respondents is mainly two person's households, followed by four and five person's households. Those living alone and empty-nesters often aged over 70 years. Housing of the respondents is often purchased from the work units and this is the key factor affecting the elderly choice of residential location; (3) overall life satisfaction of the elderly respondents is relatively high. Among the income, health, living conditions and happiness factors, happiness is slightly higher than the other three factors; relatively, satisfaction of income is low; (4) using Dichotomous Logistic Models to analyze the form of living, relationship with neighbours, surrounding service facilities and community environmental conditions, found that the large scale shopping facilities, community sports activities, community identity and relationship of neighbours result in a positive impact on life satisfaction of the elderly respondents, while the empty-nest situation, medical facilities and property management result in a negative impact on the life satisfaction of the elderly respondents.

²University Paris I, Sorbonne, France

³University of Milan Bicocca, Italy

Abstract

This paper addresses ageing as a factor in the social structuration of southern European cities. Early studies undertaken in the 1960s from a human ecology perspective presented the lifecycle of households as one of the three most important factors for describing the structure of the city. At the time this analysis was undertaken the populations of southern European cities were relatively young. Half a century later we examine how both the population and the urban form have aged. By means of focussing on Barcelona, Milan and Turin, we analyse how cities pass through different stages of their lifecycles, characterised by urbanization, suburbanization, de-urbanization and re-urbanisation. This analysis is conducted in parallel with a demographic analysis of the ageing of these cities' populations, undertaken at different spatial scales. Special emphasis is given to the relationship between ageing and social structure, and residential mobility and segregation of the cities' elderly populations. This analysis points to the importance of considering ageing along and across a number of social variables, thereby helping to further emphasise the complexity of urban change and its importance in the redesign of urban policy.

Key words:

urban ageing; urban policies

An Increase in Housing Vacancies in Cities: The Case of Japanese Cities

Tomoko Kubo

Assistant professor, Gifu University, Japan, tmkbb@gifu-u.ac.jp

Abstract

Housing vacancies play significant roles in improving the circulation of population within cities. Their permanency, however, is regarded as a problem. According to their generative processes and condition, urban housing vacancies are classified into the following categories: (1) speculative over buildings which typically caused during housing construction, (2) seasonal housing, such as student housing, corporative housing units, resort housing, and second homes, (3) vacancies caused by financial loss during an economic crisis or poverty in the outer suburbs, foreclosure in North American, for example, (4) decay of housing structure with limited repair and obsolescence, (5) houses without demand become vacant, and (6) housing vacancies are caused in shrinking settlements where economy and population have declined and ageing and low fertility have also progressed. Most of the categories are regarded as temporary vacancies, but a large proportion designated as “no demand” and “shrinking settlement” vacancies, and the latter is typically found in Japanese cities, tends to be permanent and therefore problematic. This study examines a generative process and the geographical patterns of housing vacancies in Japanese cities. Japanese housing vacancies are generated by visible and invisible regional forces within the city. In addition, factors such as ageing, housing policy, taxation systems, and behavior of the residents directly affect the generative processes, and background factors such as the residential structure, social and economic structure, housing development, and location and site of the city also play crucial roles.

Key words:

housing vacancies; Japanese cities; ageing

Informal Path: Spatial and Temporal Evolution Characteristics and Spatial Analysis of Illegal Construction in Guangzhou

Yang jinkun, Li xun

Sun Yat-sen University, Guangzhou, P. R. China, 515692285@qq.com

Abstract

Existing research on illegal construction is more focused on the social and economic characteristics of the informal settlements and illegal construction space, the formation of the reasons, policy evaluation, governance measures in foreign countries. Nevertheless, its spatial analysis is less concerned.

In China, the problem of illegal construction is the result of rapid urbanization in the transition period of the economy and the social system, which has been widely concerned by the academic circle and the government.

Taking Guangzhou as an example, this paper attempts to interpret correlation analysis of illegal construction space distribution and urban spatial structure, the goal is to forecast illegal construction outbreak area and different types of illegal construction probability space location. Combined with the theory of property rights and land rent surplus value theory, the space and time evolution mechanism of illegal construction in Guangzhou is explained through the establishment of the opportunity space and the constraint space.

Key words:

informal path; illegal construction; Guangzhou; space

Gender Differentials in Social Isolation and Self-Reported Health Status among Elderly in Low and Middle Income Countries

Tripathi, Niharika

PhD Candidate, International Institute for Population Sciences (IIPS), Mumbai- 400088, India. Email:

niharika.t2010@gmail.com

Abstract

Population ageing is often accompanied by lack of social connectedness or social isolation. However, there is a lack of clear understanding about: i) extent of gender differentials in social isolation and, ii) plausible association between social isolation and self-reported health status of elderly in low and middle income countries. This study attempt to examine the gender differentials in social isolation and its association with self-reported health status among elderly in low and middle income countries. The data for the present study is drawn from the first wave of Multicounty Study on Ageing and Adult Health (SAGE) conducted by the World Health Organization (WHO) for the following six countries- China, India, South Africa, Russian Federation, Mexico and Ghana during 2007 to 2010. Multivariate logistic regression analyses using nested models were conducted separately for male and females. Data indicates rising social isolation with age among elderly, and elderly men were less socially connected than older females. Adjusted regression result indicates that elderly with lesser social connectedness were more likely to report poor health status than others. Poor self-rated health was also related with age, education, economics status, functional status and cognitive status among both men and women.

Key words:

Population ageing; Social Isolation; Self-reported health; WHO-SAGE

Identification and Spatial Assessments of Brownfield Regeneration

Song Y, Lin Hy, Wang Sj

School of Geographical Science, Northeast Normal University, Changchun, 130024, P.R. China,
song0317@nenu.edu.cn

Abstract

The rapid urbanization and de-industrialization process has produced many under-utilized or abandoned industrial and commercial properties, commonly referred to “brownfield”. A brownfield is a property, the expansion, redevelopment, or reuse of which may be complicated by the presence or potential presence of a hazardous substance, pollutant, or contaminant. The importance of sustainable brownfield regeneration has recently been heightened by factors. However, this is a complex and multifaceted issue because much existing brownfield land not only presents environmental challenges, but also raises issues of environmental justice and social equity, since it often occurs in close proximity to disadvantaged communities. Relatively little research has systematically focuses on brownfield from the spatial view. In order to meet the needs of urban sustainable development and brownfield regeneration, the paper chooses the old industrial city Changchun as the sample areas, identifying brownfield sites and building a brownfield GIS database. Based on the this, we use the space analysis models to measure the spatial characteristics of each brownfield site, spatial concentration degree, spacial accessibility, spacial association, to evaluate the general spacial characteristics and do the accessment of location of brownfield.

Key words:

identification; spatial assessment; brownfield regeneration; Changchun

Nursing Care and Survival Show Regional Differences in Germany

Queißer-Schlade, Y., Chu, JJ., Krämer, A.

University of Bielefeld, alexander.kraemer@uni-bielefeld.de

Abstract

Regional differences in demographic change, prevalence of chronic diseases, care needs and health care provision were found in Germany. However, so far aspects in nursing care development or survival time of older people in need of care were not researched at the regional level. The aim of this study is to 1) indicate regional variation in nursing care development, and 2) identify factors associated with it among older people in need of care in the eastern part of North Rhine-Westphalia, Germany.

Accounting data of a health and long-term care insurance in Westphalia-Lippe between 2012 to 2014 (N = 17, 210) were used for the analyses. Firstly, in order to find out the regionally-specific influence on the survival time of older people in need of care, the associations between the survival time of the persons in need of care, their place of residence, and their demographic-, socio-economic characteristics were examined. Secondly, the inpatient and outpatient diagnoses of the persons were considered to discover the regional patterns and the influence of individual morbidity on nursing care development and survival time.

The log-rank test shows significant differences in 1-year survival rate of persons aged 65+ at the regional level ($p < 0.001$). Cox-Regression indicates that gender ($p < 0.001$), place of residence ($p < 0.001$), and the diagnoses ($p < 0.001$) of the older people in need of care have influence on their survival rate.

For future nursing care planning, demographic and morbidity related indicators should be considered at the regional level.

Key words:

Survival time; Nursing care; Older people in need of care; Regional difference; Morbidity

Parks and Open Green Spaces and the Elderly Men: A Study of Delhi

Jahangir, SELIM

Department of Geography, Delhi School of Economics, University of Delhi, Delhi-110007, India, selim.dse@gmail.com

Abstract

Parks and open green spaces within urban landscapes provide opportunities to older adults to experience nature, engage in light physical activity, relax and sometimes escape. Such public spaces bring older men together in the neighbourhood and provide meeting opportunities; and also thus raise the potential for developing social ties among this demographic. These public parks also bring older men from different backgrounds and engage them in shared activities and develop social relations which are significant for their care and well-being. How parks are being used and perceived by the older adults is therefore essential to understand the roles of such urban spaces in social care and well-being.

Based on 12 in- depth interviews this paper explores the different meanings that the parks as social spaces hold for these older men. This paper argues that being isolated and sometimes neglected the older men engage and involve in their daily activities in the parks with their fellow elderly. The older men perceive that due to intergenerational relation changes and rise of dual career families they are not getting proper attention from the family members. Perceiving this changing family dynamics as lacking emotional care in home, the older men find local parks as alternative spaces for their care and well-being. In this context the character of these cities, especially their infrastructures and levels of social provision should be taken into consideration while planning for the age friendly cities. Moreover proper policies have become essential to address this emerging issue in the city.

Key words:

Parks; Older men; Social care; Well-being; Everyday lives and Alternative Space

Plight of Aged Women in Modern Cities--Some Insights into their Living

Arrangements from Kolkata, India.

Banerjee CHANDREYI

Department of Geography, B.S.R Govt. Arts College, Alwar-301001(Rajasthan, India), chandreyibanerjeejnu@gmail.com

Abstract

Urbanisation today is regarded as analogous to development. Societies of the developing countries are getting constantly restructured by the forces of urbanisation. At the same time, the developing countries are experiencing rapid tempo of population ageing with *feminization of ageing* being a universal phenomenon. On one hand, while the big cities and metropolises of developing world are the centres of fulfilment for the younger generations; on the other hand, they are witnessing the erosion of traditional values and culture.

In the Indian scenario, the disintegration of the traditional joint family system is a manifestation of the forces of urbanisation. Growing aspirations and individualism of the young people as an outcome of modernisation, characteristic of the urban world, coupled with increasing urban rents and dearth of space greatly discourages generations to stay together. In this context, the aged communities specially women of urban India is progressively getting marginalized and vulnerable, ending up either staying alone or relocating themselves in old age institutions.

With this background and the city of Kolkata as the study area, this study attempts to provide an insight into the living arrangements of the aged women on the basis of data collected through field survey. The city is divided into two zones---North and South---as two distinct spatio-cultural entities; the North with a traditional flair and South as much modern, developed after independence in 1947. Accordingly, the family structures in these two zones are expected to vary.

Key words:

Urbanization; aged women; living arrangements; North and South Kolkata; spatio-cultural zones

Research on Facilities and Services for Age-Friendly Neighbourhoods

Case Study in Suzhou, China

Yu LIU, Lin YI

Xi'an Jiaotong-Liverpool University, Suzhou, 111 Ren'ai Road, P.R. China, yu.liu@xjtlu.edu.cn

Abstract

Population aging is becoming a global priority, and China is not an exception. There are already 15.6% of population over 60 years old in China in 2015, and till 2050 the number would be increased to 25.3% (Source: global AgeWatch index 2015). Under this condition, Chinese Central Government has issued a range of policies, plans and programmes to facilitate ageing-in-place. However, since ageing issue has not been fully taken into account in traditional neighbourhood planning, the existing facilities and services can hardly satisfy the arising needs of the elderly. This paper aims to provide an insight on how to plan facilities and services for age-friendly neighbourhoods based on case study in Suzhou. It combines successful international experiences and local case study and attempts to increase the age-friendliness of Chinese neighbourhoods. The results illustrate that on one hand, several necessary facilities for the elderly are missing in neighbourhoods in Suzhou, and the existing ones have not been fully appreciated by the local elderly due to the poor quality; on the other hand, the needs of the elderly are rarely revealed in current neighbourhood planning guidance or standards. At the end, it propose strategies to optimize age-friendly facilities and services, as well as implications to update the existing planning guidance, standards and instrument. It is hoped that the paper could provide some useful reference for planning age-friendly neighborhoods.

Key Words:

age-friendly neighbourhood; facilities; services

Shrinking Cities: Huge Challenges of Revitalization of Northeast China during Transformation Period

LIU F B, ZHU X G, SUN J, CHEN J

School of Architecture and Urban Planning, Nanjing University, Nanjing, 210093, P. R. China,
dg1536005@smail.nju.edu.cn

Abstract

Shrinking cities are emerging around the world beneath the wave of globalization, which has been a global phenomenon. The phenomenon actually has appeared in many cities in China, especially in the old industrial base in Northeast China, during transformation period, thus the strategy of Revitalization of Northeast China faces huge challenges. However, existing urbanization research in China mainly focuses on urbanization of growth supremacism to cater to urban development strategy of urban growth, so research results about urban shrinkage are seldom. First, this paper analyses qualitatively the logic rationality of shrinking cities appearing based on the life cycle of cities theory. Secondly, taking Northeast China for example, this paper analyses quantitatively urban shrinkage from the perspective of region based on the statistical yearbook data of 2010-2014. The study shows: ① Population economic pressure index increases, and a terrific amount of population, especially the young and highly-educated, and enterprises frequently outflow from the region. ② Both birth rate and natural population growth rate in the region are much lower than in other regions of China. ③ Urban population density decreases as a whole in the region. ④ GDP index sharply falls and economic activity gradually declines. The results indicate that currently urban shrinkage is appearing in Northeast China. Finally, this paper outlines four main aspects including "exhaustion of resources", "aging population", "aging industrial structure" "ecological environment deterioration" causing urban shrinkage. Research suggests that future research should focus on how to accomplish the sustainable development and revitalization of shrinking cities.

Key words:

shrinking cities; life-cycle theory of cities; transformation period; Northeast China

Spatial Analysis of the Supply and Demand of Affordable and Accessible Senior Housing Services in Beijing

Xiaoping SHEN¹, Shangyi ZHOU²

¹Department of Geography, Central Connecticut State University, New Britain, CT 06050, USA, shenx@ccsu.edu

²School of Geography, Beijing Normal University, Beijing 100875, P.R. China

Abstract

China's population has been rapidly aging, especially in major cities. As of 2013, nearly 1 in 4 people are age 60 or above in Beijing and other major cities, far above the national average of 13%. Although the government has set up programs to encourage people to live at home, Beijing's elderly, especially those who do not live with their adult children, are increasingly interested in moving to a senior housing facility (SHF). Given their severe shortage, many people have been on waitlists for years with some passing away before they are able to move into a facility. As such, building new and affordable SHFs has become necessary in Beijing and surrounding areas. Although the high price of urban land has been and still is a main obstacle for building SHFs in Beijing, new opportunities for development are becoming available through the implementation of the Cooperative Development Strategy of Beijing, Tianjin, and Hebei province (*Jing-Jin-Ji xietiao fazhan zhanliu*) in China's Thirteenth Five Year Plan (2016-2020) which will connect the Jing-Jin-Ji region via fast transportation networks to create a cohesive super-metropolitan region. Since this is a novel challenge in China, very few in-depth studies on the needs of SHFs especially in regards to affordable SHF in different locations have been conducted. Using statistical and survey data, this study reveals the spatial patterns of the supply and demand of SHFs on services, price range, affordability, and accessibility in Beijing and attempts to provide a better understanding of senior housing services in an aging but not affluent society.

Key words:

Senior housing services; supply-demand; spatial analysis; affordability; accessibility; Beijing

The Comparison Study on the Elderly Care Systems in Japan and China: From the Viewpoint of the Individual Dynamic Demands

SONG SHAN

Nagoya University, Nagoya, 464-8601, Japan, crystalshanshan@sina.com

Abstract

China is undergoing a rapid aging process which brings the great influence on the families and society. The contemporary care system and planning is usually designed according to the macro-static-sectional statistical materials, lacking the consideration on the individual difference and temporal changing of the elderly demands. Thus, the care provision does not satisfy the elderly demands well. Japan, as the most aged society in the world, accumulates the abundant experience of responding to the aging challenge. Furthermore, Japan shares with China a similar traditional cultural and familial values, which makes significant effect on their care consciousness. Therefore, compared with other aging or aged societies, the experience of Japan suits the Chinese social environment better and is worthy of being referenced. This paper reviews the demands-provision system of the elderly care facility and service in Japan, and makes a comparison with that of China. It puts a special eye on the demand assessment of the Japanese Long-term care system. Based on the personal life course and condition, this system evaluates and divides the care demands into several statuses, helps the elderly make their own care plans, then regularly reassesses the demands and adjusts the plan. It expresses the consideration on the individual difference and the dynamic changing of the demands. This paper suggests that a new demands-provision framework, concerning the individual difference and dynamic changing during the life course, should be made to let the Chinese care system and planning more suitable for the elderly demands.

the elderly; individual dynamic demands; life course; Long term care system; Japan; China

The Unbalanced Growth of Residential Care in Beijing City, China— Causes and Prospects

Min JIA, Yanmin ZHOU, Jingyi LIN

Tsinghua University, Beijing, 100084, P. R. China, mintyjia@163.com

Abstract

By focusing on the development of residential care facilities for the elderly (RCFEs) in China's capital city of Beijing between 1950s and 2010s, this study examines the policy orientation and local consequences of the 1980s' marketisation of the Chinese social welfare system. Data includes 362 RCFsE projects' GIS data and program information; multi-disciplinary issues among social, policy, urban planning and statutory aspects were also examined. Results shows that, within the broader context of fast population ageing in China, the growth of residential care in Beijing was shifting from a central-planned pattern to a market-dominated expansion, featured with the neo-liberalism style of development. Due to the indecisive governmental efforts in the new partnership with private sectors, reflected by the absence of master-planning and legislation of private development, the projects growth in Beijing was under trends of avoiding the market-unfavoured (less profitable) areas, such as the inner urban areas (with a very high elderly population) and rural areas, and toward the suburbanization and developing higher end and over-sized residential care facilities. These were discordant with the government's defined new role as retreating from centralised controlling to regulating and guiding the residential care development for the wide elderly public. The study therefore suggests that more ideological expounds, rules and master planning regarding to the establishment of the 'supporting' function of residential care are needed, for contributing to the deepen reform of social welfare service that toward equalised provision of residential care beds locally in the future.

Key words:

residential care facilities for the elderly; marketisation; uneven spatial distribution; China; Beijing; residential care; social welfare institutions

Assessment of Urban Transition Performance of Resource-based Cities and Influential Factors in Northeast China

Juntao Tan ^{1,2}, Pingyu Zhang ¹

¹Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Jilin Changchun, 130002, P. R. China, tanjuntao@iga.ac.cn

²University of Chinese Academy of Sciences, Beijing, 100049, P. R. China

Abstract

This article presents a sustainable development capability evaluation index system of resource-based cities according to economic, social and eco-environmental aspects using the increment of sustainable development indicators to represent urban transition performance and analyzing the transition performance of 19 resource-based cities in Northeast China from 2003 to 2012. The results show that the resource-based cities in Jilin and Liaoning province performed better than those in Heilongjiang province. Liaoyuan, Songyuan and Baishan were ranked as the top 3 resource-based cities; and Jixi, Yichun and Heihe were ranked last. Multi-resource and petroleum resource cities performed better than coal and forestry resource-based cities. Selecting 8 indicators from exploitable resource, traffic location, factor input, state policy support and urban development basis, and using the method of geographic detector, we analyzed the influential factors of urban transition performance. We determined that capital input, road density and location advantage had the greatest effects on urban transition followed by urban scale, remaining resources and the sustainable development level and that supporting policies and labor input had the least effect. In addition, the mechanism and strength of influential factors are different among the different levels studied.

Key words:

Resource-based cities; Economic transition; Assessment of performance; Old industrial base in Northeast China

Demographic and Economic Features of Small Towns in Romania

Zamfir Daniela¹, Stoica Ilinca-Valentina¹, Tălângă Cristian¹, Merciu Florentina-Cristina¹, Vîrdol Daniel Celu²

¹University of Bucharest, Faculty of Geography, Interdisciplinary centre for advanced researches on territorial dynamics (CICADIT), Bucharest, Romania, stoicailincavalentina@gmail.com

² Institute of National Statistics, Bucharest

Abstract

In Romania, after 1990, the role of many small towns has diminished in the context of deindustrialization and economic restructuring. As a result, there has gradually installed a demographic decline, under the conditions of a decrease in birth rate and a high emigration rate. The sharpest population declines of over 35% occur in cities that have registered a strong decline in the economic activities (part of these being monoindustrial). Simultaneously, in some of these cities, there is an emerging aging process that, over time, is getting stronger. There has also registered a decreased influence of small towns with their adjacent rural area, turning into real "repulsive" areas for the surrounding spaces, being unable to maintain or attract population. In this context, the first part is focused on identifying and prioritizing small towns which have registered a sharp decline in population (associated with aging), after 1990, identifying the causes and the "breaches". At the same time, the prevailing activities and the economic prospects of small towns are being analyzed. Further on, there are presented the consequences of manifesting these demographic and economic processes. Subsequently, it is investigated the way the small towns work, their role in the national system of settlements, the attractiveness degree for potential investors etc. There are also critically examined policies/strategies proposed for the readjustment of these settlements and their medium and long term development prospects.

Key words:

Small towns; Romania; demographic decline; economic processes; causes

Research of Farmhouse Pension Mode in the View of Urban-rural Mutual

Assistance——The Example of the Pension Villages in Hangzhou

Yuan Fang, Wangming Li, Lixiong Zhu

College of Civil Engineering and Architecture, Zhejiang University

Abstract

As a healthy elder-cantered proactive pension mode, farmhouse pension could efficiently meet the physical and spiritual demand of the elders. As a pension mode that sharing both the urban and the rural resources, farmhouse pension also plays an important part in breaking down the urban-rural dualistic barrier and promoting the urban-rural mutual assistance. The research is carried out based on spot investigation in some distinctive health pension villages of Hangzhou and questionnaire survey in aged people of Hangzhou City. The results show that the farmhouse pension mode is beneficial to both the urban and the rural areas. For the urban area, it could provide space for the elders, lower carbon, save energy and reduce the pension cost; for the rural area, it could accelerate the penetration of urban civilization, promote the deagriculturalization of rural workforce and the back-nurture from the urban area. However, it is also noticed that there exist some problems of the farmhouse pension mode, such as the low political support, the segmentation of the urban and rural medical insurance, the overdraft of rural resources, the inequality between facility demand and usage and the backwardness of management service. Accordingly, the strategies and suggestions to these problems are also put forward in this paper.

Key words:

urban-rural mutual assistance; farmhouse pension mode; distinctive pension villages

Assemblage, Entrepreneurial Suburbanism and the Restless (Re)Making of Suburbia in China

Li Zhigang

Wuhan University, China, zhigangli@whu.edu.cn

Abstract

This study examines the transformation of suburban communities in the last three decades in Pearl River Delta (PRD), a key laboratory for the market-led and open-door experiments of the People's Republic of China. It links the governance of suburbs in post-reform China with the issue of socio-spatial transformation, spatial production, everyday practices, and put it as a significant assemblage to integrate various types of suburban space. In this vein, this paper contributes to urban theory in general by assembling the perspectives of migration/territORIZATION, suburbanization, and entrepreneurial governance, and put them together against the context of post-reform China's recent greater transformation, i.e. urbanization. Through a long-term ethnographic examination, and building upon the macro-historical perspective, this study explores the diverse outcome of different types of suburbanism for the case PRD. As a world factory, PRD attracted billions of foreign capitals, millions of migrants, and hundred thousands of factories that reshaped its landscape. Now it is marked by the heterogeneity of social space, i.e. urbanized villages, factory blocks, commodity/social housing estates, university/science towns, cultural, ethnic, or economic enclaves clustering e-commerce traders, and so on. I argue that the restless (re)making of this assemblage is indicative of dynamic entrepreneurial suburbanism, i.e. the accumulation of capital, the financialization of land, and the bottom-up practices of local states, collectives or individuals, together with its resultant empowerment of property rights, political awareness, and (re)configuring identity. It contributes to the literature by presenting entrepreneurial suburbanism as a way of life and spatial production, especially against the context of developing or transitional economy.

employment subcenters; residential land price; beijing

Community Involvement in Urban Development in Kano Metropolis, Nigeria: The Imperative for the Creation of Sustainable City

Dankani, I. M.

Department of Geography, Usmanu Danfodiyo University, Sokoto, Nigeria, imdankani@gmail.com

Abstract

Cities in the developing world are experiencing massive expansion. This growth necessitates urban managers to enact policies/legislations to address the ever increasing urban population and guide the smooth growth/development of the municipalities. Sadly, the various policies/legislation put in place fails to achieve the desired result due to non involvement of stakeholders in decisions that are vital to the growth and development of the cities. The aim of this study is to examine the benefits community involvement might bring to sustainable growth and development of cities using Kano metropolis as a study area. Data for the study were sought via primary and secondary sources. Respondents (238) were sampled using a combination of purposive and snowballing sampling techniques. The respondents comprises of all categories of stakeholders such as individuals, religious/traditional leaders, urban managers, security agents and pressure groups. Issues critical to urban planning particularly access to land, affordable housing, infrastructural provisions, security issues were extensively discussed using focus group discussion. Major findings of the study reveal that governments do not involve community members in any decision relating to urban development. Similarly, decisions were imposed on the community without due consideration to the effect it could have on the livelihoods of the community. The study concludes by recommending involvement of the community in decisions concerning the growth and development of the study area as this will serve as the imperative for the creation of sustainable city.

Key words:

Community involvement; Urban Development; Kano; Sustainable City

Consequence of Compulsory Land Acquisition on the Livelihoods of the Urban Poor in Sokoto Metropolis Nigeria:

Dankani, I. M.¹, Raliya, H. M.²

¹Department of Geography, Usmanu Danfodiyo University, Sokoto, Nigeria, imdankani@gmail.com

²Department of Geography, Federal College of Education, Zaria, Nigeria

Abstract

Access to land in Nigeria, has been clearly explained by the 1978 Land Use Decree. Land can be allocated to an individual or corporate body by the Government either through statutory or customary allocation of right of occupancy. Similarly, the Decree empowers the Government via Section 28(1) to acquire land compulsorily from individuals and corporate bodies for provision of public services by invoking the Overriding Public Interest clause of the Decree. The Decree stipulated that compensation should be given to victims of Compulsory Acquisition in order to alleviate their ordeals and sufferings. This paper examines the consequence of compulsory land acquisition on the livelihood of the urban poor in Sokoto State, Nigeria. Five areas that experienced these acquisitions were selected purposively namely, Sokoto State University complex, Bado quarters Housing Estate, Arkilla Housing Estate, Mana Housing Estate and Gidan Man Ada Housing Estate. Respondents for the study were selected via systematic sampling technique and a total of 460 were arrived at. Major findings of the study reveal that Respondents were not adequately compensated and were provided with no livelihood alternative having taken away their houses and farmlands thereby exacerbating their situation of poverty. The study concludes by recommending proper compensation to the victims as well as implementing the recommendations of the Presidential Committee on Land Reforms during the Late president Yar'adua administration which suggested compensating landowners on the basis of the market value of the land.

Résumé

L'olympisme de l'ère moderne canalise et articule de puissantes corporations et souvent compris d'opéreuses installations monumentales (avec une utilité future contestable), d'immenses dépenses publiques, la gentrification et le retrait des populations vulnérables, en faveur du processus d'intense valorisation du sol urbain. Devant ce cadre, toute une nouvelle démarche de résistance collective a acquis de la force et s'est opposé radicalement au scénario dominant des méga-événements (LENSKYJ, 2008; BOYKOFF, 2014). Comme réponse à ces manifestations, le système olympique a officialisé la notion « d'héritage » comme objectif de chaque édition des jeux.

C'est ainsi que le «développement durable » tant acclamé a intégré le mouvement olympique pour combler la quête de légitimation. Dès lors, les candidatures aux jeux olympiques ont commencé à édifier des projets plus « verts » ou « durables » : contrôle de l'émission des gaz polluants, structures de recyclage des eaux, utilisation de l'énergie alternative et de nombreuses autres ressources à disposition des technologies contemporaines.

Cela revient donc à réfléchir sur les conditions actuelles de production de les villes olympiques : comment et en quelles circonstances et limites se réalise l'application des principes écologiques lors de chaque événement ? Comment cela peut être une source d'inégalités socio-spatiales dans le contexte de l'organisation des jeux olympique ? Notre objectif est justement de vérifier la « voie olympique » des engagements dans la cause environnementale en considérant certains projets paradigmatiques comme Londres 2012 et surtout le projet olympique de Rio de Janeiro 2016.

Mot-clés :

Villes Olympiques ; Limites du développement durable ; Jeux « verts » ; Rio de Janeiro 2016 ; Londres 2012

Does Good Local Institutional Environment Enhance Firm Survival and Growth?

Zhiji HUANG¹, Canfei HE²

¹Central University of Finance and Economics, Beijing, 100083, P. R. China, huangzhiji@cufe.edu.cn

²Peking University, Beijing, 100083, P. R. China

Abstract

An intensive literature have produced the knowledge to understand the factors, such as related variety, path dependence, influencing firm survival and growth following the scope of evolutionary economic geography. However, research on whether local institutional environment enhances firm survival and growth remains blank. In this paper, we combine local institutional environment with regional industrial evolution to establish a novel analytic framework to explore the spatiotemporal performance of firm survival and its mechanisms. Using the firm-level data from the Annual Survey of Industrial Firms during 1998-2012, China, we explore the spatiotemporal heterogeneity of firm survival and growth. The econometric results primarily illustrate that local institutional environment has significantly positive relationship with firm survival, and it could also condition regional industrial evolution. We propose that better institutional environment should be built in order to enhance firm survival and regional industrial evolution for local governments.

Key words:

Local institutional environment; Firm survival; Evolutionary economic geography

Is the Gap in the Provision of Basic Amenities between Slum and Non-slum Settlements in the Cities of West Bengal, India Really Declining?

Rahaman Mehebab, Das Dipendra Nath

Jawaharlal Nehru University, New Delhi, 110067, India, mehebab.rahaman06@gmail.com

Abstract

As advocated by various international and national agencies, access to basic amenities such as drinking water, sanitation, electricity and drainage is indispensable for a decent quality of life. Over the last two decades, the government of India has launched a gamut of programmes and schemes to improve and ensure access to basic amenities in urban areas with special provision for marginalised groups and these efforts are also supported by 'inclusive growth approach' of Twelfth Five-Year Plan (2012-2017). Keeping in view these efforts, present study analyse the level of basic amenities in slum households in comparison to non-slum households in the cities of West Bengal- a state of India. The analysis is based on the census 2011, which for the first time has provided separate data on amenities in slum areas. To understand the level of basic amenities, Household Amenity Index has been constructed using principal component analysis. Surprisingly, the results indicate that the access to basic amenities in slum and non-slum settlement is more or less equal or in some cases higher in the former. But the pertinent question is whether phenomenal increase of access to basic amenities mitigates the problems related to quality or not. Unfortunately, the answer is no. There are plenty of micro level evidences which suggest that the problems related to basic amenities are very perilous in slum areas. The findings suggest that though the access to basic amenities is quite high, quality of amenities is questionable and it needs urgent attention to enhance the overall quality of life and well-being.

Key words:

Basic amenities; Slums; Household Amenity Index; Quality of life

Linking the Politico-Administrative Fragmentation of Urban Areas to Emerging Metropolitan Authorities. The Case of European Intermediate Cities

Breuer C, Halleux J.-M.

University of Liège, Liège, Belgium, christophe.breuer@ulg.ac.be

Abstract

The local politico-administrative fragmentation of urban areas is a major feature of metropolitan governance. It has a strong influence on urban issues such as spatial planning, public services delivery, economic development and interactions with citizens and upper levels of government. These communities, municipalities and local authorities are subject to many reforms to adapt themselves to new urban realities and challenges, as evidenced by decentralization processes, municipality merging, inter-municipal association and new supra-communal solutions.

In our research, we hypothesized that features of local politico-administrative fragmentation give useful information on and are linked to the type of emerging metropolitan governance structures.

In order to test this hypothesis, we have developed four indicators to characterize politico-administrative fragmentation within urban regions: a fragmentation index for population and area (average by local unit), a Gini index (population distribution between local units) and a primacy index (share of the central local unit).

We have focused our research on European intermediate cities. These cities are home of a significant part of the European population and know new forms of metropolitan governance in various national contexts in response to pressure on local authorities. We created a database including 124 intermediate urban regions delineated by the new OECD – Eurostat methodology (2015 version). Our methodology gives harmonized data for the whole EU.

On the basis of this database, we created a new typology of urban fragmentation and compared them to metropolitan governance structures. Our results validated our hypothesis on the link between features of local politico-administrative fragmentation and emerging metropolitan governance structures.

Megaregions: Foundations, Frailties, Futures

John Harrison, Michael Hoyler

Loughborough University, Loughborough, UK, LE11 3TU, j.harrison4@lboro.ac.uk

Abstract

Megaregions have emerged to become one of the most powerful, persuasive, and dominant spatial imaginaries for explaining globalization's new urban form. Nevertheless, we argue that the rhetoric and can-do bravado surrounding megaregions has raced too far ahead of the sustained theoretical and rigorous empirical work needed to support some of the assertions, assumptions, claims and investments made in the belief that megaregions do constitute globalization's new urban form. Reflecting on the foundations, frailties and futures of megaregional research, we endeavour to demonstrate the need to move megaregional debate forward from questions of definition, identification and delimitation to questions of agency (who or what is constructing megaregions), process (how are megaregions being constructed) and specific interests (why are megaregions being constructed); something which, we argue, requires a more political and more historical – as well as economic – perspective on megaregions. The latest in a long line of spatial orthodoxies associated with 'new regionalist' approaches to urban-regional planning and governance, our work reveals opportunities and barriers to adopting megaregions as a discursive policy frame for planning and governing large urban agglomerations.

Key words:

New regionalism; megaregion; urban governance; globalization; spatial planning

Models of Urban Governance in the Post-Crisis Spain: From the *Indignados* to the New Municipal Governments in Madrid and Barcelona

Piñeira-Mantiñán, M. J., Lois-González, R. C., González-Pérez, J. M.

University of Santiago de Compostela, Santiago de Compostela, Spain, mariajose.pineira@usc.es

Abstract

The economic crisis in Spain erupted with force in 2007-2008 and presented a clear urban dimension. Along with the problems of the financial system and contagion from US and other European countries, Spain had created a housing bubble of extraordinary dimensions. Therefore, when the crisis was accompanied by closures of financial institutions, rising unemployment and an uncontrolled public deficit, its effects had a particular impact on large cities. Many families could not cope with their mortgages; they lost their jobs or suffered a drastic worsening of working conditions. The result was an increase of urban poverty and social exclusion as well as the emergence of protests on the street since 2011. Among them, the 15M movement, the *indignados* –who occupied squares and streets demanding a fair system - and anti-eviction movement became the emblems of popular response. From these movements have emerged new political parties and coalitions at the municipal level. Among the latter, those of Madrid and Barcelona have won the elections and govern the two most important cities in Spain since May 2015. The aim of this contribution is to analyze the main changes in urban governance in Madrid and Barcelona since then and to study how urban activists and social movements seek to manage differently urban crisis with its strengths and contradictions.

Key words:

Urban crisis; municipal governance; social movements; Spain

Private Property Owners and Urban Regeneration. Policy Experience from a German Case

Radzimski A.

Social Sciences Research Unit, Gran Sasso Science Institute, Viale F. Crispi 7, 67100 L'Aquila, Italy,
and Institute of Socio-Economic Geography, Adam Mickiewicz University, ul. Dziegiełowa 27, 61-680 Poznań, Poland.
adam.c.radzimski@gmail.com

Abstract

This paper addresses the involvement of private property owners in the process of urban regeneration using the Glaucha neighbourhood in Halle (Saale) as a case study. Glaucha, a disadvantaged 19th century neighbourhood, has undergone a notable change in the last years. Until the 1980s the district was a typical working class quarter, where many workers from the largest chemical industry complex in the former German Democratic Republic had lived. In the years following the German reunification, which brought a large part of industry in the Halle region to collapse, Glaucha came to be perceived as one of city's least desirable addresses, as it experienced relatively little renovation and strong outmigration. After the year 2000 a new policy initiative was started with the objective of bringing vacant residential properties back to the market. Due to dispersed ownership structure with a dominant share of small private landlords, an external consultancy was hired by the city administration to coordinate the process of neighbourhood change. Within this context, the paper takes Glaucha as an illustrative case to discuss the opportunities and risks related to this innovative approach to urban policy. The analysis is based on documents, field research and expert interviews.

The Influence of the Evolution of Employment Center on the Price of Residential Land in Beijing

Huang Daquan, Yang Xiaoqing

Beijing Normal University, China, huangdaquan@bnu.edu.cn

Abstract

After the reform and opening up of China, the market oriented reform of China's urban land market is deepening, Beijing's economic development and population grew quickly. The excessive agglomeration of population and employment to the single center of Beijing—Tian a man, brings a series of urban problems. Then, three times of the overall urban planning is formulated, intended to ease heart city's functions and population, to solve the problems of cities and to accelerate the transformation of the urban spatial structure from single center to multi center struction. In recent years, the number and scale of employment centers in Beijing has increased, and the spatial structure of the multi—center city has changed. Thoughing identifying the 1996, 2001 and 2010 year's employment centers, the paper analysis the evolution of the Beijing's employment subcentres; and through constructing hedonic price model, the paper analysis the influence on residential land price of the Beijing's evolution of employment sub centers.

Key words:

employment subcenters; residential land price; beijing

The Politics of Urban Social Innovation

Painter J, Langley P, Lewis S, McFarlane C, Vradis A

Durham University, Durham, United Kingdom, j.m.painter@durham.ac.uk

Abstract

Social innovation involves new ideas for products, services and ways of working that meet unmet social needs and create new social relationships or collaborations. Austerity can accelerate social innovation in cities, but may also push it in particular directions, with significant, but little understood, implications for urban politics and governance. This paper focuses on three essential components of urban social innovation: generating financial resources, harnessing social energy, and meeting social needs. It examines the relationship between social innovation and urban politics and governance in European cities, Athens, Berlin and Newcastle, cities with contrasting experiences of austerity since the 2008 global financial. In each city we consider how alternative finance, grassroots mobilisation and community provisioning are contributing to social innovation in austerity. We examine how such social innovations affect urban politics and governance by disrupting existing power relations and channels of legitimacy and accountability, creating new urban publics and forms of citizenship, challenging traditional institutions and ways of working, and generating competition for public services. It is important to understand the impact of social innovation on urban politics and governance to ensure the effective contribution of social innovation to future urban transformation. The research is funded by the UK Economic and Social Research Council (grant reference ES/N005988/1).

Key words:

social innovation; urban politics; urban governance

The Redevelopment of Peri-Urban Villages in the Context of Path-Dependent Land Institution Change and Its Impact on Chinese Inclusive Urbanization: The Case of Nanhai, China

Yan GUO

Department of Urban Planning, School of Urban Design, Wuhan University, China, Tiverguo@gmail.com

Abstract

Following nearly three decades of urban sprawl, China's urbanization has entered a new era of land redevelopment that encompasses built-up land in villages in a manner that is unprecedented. Village redevelopment involves both dramatic institutional change and governance restructuring. The extant literature on this redevelopment focuses primarily on top-down initiatives launched by urban governments, paying little attention to villages' responses as actual landholders. Through a case study of village redevelopment in Nanhai, this paper examines villages' behaviour during periods of institutional change and their interactions with urban governments to shape final outcomes. Institutional uncertainty emerges during path-dependent institutional change, as revealed through the absence of effectively executed planning control and unclearly defined profit sharing. As a result of this institutional uncertainty, villages and urban governments sign incomplete contracts for entire redevelopment plans. Such agreements result in disordered competition for land rents that takes the form of villages 'holding up' the government that has previously made a commitment to the village pursuant to the incomplete contract. Villages maximize their profits and attenuate the government's role in ensuring public profits, whereas government compromises related to development control challenge the capacity of limited public facilities. The government's concessions related to profit distribution result in increased inequality between more prosperous villages and other groups, such as migrant populations and remote rural villages. Research findings contribute to a comprehensive understanding of newly created governance in redevelopment and call for a critical evaluation of existing urban-renewal policies to ensure that urbanization is an inclusive process.

Key words:

China; land institution change; peri-urban villages; redevelopment; hold-up problem; inclusive urbanization

The Transactional Places of the Territorial Planning Process: Example of the *Inter-Scot* of the Lyon Metropolitan Area

Dugua Benoît

Institute of Geography and Sustainability, 1015 Lausanne, France, benoit.dugua@unil.ch

Abstract

As part of the International Geographical Congress, the paper presents the main research results based on my thesis, which was defended in January 2015. The thesis deals with the challenges of territorial planning in France analysed within a European context. The Solidarity and Urban Renewal Act (2000) creates the *Scot* (« *Schéma de cohérence territoriale* ») as territorial planning tools. These require the planning of territorial organisation in the light of sustainable goals over the long term. The *Scot* are a kind of master plan for the large scale territory. My primary case study is the construction of the territorial planning process regarding the Lyon metropolitan area. Between 2009 and 2012, the research-action project was the result of an industrial research agreement (*cifre*) within the Lyon Urban Planning Agency. The Lyon metropolitan area is comprised of not less than thirteen *Scots*. Since its creation at the beginning of the 2000s, the *inter-Scot* of the Lyon metropolitan area is a collaborative organisation which must assure an articulation between all the territorial planning exercises. My thesis addresses four main problems: the relation between plans et projects (1) ; the temporality of multiple level planning (2) ; categorizing the places of the projects (3); the interactions between the stakeholders responsible for planning (4). Finally, my thesis proposes the concept of *transactional places* to explain the new *places of projects to be prioritized* today. Those would assure the interactions required between territorial scales, stakeholders, tools, fields of intervention and temporality.

Key words:

territorial planning; Lyon metropolitan area; inter-Scot; transactional places

Transition of Self-Awareness of Sendai City, Japan, Through Its Comprehensive Plans

Masateru Hino

School of Science, Tohoku University, Sendai, 980-8575, Japan, masateru@m.tohoku.ac.jp

Abstract

All Japanese municipalities have formulated their own comprehensive plans every ten or twenty years since the late 1960s in order to carry out their planned and efficient government. These plans illustrate visions based on their functional positions in the national and regional system, their future population forecast and their identities. This study examined changes in the self-awareness of Sendai through the transition of comprehensive city plans. Sendai is the regional capital of Tohoku Region. Sendai has also been called a forest city and a university city. The fundamental direction of its comprehensive plan changed from growth-orientation to the post-growth one in the 2000s. According to the comprehensive city plan in 2011, the ability of citizens and civil society organizations which resolves various problems appearing with social changes is recognized as the most important factor keeping the vitality of the city. Moreover, the cooperation between the local government and various civil society groups became to be requested. In the spatial plan, the controlling of expansion of built-up area in the suburb and the promotion of intensive land use along the subway and railway lines were drawn. This comprehensive plan of Sendai suggests that Japanese cities began to think their own future on the recognition of post growth society.

Key words:

comprehensive city plan; city identity; post-growth city; civil society group; Sendai

Urban Water Supply and Sanitation in Uttar Pradesh: A Case Study of Basti City

Mishra Katyayni, Arun K. Singh

Department of Geography, Faculty of Science, Banaras Hindu University, Varanasi, 221005,

INDIA.Katyayni.bhu7@gmail.com

Abstract

Availability of adequate amount of water and the proper disposal of liquid and solid waste is a basic human need and critical in determining the quality of life. The Govt. of India has included the issue of water supply along with sanitation in national agenda since 1st Five Year Plan but still a large proportion of population is devoid of this basic amenity. Indian cities witness water supply for a few hours, pressure is irregular, and the quality is questionable. Substantive amount (20 to 40 per cent) is lost through leakages and illegal connections. This has brought into focus the need for planned action to manage water resources effectively by involving different groups of stakeholders. There are several issues like reliability, sustainability and affordability which affect water supply and sanitation and could be addressed by identifying alternative sources of water supply, adjusting existing policies, making institutional arrangement, strengthening operation and maintenance system, providing financial incentives, capacity building for improved service delivery and ensuring involvement of communities at various stages of planning, implementation, operation and maintenance. The paper highlights the norms set by different agencies, institutional arrangement and the status of water supply and sanitation in Basti City. Data for this work have been directly collected through a set of questionnaire from the different wings of respective urban local bodies and have been substantiated by secondary data sources which include published articles and reports.

Key words:

Basic human need; Quality of Life; Reliability; Sustainability; Affordability; Capacity Building

Utility, Satisfaction and Necessity of Urban Parks: An Empirical Study of Two Suburban Parks of Kolkata Urban Agglomeration, India

De J

Department of Geography, University of Calcutta, Kolkata – 700019, India, de.jaydipde@gmail.com

Abstract

Urban parks are the open places, green fields and riverside gardens usually maintained by public or private authorities or eventually by both jointly; and utilized for a multidimensional purpose by the citizens. Practically these parks serve as the lung of urban centers. In the urban environments, these are the locus of social integration, community building and physical development. Usually they perform as the panacea of congested, complex and stressful urban life. In the cities of developing countries, increasing population and resultant congestion of high-rises are making life wearisome. Citizen always quest for open space and fresh air. In such a circumstance trivial existence of parks is not capable of satisfying the aspirations. Here, an attempt is so made to empirically identify the utility, visitors' satisfaction and future needs through the cases of two urban parks of Kolkata conurbation, India. In the contemporaneous study, primary information is collected through visitors' perception survey conducted at Chinsurah ground and Chandernagore strand; identified and analyzed the correlation between different utility categories. At the same time, indices like Weighted Satisfaction Score (WSS), Facility wise Satisfaction Index (FSI), Urban Park Satisfaction Index (UPSI) and Urban Park Necessity Index (UPNI) are advocated to quantify the visitors' satisfaction and future necessities. It is explored that most important utilities are passive in nature. Simultaneously, satisfaction levels of visitors are average and they need parks for children most. Further, considering the visitors' opinion planning measures are promulgated for holistic development of urban parks to revitalize sustainability of citified life.

Key words:

Urban parks; Park utility; Visitors' satisfaction; Future needs; Citified life

Reorganization of Urban Old Industrial Area's Functions: A Case of Tiexi Old Industrial Area in Shenyang, China

Zhang, LM

College of Economics, Qingdao University, Qingdao, 266071, P.R. China, annazhangliming@163.com

Abstract

Urban old industrial areas exist widely around the world. Substantial social, economic and environmental issues occurred with the recession of old industrial areas, impeding the sustainable development of the host cities. The transformation and reconstruction of urban old industrial areas is an important and critical issue for city's renovation. Urban functions reflect the fundamental characteristics of one city. City's renovation refers to the reconfiguration and redevelopment of urban functions. Based on a comprehensive review of the reconstruction of urban old industrial areas, this study employs a case study approach in Tiexi old industrial area of Shenyang city, a typical brownfield redevelopment project in China.

The reconstruction process of Tiexi old industrial area was analysed from the perspective of reorganizing urban functions, including the reconstruction targets, driving mechanism, reconstruction pathways and key patterns. The reorganization of Tiexi old industrial area's urban functions coupled with land use changes, leading to spatial structure reconfiguration. During the study period, the industrial land use reduced by 644.30ha, while the residential land increased by 374.68ha. The area of land use change had been 1075.62ha, accounting for 25.40% of the total area.

Several policy recommendations on better reorganizing old industrial area's functions are proposed, such as adjusting industrial structure and optimizing special planning, improving land-use efficiency by integrated land use planning, energy saving and circular economy.

Key words:

Old industrial area; Urban function reorganization; Land use

Research on Coal Resource-exhausted Cities Low-carbon Alternative Industry Development Illustrated by the Example of Zaozhuang

Yuan Yu-ke Wang Cheng-xin

College of Geography and Environment, Shandong Normal University, Ji'nan, China, 250014

Abstract

The coal resources city sustainable development and the transformation has been the important and difficult problem in the process of Chinese modernization. This paper is illustrated by the example of Zaozhuang to get insight into the problems of coal and other leading industries and new low-carbon substitute industries' guidance to the choice of industry leading role in its huge economy. Using Delphi method to score the various industrial competitiveness of Zaozhuang and select high-tech industries, tourism and other industries. Meanwhile, this paper researches for the development of its new model to provide a typical case for the transformation of other resource-exhausted cities.

Key words:

resource-exhausted cities; low-carbon alternative industry; transformation of industrial structure

Agency and Social Construction of Space under Top-Down Planning: Resettled Rural Communities in China

Zhang M., Wu W.

Nanjing University, Nanjing, 210093, P. R. China, Min_zhjs@sina.com

Abstract

Resettled rural communities are a product of China's rapid urbanization and associated top-down planning. For local governments, relocating farmers from natural villages into new, concentrated residential neighborhoods serves the dual purpose of implementing national directives on farmland conservation and integrated urban-rural planning. For resettled residents, however, the process is akin to involuntary urbanization. This paper explores how such residents in Zhenjiang, exercise agency to reconstruct community and residential space in their new neighborhoods. Using the concept of habitus, in this case the pattern and practice of thoughts acquired during their rural lives, we show that even under top-down planning, micro resistance allows residents to continue some forms of traditional lifestyle and smooth the transition to urbanism.

Key words:

resettled rural communities; agency; habitus; top-down planning

Abstract

The dynamics of bordering processes have been examined substantially on national borders, however, not much attention has been paid to how exactly borders work on the scale of neighbourhood. This paper explores the performance of the dynamics processes occurring at the border between two different but contiguous enclaves: a gated community and an (urban) village. This paper adopts a multiple-dimensional approach that scrutinizes the functional, symbolic and social-network aspects of the neighbourhood debordering and rebordering processes. The empirical study comes from three residential borderlands in suburban Guangzhou by using the methods of semi-structural interview and observation by following. The empirical results demonstrate that residential border is becoming more permeable as a result of flows of people from the gated community to the neighbouring village area. At the same time, however, the border also becomes more rigid through processes of seeking a sense of security, of ordering and othering. Residential borderland is a transitional space in which the inclusion and exclusion of people take place. This paper also demonstrates how the processes of debordering and rebordering are embedded in the urban spatial reconfiguration of Guangzhou.

Key words:

Residential borderland; Debordering; Rebordering; enclaves; Guangzhou

Discriminated Urban Spaces: A Study of Spatial Segregation in Urban West Bengal, India

HAQUE Ismail¹

¹Centre for the Study of Regional Development (CSRD) / School of Social Sciences (SSS),

Jawaharlal Nehru University (JNU), New Delhi 110067

Presenting Author's email: ismail19_ssf@jnu.ac.in

Abstract

Given the present developments reshaping the social and spatial coherence in urban areas, a more inclusive understanding of segregation is required. Analysing latest ward-level data from 2011 Census database, this detailed study solicits to understand the magnitude of spatial segregation in the 10 most populated cities of West Bengal, India. Applying Gorard Segregation Index (2000), we attempt to examine empirically the extent and magnitude of spatial segregation in each of the cities by gender, caste, socio-economic status and access to Households-public, private and aspirational goods and we would also like to see whether degree of spatial segregation by caste is higher than segregation by socio-economic status or other select aspects. This paper surmises high degree of spatial segregation by caste in these cities. In each of the cities, caste-based spatial segregation is much pronounced than the degree of segregation by socio-economic status and gender. Level of spatial segregation by access to Households essential public goods- treated tap water and drinking water facility within premises and essential private goods-latrines within premises seems to be considerably higher as well. This paper further finds a higher correlation between wards having proportion of SC/STs population and access to Households' essential public, private and aspirational goods in most of the studied cities. This study concludes with a discussion of the key lacunas of our analysis and underscores some avenues for future research.

Key words:

Urban Space; discrimination; spatial segregation; caste; West Bengal

Does the New 'Planetary Urban' Order Let Civil Society Go off the Hook in the Postcolony?

Aditya Mohanty

PhD Student, University of Aberdeen, Aberdeen, UK, r08am15@abdn.ac.uk

Abstract

In the contemporary 'urban' condition, liberal democracy and transnational sovereignty offer us numerous avenues for cognizing the cross-cultural undertones of human geography. But scholars like Ananya Roy (2015) caution us against the adoption of '... a universal grammar of cityness, modified by (exotic) empirical variation' by harping on the celebration of a contingent historicity. Howsoever the 'planetary urbanization' (Brenner 2013) analytic precariously tinkers with our understanding of claim-making in postcolonial urban spaces. The rise of a caste-class consociation and the growth of a hegemonic middle class (Heller and Fernandes 2006), for instance, seem to have had engendered an ossification of a neoliberal ethic that definitely dares to ruffle up the very ontology of a 'postcolonial aura' (Dirlik 1994) or the very 'ordinariness' (Robinson 2005) of the city. Under such a moment of spatio-temporal catharsis, one tends to feel as if civil society is let off the hook. This paper shall use data retrieved from my current research work on neighborhood associations in Delhi and studies on gentrification and urban renewal, in cities of both the Global North and South, to prod in. In fact it argues that in order to understand subversive modes of representation amidst the growing 'specter of capital' (Chibber 2013), the ontology of a comparative urban geography needs to go beyond the dichotomy of the 'civil' and the 'political' in everyday life. Further, we do need to unabashedly get prepared for capturing the ethos of what, I prefer to term as, 'symbiotic spaces of neo-populist sovereignty'.

Key words:

Planetary Urbanisation; Civil Society; Neoliberalism; Postcolonialism

Identity Assertion and Contested urban space: An Odyssey of Lower Castes

Spatialities in an Indian City, Jammu

Singh, Devinder

Associate Professor, Department of Geography, University of Jammu, Jammu-180006, Jammu & Kashmir, India.

devinder_jmu@yahoo.co.in

Abstract

The socio-economic and socio-cultural look of India has experienced significant changes since Independence. The manifestations of these changes induced by economic, social and political processes are tangible in the Indian urban socio-spatial reality. A large dynamic urban centre appears to be a microcosm of the contemporary Indian reality. Taking a case study of Jammu, a multi-religious and multi-caste historic regional centre and the winter capital of the State of Jammu & Kashmir, the paper aims to describe and explain the traditional and contemporary socio-spatial patterns and socio-spatial dynamics of lower castes. It unravels processes generating distinct identities among lower castes. The study brings to light their struggle to produce symbolic spaces to enhance their respective visibility and strength, thereby, both enriching city's cultural life and giving new meaning to its social space. In the sense, urban space has become more contested, fragmented and attained more complexity. The research is largely based on data collected through personal interviews, schedules and participatory observations. The discussion is also based on census data from 1901-2011. In addition, maps and photographs are used to illuminate the reality.

Key words:

Lower Castes; Socio-spatial pattern; Socio-spatial dynamics; and urban social space

Limited Property Housing vs. Commodity Housing in Beijing: An Empirical Study on Resident Structures and Residential Satisfaction

Xu P, Lei Y, Hao X, Wang C

College of Resources Science and Technology, Beijing Normal University, Beijing 100875, P. R. China, xu@bnu.edu.cn

Abstract

Due to the urban-rural dual structure within China's land administration system, Limited Property Housing (LPH) - homes built on collectively-owned rural land and sold to the public - has become a unique phenomenon in China. Approaching the LPH issue from the viewpoint of demand, the research focuses on resident structure, residential situation and satisfaction of LPH, and surveys typical LPH and Commodity Housing (CH) quarters in Beijing's metropolitan area. Based on statistical analysis, a comparative study between LPH and CH residents is conducted.

Four major differences are found between LPH and CH residents: previous places of residence, family structures, educational levels, and extent to which they can afford on housing. On the flip side, some undeniable similarities between the two groups are discovered, such as household income, household status (rural or urban), occupations of and workplaces of breadwinners.

On a scale of 1 to 7, with 7 being "very satisfied", LPH residents are rated 4.09 on housing prices satisfaction, while CH residents are rated 2.84; LPH has a 4.44 on comprehensive residential satisfaction, and CH a 3.96.

By the AHP approach, the price factor is weighed 51% in this model, and therefore the difference in housing prices plays a decisive role in this evaluation of comprehensive residential satisfaction level. The difference in prices between CH and LPH is also a determining factor of LPH purchase, yet the collected data does not support the claims that LPH purchasers are a low-income, vulnerable group with low levels of education.

Post-Crisis Spanish Cities. Slumification and Gentrification in a Leading

Mediterranean Island Tourist City, Palma de Mallorca

González-Pérez, J.M.

Departament of Geography, Guillem Colom building, University of the Balearic Islands, Palma, 07122, Spain,
jesus.gonzalez@uib.es

Abstract

The bursting of the housing bubble in Spain, the world economic crisis (2008) and subsequent neoliberal austerity policies have led to profound social and urban changes in Spanish cities. The main consequence is growing inequality in post-crisis cities. The city of Palma, the capital of one of the Mediterranean's leading tourist destinations (Mallorca), is a good example and case study. In times of crisis, there is an increase in the price of housing and tourism in strongly promoted central areas, and increased austerity in outlying, more cut-off urban areas where marginalized members of the population live. An increase in the number of homeless people and the introduction of austerity policies are two consequences of the crisis. The objective of this paper is to study the city's social fragmentation through an analysis of social and urban processes put into practice during the years of the economic crisis. The main hypothesis is that post-crisis cities are more fragmented and imbalanced, with a widening gap between the richest and poorest neighbourhoods. The paper is divided into two main sections. First a study is made of gentrification processes, increases in the price of real estate, and the touristification of the old quarter. Second, urban vulnerability indicators are analysed on an intra-urban scale, with particular attention to slum areas, the homeless population and evictions. In order to compare these processes, the analyses focused on two moments in time: the housing bubble (the first decade of the 21st century) and the economic crisis (the second decade).

Key words:

post-crisis city; urban vulnerability; urban fragmentation; gentrification; evictions; housing bubble; homeless; tourist city; Palma de Mallorca

Quality of Life of Foreigners in an Industrial City from Geographical Perspective: Case of Hamamatsu City, Japan

Nishihara, J.

Faculty of Informatics, Shizuoka University, Hamamatsu 432-8011, Japan, nishihara@inf.shizuoka.ac.jp

Abstract

Immigrants generally experience poorer living conditions and quality of life in European and US cities. In Japan, after revising the Immigration Control Act in 1990, many foreigners immigrated to Japan and found employment in various non-skilled jobs. Consequently, the social geography of Japan's cities has changed drastically regarding the nationality of residents whose living conditions are expected to resemble migrant workers in western cities. This paper examines the quality of life of foreigners in Japan's cities from a geographical perspective.

This study focuses on Hamamatsu City, an industrial city, whose foreign population in 2010 was 28,000, about 3.4% of its 820,000 citizens. Brazilians account for half of the foreigners. I analyze the geographical distribution of accessibility to such daily-life facilities as grocery stores, large-scale retail stores, banks, hospitals, and child-care centers using GIS and discuss the differences in the accessibility levels between foreigners and Japanese nationals.

First, the people living in the built-up areas of Hamamatsu have achieved good overall accessibility levels, but the suburban and peripheral areas are less convenient. Second, even foreign workers with low incomes and unstable employment conditions are not greatly constrained as to where they can live. Most reside in built-up areas where they have secured slightly more convenient lifestyles for employment and shopping, supported by their strong ethnic networks, than Japanese nationals. Third, the Japanese people living in these peripheral areas, almost half of whom are seniors, are forced to live under inconvenient daily situations.

Key words:

Immigrant; Accessibility to Daily Life Facility; GIS; Quality of Life

Residential Satisfaction of Public Rental Housing in Chongqing City and its Influential Factors

Huiming Zong, Jielin Dai

School of Geographical Sciences, Southwest University, Chongqing, 400715, P. R. China, zonghuim@swu.edu.cn

Abstract

In the context of rapid urbanization, public rental housing has become one of the important ways to solve the housing difficulties of urban population in metropolitan area in China. Previous studies, however, have overwhelmingly focused on residential satisfaction in transitional urban community particularly. Little attention has been paid to residential preferences and realization in public rental housing. Therefore, based on the statistical analysis of 500 valid questionnaires, we use multivariate linear regression model methods to examine the impacts of objective factors (such as demographics, housing conditions, and commuting) on residential satisfaction. We find that single groups, the elderly and permanent immigrants have high satisfaction. Specifically, location factors have significant impact on residential satisfaction. Meanwhile, commuting time and cost also as explanatory variables produces somewhat different economic correlates of residential satisfaction. Findings from this study suggest that improving reasonable space layout programs and transportation facilitiesWánshàn de jiāotōng pèitào shèshī is important to enhance residential satisfaction of existing residents.

Small Property Right Housing Development in China: Towards a renewed understanding of urban villages

Shenjing He

Department of Urban Planning and Design, The University of Hong Kong, China, sjhe@hku.hk

Abstract

In China, skyrocketing housing prices in large cities make homeownership an unachievable dream for many. Despite a large quantity of affordable housing having been built or being built by governments, accessibility remains as a major problem in terms of the remote location of this new state-supplied housing and its stringent criteria, which exclude the large majority of rural migrants in the city, cumulating to more than 260 million in recent years. Against this backdrop, one peculiar informal housing strategy known as “Small Property Right Housing (SPRH)” is thriving on collective land owned by villagers, which has accounted for about 20% of total housing stock in the whole country. SPRH can therefore be seen as an informal countermeasure responding on the one hand, to the deficit of formal sector affordable housing supply and on the other, to towering housing demand from low-income groups and rural migrants. Constrained by their limited property rights, SPRHs are inalienable by law. Being well aware of the risks and uncertainty of SPRH, a large number of rural migrants still participate in the SPRH market. In this research I delve into an important question: What are the socio-spatial implications of SPRH (as an alternative form of homeownership) for migrants in terms of social mobility and social integration? Based on a pilot study conducted in Guangzhou, 2015, which involved 9 in-depth interviews and 394 questionnaires, this study aims to contribute to a renewed understanding of urban villages by pinpointing several new findings: 1) urban villages are more than a spring board for migrants, in which SPRH provides a counterforce for precariousness and insecurity and serve as a breeding ground for upward social mobility; 2) yet, SPRH also emerges as “clubs” for better-off migrants, which raises a new question: whether SPRH promotes social integration or creates new dynamics of segregation?

Small Property Right Housing; Urban Villages

Socio-environmental Conflicts and Poverty: The Case of the Metropolitan Area of Mexico City

ESPINOSA, Rolando

Doctorate in Geography-National Autonomous University of Mexico, Mexico City, Mexico,
rolando_eh@comunidad.unam.mx

Abstract

The process of urbanization of contemporary society has been accompanied by two disturbing phenomena: the urbanization of poverty and the environmental degradation of both urban and rural areas. These last two issues have a complex relationship among each other and with the process of urbanization itself.

This paper discusses the link between social and environmental precarization processes and the emergence of socio-environmental conflicts in urban areas. On the basis of the classic geographical scale problem, it debates the misleading antinomy opposing “anti-environmentalism” and “environmentalism” of the poor people.

The argument concludes with an example, the case of Mexico City, in order to formulate the relevance of the concept of socio-environmental conflict for the development of a critical geography of conflict. It highlights that what has emerged in large cities is a form of popular environmentalism, in the broad sense of the word, that tends to involve all kinds of social strata and classes, mobilized as a result of the undermining of their living conditions and the deterioration of their relationship with the environment.

Key words:

Socioenvironmental conflict; environmental degradation; environmentalism of the poor; Mexico City

Socio-Spatial Differentiation and the Social Construction of Resident'S Opinion about Refugees and Immigrants in Mytilene (Greece)

Petropoulou C., Micheli A., Katseniou E.

University of the Aegean, Department of Geography, University Hill, 81100 Mytilene, Lesvos, Greece,

christy.p@geo.aegean.gr

Abstract

During the summer of 2015 a noticeable flood of refugees and migrants arrived on the coast of Lesvos and particularly in the city of Mytilene (Greece). Since then, the daily number of refugees and migrants arriving on city of Mytilene (Greece) is fixed to 1500 people. For this reason the island of Lesvos has developed a great humanitarian and solidarity action in order to help them. Furthermore, this migratory flow has affected not only the change of certain land uses in the city center but also influenced on the economic and social activities of the city and on the creation of contested social spaces in the city. This study focus on the social construction of different viewpoints of residents about refugees, the ways resident's opinions are formed and affecting by the daily life experiences, the urban socio-spatial differentiation and all those socio-spatial dynamics developed in the city of Mytilene (Greece) during this time. The social data was carried out during the summer period of 2015 in four urban districts of the city approached from both qualitative and quantitative methodological tools which was applied for the determination of these dynamic characteristics approved by questionnaires, interviews, collection of articles of local press and formal discussions among residents.

Key words:

migration; socio-spatial differentiation; urban geography; contested spaces

Sprawling Informality versus Upgrading Technological Business District of Changping, Beijing

LIU Ran

College of Resource Environment and Tourism, Capital Normal University, No.105 West 3rd Ring Road North, Beijing 100048, China, liu.ran.space@hotmail.com

Abstract

Suburban Beijing is increasingly becoming a contested space witnessing the enhanced sectoral and spatial mobility of capital and people, following a series of city upgrading actions and migration control measures. Taking the Changping District as case study, this paper investigates the drives of the latest socio-spatial changes there, including the joint efforts of investors and local states in branding the Technological Business District, and the labourer's endeavors to settle down in this 'unaffordable' city. The 'urban villages' have also sprawled along the Beijing-Tibet Expressway following mass demolitions, just booming neighboring the TBD area. The surveys on 'informalities' tell a floating life story of migrant tenants, and demonstrate the housing inequality that is deeply embedded in power matrix and fiscal relations of Beijing city. Besides the above pair of 'formalities' and 'informalities', Beijing's giant welfare housing clusters, namely Huilongguan, have been also built along the Beijing-Tibet Expressway. The 'group-renting' of young college graduates has emerged in Huilongguan, for its high vacancy rate as a result of welfare housing misallocation towards free-riders. The 'group-renting' mode has settled down thousands of young IT workers, and proved the housing difficulties among these well-educated employees of new economies. In implementing the 'local developmentalism', the housing unaffordability and inaccessibility of the capital city are 'decriminalized' to be 'leverage' to force out the low-wage migrants. Apart from the tightened *hukou* controls in Beijing, more focus should be put on obstacles to financing the 'New Styled Urbanization', including its impending 'residency card' system.

Key words:

Sprawling informality; Group-renting; Technological Business District; Changping; *Hukou* reforms

Survival Mechanism of the Urban Street Vendors under Large Urban Projects during Transitional Period

——A Case Study of Wuhan Optics Valley Square

Wanzhen Tang

Hubei University, Wuhan, 430062, P. R. China, twanzhen2012@163.com

Abstract

In recent years, the researches on informal economy from the spatial view have attracted a lot of attention in urban geography. Meanwhile various informal economy phenomena appeared during the fast urbanization in China. Wuhan Optics Valley Square street vendors were selected as our study case. The related appeal and attitude of different subjects was obtained by in-depth interviews, the characteristics of spatial distribution and the social and economic of the Optics Valley Square informal activity were analyzed by the plotting of field survey. We found that there exists some special status for the street vendors. Firstly, the street where vendors are selling is strongly affected by large-scale urban development projects. Specific performances of its influence are in temporary scope of operation, failure of internal space control and local concentration distribution characteristics of commodity. Secondly, vendors normally mobile and their stalls are relatively stable. Vendors' business hours and stalls in and around my study area have changed with the project's process, while vendors within study area have fixed business hours and stalls. Thirdly, vendors' identities are different and complex, such as diversification of sources, trend of young and highly educated and the participation of minority groups and even they control the street and so on. The forming mechanism is closely related to spatial reconstruction of large urban projects, the regional politics under particular location and vendors' coping abilities and aspirations.

Key words:

transitional period; large urban development projects; informal economy; street vendors

The Interaction between Urban Space and Graffiti in Japan, Taiwan and Hong Kong

Matsumura Yoshihisa

Hannan University, Osaka, Japan, matsumuy@hannan-u.ac.jp

Abstract

The Hip-hop culture consisting of rap, DJ, break dance and graffiti emerged in New York in the 1970's and has continuously flowed into East Asia's big cities since the mid 1980's. With the exception of graffiti as a form of vandalism against the urban function, this culture has become widely accepted and established in East Asia from the 1990's through until the 2000s, without any considerable frictions. At the same time, some graffiti artists, while maintaining a tense relation with public authorities, have developed their own style into a fine art that focuses on urban public spaces and streets. From the mid-2000s, as a result of the discussions on the "creative city," creative activities and artists increasingly received attention as a new way of encouraging urban regeneration. Within this, graffiti and wall art have also been recognized as important contributions to move beyond the stubborn "broken windows theory".

In this presentation, through comparative study, I examine the various connections between graffiti, artists, private companies, governments and local communities by focusing on particular characteristics of urban space. "Nishinari Wall Art Nippon" in Osaka, the activities of "CITYMARX" near Taipei Cinema Park and "The Pier-2 Art Center" in Taiwan and "Hong Kong Walls" in Hong Kong etc. are used as case studies. It is widely claimed that graffiti may trigger gentrification and social exclusion. However, this paper shows that graffiti also has great potential to encourage local communities, engrave urban memories for facing the future and attract a lot of visitors.

The Occidental Isn't Accidental: Life among Baku's Steel Metaphors and Black Gold

Tasch J

Department of Geography & Environmental Planning Towson University, 8000 York Road, Towson, Maryland 21252,
JTasch@Towson.edu

Abstract

Reminiscent of Lenin's 1916 observation that Baku "had transformed from a contemptible town into a first-rate industrial center of Russia," the contemporary capital of Azerbaijan has become a planned stage-set of modernity. Largely liberated from budgetary constraints by oil, and notwithstanding its pre-existing 19th century masonry cityscape, Baku has become an experimental urban center where designers' imagination and plasticity of form now dominate the skyline. But modern Baku, with its newly constructed hotels and imported London taxicabs, is the seat of a central governmental apparatus that imposes a social contract that offers futuristic wonders in exchange for civil obedience. While contemporary Baku is heralded by its central government as the economic, cultural, and social hub of the Caucasus, for Baku's residents this rapid cosmopolitan transformation is, by turns, inspiring, threatening, alienating and confusing. Inside the crucible of Azerbaijan's post-Soviet modernity, residents debate and deliberate what it means to be Azerbaijani, in a city that claims "European Charm of the Orient." This paper reflects on the importation of "European" features the powerful feel will maintain their authority, in complement with the ways that diverse, nostalgic, and hopeful residents are negotiating the parameters by which the city—and nation—is run.

The Pop-Up World of Adolescents: Peri-Urban Spaces Transformed

Robertson, M

La Trobe University, Melbourne, Australia. Email m.robertson@latrobe.edu.au

Abstract

It's been a long dry summer. School is back for the start of another year. Students report: 'Nothing much has changed – the classrooms look the same and the teachers seem nice but time will tell. We have exams looming. I know I need to knuckle down and start studying. The problem is my mind wonders off to beaches and cinemas, and the local cafés and park and the new pop-up clothing shop in the local shopping mall'. It's October 2014. Asked about their views and visions of the spaces and places where they live young people aged 12-15 years report in focus groups (N~240) their first concern is terrorism. 'Sending our people to conflict places will not help'. 'Planes link people'. People are mobile. 'My Mum got married in Bali'. 'Racism is pretty bad'. 'People say things but laugh it off. It's bullying'. 'Self-harm is kind of bullying. Then there is suicide'. Such are perceptions of life in the peri-urban zone of metropolitan Melbourne (Australia). Multi-ethnic communities bring together families from diverse socio-cultural backgrounds. Mostly bilingual, these young people live in complex worlds. They are imaginative and resourceful – they merge the hyperreal of their online and everyday lives with seamless ease. Supportive of one another, adolescents explain their hopes and dreams for the future. The school and local community agencies are part of the developmental 'glue' that enable young people to learn how to manage their spaces – provided they make the time to listen.

The Role of Social Capital in Community Recreation and Informal Settlements (Case Study: Neighborhood Saadi, Shiraz)

Dr. Movahed. A¹, Izadi.P²

¹Associate of professor, Kharazmi University, Iran, Tehran, movahed@khu.ac.ir

²Ph. Student of Sistan and Baluchestan University, Iran, Zahedan

Abstract

Needs of low-income urban housing market, increasing demand for housing and informal settlements in the city has created a sort of informal settlements. Because Informal settlements causes poverty, and also endangering the environment and impose heavy costs to resolve problems is a serious threat to the stability and cohesion of the urban population, so these problems cause city managers to think about changes in this kind of settlement. Social regeneration of these settlements due to social capital as assets in the communities in these settlements is the perfect solution for organizing these neighborhoods. The purpose of this study is to evaluate the role of social capital on social regeneration of an informal neighborhood in order to sustainable development. The method of study is descriptive-analytic and using field study and Questionnaire. The results show that there is a significant direct relationship between social regeneration and indicators of social capital in the Saadi neighborhood. The level of Social capital at this neighborhood is moderate and the use of these assets (social capital) can lead to facilitate social regeneration in this informal neighborhood.

The Social Spatial Factors in the Areas of Creative Industry Clusters—An Empirical Research Based on the Areas in Tokyo

Xinyue Gan

School of Architecture, Tsinghua University, Beijing, 100083, P. R. China, ganxy813@163.com

Abstract

The rise of the creative industry has provided the new driving force for those post-industrial cities. Even though the good results of urban regeneration because of creative industry are mostly mentioned, it is important to analyze objectively the negative results of urban regeneration based on the creative industry clustered. This paper is trying to describe the relationship between creative industry clustered and the result of urban regeneration—the change of social spatial factors. Two variables were firstly constructed to describe the cluster degree of creative industry and the social spatial factors. Taking the 127 administrative units in the inner city of Tokyo as the study samples, the creative industry clustered of which were most obvious in the city. And then, by means of regression analysis, the paper found that there was a significant correlation between cultural creative industry clustered and the cluster of high income society. And in these areas, with a lot of low income society who lived in the areas more than 20 years moved out from 2005 to 2010, the Homogenization of social class was increasingly obvious. Finally, by means of cluster analysis and spatial analysis, the paper found that the areas, which the cluster degree of cultural creative industry and high income society were both high, were highly intensive in the space, the polarization of social space was obvious. The result showed that the social justice and social class diversity should not be ignored when in the process of the cultural creative industry-oriented urban regeneration.

Key words:

The Spatial Difference Study of Hainan'S Urbanization Development in the Post-Crisis Era

Chen Ting¹, Chen Zhongnuan¹, Tian Liang²

¹School of Geography Science, South China Normal University, Guangzhou 510631, China, 2539249215@qq.com

²Tourism school, Hainan University, Haikou 570228

Abstract

Economic crisis has brought great impact to the world, Hainan Province which as China's largest special economic zone will inevitably suffer, and urbanization is an important engine of economic and social development, in the post-crisis era, clear status and trends of urbanization development in Hainan Province has great significance for the choice of urbanization route and economic development strategy. Therefore, Article based on entropy method, from the demographic, social, economic, geographical landscape to build four dimensions of urbanization comprehensive evaluation index system, to evaluate the 18 counties of Hainan 2011-2013 urbanization level, and with the ARCGIS software and spatial auto-correlation analysis, the sample standard deviation of the method, In order to explore the spatial variation of urbanization development in Hainan Province in post-crisis era, the results showed that: (1) The comprehensive level of urbanization in Hainan province in recent years in the small amplitude increase year by year, but the regional difference is great, form "the bipolar structure", and the eastern city of urbanization level is high; (2) The spatial auto-correlation analysis shows that the regional urbanization level of Hainan province does not appear in the spatial distribution of the characteristics of similar value agglomeration, and there is a negative correlation relationship. (3) The regional differences in the types of urbanization are obvious, where coexistence of serious lag, lag, lead, lead, lead-based cities, and the "dual-core" cities of urbanization is advance of economic development level, city are positive type at a low level at urbanization and economic development.

Key words:

The Vision of the Neighborhood and its Impact on Norms and Behaviors

Cieslik, A

New Jersey City University, Jersey City, USA, acieslik@njcu.edu

Abstract

This paper argues that unpacking the meaning of “neighborhood” for different groups can shed light on the course and significance of everyday encounters in public space. I argue that the modes of interaction and conviviality are shaped not only by ideas about the “other” but also by ideas about places/neighborhoods. Geographers have shown that neighborhood is a contentious concept. It is contentious not only because its boundaries are often fluid and not formally codified, but also because the ideas about what constitutes a neighborhood are shaped by individual experiences. In this paper I am less interested in the drawing and redrawing of boundaries and definitions, and more interested in the socially and culturally created visions of the neighborhood.

The paper is based on two years of ethnographic research in the superdiverse neighborhood of Astoria (NY), including participant observation, photography, video recordings and semi-structured interviews. It presents a section of a larger research project, Global DiverCities, ran by the Max Planck Institute for the Study of Religious and Ethnic Diversity. In this analysis I focus on people’s motivations behind moving to the neighborhood, their experiences of living there, and their understandings of the neighborhood. In distinguish three “neighborhood orientations”: the gentrifier, the working-class local, and the recent immigrant. They are not meant to be an exhaustive list of possible neighborhood orientations, but rather examples of how the different ways of thinking about Astoria are impacting the way people act and interact in public spaces.

Key words:

superdiversity; immigration; urban; neighborhood; encounter

Urban Adaptive Governance of Marginal Social Environments

Paraschiv M, Ianoş I, Saghin I

Interdisciplinary Center for Advanced Research on Territorial Dynamics (CICADIT), University of Bucharest, Romania,

mirela.paraschiv@geo.unibuc.ro

Abstract

Urban organisms are continuously challenged by territorial processes and phenomena that impose concerted strategies, policies and actions. Homelessness, as the extreme expression of urban poverty, impacts the urban environment resulting in social and environmental issues and the creation of contested spaces. Among other European countries, Romania gathers massive rates of homelessness while Bucharest attracts extensive shares of the national poorest population. The study conducts a qualitative assessment of the social environment in Bucharest with a focus on the required governance approach to deal with the territorial implications resulted from the interaction between homelessness and the general population in the framework of marginal urban spaces as product of social conflict. Based on surveys and interviews carried out with different actors of the urban space, the analysis involved: the identification of potential areas of conflict based on the areas of homelessness concentration inside the urban environment; and the assessment of the present homelessness managing policies and actions in the light of adaptive governance as a tool of sustainable territorial planning. The main findings evidence that current public and private management of marginal social environments in Bucharest involves dispersed, inconsistent and impulsive actions. The constructed model of adaptive governance in the context of extreme urban poverty-generated conflicts aims at managing social issues and avoiding the creation of spaces of crisis. The analysis' conclusions ensure helpful knowledge for the urban planners and policy makers to develop efficient planning processes that increase the quality of urban social environments and support the sustainable development of cities.

Key words:

homelessness; contested spaces; social conflict; adaptive governance

Village Autonomous Non-Agricultural Development and Social Inequality during Rapid Urbanization: The Case of Nanhai, China

Yan GUO

Department of Urban Planning, School of Urban Design, Wuhan University

Tiverguo@gmail.com; Tiverguo@whu.edu.cn

Abstract

Social inequality and spatial differentiation are not uncommon in the China's cities where discrimination against rural-urban migrants is institutionalized by the urban household registration. In the dynamically growing regions where industrialization and urbanization are driven by both the urban state and rural villages, rural non-agricultural development has attracted an influx of migrants to villages to work in their non-agricultural sectors. Through an in-depth case study of Nanhai, this paper reveals unexpectedly serious social inequality and segregation between the local villagers and migrant workers in the villages that are effectively urbanizing. Traditional rural egalitarianism serves village community members exclusively because of the institution of villages as autonomous and exclusive social and economic organizations. It is the land rent driven by urbanization as village entitlements that institutionalize the inequality between the two peoples, and inequality has been deteriorating along with the progressive urbanization as villages rely on land rent and land rent increases much more than wages do. In conclusion, we suggest that place-specific exclusive provision and entitlement should be reconsidered in the context of urbanization and migration, and land rent should be taxed and used for the provision of social and public goods in the land-scarce regions, so as to make urbanization inclusive.

Key words:

Rural non-agricultural development; social equality; autonomous and exclusive villages; land rent; inclusive urbanization; China

Community Attachment among Guangzhou Public Housing Residents

Dixiang Xie, Jiang Chang

Guangdong University of Technology, Guangzhou, 510090, P. R. China, xiedixiang@126.com

Abstract

Since China's housing reform in 1998, housing conditions of low-income residents have partially improved. Besides the quantity of public housing, the quality of community attachment of residents should get more attention. Following a literature review, our study examined community attachment among three samples of Guangzhou public housing residents using surveys. The multiple linear regression model (MLRM) was utilized. Results showed that (1) the physical predictors, such as housing conditions, community environment and public service facilities, had an effect on community attachment. Among these physical predictors, community environment played the most important role. (2) Social predictors, such as community ties and sense of security, had a significantly positive effect on community attachment. (3) Social predictors were mediator variables between physical predictors and community attachment. Therefore, during the process of public housing construction, local governments and developers should create a favorable landscape environment, hygienic conditions and public security conditions. In addition, they also need to provide sufficient public space such as squares and green space to facilitate communication. Furthermore, a new community governance structure should be created, self-management of residents should be guided and community organizations should be set up to cultivate community assets and further improve community attachment of public housing residents.

Key words:

public housing; community attachment; sense of belonging; sentiment

Center of Integrated Geographic Information Analysis, School of Geography and Planning, Sun Yat-sen University, Guangzhou, 510275, P. R. China, songgwen@126.com

Abstract

An integration of social and physical environment (social disorganization and routine activity theory) can help understand crime more comprehensively, but the question that the discrepancy of effects of integrated theory in analyzing crime in day-time and night-time is under discovered. To fill this gap, using data of theft reports to police, social factors from the principal component analysis of census data (social disorganization theory) and land use variables (daily routine activity theory), spatial lagged negative binominal regression models are built for day-time (7:00-18:59) and night-time (19:00-6:59) separately.

Results show that subway stations, daily shops density and net-bars density are positively related to theft rate and bars and entertainment facilities density is non-significant in both models, whereas bus stations and convenience stores density are only significant in day-time model and restaurants density is only significant in night time. With regard to social environment factors, aging factor and suburb factor serve to the decrease of theft rate in day and night model. No other social factors are significant in day-time model, while high educated factor and commodity house factor are positively related to theft rate in night-time model. Theft rate in night-time has stronger relationship with social factors than that in day-time.

Moreover, daily routine activity theory works better than social disorganization theory in analyzing theft rates and a combination of routine activity theory and social disorganization theory can help understand crime better in this empirical study. Effects of models in the night-time are better than that in the daytime. Policy implication is also discussed in the passage.

Key words:

Theft rate; Day-time; Night-time; Daily routine activity; Social disorganization

Advancing the 'Criminology of Place': Situating Causal Mechanisms in Space and Time

Jon Bannister, Anthony O'Sullivan and Ellie Bates

Manchester Metropolitan University, Manchester, United Kingdom, Jon.Bannister@mmu.ac.uk

Abstract

There is a non-random intra-urban distribution of crime, with distinct patterns typically manifest at macro, meso and micro scales. Moreover, the smaller the spatial unit of analysis interrogated the greater the contrast found in the distribution of crime between these units, with crime tending to cluster and persist at a small number of locations. Theoretical account of this patterning has been dominated (particularly at the micro scale) by a set of opportunity theories, with more limited endeavour being made to engage accounts rooted in social disorganisation theories. Against this backdrop, this paper develops a holistic theoretical framework to interrogate the criminology of place and, specifically, seeks to situate the causal mechanisms underpinning the criminology of place in space and time. The paper then progresses to outline the methodological and data challenges that underpin operationalization of this framework. Ultimately, the paper identifies the value and limitations of a multi-scalar and time sensitive theoretical and empirical model of the criminology of place to crime control agencies seeking to develop effective, efficient and legitimate crime reduction strategies.

Can Gated Communities Increase Security? An Innovative Analysis of Burglary Record and Victimization Survey Data in Urban China

Jiang C, Liu L, Zhou S

Center of Integrated Geographic Information Analysis, School of Geography and Planning, Sun Yat-sen University, Guangzhou, 510275, P. R. China, jchao@mail3.sysu.edu.cn

Abstract

Although gated communities develop rapidly around the world as they are supposed to provide secure environment through the creation of exclusive areas, great theoretical debates arise on their practical effects on crime prevention, which has received global attentions from various fields of urban planning, community management, and criminology. However, due to some conceptual or methodological limitations such as the disintegration of gated communities, the “small number” problem, and the over-reliance on single crime data sources, most of the previous empirical research fail to resolve these debates. In addition, while the context-specific relationship between crime and environment is widely recognized, no empirical case studies have been carried out in Chinese urban context. Under these backgrounds, this study proposes an innovative method with Monte Carlo simulation to analyze both the burglary record and victimization survey data in gated and non-gated communities in China with an aim to empirically validate these theoretical concerns. With DP peninsula as a research case, this study shows that gated communities do not have statistically significantly less burglaries than non-gated communities, indicating that gated communities cannot necessarily increase security, and providing partial support for crime pattern theory. It is the location, not the community type, that matters in inducing statistically significantly more burglaries. These results have great implications on the elaboration of effective crime prevention strategies through environmental planning and design.

Comparisons of the Community Environment Effects on Burglary and Outdoor-Theft: A Case Study of ZH Peninsula in ZG City

LONG Dongping¹, LIU Lin^{1,2}, ZHOU Suhong¹

¹Center of Integrated Geographic Information Analysis, School of Geography and Planning, Sun Yat-sen University, Guangzhou 510275, China, longdongping2012@163.com

²Department of Geography, University of Cincinnati, OH45221-0131, USA

Abstract

Burglary and outdoor-theft, just like twin brothers, happen in different places whilst share similar characteristics when it comes to spatial distribution. As we all know, the essential attributes of community conditions are significant factors that affect urban crime, but it hasn't been explored and tested that what factors of community conditions influence the analogous spatial pattern of burglary and outdoor-theft, not to mention the mechanism that how community conditions act on them. Therefore, drawing on routine activities theory, crime prevention through environmental design (CPTED) and defensible space, utilizing multi-source heterogeneous spatio-temporal data of ZH peninsula, ZG city in southern China, the purposes of this study are to examine how the built environment and social environment of neighborhoods affect burglary and outdoor-theft as well we carry out a comparative analysis with partial least squares method. Results suggest that there are some regularities in ZH peninsula, which means under the background of built environment, the influences of burglary are relatively concentrated, while the influences of outdoor-theft are more dispersed. There exist some relative commonalities and differences in the fact that the social environment and built environment influence and act on burglary and outdoor-theft. On the one hand, the population density, the proportion of juvenile, the density of bus stops and the distance to the city center what show significant impact on the occurrence of burglary and outdoor-theft. What's more, their directions of forces are consistent. On the other hand, the density of road network, the density of retail business, and the density of catering and accommodation are the dominant factor of outdoor-theft. Meanwhile, the education level of residents is the significant factor of burglary. The extension of the results may well provide references for associated prevention and control specific to burglary and outdoor-theft in the communities.

Key words:

community environment; burglary; outdoor-theft; comparisons; partial least square method

Crime and Public Transportation: A Case Study of Delhi for Crime Prevention through Place Design and Planning

Dubey, R. N.

Dr.B.R.Ambedkar College, University of Delhi, Delhi-110094, India, drrndubey@yahoo.com

Abstract

The occurrence of crime on the public transportation system is an important issue particularly in the metro-cities. Fear of personal safety may cause changes in habits of using mode of transportation. People may stay away from high crime places. Walking to a bus, rail/metro rail station, waiting for the vehicles to arrive, and traveling on the public transportation system are situation where a person may become victim of crime. Although crime can occur anywhere in a city but it happens mostly at the places on transit routes. Transit stations are public spaces that mix a wide range of constantly interchanging visitors together. National Capital Territory, Delhi has more than 16 million population with varied nature. It has large fleet of bus, metro-train system along with railways and auto-taxi services. Here crime rate is very high and growing rapidly despite all efforts by Delhi police. Occurrence of crimes on transportation system affect people's particularly women decisions to use public transport leading to more use of private vehicles. The study suggests that in the study area, along with policing and the crime justice system, place design and planning play an important role in minimizing the occurrence of crimes. The study is useful for urban planning and management along with framing policies for the crime prevention in metropolitan cities.

Does Rainfall Affect All the Areas of Larceny? -A Case Study in a Beltway Area of ZG City, China

Yu HJ , Song GW , Liu L

Center of Integrated Geographic Information Analysis, School of Geography and Planning, Sun Yat-sen University, Guangzhou, 510000, P. R. China, liulin2@mail.sysu.edu.cn

Abstract

As an important indicator of the weather changes, rainfall can influence urban crime by interfering people's travel activities, such as larceny. But the research about whether the rainfall can affect all the areas of larceny and how the influential mechanism operates is a void. Based on the routine activity theory, this study firstly divides all the police districts in the beltway area of ZG city into two group according to whether rainfall affect local larceny, then chooses independent variables reflecting social property and activities, finally builds a binary logistic regression equation as interpretation model. The result shows that nearly 1/5 of the police districts show the conspicuous correlation of rainfall on larceny when the rainfall is greater than 10mm/m². The police districts where concentrating young migrant workers, midscale and upscale apartments, bars, terminal markets, banks, small shopping malls, community parks, subway stations can be more likely to get the influence of rainfall on larceny, because these places are easier to attract non-essential activities which can be cancelled when raining heavily (such as entertainment), and the supervision can be enhanced with people decreasing. In contrast, higher bank density may bring local larceny less possible to be influenced, because there are mainly essential activities which can't be changed because of raining (such as work) nearby, and the supervision can keep high level no matter how many people there.

Key words:

Rainfall; larceny; influential mechanism; routine activity

Enlightenments on Antiterrorism Strikes from Europe's "New Normal"

Li, Y., Li. M.

China Executive Leadership Academy Pudong, Shanghai, 201204, P.R. China, liyijing@celap.org.cn

Abstract

The geography of crime theory emphasizes the effects of place, time and environment in shaping crimes, and proposes to take the criminogenic and crime-mediating environmental conditions into consideration when analyzing crime issues. In the previous 15 years, Western Europe has seen more than 60 terrorist attacks with more than 600 citizens dead from the Islamic State murders, inducing the regions into a "new normal" state of combating terrorism jointly. Terrorist attack is one of the most serious organized crimes globally, and researchers in fields of politics, diplomacy, international relations, criminology and geopolitics tend to conduct lots of analyses, especially after the murders in Paris on 13th, Nov. 2015, and the bombings in Brussels on 22nd, March, 2016. However, besides of the qualitative analyses, quantitative studies so far are mainly focusing on the description of temporal trend, leaving an eager requirement for a more intuitive illustration of the spatial pattern change, as well as the rationale (if there is) for location selection.

This study overlaid the terrorist attacks spatial-temporal data in Western Europe in previous 15 years, with corresponding demographic, socio-economic conditions in ArcGIS 10. It is designed to build up spatio-temporal models on identifying the criminogenic and crime mediating conditions to terrorist attacks; in another word, the underlying objective environmental rationale for choosing specific region, or place, to conduct the crimes. It aims to provide suggestions and references for antiterrorism strikes from a geographer view, through inhibiting the effects of criminogenic conditions and promoting crime-mediating conditions' influences, to reduce the environmental opportunities for committing terrorist crimes, and further to bring us some enlightenments for local antiterrorism in metropolises.

Antiterrorism strikes; geography of crime; GIS; spatio-temporal pattern

Examining the Impact of both Burglars' Home Area and Target Area on Journey to Crime

Xiao LZ¹, Liu L^{1,2,*}, Zhou SH¹, Song GW¹, Feng JX¹, Jiang C¹

¹Center of Integrated Geographic Information Analysis, School of Geography and Planning, Sun Yat-sen University, Guangzhou, 510275, China, xiaoluzi@mail2.sysu.edu.cn

²Department of Geography, University of Cincinnati, Cincinnati, OH 45221-0131, USA

Abstract

Following the considerable studies of journey to crime, this study tries to explain the distance-decay pattern of burglars based on the rational choice theory. It extends the current literature by taking the characteristics of both the burglars' home area and target area into account, in addition to the burglars' individual factors. Using data on 3138 burglary trips in ZG City, one of the bustling metropolises in China, we apply a zero-inflated negative binomial regression model of journey-to-crime distance to gain insight into the mechanism of burglars' target selection. The model contains two parts—the regular negative binomial regression which describes the relationship between the distance and factors when the burglar's living area and target area are not in the same police district, and the zero-inflated model that tries to shed light on the reason why some offenders tend to commit crime in their living area. Results reveal that when controlling the individual-level factors, burglars living in a deprived area with more old houses and transient populations may travel longer distance to commit; to the contrary, those living in a more affluent home area may shorten their travel distance. As for the target area selection, a deprived target area tends to attract burglars from nearby areas, and conversely, an affluent target area may attract burglars from distant areas. In addition, the convenience of taking a metro or bus may expand the travel distance. The salience of these findings may help improve the understanding of journey to crime studies.

Key words:

rational choice theory; journey to crime; burglary; China

Examining the Impact of Road Types on Larceny Rates:

An Empirical Analysis of ZG City, China

Fangye D; Lin L

Center of Integrated Geographic Information Analysis, School of Geography and Planning, Sun Yat-sen University, Guangzhou, 510275, P. R. China, liulin2@mail.sysu.edu.cn

Abstract

It has been widely accepted that the road density influences the spatial distribution of crime. However, the impact of various kinds of road network on crime risk remains hotly debated. Based on the routine activity theory, this paper takes the socio-economic environment of ZG city into account and focuses on the role of different road types on the location of larceny. For the analysis, 75,113 cases of larceny in 2013 are extracted from the 110 alarm data of ZG city. The regression model results show that the densities of secondary roads, branch roads, other vehicle-available roads and vehicle-unavailable roads are significantly related to larceny rates when the model is controlled for the other environmental factors. The findings indicate that vehicle-available roads and vehicle-unavailable roads have different effects on the larceny rates. Increasing the density of vehicle-available roads has an adverse effect on larceny rates while increasing the density of vehicle-unavailable roads has a positive effect on larceny rates. The mechanism of this phenomenon may be related to the interaction of suitable targets, motivated offenders and incapable guardian in space and time. In contrast to many of the prior researches, here we make a quantitative analysis on the influence of the density of different types of road on the larceny rates.

Key words:

larceny rate; road types; vehicle-available roads; vehicle-unavailable roads

Northeast Students Facing Insecure Environment in India

Thounaojam Ronald

University of Mumbai, India, ronald251092@gmail.com

Abstract

Rapid pace of urbanization in the Country is bringing migrants from all over the country. Cosmopolitan cities are becoming more and more heterogeneous drawing people from different ethnic background so called Cosmopolitanism when gets express into everyday social cultural practices it often comes in the form of complete heterogeneity, the same situation is aggravated with the constant conflicts of various socio- cultural and economic groups over urban space. The narrow politics of place, space and identity becomes very prominent in everyday life specifically of migrants. The notion of “WE and THEY” create insecure environment for migrants. Migrants find a huge difference between what they expected and what they experience. The insecurity that is felt right from eating habits, faiths and social systems, customs and costumes to norms of social behavior and discriminatory practices threatens the everyday life of migrants. Insecurity felt by north-eastern migrants becomes grave with their Mongoloid features and fair skin that often makes them distinct in public spaces. The language barrier becomes most significant with the difference and wrongly pronounced “HINDI” by them. Viewing North east as terrorists and anti-nationalists. Use of obscene languages by local people is one of the most prominent form of INSULT faced, and several times they were addressed publically as “CHINKY CHINKY-MONKEYS, CHINI MALAI” by the local people and even by Officials and Authorities, and also many times addressed as Nepali, all this leads to increased insecurity in urbanized place that faced.

Open-plan Suburb to Fortified Suburb: Home Fortification in Soneike, Cape Town

Cronje C, Spocter M

Department of Geography and Environmental Studies, Stellenbosch University, Stellenbosch, South Africa,
mspocter@sun.ac.za

Abstract

The management of crime and violence finds expression in the built environment. Citizen-driven home fortification has changed the character of established residential suburbs as the populace attempts to mitigate unacceptably high crimes rates in South Africa. The crime prevention through environmental design (CPTED) thesis brings together a range of interventions, including target hardening and territoriality to protect against criminal activity in the residential environment. The addition of walls and fences and an assortment of security paraphernalia to existing houses is an attempt by citizens to fortify themselves against residential burglaries and robberies. This study uses a mixed-methods approach to track how a suburb in Cape Town, South Africa, initially developed as an open-plan suburb, has undergone transformation into a suburb which has become increasingly fortified. The reasons for citizen-driven home fortification are explored as well as the spatial dimensions of residential securedness in the suburb. Most houses display at least one type of security feature, with signage of private armed-response companies and walls and/or fences predominating. Residents maintain that fortification not only reduces the possibility of crime victimisation, but that it also insulates them from contact with people deemed to be 'out of place' in the suburb. It was found that while home fortification does shut out criminals, it also impacts negatively on neighbourhood interactions between residents. The lack of neighbourhood cohesion is especially acute as the suburb has desegregated from being previously whites-only to a racially- and culturally-mixed suburb.

Key words:

Cape Town; crime; environmental design; fortification; neighbourhood; residential; target hardening; territoriality; victimisation

Proximity Factor and Risk Perception of Urban Terror

Sundoko, H.F., Akbar, R., Zulkaidi, D., and Argo, T.A.

Institut Teknologi Bandung, Bandung, Indonesia, rum1328@yahoo.com

Abstract

Urban terrorism has widely spread as common threat in many large and important cities around the globe. The existence of this issues has interfered public sense of security as it evolves to reach softer target to maximize the effect in public spaces. In contrast to the western society, study covering risk perception toward terror threat is not commonly discussing in Southeast Asia especially in Indonesia where terrorist attack hit its capital cities several times. There is wide gap of knowledge in non-western countries regarding risk perception of terror in urban context. In line with that, proximate attribute in which people works to primary and high profile of potential terror target assumed play significant factor to the feeling of security. This study tries to analyze risk perception of terror threat and its relationship with the proximity factor in urban area. Previous empirical research conducted in western society context will be referred to lead discussion about the similarities and differences within security culture.

Key words:

risk perception; urban terror; proximity; security

Risk Risks Terrain of the Central Area of Wuhan City

ZHENG Wensheng^{1, 2}, ZHUO Rongrong^{1, 2}, WANG Xiaofang^{1, 2}

¹Key Laboratory for Geographical Process Analysis & Simulation, Hubei Province, Central China Normal University, Wuhan 430079, China, zhengwensheng@mail.ccnu.edu.cn

²Academy of Wuhan Metropolitan Area, Hubei Development and Reform Commission & Central China Normal University, Wuhan 430079, China

Abstract

Risk Terrain Modeling is an emerging approach to identify crime risks that come from features of a landscape and model how they co-relate to create unique behavior settings for crime. This article firstly construct a hierarchy of crime space composed of base space, joint space, agglomeration space and space of places based on the theories of geography of crime, then select ten crime risk factors including population density, office buildings, residence districts, configuration of urban road network, crime near repeats, commercial facilities, automated teller machines, internet bars, hospitals, and bus and subway stations to be their concrete manifestation. Taking the central area of Wuhan City as case study area, the court verdicts involving robbery, snatch and theft crime as crime data resources, we explore the correlation between crime risk factors and distribution of crime using Geographically Weighted Regression model. The above crime risk factors, except the factor of residence districts that turned out to has no significant correlation with the spatial distribution of crime in study area, are used as the variables and assigned different weights to model the crime risk terrain of the central area of Wuhan City. Not only articulating vulnerable areas in city, our study can also make scientific and accurate forecasts of where the crime will more likely to occur.

Key words:

Risk risks terrain; Crime risk factors; Distribution of crime; Wuhan City

Seeking for Solidarity and Security in Queer(ed) Circles in Istanbul

Zerey, NZ, Neyir Zerey

METU, Istanbul, Turkey, neyirezerey@gmail.com

Abstract

Creation of gay ghettos has occupied substantial place in the examination of LGBTIQ's safe places. These crafted spaces, with no high walls or niche security systems, have created zones of safety to many. Gay ghettos do not necessarily exist in every metropolitan city and Istanbul is no different.

The fieldwork I conducted to better understand geographical positioning and the everyday life practices of LGBTIQ identified individuals in Istanbul has shown that seeking for security and solidarity and socio-economical status are some of the dynamics for moving to relatively more mixed (with multiple ethnic, religious minorities and students), more tolerant neighbourhoods. In this geographical context, the feeling of security is not attained by turning these places into gay ghettos but rather by 'queering' them. As a result of this securitization, the feeling of "being stuck into 'closed circles'" arises.

Insecurity in urban spaces is largely boosted by state policies too. Even though my research results show that respondents of this study are more inclined to think that their life in the city has not changed or even become easier compared to the past five years, once they mentally map their daily activities, they realize how limited their space usage is and how insecure they feel once they step away from the safe circles they created. The mental mapping technique I applied in this research is supported with in-depth interviews adding up to the mental recreation of safety notion, which will eventually contribute to the existing knowledge on compartmentalized spaces.

Key words:

Urban; LGBTIQ; Ghetto; Queer; Neighbourhood; Security; Solidarity

Spatial Pattern and Formation Mechanism of Distribution of Burglars in ZG City, China

Jiaxin Feng, Luzi Xiao, Lin Liu, Guangwen Song

School of Geography Science and Planning, Center of Integrated Geographic Information Analysis, Sun Yat-sen University, Guangzhou, 510275, P. R. China, fengjx5@mail2.sysu.edu.cn

Abstract

Residential burglary is one of the most common crimes in ZG City, China, which draws great attention of local police. Theoretically, combining burglars' spatial distribution with journey to crime will contribute to crime prevention and control. However, the spatial pattern and formation mechanism of burglars' distribution have not yet been fully explored in the prior research. To address this, the paper uses a data set on 2709 burglars in 2055 neighbourhoods in ZG to analyse the living space of burglars. When it comes to spatial pattern, there exists a significant spatial autocorrelation, revealing that most burglars live at the edge of the main urban area and in the vice city, turning urban area into high kernel density value zones. In terms of formation mechanism, the paper estimates a zero-inflated negative binomial regression model to explore the impact of community environment, including social environment and physical environment, on burglars' spatial distribution. Results strongly support the social disorganization theory and can be concluded as follows. Low social status, poor economic condition, high residential mobility, high proportion of exotic population and young adults, high transportation accessibility and proportion of low-level residential land tremendously appeal to more burglars living in the same community. Additionally, the higher the proportion of young adults, residential mobility, transportation accessibility and the proportion of low-level residential land the community have, the more likely burglars are to appear for the first time in the community. The results provide helpful information for the police, facilitating the prevention and control of burglary.

burglar; spatial pattern; formation mechanism; social disorganization; zero-inflated negative binomial regression

Spatial Pattern of Crimes and Contextual Neighborhood Characteristics in Changchun, China

Daqian Liu¹, Wei Song², Chunliang Xiu³

¹Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Changchun, 130102, P. R. China, liudaqian@iga.ac.cn

²Department of Geography and Geosciences, University of Louisville, Louisville, 40209, KY, USA

³School of Geographical Sciences, Northeast Normal University, Changchun, 130024, P. P. China

Abstract

Although crime is one of the major challenges facing Chinese cities, limited empirical research has been done about crime patterns in China, especially when it comes to the spatial pattern of urban crimes. Spatial analysis of crime is still in its infant stage in China. Based on data collected at police precincts level from the Public Security Bureau of Changchun, we examined spatial patterns of leading crimes in Changchun using spatial statistics and Geographic Information Systems (GIS). Specifically, we explored the spatial distribution of crimes and detected crime hotspots, or statistically significant locales of high crime rates in Changchun. Further, we conducted multiple linear regression analysis to assess the impacts of contextual neighborhood characteristics on crimes across the city. The results show that the risk of crimes varies noticeably in Changchun, with high crime rates significantly concentrated in the central area where the CBD and the main commercial areas are located. Our analyses also reveal that spatial variations in crime rates are socially and economically structured. Variables representing the neighborhood socioeconomic, demographic, especially land use characteristics proved to be strongly associated with the spatial distribution of crimes across the city of Changchun. These results are largely in line with the routine activities theory, social disorganization theory, and the framework of crime prevention through environmental design, which emphasize the importance of opportunities, local social context and environmental design in shaping the spatial pattern of urban crimes.

Key words:

Crimes; spatial pattern; crime hotspots; neighborhood characteristics; China

State of Security in Urban Nigeria and Responses of Urban Actors

Dr. Rigon A., Ogunleye O.J.

University of Witwatersrand, Johannesburg, South Africa, ogunleye.o.j@gmail.com

Abstract

The explicit goal of the Nigerian government is to improve the standard of living and wellbeing of citizens. Although, the conceptualisation of wellbeing has been a source of debate which is reflective in an extensive academic literature, what various authors agree on is the multidimensional character of well-being and the fact that different dimensions are deeply intertwined. The broad notion of security was amongst the different notion through which well-being was conceptualised by the interviewees in this research. This conceptualisation fits within the conceptualisation of wellbeing proposed by Sarah White (2010), which sees (in)security has been an integral part of wellbeing. This research revealed how the limited availability of public goods such as safety and security, as well as infrastructure and services, may affect urban well-being even in the presence of growing income levels. The research also highlighted a range of very important citizenship practices, at different scale, aimed at ensuring security of lives and properties in five cities in Nigeria.

Key words:

Wellbeing; security; citizen practices

The Effect of Land Use on Street Robbery Based on GWPR Model

Weiham Xie, Suhong Zhou, Guangwen Song

School of Geography and Planning, Sun Yat-sen University, Guangzhou, 510275, P.R. China,

eeszsh@mail.sysu.edu.cn (corresponding author)

Abstract

According to environmental criminology, built environment, especially land use may have some effects on the occurrence of criminal behaviors. The research to the relationship between crime and the land use can provide a new perspective of crime prevention from the angle of urban planning. However, most of the existing researches used the global model, less to consider the factor of spatial differences, which can be improved by the Geographical Weighted Poisson Regression (GWPR). Therefore, this article studies the effect of land use on the distribution of robbery cases happened in the urban area of H city by GWPR model. The results show that the correlation between residential land use and street robbery cases appears to be negative; how the commercial and business land use affect the cases distribution depends on their spatial form, the individual high-rise commercial complex building attracts less street robberies while the street-side mode of commercial land use attracts more; the positive correlation between industrial land and cases only appears in the old city; tourism scenic spot has negative effect on street robberies; besides, relationship between the street and transportation land use is affected by the transport-facilities, road-grades and road-network pattern. In addition, there are some spatial differences on the relationship between primary land use and street robbery, and the summarize of spatial pattern may help to urban planning and police prevention.

Key words:

land use; street robbery; GWPR; the urban area of H city

The Feeling of Insecurity and Social Space

Tripathi V.

Department of Geography, Delhi School of Economics, University of Delhi, Delhi - 110021, India,
vivektripathi21@gmail.com.

Abstract

Insecurity is a socially constructed feeling (Glassner 1999). There are several factors working at different hierarchical level in shaping and reproducing the modern social space. The modern social space is amalgamation of accumulated interaction of feelings, communication, ideology and behavior of human (Schelling 1971). This social space is manifested at actual and virtual space and media plays an important role in shaping and re-shaping it. This paper attempts to explore the process of insecure space creation; analyse how do these insecure spaces contribute to the feeling of insecurity and reduced mobility? This paper adopts qualitative semi structured interview method and a case study of Delhi to conceptualize the increasing fear of crime and insecurity in urban spaces of India. This paper examines the factors working in making the city less liveable and threatening.

The status of Delhi as the capital city of India makes it the center of attraction for all significant and non-significant happenings. Despite of improved infrastructure and better services available, this attention has invariably taken its toll on this brimming capital in the form of increased feeling of insecurity in Delhi. This feeling of insecurity and fear of crime in Delhi has further limited inter-city and intra-city mobility of the Indian people (Tuan 1979). The reduced mobility accentuates the feeling of insecurity, segregation and seclusion (Low 2001; Wehrheim 2003). This paper helps in providing solution to the problem of insecurity and explains the process of construction of unsafe social space.

Insecurity; Social Space; Virtual Space; Fear of Crime; Crime; Violence; Urban; Mobility; Delhi; India

Urban Security and Citizenship Practices: Insights from Lagos and Johannesburg

Ogunleye, O.J

University of Witwatersrand, Johannesburg, South Africa, ogunleye.o.j@gmail.com

Abstract

Sarah White (2010) conceptualisation of well-being revealed in (security) to be integral to the wellbeing of individuals. Also, the broad notion of security has been amongst the different notion through which well-being has been conceptualised in existing research. Furthermore, existing research have revealed how the limited availability of public goods such as safety and security, as well as, infrastructure and services may affect urban well-being even in the presence of growing income levels.

The issues underpinning Africa's security crisis has been linked to the continent's severe developmental failure, which can be traced to larger issues such as: civil war and conflict, poverty, bad policy and poor governance, endemic financial and debt crisis, crumbling of physical infrastructure and breakdown of public service, escalation of unemployment, corruption, disinvesting of private capital and transfer of substantial amounts of private wealth overseas. This has led to a situation where economic and social conditions have steadily worsened and insecurity and instability have increased. Due to this state of (in)security, urbanites have had to resort to innovative means of ensuring life and properties in urban areas.

This work builds on a previous study by the researcher, which highlighted a range of very important citizenship practices, at different scale, aimed at ensuring security of lives and properties in five cities in Nigeria. However, this work goes a step further by exploration the practices of citizens and actors in Lagos and Johannesburg aimed at ensuring security of lives and properties in these two cities.

Key words:

Wellbeing, security; citizen practices

A Study of the Remaining Traditional Landscapes in Urbanized Regions

Mariko Sugitani

Graduate student, Hiroshima University, Japan, mrk_geoid32@yahoo.co.jp

Abstract

With the progress of urbanization, modern landscapes have become more common. The housing landscape has also similarly changed. Advances in construction technology and a drive to reduce costs have caused this change in landscapes. Now, homogeneous housing landscapes designed and built by construction companies exist everywhere in Japan. Traditional-style houses have been rapidly disappearing save for 'important preservation district with historic buildings'. I chose Higashi-Hiroshima city as a subject for this study. For the last several decades, the city landscape has changed, mainly because Hiroshima University moved into the area. In particular, the transformation of the townscape in the city center of the Saijo basin is a noticeable example. Saijo basin has a unique landscape of traditional Japanese houses with reddish-brown roof shingles and white walls scattered in rural paddy-field districts. This area is recognized by residents and visitors for its individual landscape, but this area is not officially protected as a historic landscape. There are few traditional landscapes left in the area aside from those in urbanization control areas near the city center. Paddy-field and traditional houses are currently left intact in urbanization control areas, but changing lifestyles in the neighborhood and the replacement of run-down buildings will bring about the loss of the historic landscape in the future. In this study, I interviewed residents living in urbanization control areas and housing estates to clarify their concerns about changing landscapes. I asked questions about the exterior of their houses, how they feel about traditional landscapes.

Key words:

housing landscapes; traditional houses; urbanization control areas; residents mind

Aesthetic Experience as Urban Heritage

Bratt, J.

Arizona State University, Tempe, Arizona, United States, jdbbratt@asu.edu

Abstract

The materiality of place has long been central to concepts of urban heritage, with built environments often comprising the objects of conservation discourse and practice. UNESCO, meanwhile, has countered such emphasis on materiality in heritage conservation with calls for the safeguarding of social practices and rituals as 'intangible heritage'. Definitions of intangible heritage, however, restrict it to well-defined 'traditions' associated with particular identity groups. For both the tangible and the intangible, a bias toward the symbolic and the extraordinary continues to affect what gets counted as heritage. The distinction between tangible and intangible, moreover, reinforces a distinction between place and practice; "the richness of place as a lived and meaningful location gets reduced to a landscape function – a coherent, largely visual, material topography," while "more fluid meanings associated with historic practice are, for the most part, lost" (Cresswell and Hoskins 2008: 393). In cities, such 'fluid meanings' are those of everyday activities and ambiances that, while ephemeral and ordinary, are bound up with built environments as historical and cultural sites and are key to their significance. In this paper, I consider place in terms of its "experiential fluidity" (Cresswell and Hoskins 2008: 395), the more-than-tangible social interaction and sensory immersion that helps give any site its meaning, and explore the possibility of an urban heritage concept that reflects this meaning.

Comparative Study on the Change of Block Vitality in Beijing Shichahai Historic District

ZHANG Jingyu, ZHANG Jingqiu

College of Arts and Science of Beijing Union University, Beijing 100191, China, jingqiu@buu.edu.cn

Abstract

Using geographic information technology and space syntax theory, this paper is comparatively analysed the changing types of land use and the change of alleys texture of Beijing Shichahai Historical District between 1948 and 2015. The data and information of urban space is extracted by the history maps, Google map and historical literatures. The research shows that (1) The types of land use have been transformed from single function to multiple functions, mainly from residential type to residential, commercial, educational and other types; (2) In the last 70 years after the foundation of New China, the degree of spatial integration of Shichahai Historical District has been increased and the difference of spatial integration is reduced; (3) With the gradual improvement of transport system, including the construction of Ping'an Street, the alleys' rectification and increasing the number of roads, the block connectivity of Shichahai Historic District is upgraded obviously. Due to the mixed land use and the transport improvement, the block vitality of Shichahai Historic District changes effectively.

Key words:

Shichahai historic district; mixed land use; spatial integration; the vitality of block; space syntax

Cultural Heritage: The Past Influences the Present—Case Study on the House

Influenced by Timber-Framed House in Selly Oak, Birmingham, UK

Weimin QUE

College of Urban & Environmental Science, Peking University, Beijing, 100871, P.R. China, wmque@urban.pku.edu.cn

Abstract

In the heritage system, timber-framed house is typed into architecture heritage, urban heritage and Cultural heritage. This essay discusses the cultural heritage-the past influences the present and future, case study on the house influenced by timber-framed house in Selly Oak, Birmingham, UK.

The geographical area of this paper is Ward of Selly Oak, Birmingham, UK, with 4.5 square km (length is 3000 meters in west-east and width is 1500 meters in north-south). within the area, there are 69 main streets (61 roads, 2 avenues, 5 lanes and 1 Blvd), 59 branch streets (2 walks, 3 ways, 7 roads, 2 mews, 6 groves, 2 gardens, 1 end, 6 Drives, 9 closes, 3 crofts 1 crescent, 10 aves and 2 nuns). The total length of the street is over 42,000 meters. (Plate I)

There are 246 houses influenced by traditional timber-frame (reflected on the outside of the house) among about 10,000 house (detached, semi-detached, terrace), they are distributed separately, but around Selly Park and Oaktree Place are two concentrate distribution places. (Plate III)

The aspects for evaluating the timber-framed architecture includes location (in downtown of the city, suburb or countryside), function (manor, cottage, castle, garden, church-God's house, priest's house, town house, farmhouse etc.), inner space (huge, small), outside shape (types of H, T, L, I, C, etc.; stories of 1, 1.5, 2, 2.5, 3, etc.), outside timber-frame (numbers of gable, gate, window, dormer, porch, etc. or sides of wall), color painted on the timber (black, white, red, blue, green, yellow, pink, brown etc.).

After searching each house in Selly Oak, the essay concludes as follows: A. During the construction of house since the end of 19th century, traditional timber-frame deeply influenced the designer who designed the house in Selly Oak; B. During 1900-1920, timber-frame used in the house construction as both real function and decoration, after 1950, timber-frame reflected outside of the house are mainly decorated. C. The house construction and timber-framed house in Selly Oak had contributed to the Movement of City Garden: (1) The principal clause of the covenants for residential development around Selly Pack reflects the main spirit of Garden City, but it proposed about 40 years earlier than the later; (2) Selly Oak become the green suburb or green belt which provided the high quality environment for human living, especially near the black country, since late of 19th century; (3) Selly Manor House had been moved into the heart of Bournville, became the landmark house in the model of Garden Village.

Key words:

cultural heritage; House influenced by traditional timber-frame; timber-framed architecture; Selly Oak

Globalization and Locality of Zhongshan Almond Cake: Comparative Study of Time-honored Brands of Huizan and Juxiangyuan

Ding Shaolian

Tourism Management Teaching and Research Office of College of Forestry and landscape architecture of South China Agricultural University

Room 507, College of Forestry and landscape architecture of South China Agricultural University, Wushan Street, Tianhe District, Guangzhou, 510642, P.R. China, dsljcx@scau.edu.cn

Abstract

At the end of 1970s, China began to implement the reform and opening-up policy to cope with the globalization, which accelerated the progress of urbanization and modernization in China. Except economic growth and efficiency improvement, urbanization also reshapes China's urban space. That is to say, the urban historic elements are replaced by the mainstream modern landscape, which has posed an increasingly severe challenge for the continuation of sense of place in the city. As such, time-honored brands tend to have a sort of inextricable connection with the place and their inheritances plays an important role in the maintenance of the sense of place within urban areas due to their deep historical origins with the region.

From the sense of place perspective, this study takes two time-honored almond cake brands—Huizan and Juxiangyuan as examples to reveal how the two brands address the globalization and participate in the local construction through data analyzing collected by observation, interview and literature study. The research finds that, in the globalization, Huizan, under the pressure of land rent, finally settled in its own real estate outside of Historical Landscape Conservation Area and insisted its traditional operation mode of small manual workshop, but the brand won more popularity of the locals. On the contrary, Juxiangyuan take a different strategy to cope with the globalization by transforming the production mode from traditional manual workshop to standard production. The later has applied the reputation of "Century-old Time-honored Brand" in China successfully and thus it has become the symbol of Zhongshan for foreigners. However, the locals refused to buy Juxiangyuan's standard products and turn to Huizan who insists the traditional manual workshop mode to buy the cakes to realize their identity and satisfy their pride as the locals of Zhongshan. The different performances of the two time-honored almond cake brands in the globalization demonstrate a progressive sense of place as Massey said in 1993. The locality and the globalization of the Cake promoted by two deferent motive force could develop simultaneously. It seems that the sense of place and the globalization are two interdependent powers if the local place could bring people the dignity and satisfy the communication space of acquaintances who are experiencing transition period from the local acquaintance society to the globalized stranger society.

Key words:

locality; globalization; Sense of place; Time-honored Brands, Zhongshan City

Historical Geographical Reconstruction of a Few Islands of Hangang River, Seoul

YANG Bo Kyung

Sungshin Women's University, The Korean Geographical Society, Seoul, Republic of Korea, ybk@sungshin.ac.kr

Abstract

Hangang river is the major river flowing through the center of Seoul which is the capital and heart of Korea. Also it is located in the middle of the Korean peninsula and has the largest river basin area that the people can live in the Korean peninsula. Seoul's cultural identity as a two-thousand-year old city started from the capital of the ancient kingdom Baekje (18BC~660AD). Hanseong, the early capital of Baekje (18BC~475AD) was located just south of the Han River. However, there has been a number of opinions as to the location of Hanseong. In recent years, Pungnapdoseong Fortress is recognized as Hanseong.

This study examined the location and history of a few of islands such as Mudongdo Islands, Burido islands that had existed in the Han River near the Pungnapdoseong. Since the 1970s with the development of Gangnam area of southern part of Seoul, these islands had buried away. The old documents, old gazetteers, and old maps, modern and contemporary maps, cadastral maps, aerial photos, field survey and interviews with the residents are used to investigate.

Historical geographical restoration of these disappeared islands is an important indicator to trace the flow changes of the Hangang river and the rapid regional change of the human environment associated with the development of the new town development of Seoul.

Key words:

Hangang river; Seoul; historical geographical reconstruction; Gangnam area of Seoul; Mudongdo islands; Burido islands; new town development

Ruined Place, Collective Memory and Place Identity in Post-2008 Earthquake

Beichuan, China

Lili Qian

Nanjing University, Nanjing, 210000, P. R. China, lilyq1119@126.com

Abstract

Place is a core concept in human geography and environmental studies, place related bonds, especially the affective bonds between people and place, attracts extensive attentions. A ruined town and its former residents are suggestive of people's negative experiences within this area, and as such serve to illustrate people's other side of sense of place. This paper explores the county town of Beichuan, which was badly destroyed in the 2008 earthquake, and subsequently protected as a ruined heritage, as an example of the complex relationship between people and place. Place based memory and identity are choose as two indicators to reflect the special sense of place. Both qualitative and quantitative methods were used to reveal locals' collective memory of each ruined places and place identity toward whole town. Through comparisons and discussions, we came to know locals' special sense of place that Beichuan is a complex and mnemonic place that post-quake memories of negative experiences with cognitions of loss and tragedy are interwoven with pre-quake memories of the positive, nostalgic feelings of home, work place. It is a place many want to forget, but cannot easily avoided, and an abstract place that most people loved and feel a deep attached. Hopefully this research can apply lessons from place perception after such a catastrophic loss and embrace the relief practice of post-disaster reconstruction.

Key words:

ruined place; collective memory; place identity; earthquake heritage; China; Beichuan

Russian-Chinese Common Historical Heritage: Phenomenon and Research

Mazurov Yu.L.

Lomonosov Moscow State University, Moscow, Russia, jmazurov@yandex.ru

Abstract

Modern human society becomes increasingly aware of heritage as an indispensable condition for its development. Heritage implies both the values of our natural environment and those of – people's culture as commonly represented in both tangible and intangible historic and cultural monuments. Heritage is the memory of our past and present that may have an impact on our future. Heritage is what people select from a world of values and put into a special category that needs to be passed from one generation to another. In some cases heritage properties could be valuable not for one nation but for two or even more peoples. Such objects may be caused by close historical contacts in cases of joint struggle for the triumph of the humanistic ideals or joint participation in important historical events. Such properties should be considered as the common historical heritage of the peoples concerned. Iconic and recognized the property of the common heritage is, in particular, the obelisk of Sino-Soviet friendship in front of the Museum of History in Lushun. The list of such examples can be continued, which already allows us to speak about the Russian-Chinese heritage as a phenomenon of particular importance for both countries. There is no doubt that this phenomenon needs to be studied, including - with geographical positions. Russia and China have a common historical heritage and its inclusion in the scope of cultural policy can actively contribute to further strengthening of relations between the two countries in the interests of their peoples.

Key words:

Common historical heritage; cultural monuments; national interests

The Emotional Memory and Perceptions of Urban Industrial Heritage

Fan Xiaojun

School of hospitality and tourism management, Shenyang Normal University, Shenyang, 110034, P. R. China,

fanxiaojun9@163.com

Abstract

Industrial heritage is the witness of industrialization and modernization, also a true portrayal of the people's life and social changes. The process of industrialization in China is closely related to urban development, and industrial heritage has become an important issue in urban renewal. A large number of Industrial relics and intangible heritage is rapidly disappearing and industrial civilization in some areas has become a historical fracture. Among many reasons of these problems, the role of emotional factors can not be ignored. In this study, the meaning and interpretation of industrial space are explored through the analysis of the tourists' perceptions from the perspective of emotional memory. It was found that as a production space with a distance to everyday life, the emotional dependence in the industrial heritage space is less than living space. On the other hand, the obvious absence of working class as the main body of space in the protection and reuse process, affect the emotion expression in the space practice further. Industrial heritage space is understood as a cultural and artistic place of consumption and leisure, rather than a memory space of industrial civilization. The question is how to deliver the industrial memory to future generations?

Key words:

industrial heritage; interpretation; creative park; reuse

Urban Heritage Conservation and Management: A Geographical Analysis of Udaipur City of Rajasthan, India

Prof. P. R. Vyas

Professor and Head, Department of Geography, M. L. Sukhadia University,
Udaipur 313001Raj. INDIA, prvyasgeog@gmail.com

Abstract

Urban heritage one area that always considered as humane, socio- cultural and economic asset observed by various historic layering of values that have been produced by successive and existing cultures and an accumulation of traditions and experiences, recognized as such in their diversity. Considering the dynamic nature of living cities reflecting that urbanization is rapid and frequently uncontrolled process of development is transforming urban areas and their settings specially changes in historical heritage. That may cause fragmentation and deterioration to urban heritage with deep impacts on community values. However, the paper explores how the changes are taking place over time and space on historic heritage of medieval age Udaipur city of Rajasthan state in India. It deals the study of policies, issues and challenges for conservation of urban heritage. For this purpose, two major indicators have been taken into consideration for study which is tangible heritage like historical buildings, physical structures etc. and Intangible heritage including socio – cultural traditions. Further quantitative analysis of correlation techniques is applied to understand the interrelationship between explained variable that is historical heritage and explanatory variables such as tourism, cultural traditions, social composition etc. Finally, Regression analysis is also applied to understand the trends over time among variables for future planning. Finally, future strategies have been proposed towards conservation and management of historical heritage through implementation of policies and landscape approach supporting urban sustainability.

Key words:

Urban heritage; transforming; fragmentation; deterioration; architecture; Infrastructural Development; landscape approach

Yawata Ironworks as Transnational Geoheritage: Looking behind the Scenes of a late 19th Century Japanese/German Investment Project

Soyez, D.

University of Cologne/Germany, Institute of Geography, Albertus-Magnus-Platz, D-50923 Köln

d.soyez@uni-koeln.de

Abstract

Yawata Iron and Steel Works was the first modern, coke-based integrated iron and steel plant in Japan. Construction of the plant by the renowned German iron, steel and machinery manufacturer Gutehoffnungshütte (GHH) as the primary contractor began in 1897 and was completed in 1901.

Arguably, Yawata represents both the first step toward, and the main symbol of, the country's late 19th/early 20th century industrialization during the so-called Meiji Industrial Revolution. It was recently awarded UNESCO World Cultural Heritage status together with 22 other sites dating from this period. Yawata can be regarded as a true fusion of Japanese-German competence, as exemplified by the pervasive tangible and intangible legacies both in Japan and Germany. These find expression not only in particular sites and buildings in both countries, but also in archival resources, in Germany mainly at Rhineland-Westphalia Economic Archives/RWWA, Cologne, housing the GHH documents. Thus, the Yawata project can serve as a model for demonstrating both the importance of and potential for a new, decidedly transnational perspective on heritage endeavours.

The main objective of the presentation will be a specific look behind the scenes, based on the archive in Cologne, in order to take stock of specific planning problems, blunders and intercultural collisions, i.e. elements of an almost adventurous investment project normally not addressed or even deliberately concealed in heritage valorizations. The main idea behind this is to, hopefully, enrich future interpretation strategies by adding decidedly real life flavours to run-of-the-mill narratives about inventive engineers, diligent workers, creative architects or visionary entrepreneurs, thus adhering to Tilden's well-known dictum that the chief aim of interpretation is not instruction but provocation.

Study on the Spatial Pattern of Capital in the Perspective of Human Settlements

TIAN ShenZhen¹, LI XueMing^{1,2}

¹School of Urban and Environmental Sciences, Liaoning Normal University, Dalian 116029, China, shenzhen890038@163.com

²Centre for Marine Economy and Sustainable Development Research, Liaoning Normal University, Dalian 116029, China

Abstract

Relying on the science of human settlements, from the Chinese prehistoric to Ming Qing Dynasties are elected as a time axis, to study on the spatial structure, the combination pattern and the spatial pattern of human settlements in the capital city. The evolution law of urban spatial structure:(1) From the Qin Han to the Ming Qing, the axis law always dominates the spatial structure of the capital of China;(2) From pre Qin to Ming and Qing Dynasties, the decentralized "mass structure" gradually evolved into a centralized "nested structure";(3) From the prehistoric to the Ming Qing, the capital (settlement) of the flat form evolved from irregular form to regular form and then to the irregular form. The Evolution law of combination pattern(1)Node element, the quantity is more abundant and the space distribution is more reasonable;(2)Path system, evolved from a single to multi layer; The spatial pattern of human settlements:(1) Prehistoric and the pre Qin, river human settlements civilization and Center characteristics of human settlements are formed;(2)Qin Han Dynasty ,the axis law is used in the construction of human settlements;(3)Wei Jin Nan Bei Chao, The emergence of "planning map" indicates that the construction of urban human settlements has reached a new level;(4)Sui Tang , city layout is Central symmetry;(5)The Song Yuan, the street system replaced the "Lifang";(6) The Ming Qing , siheyuan unit ,the lane system , Street system, axes city together constitute the most perfect human settlement construction system of Chinese feudal society.

Key words:

spatial structure; combination pattern; Human settlements spatial pattern; ancient capital

Abstract

China's massive rural-to-urban migration has increasingly drawn domestic and international attention in research and policy making. Literature has shown negative effects of migration on children's development, especially among rural-to-urban migrant children in China. However, to what extent migration affects children's development and how children's own personality and the family, school, and community contexts mediate the effect of migration on children's development are rarely examined. Based on a newly collected dataset from 775 children in the fall of 2015 in Beijing, the current study will: 1) examine migration and perceived stigma among rural-to-urban migrant children; 2) compare personality and the family, school, and community contexts, and development outcomes between urban native children and rural-to-urban migrant children; and 3) conduct a structural equation model to explore the relationships between migration and children's development, mediated by perceived stigma, personality, and the family, school, and community contexts. We are currently in the process of cleaning data and analyzing data. We will have finished a draft manuscript before the conference.

Assessment of Livelihood Vulnerability of Land-Lost Farmers in Urban Fringe: A Case Study of Xi'an, China

Huang Xiaojun

Urban and Environmental Science College, Northwest University, Xi'an, 710127, P. R. China, huangxj@nwu.edu.cn

Abstract

Many researches of rural household livelihood vulnerability to climate change and extreme weather events such as drought, flood and typhoon has received broad attention, but with relatively few attempts to involve livelihood vulnerability to the effects of social, economic or spatial variation. With rapid urban spatial expansion in China, many farmers lived in urban fringe face a great risk of livelihoods because of losing farmland. The livelihood of land-lost farmers has become a very important social issue in China. This article applies the livelihood vulnerability analytical framework to the case of lost-land farmers of urban fringe in Xi'an that are exposed to land use change. In this paper, we construct livelihood vulnerability evaluating indicators and assess livelihood vulnerability of lost-land farmers from sensitivity and response capacity. The study is based on mixed qualitative and quantitative analysis, combining data from in-person interviews and household surveys in 2015. Four types of livelihood vulnerability are found including high sensitivity and high response capacity, low sensitivity and high response capacity, low sensitivity and low response capacity, high sensitivity and low response capacity. The different crop types before losing land is the most important factor to impact on the sensitivity of lost-land farmers, but no significant impact on response capacity. Rentable house, income diversity, education level, social connection and land compensation are major obstacles to limit response capability of land-lost farmers. This study highlights the need for lost-land farmers to improve their education level and occupational skill and enhance their capacity for sustainable and diversified livelihood. Simultaneously, local government also need to provide livelihood assistance by employment training, improving social welfare and avoiding excessive urban spatial expansion.

Key words:

livelihood vulnerability; urbanization; lost-land farmers; land use; urban fringe

Borders in a City under Transformation: Research from Guangzhou

Breitung, W., et al.

XJTLU, Suzhou, 215123, P. R. China, breitung@gmail.com

Abstract

Contemporary Chinese cities have been described with the term "enclave urbanism" as a patchwork of bounded spaces such as gated commodity housing estates and urbanised villages. This term implies separation, segregation and fragmentation. As border geographers, the authors of this paper have done many years of fieldwork in Guangzhou to better understand the dynamics of the actual borders between these enclaves and the role of these borders in the context of urban transformation. They can now present a much more differentiated picture, which also includes accounts of connectivity and permeability. Beyond analysing especially, the social and cultural dimensions of urban space in Guangzhou, the paper aims at bridging the gap between border studies and urban geography. It argues that border researchers can with their methods and concepts significantly contribute to the understanding of urban space, which in turn helps them to overcome their often implicit nation-centric concept of borders.

Key words:

Borders; enclave urbanism; urban borderlands; gated communities; transforming cities; Guangzhou; China

Capitalization of Urban Land and Multiplicities of Governance Regimes in Lanzhou, China: Toward an Alliance-Based Space Development

J Guo

Institute of Geography at Heidelberg University, Heidelberg, 69120, Germany, jie.guo@geog.uni-heidelberg.de

Abstract

Urban renewal and land redevelopment in China has recently become one of the topics receiving much attention from researchers. However, understanding of the multiplicities of local governance in producing urban space, beyond the analytical framework in relation to urban governance regimes as singular and mutually exclusive, is still insufficient.

By examining the process of large-scale urban renewal with capital-led land development in Lanzhou traditional industrial areas, in this paper, we discuss a kind of alliance-based governance emerged at urban scale in the context of China's neoliberal turning, and the underlying mechanism that shapes, while is in turn reshaped by the interactions as well as power relations among multiple stakeholders (i.e. governments at all level, relocated enterprises, employees, property developers, etc.).

This study finally draws the following conclusions. With the competitive bargaining and strength gambling of stakeholders, an interest-distribution mechanism dominated by Lanzhou municipal government comes on the scene. Through the mechanism, all stakeholders have eventually voluntarily or involuntarily got involved in such speculative redevelopment processes, and reached various alliances for common interests. However, due to the inherent instability of this mechanism, the partnerships of government's conception are rather fragile and unstable, and are easily to be broken. As a result, accompanied with series of explicit and implicit competition and resistance, as well as repeated and complex negotiations within the alliance, the established interest relationships are constantly shaped and reshaped, which thereby affects the ways and consequences of the production of urban space.

Key words:

Neoliberal urbanism; urban renewal; alliance-based governance; industrial land redevelopment

China's Urbanisation from Below: A Tale of Two Villages

Ya Ping WANG¹, Yanglin WANG²

¹Professor and Chair in Global City Futures, Urban Studies, School of Social and Political Sciences, University of Glasgow, Glasgow, G12 8RS, UK. yaping.wang@glasgow.ac.uk

²Professor in College of Urban and Environmental Sciences, Beijing University, Beijing China

Abstract

Research on China's urbanisation focuses mainly on large-scale project based developments in large cities. Urbanisation is however a very complex process which happens at many different levels and places, and involves very different players and communities. Apart from the government and plan led changes in cities, China is also undergoing a process of bottom up urbanisation which is organised and led by villagers, especially in the suburban areas of large cities. This bottom up development has affected a significant proportion of rural residents and contributed enormously to the overall social and economic transformation in China. Different from the homogenous top down urban planning and development approach, village led urbanisation follows very different, sometime innovative approaches that reflect different local socio-economic and cultural values. This study examines land development and residential changes in two suburban villages which have achieved some forms of urbanisation. It gives particular attentions to the differences of bottom up urbanisation emerged in the North and the South regions; and aims to highlight the benefits and problems from such development. The paper helps to identify alternative approaches and policy options to land development for China's urban future.

Deliberating Environment into Planning: Perspectives from Politics of Scale

Chen Yanyan, Prof. Xu Jiang

Department of Geography and Resource Management, the Chinese University of Hong Kong, Hong Kong, P. R. China,
chnyanyan@gmail.com

Abstract

Over the past 20 years, environmental issues have been at the center of public debate all round the world. Confronting with mounting environmental pressure, Chinese governments have realized the importance of sustainable city and started to incorporate such green considerations in the urban plans. Yet, the meaning of environment in the planning field is always problematic, and the ways that environmental principles translated into planning practices relied heavily on the interpretation by different scales of state. This study attempts to examine how the Chinese governments have adapted to the changing environmental problems through urban planning. The specific focus is on various institutional response and planning practices at different scales of state. Through an engagement with the debates on the politics of scale, the argument is made that a new interpretation of environmental planning must be sensitive to the politics of scale. This study provides an overview of planning interpretation and practices of both central and local governments, and seeks to illustrate how planning the environment involves the political process of scaling objects and constraints caused by environment among different scales of governments. Guangzhou is taken as a case study for further empirical examination. It is found that the failure of spatial regulation on environment has resulted in an enforcement of environmental assessment in urban planning, through which the central government attempts to internalize the environment regulation into the planning system.

Urban planning system; politics of scale

Development of a New City Centre and Functional Changes of Urban Villages in Guangzhou, China

Onodera, J.

Yokohama City University, Yokohama, Japan, jonodera@yokohama-cu.ac.jp

Abstract

This research aims at explaining the functional changes of 'urban villages' in Guangzhou through a case study of Liede Village near Zhujiang New City Centre. Liede Village was a typical urban village accommodating a large number of migrant workers in the 1990s, while land owned collectively was gradually expropriated. The original village was eventually destroyed in 2007 and became a new community of 37 high-rise apartments in 2010. Almost all the native residents returned to the village, while the migrant workers were replaced by white-collar workers, who worked in the city centre. Many of these are young, unmarried and highly-educated, including managers, professionals and foreigners. Liede Village, as a collectively-owned entity, established the Liede Economic Development Company, which capitalized the compensation from the land expropriation. The villagers receive quite a dividend as shareholders, as well as considerable rental income from the apartments they acquired as part of the compensation. Since these buildings and land are still collectively owned, the villagers are not allowed to sell the houses and have no choice but to let them out, to utilize the properties effectively. In fact, the area is popular among white-collar workers because it provides accommodation at bargain rents near the CBD. Furthermore, collective ownership means that a shareholder's stake is inherited by family members, so that the village framework is firmly maintained. It can thus be concluded that such non-market spaces as urban villages do contribute to the economic development of a city at different stages.

Development of State Capitalism and Cities of Special Economic Zones in Xinjiang, China

Li, Yuhui

Department of Sociology& Anthropology, Rowan University, Glassboro, NJ 08028, USA, li@rowan.edu

Abstract

Horgos and Kashgar are cities in Xinjiang of northwestern China. Both of them have recently been promoted to cities of Special Economic Zones (SEZs), a status enjoyed by only a handful of cities in China. Except for Horgos and Kashgar, all other SEZs in China are located in the coastal region. This paper studies the background and processes of the change of status of Horgos and Kashgar. I argue that the main reason for China to promote these two cities is to enhance the country's state building capacity and facilitate China's ambitious plans to expand its geopolitical and economic influence in the world. The construction and development of Horgos in northern Xinjiang and Kashgar in southern Xinjiang are part of China's efforts to revitalize the ancient silk-road campaign, also known as One Belt, One Road (OBOR), launched by the current administration of China. I demonstrate that the mechanism and process of promoting these two cities is very similar to China's developmental approaches in its western region, e.g., the Great Western Development Strategy that started at the end of the last century. These campaigns follow a top-down and authoritarian approach, which is very different from the developmental strategies of the coastal area of China. In addition, I argue that the rapid development of Horgos and Kashgar will help with China's modernization plans domestically and internationally. But it may also have a negative impact on the already tense racial relations in China.

Key words:

Xinjiang; Racial Relations; Cities of Economic Zones; Urban Expansion

Do Professional Exhibitions Make the Emerging 'Capital of Design' More Creative?

—A Case Study of Beijing, China

Huang X., Chen K., Zhu H.

Beijing Normal University, Beijing, 100875, P. R. China, huangxue@mail.bnu.edu.cn

Correspondence author: Huasheng Zhu, zhuhs@bnu.edu.cn

Abstract

The role of trade fairs and professional exhibitions, termed as 'temporary clusters', in the knowledge transmission and creation has been highlighted in the innovation literature. It is believed that those activities can temporarily facilitate face-to-face communications and bring about new ideas. The scholars focus their interest on the manufacturing world, but pay little attention to cultural and creative sectors. Actually, holding international professional exhibitions is taken as one of important factors in the membership application to the global creative cities network (GCTN). In such field that novelty, creation and innovation are emphasized as the essential, do professional exhibitions provide knowledge channels for local creative firms to get access to the freshness outside? This paper takes Beijing, an emerging capital of design in the GCTN as an example to find the answer. The authors made questionnaire survey and interviewed with 47 local firms attending Beijing Design Week, an international design faire from October 2015 to March 2016. Through qualitative and quantitative analyse, this paper will explain what, why, and how 'temporary clusters' change the creative cities in terms of knowledge innovation.

Key words:

creative industries; professional exhibitions; temporary cluster; Knowledge innovation; creative cities; Beijing

Domestic Investment-Induced Urbanization in Inland China in the Era of Globalization: Case Study of the Changzhutan (CZT) Region

Dai Lizhu

Guangzhou University, Guangzhou, 510405, P. R. China, daisy840228@hotmail.com

Abstract

As a response to the Global Economic Crisis of 2008, the Chinese government has started to take domestic demand as one of the key national development strategies. Thus new Extended Metropolitan Regions (EMRs) in Inland China are being designated as major platforms to promote domestic demand. Under such new global economic environment and Chinese national policy context, these EMRs might not share the same spatial characteristics and mechanisms in the course of their growth and development as those in the coastal areas. Using the Changzhutan (CZT) region as an example and its comparison with EMRs in Coastal China, the paper argues that a new subset of urbanization in China is under way since 2000, i.e. a new region-based urbanization driven by the combined forces of domestic demand and globalisation has been unfolding in Central China. Classified as a new category of EMR, i.e. EMR II, these newly emerging EMRs in Inland China feature domestic investment and demand as key drivers, as well as being characterized by the 'backflow' of local people and 'low-carbon' trends of its manufacturing sectors.

Economic Crisis, Neo-liberalism and China's Urban Planning Policies in Transition

YU Taofang, LI Na

Dept. of Urban Planning, Tsinghua University, Beijing, 100084, P. R. China, yutaofang@tsinghua.edu.cn

Chinese Society for Urban Studies, Beijing, 100084, P. R. China, lina7485@hotmail.com

Abstract

Since 2008, the world is undergoing a new round of large-scale economic crisis. For tackling with the global economic crisis and domestic economic overheating, the Chinese government has also experienced many theoretical and practical attempts, which are deeply influencing the change directions of long-term urban strategic planning and short-term actions. In this paper, urban planning policies responding to mitigating and adapting the economic crisis are summarized based on Neo-liberalism model from different countries and areas of the world. And then, the urban planning policies in China since 2008 are analyzed, focusing on spatial differences of marginal benefits of the investments, such as to different sized cities. The final part is the strategic suggestions on China's Urban Planning from adapting to the New Normal trends. Firstly, urban planning policy should respect more the urban development (including the current situations judgment) laws, which in China's context are most multi-disciplinary mixed; secondly, in the long-term, the China's urban planning policy in transition should correctly handle the market optimal roles and the government equilibrium functions; Thirdly, in the short-term, the 13th five year Period is most important for China both from the global economic crisis and from the domestic overheating economy adjustment, besides the Supply side policies, the Urban planning and investment policies should not ignore the necessities of new Keynesian liberalism strategies from the "demand side", such as focusing more on East China, more on Core Central Areas of the Cities, and more on Mega Cities/ Mega City-regions as well.

Economics Crisis; Neo-liberal urban planning; Marginal Benefit Analysis

Empirical Test on the Relationship between Urban Basic-Nonbasic Economic Activities in China Based on the Theory of Economic Base

Guan Haoming^{1,2}, Zhang Pingyu¹

¹Northeast Institute of Geography and Agroecology, Chinese Academy Sciences, Changchun, 130002, P. R. China

²University of Chinese Academy of Sciences, Beijing, 100049, P. R. China, E-mail: guanhaoming@iga.ac.cn

Abstract

Economic base theory is one of the classical theories of urban economic activities, but the theory is not fully recognized and has not been completely denied. Based on the improved location quotient method, linear regression model and VAR model, the small and medium-sized cities of Jilin Province, Sanya City, Haikou City, Shenzhen city and Guangzhou city are selected as the empirical test objects. The results of the study can draw the three main findings. First, for a city with considerable scale and a certain level, the proportion of basic-nonbasic economic activities gradually decreased with the expansion of the scale of the city. Second, using the marginal multiplier method to estimate the "multiplier effects" is effective, the average multiplier method to estimate the "multiplier effects" is obviously insufficient. Third, the "multiplier effects" caused by the basic economic activities of the larger cities is weakened, and the urban economic activities are not in line with the basic economic model, which is shown as the interdependent model of basic-nonbasic economic activities. Based on the empirical results, two hypotheses are put forward. First, for a small size city, the basic economic activities could have a "multiplier effects" which is related to the size of the basic economic activities and the growth rate of the basic economic activities. Second, for a small city and small cities in a region as a whole, the driving force of development could be evaluated by comparing the value of "marginal multiplier" with 1.

Land Expropriation, Demolition and Displacement in China's Rapid Urbanization

Process

Max Lu

Department of Geography, Kansas State University, Manhattan, KS 66506, USA, maxlu@ksu.edu

Abstract

In China's post-reform rush toward industrialization and urbanization, a large amount of rural land has been expropriated for non-agricultural purposes and many urban areas have been redeveloped. "Chaiqian" (拆迁, demolition and displacement) has been a ubiquitous phenomenon in China that has not only displaced millions of people but also given rise to numerous protests and petitions stemmed from unfair compensations or farmers' unwillingness to give up their land. The tensions are especially high on the exurban fringes of Chinese cities. This study examines this issue based on media reports and the author's field work in East China's Zhejiang province. The compensation policy for land expropriation and residential demolition appears to vary significantly, as do local reactions to "chaiqian." The paper compares Chinese practices concerning land expropriation, demolition and displacement with those of developed countries and offers lessons for China to address this inevitable issue in the urbanization process.

Key words:

urbanization; land expropriation; displacement; China

Manufacturing Decentralization and Local Government Policy in Intra-Metropolis: The Case of Guangzhou, China

Jiang Li, Yang Chun

Geography Department of HongKong Baptist University, HongKong SAR, China, 15484742@hkbu.edu.hk

Abstract

Understanding manufacturing decentralization at the intra-metropolitan level is of great interest to urban planners and geographers. However, there is a gap in the research with respect to data related to manufacturing decentralization and the role of local government policy after 2000. With the aid of Geographic Information System (GIS) techniques, this paper examines employment census data from 2004, 2008 and 2013 to better understand the influence of local government policy on this decentralization in the Chinese intra-metropolis of Guangzhou. We also use brief telephone interviews and in-depth personal interviews to gain additional insight. The results suggest that manufacturing activities decentralized from the city center to the suburbs more rapidly during the period from 2008 to 2013 than from 2004 to 2008. This situation holds for both heavy and light manufacturing. However, heavy manufacturing decentralized even more rapidly than light manufacturing, which leads us to examine the theory of Christaller's urban spatial structure model and Alonso's urban land use model. In sum, we find that this decentralization in Guangzhou is due to the local government formulating plans, implementing policies, and providing incentives to manufacturing firms.

Key Words:

local government policy; decentralization; manufacturing activities; Guangzhou intra-metropolis

Location, Geographical Relationship and Choice of Migration Destination of Floating Population in China

Wang Ying-ying, Tong Yu-fen

School of Labor Economics, Capital University of Economics and Business, Beijing 100070, wyy19880608@sina.com

Abstract

Based on the analytical framework of the new economic geography theory, this paper uses binary logit model to analyze the impact of location and geographical relationship on the choices of inflows by migrants in consideration of individual heterogeneity and inflows' heterogeneity, in order to explain the reasons for the formation of the distribution pattern of the floating population in China from microscopic perspective. Studies have shown that: the location and geographical relationship significantly affect floating population's inflows option. Specifically, the positive impact of traffic access degree and non-farm employment density far exceeded the negative effect of geographic distance, due to the traffic access degree of megacities such as Beijing, Shanghai, Guangzhou and Shenzhen and so on is far ahead of other inflows, and non-agricultural employment density is also higher than other cities, which appeal a large number of floating population flow into large cities by overcoming the obstruction of geographical distance; and the influence of geographical relationship on the choice of inflows by migrants is more about economic links and dependencies, rather than pure geographic close. In addition, the heterogeneity within megacities and between individual migrants is significant, which cannot be ignored.

Key words:

Location; Geographical Relationship; Choice of Migration Destination; Megacities

Making the Urban Public in Post-Reform China

Junxi Qian

Centre for Cultural Industry and Cultural Geography, South China Normal University, Guangzhou, China, Singapore Management University, Singapore, junxi.qian@gmail.com

Abstract

The post-reform Chinese urban society and polity are characterised by a limited extent of social and political liberalisation, and unprecedented diversification of social identities, value orientations and interests. As a result, it is possible for individuals and social groups to appropriate multifarious spatial-temporal affordances to accommodate diverse needs and appeals. Against this backdrop, this presentation interrogates the post-reform Chinese urbanism by focusing on urban public sphere. While acknowledging the Anglo-European root of the notion of urban public, this presentation asks the following questions: (1) did the modern Chinese urbanism, inherently susceptible to Western notions of modernity and rational organization, witness the emergence of an urban public sphere where various actors articulate and negotiate views, interests and identities by partaking in a “world of strangers”; (2) if so, how do various urban publics unfold in the post-reform context, and what implications do they have for the entangled relations between state, society and the market? To do so, this presentation engages three strands of analyses. First, it traces the emergence of nascent public cultures and public consciousness following the early modernisation of Chinese cities during the late Qing and Republican eras, and how urban publics came under state control in the Maoist period. Second, it reviews various practices of public spaces in post-reform urban China. Finally, it thinks theoretically and conceptually, albeit tentatively, the usefulness of the idea of urban public to the analysis of post-reform Chinese urbanism, while comparing Chinese experiences to the literature on urban publics in the West.

Key words:

urban public; public space; urbanism; post-reform China

MEDIUM PANEL- The Transformation of Urban Lifestyles in a Medium-Size City: The Case of Datong at the Beginning of the 21st Century

AUDIN Judith

Post-doc for the MEDIUM Project, CHERPA, Sciences Po Aix, Aix-en-Provence, France/based in China at Hangzhou Normal University and Datong University, judith.audin@ehess.fr

Abstract

While research in urban studies in China becomes more developed on major cities (Beijing, Shanghai, Chongqing, Guangzhou), it is still less the case for medium-sized cities. Based on multi-sited ethnographic research within the MEDIUM project, this paper offers to analyse the evolution and configurations of urban lifestyles in a medium-sized city with an industrial background, Datong, located in the northern part of Shanxi province. Studying residential practices and housing issues allows to understand the power networks and social practices in medium-sized cities in China

This paper will present the context and social consequences of a major urban renewal (*chaiqian*) policy carried out on a large scale both in the city center (城区 *chengqu*) and in the mine district (矿区 *kuangqu*) by the former Mayor Geng Yanbo from 2005 to 2012. We will study physical consequences such as the way the urban space get transformed along with the evolution of city politics. But we will also study social consequences on the urban ways of life. What are the normative effects of this policy ? What image of « the good life » is promoted by the state authorities through this process? The paper will then raise the issue of the transformation of urban lifestyles in Penghuqu, a new residential district of Datong. How do the inhabitants reinvent their daily life practices within this new environment ?

This neighbourhood study is based on ethnographic research in the city of Datong where the author studied everyday life practices in the city.

Key words:

Datong (Shanxi) local context; demolition-relocation (*chaiqian*); housing issues; urban lifestyles; multi-sited ethnographic research; social norms; power networks

Migrant Integration in Peri-urban Beijing -- Is Neighbourhood a Device?

Liu, S., Wu, F., Zhang, F.

The Bartlett School of Planning, UCL Faculty of the Built Environment, London, WC1H 0NN, the United Kingdom (UK),
siyao.liu.14@ucl.ac.uk

Abstract

Studies on ethno-cultural enclaves and mixed neighbourhoods show a highly complicated relationship and a vague connection between integration into mainstream society and neighbourhood characteristics. Segmented assimilation theory and empirical study in ethno-cultural enclaves and mixed residential communities provide an insight that neighbourhoods may play either positive or negative roles in Chinese internal migrants' integration. This research aims to interrogate the potential correlation between the migrant integration and neighbourhood types. Via an anthropological approach--participant observation, qualitative data of migrant households' daily life in four neighbourhoods are collected and analysed. Then through ethnographic narrative, the processes of their different integration approaches are unfolded and the dynamics behind are clarified. The results illustrate that firstly neighbourhood type is significantly related to the outcomes of migrant integration; secondly different neighbourhoods provide various approaches for migrant to integrate into receiving city. The reason is that neighbourhood is an important space in which economic integration and acculturation happens or social networks are knitted. The existence or absence of above upward mobility in different neighbourhoods either provides pathways for the adaptation into a new urban society or the hindering of integration. However, insufficient interaction with neighbours may not necessarily mean unsuccessful integration into city as neighbourhood is not the only place for migrants to integrate, their upward mobility might be achieved outside the residential communities that they live in. As migrant integration is found significantly influenced by neighbourhood types, the finding develops segmented assimilation theory that spatial distribution is another determinant of integration. This detailed empirical investigation also fills the gap of Wu, F. and Logan, J.R.'s research which mainly focuses on the statistics without detailed neighbourhood level observation.

Key words:

migrant integration; segmented assimilation; Chinese migrants; neighbourhood governance; urban anthropology

Migrant's Subjective Well-being in Urban China: A Case Study from Guangzhou

Yuqi Liu, Fulong Wu, Fangzhu Zhang, Zhigang Li

Bartlett School of Planning, University College London, 14 Upper Woburn Place, London, WC1H 0NN, United Kingdom,
yuqi.liu.13@ucl.ac.uk

Abstract

There has been a surge of migration in China within the process of rapid urbanization. Although ten millions of migrants work and live in the city, most of them are denied urban citizenship and regarded as outsiders in the city. Such predicaments undermine migrant's subjective well-being and their willing to settle down in the city, which causes the stagnation of urbanization in China. By using the method of multi-level modelling, this research aims to investigate the patterns and determinants of migrant's subjective well-being in Urban China, particularly the impacts from neighbourhood. Based on the data collected from questionnaire surveys and in-depth interviews, this research explored the patterns and determinants of migrant's subjective well-being. We found that the extent of migrant's subjective well-being is much lower than that of local civilians. Migrant's subjective well-being is determined by his/her livelihood in the city, social support, family organization strategy and neighbourly interaction. In particular, migrants who reside in a well-equipped and socially harmonious neighbourhood have higher extent of subjective well-being than those who do not. This research contributes to our understanding of migrant's livelihood in Urban China by examining the impacts of neighbourhood and the cohort effects on migrant's subjective well-being.

Key words:

migrants; subjective well-being; neighbourhood; multi-level modelling; Urban China

Paving the Way for Growth: Rail Transit Development and Suburbanization in Shanghai

Jie Shen

School of Social Development and Public Policy, Fudan University, Shanghai, 200433, China, Email: Shenj@fudan.edu.cn

Abstract

Transportation infrastructure is key catalysts for suburbanization. The prevalence of the automobile and the creation of the freeway systems triggered post-war mass suburbanization in many western cities. The adaptation to this mode of transportation further induced a distinct suburban morphology, which is characterised by low density and strict land-use specialisation. In Chinese cities, however, rail transit systems and high density development is particularly salient in suburbanization. While existing literature frames the mode with the concept of Transit-Oriented Development (TOD) and treats it a solution to car-dependent sprawl, this paper investigates the development of metropolitan rail transit systems and its role in suburbanization from a critical perspective. Research findings are based on a detailed case study based on Shanghai and one of its rail line connecting downtown Shanghai to the suburban district Songjiang. By linking land sales, residential development and infrastructure funding, the construction of metro lines actually opens up the suburban space for capital accumulation and functions as a key tool for state interventions. The development of metropolitan rail transit systems also illustrates the changing modalities of suburban governance in China, which breaks the conventional topdown city-suburb\centre-periphery relationships and reflects increased horizontal negotiation and cooperation.

Key words:

suburbanization; rail transit development; suburban governance; Shanghai

Positive Youth Development of Urban Native Children and Rural-to-Urban Migrant Children in Beijing

Wen M¹, Lin D², Wang W³

³Associate Professor, Renmin University, China

Abstract

Issues on the causes and consequences of large-scale rural-to-urban migration in China have drawn increasing research and policy attention in the recent years. Most studies have focused on describing and explaining life circumstances and outcomes of rural left-behind children and rural-to-urban migrant workers in this massive population movement. Less work has been done to examine how rural-to-urban migrant children fare compared to their urban native counterparts. In addition, most studies have focused on negative child outcomes such as loneliness and depression with more positive sides of youth development less addressed. Given this background, this study has three purposes: 1) conceptualize and operationalize a positive youth development concept, a comprehensive measure of intra-personal assets a child possesses, based on the child development literature developed in the USA; 2) examine whether rural-to-urban migrant children differ than their urban native counterpart in Beijing in positive youth development; and 3) explore whether family and school contexts offer some explanations for these differences (if observed). Data used in this study were collected in the fall of 2015 in Beijing. We are currently in the process of cleaning data and running data analysis. We will have finished a draft manuscript before the conference.

Rural-to-urban migration; child development; positive youth development; family; school

Practical Features of Affordable Housing Policies at Local Level in Urban China: Lessons from Guangzhou and Chongqing

QiuJunli, Liu Yuting

South China University of Technology, Guangzhou, 510641, China, marji123@sina.com

Abstract

In the past decades, drastic transformation from a welfare-state housing system to a market-oriented one has helped to shape a new affordable housing system in China. Local government has replaced the central government to become the main provider of affordable housing. Although affordable housing policies and its various implications have received extensive attention, practical feature of policy implementation at local level is a less touched area. Based on the empirical studies of the practices in Guangzhou and Chongqing, this paper aims to provide an in-depth analysis of local authorities' practical characteristics of affordable housing policies in the context of Socialist marketization, and then tries to identify the main influencing factors contributed to this. We argue that practices in Guangzhou and Chongqing represent two typical models in China - local authority with multiple interested groups commonly acted as providers and local government as the only provider respectively. However, significant differences between historical periods of affordable housing provision, mismatch between supply and demand, and clustered distributions of large-scale affordable housing estates with disadvantaged locations are main features at local level. Further analysis illustrates that strong policy constraints from the central government, and local authorities' inclination to responsible for higher government instead of low-incomers are dominant factors to municipal practices; while real estate-oriented urban growth, land leasing system, and social-economic conditions exacerbate this situation. In general, inappropriate division of responsibilities and rights of affordable housing provision between the central and local governments basically leads to municipalities' underpower to implement affordable housing policies.

Key words:

affordable housing policy; practical features; influencing factors; Guangzhou; Chongqing

Proposed Cultural Quotient with its Quantitative Empirical Application to Chinese Cities

LIN Jing, CAI Jianming

Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing, 100101, P. R. China, linjingamy@163.com

Abstract

It has long been recognized that culture is a significant driving force for urban development. Nowadays, it appears that culture is playing an increasingly important role in promoting urban sustainable development when innovation becomes the main driver of economic growth and urban competitiveness. Yet there's few proof of cultural importance in quantitative way in this regard. This paper therefore is trying to quantify the cultural importance to urban development by proposing an index system consisting the 6 dimensions identified by literature review dubbed as the Cultural Quotient (CQ). Based on the created CQ index system, an integrated database of 263 prefectural-level cities in China is established. Then CQ value for each city is measured by applying factor analysis using SPSS. Following that, correlation and regression analysis are made between CQ values and City Economic Performance (CEP) as well as Urban Comprehensive Competitiveness (UCC) imported from other official data sources, to explore the relationship between CQ and CEP as well as CQ and UCC in quantitative way. The result shows there's a high positive relationship between the two, especially between CQ and city performance in innovative economy. It implies that as a driver with the most durable influencing power, culture is critical to innovative urban sustainable development and needs to be carefully studied in details. This paper makes its contribution in establishing a measuring index and the empirical application in China. Yet more cases for other countries need to be included for more concrete proof of the statement.

Keywords:

Cultural Quotient; urban competitiveness; innovative economy; Chinese cities

Regulating Urban Belonging: China's *Hukou* System and Processes of Intra-national Bordering

Johnson, L

University of Kentucky, Lexington, KY 40508, U.S.A. a.leif.johnson@gmail.com

Abstract

As members of history's largest rural-urban migration, the migrants who make up a great portion of urban China's low-wage labor force and burgeoning population face unique challenges. Although the trajectories of their movements do not cross international boundaries, most are legally prevented from ever gaining full status within China's *hukou* system of household registration. This system parallels national citizenship policies in important ways, providing an alternative to standard understandings of how the legal boundaries around communities are drawn. While scholars studying international migration have noted that the regulations governing internal migration in China are closely related to policies regulating international migration, empirical work bringing the *hukou* system into relation with theoretical developments in (international) migration studies is scarce. Based on a series of qualitative interviews conducted in Shanghai and rural Anhui province, I argue that the structure and effects of the *hukou* system demonstrate clearly that the boundaries of national territory cannot be considered as the exclusive site from which bordering processes emanate. Bridging the gap between scholarship of Chinese migration and international boundary-making, I position this argument as an extension of the recent trend in border studies to understand bordering processes as taking place beyond the territorial boundaries of the nation state.

Review and Reflection on the Renewal and Reconstruction of Shenyang Tiexi

Industrial Zone

Guan Haoming^{1,2}, Zhang Pingyu¹

¹Northeast Institute of Geography and Agroecology, Chinese Academy Sciences, Changchun, 130002, P. R. China

²University of Chinese Academy of Sciences, Beijing, 100049, P. R. China, guanhaoming@iga.ac.cn

Abstract

Shenyang Tiexi Industrial Zone (STIZ) was a famous old industrial zone, which was formed under the planned economy system. Prior to 2002, the strategy of the technical transformation did not make STIZ to get rid of dilemma. In 2002, STIZ creatively solved the problem of "where the money come from, where people go", was a strong typical zone in the last 10 years of the Northeast China's revitalization process. This paper firstly briefly reviews the development process of STIZ since the implementation of the industrial relocation plan. Secondly, the author generalizes the "Tiexi Model" that mainly includes three aspects: 1) Shenyang Municipal Government merged STIZ with Shenyang Economic and Technological Development Zone (SETDZ), the merger of STIZ with SETDZ broke through the restriction of the institution; 2) The funds of renewal and reconstruction mainly came from the differential land rent; 3) Urban spatial restructuring promote industrial transformation. Thirdly, the paper points out a series of new problems arising from the rapid urban renewal in the urban functional space structure, industrial structure, economic growth pattern, employment and so on. Finally, the author reflects on the existing problems from the theoretical framework of resilient city in order to provide a new way of thinking for the development of STIZ in the context of a new round of Northeast China's revitalization.

Urban reconstruction; Spatial restructuring; Institutional transition; Resilient city; Shenyang Tiexi Industrial Zone

Saving Beijing (China). A Perspective of Political Ecology

Guillaume GIROIR

University of Orléans, Department of geography (France) ; guillaume.giroir@yahoo.com

Abstract

The major fact of the XXIst century is probably represented by the rise of so-called emerging countries. The rapid emergence of these often very populated countries with a high growth rate represents a major and specific challenge in terms of sustainability. How to reconcile emergence process and paradigm of sustainability?

This issue involves theoretical but also practical aspects, especially important in the megacities of emerging countries. Powerful demographic and economic concentrations, the megacities are considered as anti-models in matter of sustainability, but also laboratories of ecological transition.

In this context, the case of Beijing, megacity of over 21 million inhabitants, the capital of a country of nearly 1.4 billion people and 2nd world GDP, therefore a symbol of the emerging countries, offers a privileged field of both observation and reflection.

In the 1950s, some researchers suggested to separate the old town from the new town. Bumping into a real taboo, they were not followed by Mao. The best known of them, Liang Sicheng (1901-1972), considered as the father of modern architecture in China, advocated to keep Beijing as a political and cultural center, not an economic center. He wanted to keep the walls and gates of the old Beijing, creating a new city to the West, at some distance from the existing urban center. Its considered conservative stance earned him severe criticism in the 1950s, especially during the Cultural Revolution, where he was persecuted.

Over fifty years later, Beijing is experiencing a multifaceted environmental disaster, including sometimes extreme air pollution (cf. "airpocalypse", 空气 末日, *kongqi mori*) is only the most visible part. For the period between 2008 and 2015, only 20% of days have a good air quality.

In the first part, it will therefore be to present the unsustainability forms characterizing the urban anti-model of Beijing. A second part will show the counter-measures against the urban crisis of the capital by the Chinese government. In a third and final part, we develop a set of prospective thoughts, particularly on the issue of the transfer of the capital outside of Beijing and the need for China to introduce decentralization.

sustainable development ; political ecology ; China ; Beijing

Scenario-based Analysis: How Many Human Settlements Need to Be Designated as Cities in China?

CAI Jianming, LIN Jing

Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing, 100101, P. R. China, caijm@igsnr.ac.cn

Abstract

China now is in the transition period moving from a kick-off urban society towards a saturated society with a high urbanization level, probably to reach 70% with the added urban population approximately 300 million. It requires us to carefully reconsider how to optimize the urban population distribution in China for the coming 20 years. This paper thus tries to apply the scenario-based approach to analyze how many human settlements need to be designated as cities in China through elaboration on official criteria for city designation and its evolution first, and then various scenarios for city designation, urban distribution and spatial reorganization are projected and discussed. Based on this, some policy suggestions are put forward accordingly.

Keywords:

scenario analysis; human settlements; city designation; newly designated cities; China

Territory and Identity in Globalizing Chinese Cities in the Views of Foreigners – the case of Guangzhou city

Feng Lei

Sun Yat-sen University, School of Geography and Planning, Guangzhou, 510275, P. R. China, earthdoctor@126.com

Abstract

With the comprehensive development of China's opening to the outside world, more and more foreigners come to China. The Pearl River Delta region is recognized as a window of the mainland, also as one of the most popular destinations for foreigners to travel, work or study. So how do foreigners view their life in Chinese cities? What kinds of images are Chinese cities showing the world? And what are the differences between foreigners and Chinese people in thinking about the regional identity? These questions are meaningful which are related to the establishment of international image of China and Chinese cities, also related to the major issue of the development of cities as well as the whole country. This study takes Guangzhou City as an example, one of the most populated city in the Pearl River Delta, aims to clarify the identity of foreigners individually, and the regional identity of Guangzhou city collectively. The research was mainly conducted among the foreigner students in colleges and universities in Guangzhou City, and immigrant workers and travelers living in Guangzhou. In-depth interviews were conducted to obtain the first-hand data, combined with domestic and foreign media reports, social network service site and other information sources to analyze the formation and transformation of Guangzhou's regional identity.

foreigner; identity; territory; Guangzhou

The Production of Space and Sustainability of the "Ghost City":

A Case Study of Ordos, Inner Mongolia

Guanwen Yin

School of Geography and Environment, Shandong Normal University, Jinan, Shandong, 250014, P. R. China,
yingw@sdsu.edu.cn

Abstract

Since the 2000s, urban space has expanded rapidly along with the construction of new cities in China. Also, a large number of "ghost cities" with empty housing and inadequate economic activities are emerging in this urban transformation process. Taking Kangbashi New City of Ordos as a case study, this research aims to solve the myth of the "ghost city" from the perspective of "production of space". Through intensive interviews and fieldwork conducted during 2010~2015, it is found that the local government has played a dominant role through a series of administrative measures, including avoidance of central state regulations, land leasing, high standard infrastructure construction, relocation policies and industrial attraction in the production of the new city. Moreover, the enterprises and citizens have involved actively in the new city production through residential quarter construction and real estate speculation. Furthermore, this research estimates the sustainability of the new city, and it is found that underdeveloped industrialization, slow population agglomeration and real estate bubbles are the primary threats to the new city development.

Key words:

ghost city; production of space; sustainability; Ordos; China

The Spatial Agglomeration of Modern Service Industry in Consular District with Urban Globalization: The Case of Shanghai

Lin Mei^{1,2}, Fang Lyu²

¹Key Laboratory for Geographical Process Analysis & Simulation of Hubei province, Central China Normal University, meilin1212@foxmail.com

²Sustainable Development Research Institute, Central China Normal University, Wuhan, Hubei, 430079, China

Abstract

Consular district is a area that the landscape carrier of political functions in global city and the interaction between diverse actors in the process of urban globalization, which embodies the level of urban globalization and has a comprehensive effect on urban development. Economic factors in the consular district include modern service industry clusters elements, such as commercial, financial, leasing, real estate, hotels and leisure industry generated in the consular district and its adjacent areas which are driven and supported the construction of the consular district in the city. Due to the obvious location characteristic of the economic elements, the consular district has become the most active areas of the export-oriented economy in the process of urban globalization. In this paper, spatial Gini coefficient, location index and EG index are being used comprehensively to construct the spatial intensity model of economic elements in the consular district, through quantitative analysis and comparative methods to examine data from Shanghai city, we found that the economic elements of the consular district have formed a circular layer structure, including the kernel ring, the industrial agglomeration circle and the living circle, among which the economic elements interact closely. Based on this analysis, this paper discusses the spatial characteristics and formation mechanism of the economic elements in the consular district. The economic development of Shanghai's consular district shows that the agglomeration of economic elements in the consular district can activate and promote development of urban globalization, bring a good multiplier effect, and form a new growth pole within the city.

consular district; economic elements; industrial cluster; spatial characteristics

The Vanishing Rurality: Restructuring and Changes in Guangdong “Urban Villages”

Hong CHEN

South China Normal University, Guangzhou 510631, P. R. China, hongchk@foxmail.com

Abstract

China has been urbanizing rapidly since the late 1980s with tremendous economic growth and social changes. The new-type urbanization and “three rural issues” have gained their popularity in academics. This project chooses several villages located in different Guangdong municipalities as case study areas, tells the stories of two contradictions induced by the “rural-urban dichotomy”, and sheds light on the interaction and relationship between the process of urbanization and the persistence of rurality in China, as well as to discuss the questions that how urbanization vanish peasants and villages, how the rural traditional patterns have been revived, and why there are two completely opposite results of Chinese urbanization. Research methods is mixed through combining quantitative and qualitative analyses including statistical analysis, field observation, interviews and questionnaires, personal life history and discourse analysis. It tends to enrich the existing literature focus on the new-type urbanization and rural restructuring in China from the highlight of qualitative analysis and adoption of institutional analytic framework.

Key words:

rurality; rural restructuring; “urban villages”; new-type urbanization; China

Transformation of China's Old Industrial City: The Example of Regenerating Shenyang Tiexi Area

Zhang Pingyu

Northeast Institute of Geography and Agroecology, CAS, Changchun, 130102, P. R. China, zhangpy@iga.ac.cn

Abstract

China has experienced fast urbanization over three decades since the reform and opening up, a considerable studies have been focused on the transformation of the large cities such as Beijing, Shanghai and Guangzhou in the coastal area, however, how a large number of the inner-land old industrial cities developed and transformed still remains a less touched topic. This research takes one of typical old industrial city Shenyang, the provincial capital city of Liaoning as example, to demonstrate its transformation by exploring the regenerating process of Tiexi industrial area in the city. The research reveals that strong intervention of central and local government, gradual marketization reform and involvement in globalization have played key roles in achieving Tiexi's regeneration up to date. What could sustain on-going transformation of Tiexi area in face of the new normal economy and society? How to adapt to new circumstance? The author attempts to discuss this issues from urban resilience approach. In conclusion, to regenerate old industrial area is inevitable for the transformation of traditional industrial city, Shenyang Tiexi example give us some experiences and implications with Chinese characteristics, and for continuing the regeneration process, we need to understand and utilize the resilient character of city to cope with new challenges. (NSFC:41571152)

Understanding the Formation of China's Property « Bubbles » from the Perspective of the Developmental State

Natacha Aveline-Dubach

Géographie-cités, university Paris 1-Panthéon Sorbonne, Paris 75007, France, aveline@jp.cnrs.fr

Abstract

Over the past decade, China's urban property markets have undergone skyrocketing prices. Scholars have debated about the way to interpret these mechanisms. This paper does not take part in the discussion regarding the bubble hypothesis but rather outlines the politico-institutional drivers of these property booms. Following Wu's argument on the centrality of property development in China's macroeconomic policy (Wu, 2015), the paper mobilizes the Developmental State framework (Johnson, 1985, Zhu, 2004). It highlights the productivist strategy of the state at both central and local levels, the financial repression driven by the need to control the allocation of banking credit, and the subsequent use of housing as an investment vehicle against a background of residual welfare. This perspective also provides insight into the surprisingly weak involvement of foreign capital in China's property markets, another commonality with neighboring developmental states that relativizes the uniqueness of China's real estate dynamics.

Key words:

Development state; property markets; housing markets; grey finance; foreign investment in real estate; property bubble

Urban Living Space Evolution and Spatial Mechanisms Analysis in Metropolitan Fringe

——a Case Study of the Area along Chaoyang Road and Chaoyang North Road in Beijing

Li Yuanxi, Wang Kaiyong

Institute of Geographic Sciences and Natural Resources Research, CAS, University of Chinese Academy of Sciences, Beijing, 100101, P. R. China, liyuanxi15@mails.ucas.ac.cn

Abstract

The area along Chaoyang Road and Chaoyang North Road in Beijing is in typical metropolitan fringe, so this paper take this area as a case study. With RS data, GIS techniques and field work, the study achieves the urban living space classification maps of 2005 and 2014. Using the area calculate, buffer and overlay functions of ArcGIS 10.1, the study analyzes the spatial evolution patterns and mechanisms. It is found that great changes have taken place in the last ten years, which showed that the scale of urban living space evolution is massive and its forms are various. Constructing modern residence and reconstructing urban village are two themes of urban living space evolution. Different evolution forms occurred at different distance along the transport artery. From the near the distant, they are constructing modern residence with consumption space and public service space, then constructing recreation space on underdeveloped land, then relocating work space. The expansion speed index decreases from north to south of the research area. The distribution of consumption space, parks, green space, kindergartens, primary schools and high schools is not even in the spatial distribution. Eastern area, southern and northern marginal area is need to strengthen these spaces especially, which can optimize the spatial structure and improve the living environment.

Key words:

urban fringe; urban living space; evolution; along transport artery; Beijing

Urban Village Redevelopment in China: A Case Study of Guangzhou

Weilong Zhang

University College London, United Kingdom, w.zhang.12@ucl.ac.uk

Abstract

There is a plenty of existing researches on China's urbanisation revealing the process of urban expansion of cities and towns, but little touch on the modality of redevelopment in China's cities. From late 2000s, China's economy enters a new stage of 'new normal', so-called 'Xinchangtai' in Chinese. Against the context, a remarkable change has been noted within the field of urbanisation in China, as the role of planning as a major tool for growth has come to end. The growth-oriented ideology underlying China's planning is ending. The golden age of China's spatial production as well as planning is gradually disappearing. Now the focus of urban China's spatial production turns and moves into a new stage of pro-redevelopment, so to improve the efficiency of land use, place making, promote various types of consumptions, and sustain a high speed economic growth. This research examines the practices of urban village redevelopment in Guangzhou. On the one hand, it discusses the policy evolution of village redevelopment of government in different levels from central, provincial and to local, to explain the governance change in village redevelopment. On the other hand, it intends to demonstrate the evolving power of villages' collectives and villagers, as well as the contestation and negotiations between villagers and local government within the processes of redevelopment, in order to shed light on the impact of collective power on the evolution of governance of urban redevelopment.

A Coffeehouse Neo-Tribe in the Making? Exploring a Fluid Cultural Turf in Post-Reform Chinese Urbanism

Qian J, Lv Z

Centre for Cultural Industry and Cultural Geography, School of Geography, South China Normal University, Shipai Campus, Guangzhou, 510631, China, junxi.qian@gmail.com

Abstract

Since the implementation of the Opening and Reform Policy, Chinese urbanism has witnessed the rise of a consumer society. Consumers, as mindful and reflective social agents, are engaged in the re-fashioning of collective values and identities through activities and practices of consumption. This paper examines the zeal of young, wealthy and educated urbanites in the post-reform urban China for the coffeehouse. With an empirical study based on Guangzhou, this paper takes the coffeehouse as a locus of meeting between globalized meanings and locally mediated practices. Above all, the paper asks whether coffeehouses, as lived habitus constituted by situated rituals, customs, codes and cultural meanings, contribute to the formation of collective values and identities of coffeehouse consumers. The empirical findings suggest a positive answer, since the multiple, and often ritualized, routines of socialities and activities clearly break away with the identity of unreflective consumer that dominant social discourses appear to reify. Coffeehouse consumers not only reproduce cultural experiences of consumption-empowered cosmopolitans of the global age; they also negotiate, and sometimes even resist recent cultural changes in urban China. First, coffeehouses are defined as heterotopic “retreat” from fast-paced urban life that encourages self-reflection and spiritual comfort in a society dominated by instrumental rationality. Second, coffeehouses are social settings conducive to more “authentic” socialities not distorted by the impersonal logic of “office culture”. Finally, early-career entrepreneurs frequently use coffeehouses for the exchange of ideas and information; and trust established in such social milieus facilitate both innovation and self-actualization.

Key words:

coffeehouse; neo-tribe; cultural turf; urbanism; post-reform China

Economic Transition and Restructuring of Manufacturing Spaces in Urban China:

The Evidence from Nanjing

GAO Jinlong¹, WEI Yehua Dennis², YUAN Feng¹

¹ Key Laboratory of Watershed Geographic Sciences, Chinese Academy of Sciences, Nanjing 210008, China, Nanjing Institute of Geography and Limnology, Chinese Academy of Sciences, Nanjing 210008, China, jlgao@niglas.ac.cn

² Department of Geography, University of Utah, Salt Lake City, UT 84112, USA

Abstract

China has undergone substantial industrial and spatial restructuring since the economic transition. The triple process of globalization, marketization and decentralization has a significant influence on the restructuring of manufacturing spaces in urban China. Using the data from the basic unit survey and second economic census conducted in 2001 and 2008 respectively, we investigated the restructuring process of the manufacturing spaces in Nanjing. The result implies that with the suburbanization of the manufactures, multiple specialized areas emerged in the outskirts of Nanjing. In particular, the development zones gradually became the major base of those manufacturing firms. And a hub-and-spoke pattern has also been detected with the development of traffic infrastructures and the construction of the development zones in Nanjing. Employing the Binary Logistic model and spatial autocorrelation models (SLM/SEM), we also found that the global factors of foreign investment and the export degree of industries, the market factors encompassing the urban land price and the development of non-state/collective enterprises, as well as two dummy variables of development zones and city center indicating the force of decentralization have highly significant impact on the failure/migration and re-agglomeration of manufacturing firms in Nanjing, together with other location, industrial, and regional factors including the distance to the highway, distance to the airport, pollution intensive, hi-tech intensive, land supply, and density of roads.

Key words:

manufacturing space; spatial restructuring; suburbanization; economic transition; Nanjing, China

Innovation and Urbanization Capacity in Small, Unevenly Developed Economies: A Case Study of 17 Cities in a Coastal Province

Liu Lei

Beijing normal university, China, 469995836@qq.com

Abstract

The city is an agent of innovation, and sustainable economic and social development depend on this innovation to maintain a city's education, human resources, science and technology. Innovation also allows for strategic choices that can lead to new models of urbanization. This study analyzed the correlation between urban innovation and levels of urbanization for 17 cities in Shandong Province. Overall, a significant correlation between a city's capacity for innovation and its level of urbanization was found for the cities. The a significantly improvement over time, most of the cities are in moderate or high level of coupling degree. Coupling degree shows a significantly spatially "center-periphery" distribution, indicating the radiation and leading role of key cities. The overall coordination degree of city's capacity for innovation and urbanization of cities in Shandong Province is low, but presents a significant improvement over time. Most of the cities with high degree of coordination distribute along Jiao-Ji Railway with Jinan City and Qingdao City are the core and endpoints. The coordination of the northern region of Jiao-Ji Railway significantly higher than the southern region.

Key words:

City's capacity for innovation; Urbanization; Coupling coordination analysis

Spatial Hierarchy inside the World City Network and Emerging Pathways of Chinese World Cities

Ilya Chubarov^{1,2}, Rejep Kurbanov¹

¹Institute of Geography, Russian Academy of Sciences. 119017. Russia, Moscow, Staromonetny per., 29.

²Institute of Far Eastern Studies, Russian Academy of Sciences. 117218. Russia, Moscow, Nakhimovsky, 32,
ilya.chubarov@gmail.com

Abstract

The first part of research provides a new approach to measuring a spatial structure of world city network (WCN). Based upon the results of media-popular 'global city rankings' produced by several international think tanks (PWC, Mori Foundation, The Economist and A.T. Kearney), and inspired from the broader context of global intereactions, our calculation allowed to reveal global urban hierarchy and divide it in several subnetworks of world cities. The second part of the paper contains more detailed analysys of Chinese situation with special attention on emerging pathways of those Chinese world cities, identified earlier as part of WCN. Analysis shows that Hong Kong clearly stands out as 'global gateway city' (well-positioned as center of commerce and meditation services), Beijing is very typical 'global capital' (with prominent positions inside international political, media, cultural fields and national control and political center), while Shanghai, Guangzhou and Shenzhen shares the common features of 'global industrial city' (manufacturing and logistics are fields of specialization).

Key words:

China; Hong Kong; Beijing; Shanghai; Guangzhou; Shenzhen; hierarchy; global city; world city; networks; globalization

Spatial Reconstruction of City Museum in China during the Period of Institutional Transformation: A Case Study of Chengdu City

Liu Run

Hubei University, Wuhan, 430062, P. R. China, liur@hubu.edu.cn

Abstract

In the context of globalization, museum as an important spatial carrier to enhance the city's international cultural competitiveness, is increasingly integrated into urban development strategies at home and abroad in the most recent decades. In China, museum, as it has come to be known, once was an administrative organ relying heavily on government subsidies to survive in the planned economy period, so its spatial construction (include site selection, function configuration, architecture style, spatial combination and so on) was mainly to meet political demands at that time. However, such spatial construction has hindered the effective play of museum's social and economic function at present. Thus spatial reconstruction is extremely necessary for museum to release its economic and cultural vitality, more and more city governments, museum creators has taken a series of measures of spatial reconstruction to build the museum as an important urban cultural and commercial space. In order to understand better the museum why and how to be carried out spatial reconstruction, this paper takes Chengdu city as a case study, adopts qualitative research methods such as depth interviews, participant observation and text carding, analyzes the background and situation of museum reconstruction, discusses in-depth the spatial (re)construction of museum in the planned economy period and in the market economy period, and finally provides a reflection about spatial reconstruction based on museum as a social public goods.

Key words:

Spatial reconstruction; museum; institutional transformation; Chengdu

Study on Establishing Unified Urban and Rural Construction Land Market

Min Jiang¹, Xiaoting Xu², Qinfang Li^{3,*}

¹Institute of Geographic Science and Natural Resource Research, CAS, Beijing, 100101, P. R. China,
jiangmin.15b@igsnrr.ac.cn

³School of Earth Science and Resources, Chang'an University, Xi'an 710054, P. R. China

Abstract

Urban-rural dual structure is the major character of construction land market in China, which impedes the fast, fair, efficient transfer of land resources. Land market reform is always the research hotspots of land use policy in China. However, current studies focus on single aspects mostly, such as land expropriation system, collective owned land transfer, but rarely propose systemically reform measures. In this paper, we combine literature analysis, summarizing method and system analysis method to analyse the institutional obstacles to establish unified urban and rural construction land market in China. Then we propose a series of systemically reform measures to build the unified land market: 1) Taking the improvement of land expropriation institution and direct transaction of rural collective construction land as a breakthrough, the unified construction land market can be established via three aspects, including expanding rights, reform land expropriation system, and systematically supporting measures. In the new institution, urban and rural construction land have the same rights and government only inspects and controls the market; 2) The systematically supporting measures, such as perfecting land laws and regulation, rural land property system, tax system, transaction platform, and changing government function, are needed to ensure the establishment of unified urban and rural construction market comes true. The results have guiding significance and application value of solving problems resulted by the dual structure of rural and urban construction land.

Key words: dural structure; construction land market; reform measure

The Effect of Legal Title on Housing Tenure Choice

—Taking Changping in Beijing as a Case

Daquan Huang, Mengyuan liu, Hua Zhang, Xingshuo Zhao, Teqi Dai

School of Geography, Beijing Normal University, Beijing 100875, China, bnuliumengyuan@163.com

Abstract

Small-property-rights house is a kind of informal housing in china. Because of the high price of house and property purchase limits, there are not enough available houses in big cities, so lower-cost small-property-rights house in suburb is another choice for many people. While lacking the legal title, and some infrastructure, households' housing tenure choice for small-property-rights house may not be same as commodity house. We examine the effect of legal title on housing tenure choice in Changping, Beijing, choosing household characteristic and house feature two aspects control variables. The results find that residents of small-property-rights house enjoy a fairly high degree of de facto security of their properties, while the legal title does decrease their willing to purchase the house. In this case, government could combine small-property-rights house with low-rent house to help alleviate the pressure of housing shortage.

Key words:

Small-property-rights house; legal title; tenure choice; China

The Structure Characteristics and Evolution Mechanism of APS Enterprises Network in Northeast China

Zhangxian Feng

School of Geographical Sciences, Northeast Normal University, Changchun Jilin

Abstract

Northeast China is a typical economic region which has an advanced enterprises network. The enterprises network has more obvious regional characteristics. It has experienced a long evolution process and has been developed relatively mature. Those characteristics make the region be suitable to launch a regional research.

Advanced producer service (APS) is an important carrier of global production networks, to the northeast region economic geography the basis of system theory research has important significance. Division of labor and the contact is an important theory, regional economic system theory and production network in northeast China both in concept and operation mechanism is part of the regional economic system, with the regional general attributes. Of the northeast regional financial services, insurance, logistics and other related industry network research has shown that APS in northeast China network dynamic characteristics, level and scale difference, envelops heterogeneity and diversity of characteristics, overlapping and nested characteristics, the agglomeration characteristics again.

From the point of evolution mechanism, the APS enterprises network in northeast China with the complexity of the regional economy system, under the condition changes, can present a network overlap, nested, center, transition and other space level change characteristic, and stage of development, management pattern, policy and local culture are more profound influence on production network.

Key words:

APS enterprises network; structure characteristics; evolution mechanism; Northeast China

Unintentional Segregation: The Prevailing Gated Communities in China

Weixuan Song, Peiyang Chen, Yaqi Yuan

Nanjing Institute of Geography and Limnology, Chinese Academy of Sciences, Nanjing, 210008, P. R. China,

Wxsong@niglas.ac.cn

Abstract

With the large-scale urban renewal at the turn of last century, gated communities sprung up and spread rapidly across almost all cities in China. The empirical research on Nanjing finds that: (1) gated community is the main development model of newly built community in China, emerging under the background of social stratification and housing supply market reform in the transition period. It is popular for catering to the high grade and modern residential demand by the group with relatively high economic and social status. Simultaneously, (2) The high-grade gated communities in Nanjing are mainly distributed over city center and the areas in a region of mountains and streams outside the Ming City Wall, as collages in the traditional space of the city in the form of mosaic. The residential space shows that being mixed by all parts of society in large scale and inhabited by homogeneous population in small scale, presenting the core-edge structure. (3) Gated community in China is quite different from member or “club” oriented community in western countries. While, gated community in China is only a community in exterior form and the community cultural characteristics, collective consciousness and sense of belonging is not strong. (4) Gated community is a relatively ideal mode of living space for individuals. However, it has brought negative effects including the collapse of traditional neighbourhood relations, privatization of public space of waterfront, and intensifying of social exclusion and residential segregation, which challenges social fairness and space justice.

Key words:

Gated communities; residential differentiation; urban renewal; Nanjing

A Landsat 8 OLI-based, robust model for estimating the diffuse attenuation coefficient in dynamic, turbid Dongting Lake

Zhubin Zheng, Yunmei Li, Jingli Ren

(Zheng, Z. Z., Zhubin Zheng)

School of Geography science, Nanjing Normal University, Nanjing, Jiangsu, 210023, P. R. China, zhengspace@126.com

Abstract

The diffuse attenuation coefficient, $K_d(\lambda)$, is an important optical property that can be linked to light penetration and availability in aquatic systems, and $K_d(490)$ usually considered as a proxy for water quality. Detection of $K_d(\lambda)$ by means of remote sensing can provide significant assistance in understanding water environment conditions and many biogeochemical processes. Even when existing algorithms exhibit good performance in clear Open Ocean and turbid coastal waters, accurate estimation of highly turbid inland water bodies can still be a challenge due to their bio-optical complexity. We addressed this challenge by using the new Landsat 8 Operational Land Imager (OLI) images. As extremely turbid inland waters over Dongting Lake in China, a robust empirical algorithm to determine the diffuse attenuation coefficient of downwelling at a wavelength of 490 nm ($K_d(490)$) from spectral remote sensing reflectance has been derived from the Landsat 8 OLI images. The $K_d(490)$ estimation model was proposed using band ratio model of OLI5 and OLI2 from Landsat 8 OLI images, which was strongly correlated with in-situ $K_d(490)$ ($R^2 = 0.791$, $MAPE = 26.85\%$, and $RMSE = 0.791\text{m}^{-1}$). Based on the acceptable performance of OLI image-based atmospheric correction and $K_d(490)$ validation, the algorithm was subsequently applied to OLI images to estimate $K_d(490)$ variation from April 2013 to April 2016. The distributions of $K_d(490)$ for Dongting Lake exhibits a significant spatial and temporal heterogeneity. Generally, there was strong monthly variability in $K_d(490)$ over the entire lake along with high variability of lake area, and the $K_d(490)$ values shows the typical temporal characteristics. The spatial heterogeneity, significantly higher in Main channel and Eastern of East Dongting Lake. Our results show that for Dongting Lake, estimated $K_d(490)$ data from the pre-existing models exhibited the poorer performance than the new retrieval model we proposed here, since the higher spatial resolution and signal-to-noise ratios (SNRs) for the Landsat 8 OLI, as well as the quantization. Our new algorithm proposed in this study has great potential of water quality and environmental conditions in the extremely turbid, shallow lake. It must be emphasized, however, that this algorithm may, at present, only be used for regional applications with $K_d(490)$ in Dongting Lake, because our measurements with $K_d(490)$ larger than this value in other regional waters with different bio-optical conditions and sediment types, the coefficients of the empirical optical model need to be calibrated. The study methodology could be easily extended to other similar lakes to assess temporal and spatial $K_d(490)$ patterns, and the information provided here is critical for future long-term efforts to document and monitor the water parameters in Dongting Lake.

diffuse attenuation coefficient; Landsat 8 Operational Land Imager (OLI); Dongting Lake

Case Study on Water Contamination in Some Bigger Depression of South Gobi Region of Mongolia

Erdenechimeg Badamgarav

Institute of Geography and Geoecology, MAS, Mongolia, erdenechimegb@gmail.com

Abstract

The groundwater resources are relatively low in South Gobi region of Mongolia and the water quality are deteriorated in last decades and the mineralization and hardness of groundwater is over the drinking water standards. Droughts are being significantly depending from the evaporation changes exceeds over the precipitation increases in last few years. The potential groundwater resources low there due to ground water resources to some extent but the groundwater recharge is very low.

In this poster presented the result of case study of determination ground water contamination by using chemical and heavy metal analysis and isotope method in framework of fundamental research study of "Evaluation of groundwater resources in some bigger depression of Gobi region" in 2013-2015.

We have concluded that evaporation processes appears much in the dug well water in area of depression of South Gobi region Mongolia by the result of isotope analysis in this research study.

The results of chemical analysis have been shown that in the 9 production well water was bicarbonate class, and sodium group water dominated on those wells. In the 4 well water was chloride class and sodium group water and in 3 well water are bicarbonate and chloride class and sodium group and 1 well water was bicarbonate and chloride class and magnesium group water. Highest mineralization 906.4 mg/l appears on the Old Haya Brigad well (GW-13) water and most of fresh water appears in the Tsavchir well and the mineralization is 417.1 mg/l (2013).

The heavy metal contents of groundwater in South Gobi region of Mongolia are very much over the drinking water standard, for example Pb content was 34 times more, As content was 21 times more, Ni content was 8 times more and Co content was 8 times more than the drinking water standard near the bigger mining industrial area.

A Spatial Study of Access to Safe Water and Sanitation Condition and its Implication on Health in the Dhalai District of Tripura; India

Ms. Debbarma Jimmi; Dr. Das Pan Nibedita

Tripura University; Agartala; India and jimmigeo@tripurauniv.in

Abstract

Access to good quality water and improved sanitation plays vital role for developmental activities and is one of the basic right to healthy life. The global importance of water; sanitation and hygiene for development; poverty reduction and health is reflected in the United Nations Millennium Development Goals; in the reports of the United Nations Commission on Sustainable Development. Unsafe water; poor sanitation and deficient hygiene affect the life of an estimated 1.7 million people annually; particularly as a result of diarrhoeal diseases (WHO; 2002; Ashbolt; 2004). It is estimated that 58% or 842 000 deaths per year; is attributable to unsafe water supply; sanitation and hygiene and includes 361 000 deaths of children under age five; mostly in developing countries (WHO 2014). The present study area; Dhalai district is one of the most economically and socially backward district of Tripura located between two hill ranges of Atharamura and Sakhan range. More than 70 per cent of its area is covered by hill and forest. The Dhalai district is highly prone to diseases like Malaria; Diarrhea and Japanese Encephalitis. In summer 2014; there was a large outbreak of Malaria across the district. The region also suffers from water scarcity during the dry season and problems of water quality. Iron content is found in excessive amount in the ground water of Dhalai district. It has also been found that the district has high incidence of open defecation particularly in the interior hilly and forested areas; therefore diarrhoea is a common problem due to mixing of human excreta into drinking water sources in many of the villages. The present study therefore makes an attempt to spatially examine the status of access to safe water and sanitation condition. The study will also explore the relationship between safe drinking water and sanitation condition upon health of the population of Dhalai district. The present study is based on primary data collected from the households of selected villages along with secondary data on ground water quality. Map Info software has been applied for mapping and correlation statistics to understand the relationship studies.

Abstract

Chromophoric dissolved organic matter (CDOM) in riverine systems can be affected by environmental conditions and land-use; and thus could provide important information regarding human activities in surrounding landscapes. The optical properties of water samples collected at 42 locations across the Liaoh River (LHR; China) watershed were examined using UV-VIS and fluorescence spectroscopy to determine CDOM characteristics; composition and sources. Trophic state index (TSI_M) indicated that all the sites investigated were mesotrophic; and 64 % of them were eutrophic. High spectral slope values and low SUVA₂₅₄ (the specific UV absorption) values indicated that CDOM in the LHR was primarily comprised of low molecular weight organic substances. Although the spatial variation of TSI and fluorescence intensity did not follow a similar pattern; analysis of excitation-emission matrices (EEMs) contour plots showed that CDOM in water samples collected from upstream locations exhibited fulvic-acid-like characteristics whereas protein-like substances were most likely predominant in samples collected in estuarine areas and downstream from large cities. These patterns were interpreted as indicative of water pollution from urban and industrial activities in several downstream sections of the LHR watershed.

Continental-Scale Controls on Pathogen Concentrations across the Ganges

Watershed

Milledge D.G. Gurjar S.; Sinha R. Tare V.; Carbonneau P.E.

Department of Geography; Durham University; Durham; UK; patrice.carbonneau@durham.ac.uk

Abstract

The Ganges is one of the most important rivers in Asia with a population of 475 million inhabitants residing in its basin. This basin is characterised by source areas in the high Himalayas which have a low population density and lowlands areas where agricultural and industrial activity deliver heavy pollution loads to surface waters. Furthermore; regional sewage treatment infrastructure is poorly developed leading to further pollution from human sources. Assessing the exact levels of pollution across the entire basin has always been challenging and; despite the general awareness of poor water quality at certain key locations; there is little knowledge of the continental-scale patterns and possible predictors of water quality degradation in Northern India. Here we present an analysis of a large database of water quality data recorded from 96 stations across the Gangetic system. By using a novel approach and using flow accumulation algorithms to calculate upstream population densities; we show that total upstream population is a strong predictor of local water quality which performs much better than local population. This predictive relationship of water quality has allowed us to produce the first detailed map of expected water quality for the entire Ganges basin. We find that *ca* 85% of the inhabitants in the basin; 403 million people; can expect to have their local surface waters failing both safe drinking and safe bathing standards. Our findings have important policy implications in the light of recent efforts by the Modi administration to restore the national river of India.

Effects of Habitat Loss and Fragmentation on Surface Water Quality: A Case of the Shenzhen River Cross-border Watershed

Xie Yu Jing, Wang XiangRong, Ng Cho Nam, Fan ZhengQiu

Fudan University; Shanghai; 200433; P. R. China; xiejy@fudan.edu.cn

Abstract

This study attempts to examine the correlation of habitat loss and fragmentation with surface water quality variation in the Shenzhen River cross-border watershed. A compound and normalization indicator NP/MPS was proposed; which can disentangle the fragmentation effect from pure habitat loss; can be compared among different spatial scales; and be easily understood and applied by decision makers. Five variables were selected to present the water quality; namely SS; BOD; DO; AN and TP. ANOVA test was adopted to examine if water quality changed with time and space; and the stepwise multiple regression model was used to examine if habitat loss and fragmentation are correlated with or have effects on water quality variation. Hypotheses proposed in the introduction part have been successfully tested: (1) habitat loss and fragmentation were tightly correlated with water quality variation; (2) the correlations were varying among different water quality variables and exploratory variables; as well as across different spatial scales; (3) habitat loss; compared with fragmentation; generally plays a more important role in affecting water quality; and (4) relationships between water quality and habitat fragmentation showed great discrepancies between the Hong Kong side and Shenzhen side. Our adopted method was proved to be effective in providing a sound foundation for future watershed management and landscape planning.

Globalization of Water Resources through Virtual Water Trade

H. Yang

Swiss Federal Institute of Aquatic Science and Technology (Eawag); Ueberlandstrasse 133; 8600 Duebendorf; Switzerland. Email: hong.yang@eawag.ch

Abstract

Amid the increasing water scarcity in many parts of the world; virtual water trade as both a policy instrument and practical means to balance the local; national and global water budget has received much attention in recent years. As the largest water user; accounting for over 80% of the global total water withdrawal; food production is directly affected by water scarcity. In many water scarce countries; an increasing amount of food is being imported to meet the domestic food demand. For these countries; importing food is virtually equivalent to importing water that would otherwise be needed for producing the food locally. Building upon the knowledge of virtual water accounting in the literature; this study assesses the efficiency of water use embodied in the international food trade from the perspectives of exporting and importing countries and at the global and country levels. The role of virtual water trade in redistributing global water resources and compensating for water scarcity is assessed. The investigation reveals that the virtual water flows primarily from countries of high crop water productivity to countries of low crop water productivity; generating a global saving in water use. Meanwhile; the total virtual water trade is dominated by green virtual water. The study ; however; raises awareness of the limited effect of water scarcity on the global virtual water trade and the negative implications of the global water saving for the water use efficiency and food security in importing countries and the environment in exporting countries. The analysis shows the complexity in evaluating the efficiency gains in the international virtual water trade. The findings of the study; nevertheless; call for a greater emphasis on rainfed agriculture to improve the global food security and environmental sustainability.

Heavy Metal Flows in Mouth Areas of the Volga; Don and Kuban River

Tkachenko A.N.; Tkachenko O.V.; Lychagin M.Yu.; Kasimov N.S.

Faculty of Geography; Lomonosov Moscow State University; Moscow; 119991; Russia; tkachenkomsu@yandex.ru

Abstract

River mouth areas occupy the lowermost parts of river basins; and thus reflect anthropogenic impacts on the river catchments. Evaluation of pollutant flows in the mouth areas is an important approach for the environmental assessment of river basins. However; this is one of the least studied topics of aquatic geochemistry. In this paper; we present the attempt to quantify heavy metal flows in aquatic systems of Volga; Don and Kuban River deltas for the low water period; and to analyse the spatiotemporal changes of heavy metal content and environmental variables.

We found that the most important natural factors of the metal fluxes formation are the hydrodynamic activity of the water streams and the presence of geochemical barriers on the flow path. Aquatic systems are subjected also to the impact of large settlements located in river mouths (Astrakhan; Rostov-on-Don; Azov; Temryuk). The results showed that heavy metal runoff in the Volga River delta considerably exceeds the runoff in the Don and Kuban River deltas. Don River mouth area distinguished by higher total metal runoff while Kuban delta showed larger flows of suspended forms of majority of metals (Cu; Ni; Cr; Co; Cd; Pb). For all the studied river deltas; the share of suspended forms of heavy metals was found significantly lower in comparison with the world averages. This is mainly due to the relatively low content of suspended matter in the deltaic water streams.

How Extent Does Rainfall Intensity Affect the Enrichment of Nitrogen and Phosphorus in the Dry and Paddy Fields?

Xiaolin Liu, Changsen Zhao*, Shengtian Yang

1.State Key Laboratory of Remote Sensing Science; Jointly Sponsored by Beijing Normal University and the Institute of Remote Sensing Applications of Chinese Academy of Sciences; Research Center for Remote Sensing and GIS; Beijing Key Laboratory for Remote Sensing of Environment and Digital Cities; School of Geography; Beijing Normal University; Beijing 100875; P.R. China; zhaochangsen@bnu.edu.cn

Abstract

There are few studies specially focusing on the rainfall intensity as a key factor in the enrichment of nitrogen and phosphorus in the high-latitude agricultural field. Different crops have different response to the rainfall intensity. In order to research on migration and transformation of nitrogen and phosphorus in the fields with different crops; we took samples before and after the rain in two typical fields (maize and paddy) in the northeast China. Then the content of nitrogen and phosphorus in the water were tested in the laboratory. Total; nitrate; ammonium nitrogen; total phosphorus and soluble phosphorus in the interval of 5 days; 10 days; half a month and a month after the rainfall were also sampled and tested. Results show: (1) Nitrogen and phosphorous have different response curve to the same rainfall intensity. (2)The content of nitrogen and phosphorous will have a peak in 2 or 3 days after the rainfall; while the timing of peak changes along with the rainfall intensity positively.(3) In the maize and paddy fields the contents have entirely different value after a rainfall with that of the former greater than the latter. These results can provide firm basis for research on the source and process of agricultural non-point source pollution.

Rainfall intensity; Nitrogen and Phosphorous; enrichment; response

Impact of Water Quality on Human Health in Arid and Semi-Arid Regions of Rajasthan (India)

Kateja; A.

University of Rajasthan; Jaipur; India -302004; alpanakateja@gmail.com

Abstract

Water quality is key to human and ecosystem health. In a water deficit state of Rajasthan which consists of mainly arid and semi-arid regions; the quality of water is under continuous threat due to increasing population and climate variability. Demand supply imbalance has led to precarious condition of water resources. Human settlements; disposal of sewerage and industrial effluent are the main factors for degradation of water resource. Excess use of canal irrigation has culminated in water logging and salinity. Overexploitation of ground water has resulted in extraordinary levels of fluoride and arsenic problem. Deteriorating water quality has serious consequences for human health. The paper presents an account of water quality issues in Rajasthan and its impact on human health. It suggests a multi-sectoral approach to freshwater and waste water management to succeed in the face of threats to human health and environmental degradation.

Arid; Semi- arid; Water resources; Human health; Climate Variability

Impacts of Rural Clusters and Urban Slum areas on the River Haora; Tripura

Shreya Bandyopadhyay¹ and Sunil Kumar De^{2,*}

¹ Department of Geography; Adamas University; Barast- Barrackpore Road; Kolkata-700126; India

² Department of Geography; North Eastern Hill University; Shillong – 793022; India

desunil@yahoo.com

Abstract

Rapid exploration of population within the Haora River Basin is forcing the poor class people to settle down along the river without proper housing; sanitation and drinking water facilities. From the source up to the mouth of the Haora River; all the rural clusters as well as urban slum areas use *kachha sanitary system* (latrines; empty all their fecal matter directly into the river). These *kachha latrines* are the major sources of the solid waste within the Haora River. This paper is mainly concentrating in quantifying the impact of solid waste disposal coming from those *kachha latrines* as well as from other anthropogenic sources; such as garbage disposal and other major outlets. The impacts of deteriorating water quality of the Haora River is also analysed through household survey on the use of water by the slum and rural areas along the river and also by testing different parameters of the river water in the laboratory. A perception survey has also been carried out about the frequency of different water borne diseases.

Form the analysis it is found that particularly along the lower stretch of the Haora River the amount of solid waste disposal is more than 3000 heads/sq. km/day. This much amount of solid waste is a severe threat to the river that leads several water borne diseases. A distribution map of the acuteness of the diseases has been prepared from which it is found that about 28% stretch of the river is having acute risk of epidemic and other hazards.

Key words:

Slum; Kachha sanitary system; solid waste disposal; acuteness of disease

Investigating Human Health Implications of Surface and Ground Water

Consumption in the Sokoto-Rima Floodplain; Sokoto; North-west Nigeria

Dr Abubakar; Sheikh D.¹; Mr Gaddafi; Bala²

¹Department of Geography; Faculty of Natural Sciences; Ibrahim Badamasi Babangida University; Lapai;
sheikh.abubakar@udusok.edu.ng

²Department of Geography; Faculty of Social Sciences; Usmanu Danfodiyo University; Sokoto

Abstract

This research was carried out to study the surface and ground water quality in the Sokoto-Rima floodplain and eventually determine the health implications of consuming it. Five samples points was selected systematically and in each sample point; three samples were taken each of ground (tube well); and surface (river) water. The surface water is taken from the river at hundred meters interval; the sampling was repeated after 20days. A total of 30 samples (1st batch-15 and 2nd batch-15) were collected. Data obtained from laboratory test were subjected to mean and standard Deviation; Pearson correlation; and paired test analysis was used to compare the means of surface and ground water pollutants. The results from the analysis show that: positive correlation exist in pH; BOD; TDS; TSS; NO₃⁻; SO₄²⁻. While; negative correlation in DO; Cl⁻; PO₄³⁻ and K⁺. Paired test between surface and ground water pollution shows that: the mean difference of pH; BOD; PO₄³⁻ and K⁺ are significant at p<0.01 (2-tailed) and Cl⁻ is significant at p< 0.05 (2-tailed). DO; TSS; Cl⁻; PO₄; NO₃; and SO₄ are within the WHO standards. While; BOD; TDS and SO₄ (in NIS); are above the standard. These results were correlated with the WHO standard of water quality and finally tested for positive relationship with common ailments and/or sicknesses. The study therefore; concludes that; the quality of the surface and ground water in the area is a determinant of the soil characteristics and has a positive relationship with the health characteristics of the surrounding communities.

Retrieval of Chlorophyll-a Concentration of the Nine Plateau Lakes in Yunnan

Province Based on MODIS Data

Dan Chong¹; Haojie Li¹; Shuo Fan¹; Jiaojiao Li¹; Jie Wang²; Shiqiang Zhang¹

¹College of Urban and Environmental Science; Northwest University; Xi'an; 710127; P. R. China; zhangsq@lzb.ac.cn

²Institute of Water Resources and Hydropower Research of Yunnan Province; Kunming; 650228; P. R. China

Abstract

Chlorophyll-a concentration is an important parameter to reflect the degree of eutrophication in water. The dynamic observation of the chlorophyll-a concentration based on the remote sensing data in Lakes has attracted more and more attention. Based on the measured data and MODIS data; this study retrieves the chlorophyll-a concentration of nine plateau lakes in Yunnan Province. Firstly; the optimum statistical model of each lake is established by the combination of the radiation of the different bands of MODIS data based on the measured data of chlorophyll-a concentration in 2010-2012. Secondly; the retrieval model of the nine lakes is verified by the measured data of the chlorophyll-a concentration from 2013 to 2014 with the Root Mean of Standard Deviation (RMSE); the Standard Deviation; and the Nash efficiency coefficient (NSE). Finally; the spatial-temporal distribution(space distribution and dynamic change) of chlorophyll-a is retrieved by the optimal model. The results show that the chlorophyll-a concentration of space distribution is more in line with the professional judgment; and provides an important reference for further optimization of the measured sites. From the view of interannual variability; the chlorophyll-a concentration of Dianchi Lake; Erhai Lake; Xingyun Lake and Yilong Lake fluctuates greater in 2010-2014; which of Fuxian Lake; Chenghai Lake; Qilu Lake and Lugu Lake remains relatively stable; and which of Yangzonghai shows a decreasing trend.

chlorophyll-a concentration; MODIS; remote sensing retrieval; dynamic change; monitoring

Sanitization of Aqua-environment Contaminated with Arsenic by Bio- fabricated Nanoparticles

Das T K and Mukherjee T

Department of Biochemistry and Biophysics; University of Kalyani; Kalyani-741235; India

Email: tapandas@klyuniv.ac.in

Abstract

The present study involves the development of adsorbent containing silver nanoparticles for arsenate removal using silver reducing property of a novel fungal strain *Aspergillusfoetidus* MTCC8876. Biological reduction of silver by the isolate has been deduced at various time intervals. The fungal biomass after biological silver reduction were harvested and subjected to carbonization and its properties were analyzed using Fourier Transform Infra-Red spectroscopy; X-ray diffraction; scanning electron microscope attached with energy dispersive spectroscopy; BET surface area analysis; field emission scanning electron microscope and transmission electron microscope. The average size of the silver nanoparticles present on the surface of the carbonized silver containing fungal cell (CSF) was 35 nm. The carbonized control fungal cells (CCF) did not contain any particles on its surface. As (V) adsorption efficiency of CCF and CSF was deduced in batch mode by varying parameters like contact time; initial concentration; and pH. Desorption studies were also carried out by varying the pH. The CSF was proved to be exceptionally efficient in arsenate removal when compared to CCF.

Source Vulnerability Mapping in Karst Aquifers by COP and PaPRIK_a Methods in Aleshtar Basin (West of Iran)

Saffari Amir¹; Hatamifard Ramin²

¹ Associate Professor; Department of Geographical Sci; Kharazmi University; Tehran; Iran.saffari@khu.ac.ir

² Ph.D. Student in Geomorphology; Kharazmi University; Tehran; Iran

Abstract

Karstic aquifers are well known for their vulnerability to groundwater contamination. This is due to characteristics such as thin soils and point recharge in dolines; shafts; and swallow holes. In karstic areas; groundwater is often the only freshwater source. In case of groundwater resources; vulnerability maps of the aquifers are an important tool for the groundwater management and protection. The purpose of this paper is vulnerability mapping of karstic aquifers in Aleshtar basin (West Iran) to contamination by using COP and PaPRIK_a methods and management for preserve of these water resources. The Aleshtar basin; where a large and deep carbonate aquifer; affected by karstic and fracturing phenomena; is located. PaPRIK_a; Protection of karst Aquifers which is based on four criteria: **P**rotection; **R**eservoir; **I**nfiltration and **K**arstification degree and **C**OP; **C**oncentration of flow; **O**verlying layers; and **P**recipitation regime; are also suggested for karstic aquifer vulnerability analysis. Results of the PaPRIK_a approach categorize karst plains into three zones with; high; moderate and low sensitivity. In other words; these classes are covers 11; 65 and 23.4 percent of the study area respectively.

In addition of the COP approach that show in study area COP coefficient between 0.5-12 is varies. Due to high rainfall and low slope; C Parameter (Concentration of flow) most significant role of recharge and karst aquifer vulnerability in the study area. Finally; the result shows that the karst aquifer Aleshtar is a conduit flow system. So fissured carbonate aquifers (diffuse flow systems) are less vulnerable than karst aquifers (conduit flow systems).

Vulnerability mapping; karst aquifers; COP method; PaPRIK_a method; Iran.

Spatio-Temporal Pattern of Microbiological Drinking Water Contamination in Germany: The Roles of Climate and Sociodemographic Change

Karthe D

Helmholtz Centre for Environmental Research; Magdeburg; Germany; daniel.karthe@ufz.de

Abstract

In Germany; drinking water is considered to be safe straight from the tap; and there is a long tradition of both chemical and microbiological surveillance. Contaminations do occur; however; and a deterioration of microbiological water quality is the most common case. This is partly due to the complexity of drinking water supply systems; and the relatively old age of most water supply infrastructures in Germany.

In the recent past; two independent developments have received increasing attention with regard to drinking water safety in Germany: climate change; and sociodemographic changes. Recent studies have shown that areas with a shrinking population are over proportionately affected by problems with drinking water hygiene; as are peripheral rural regions. Hypothetical explanations for this pattern are infrastructural overcapacities; increased water transit times and a lack of revenue (and thus investment capabilities) by water suppliers. Climate change; on the other hand; is relevant for drinking water supply in two ways: it (a) leads to an increase in average temperatures which is beneficial for some pathogenic microorganisms; and it (b) is associated with an increasing trend towards hydro-meteorological extremes (heavy precipitation events and droughts); which were identified as the underlying causes of major contamination events in industrialized countries in the recent past.

In the future; ongoing climate and socio-demographic changes are expected to create greater challenges for drinking water hygiene than today. Therefore; adaptations are needed in order to maintain a high level of drinking water safety.

The Role of Safe Water Management in Diverting the Risk of Adverse Pregnancy

Outcome: A Study Focusing the Rural India

Pal; K.; Jain; N.

International Institute for Population Sciences; Mumbai; India 400088; Kabirpal2008@gmail.com

Abstract

Scarcity of clean water coupled with poor sanitation and hygiene contribute to a considerable proportion of global burden of disease. Although there is a paucity of rigorous research showing the degrading effect of limited accessibility to clean water on maternal health and pregnancy outcomes; emerging evidence indicates a link between these. This study using the latest round of India Human Development Survey conducted in 2011-12 aims to assess the association of limited access to safe water resources and drinking water management practices with pregnancy outcomes in rural India. Multinomial logit regressions were used to estimate the unadjusted and adjusted odds ratio with 95% of confidence interval. Result shows that less than half of the women in rural areas of India have improved source of water in their compound. Main sources of improved water used were piped water; hand pump and tube well. Almost 75% women store the drinking water in vessel covered with lid; yet pouring practices involve hand contact with water. Almost 80% women do not purify the water before drinking. The adverse pregnancy outcomes like still births and spontaneous abortions were significantly associated with both unimproved water source and water management practices. This study contributes to the scarce literature providing the association between access to safe water and maternal health. Programs working towards improving maternal health must also include the provision of improved water; sanitation and hygiene as their core strategies besides increasing knowledge of family planning methods; improving access to quality maternal health care.

The Study of Monitoring Total Suspended Substance in Donghu Lake in Wuhan Based on HJ-1A/1B Remote Sensing CCD Data

Lu Jianjun; Dong Zhiwen

China University of Geosciences; Wuhan; 430000; P. R. China; 719454741@qq.com

Abstract

To implement a large area of water quality monitoring; remote sensing offers the possibility. This paper takes Donghu Lake in Wuhan as the research area. Pearson correlation analysis was used to analyze the correlation between the band and band combination with the total suspended substance; and the best inversion band and band combination were determined; by using the HJ1A/1B CCD data. The RBF neural network was trained by the data of the measured spectrum and the total suspended substance concentration of water as the training sample; after this the RBF neural network model was formed. The atmospheric correction of satellite data could obtain more accurate remote sensing reflectance; and by means of field observation results of water in optically shallow waters to divide the lake; and do the bottom reflection correction after the atmospheric correction. Finally; the total suspended substance concentration of the lake was inverted by the accurate remote sensing reflectance.

The Value of Forest Recovery for Water Quality and Health

Arce-Nazario; J.A.

University of Puerto Rico at Cayey; Cayey; Puerto Rico. javier.arce@upr.edu

Abstract

In the last 50 years Puerto Rico has been transformed from a highly deforested agricultural landscape to a landscape dominated by secondary forests in the mountains and urban development in the plains. These transformations have shaped the current water quality. We observe how the levels of nitrogen; phosphorous; faecal bacteria; turbidity and temperature increased in urbanized areas; while they were reduced in watersheds that became naturally reforested. We used the extensive historical database of water quality in Puerto Rico starting from the 1950s to the present; and historical land use maps of Puerto Rico; to demonstrate the correlations in transformations of water quality in Puerto Rico. In this presentation I will give particular attention to levels of nitrogen; faecal contamination and sediments in water; and how precipitation and watershed composition shaped these variables. Using data from the Puerto Rican health department and data on the expenditures of the government water authority I demonstrate how these transformations in watershed composition translate to safer water quality and to reductions in the cost of water treatment for forested watersheds.

safe drinking water; ecosystem services; watershed analysis; faecal contamination; land cover change

Water Related Health Issues Study In Upper Catchment of Maha Oya River Basin- Sri Lanka

Ranjana. U.K. Piyadasa; D.S.Matharaarachchi

Department of Geography; University of Colombo; Colombo 03; Sri Lanka; ranjana@geo.cmb.ac.lk

Abstract

Water resources exist in environments comprising complex dynamic geo-morphological and ecological systems that are extremely sensitive to misuse by man. The research study aimed to identify evaluate the water quality variation; water pollution by human activities and in upper catchment of the Maha Oya river basin located in Kegalle and Mahanuwara District in central Sri Lanka. Dug wells in the catchment of the Maha Oya were selected to identify ground water quality changes due to water pollution in the river. GIS package ArcMap10 was used to identify the water quality changes in river and as well as ground water pollution area. Water samples were assessed for selected parameters; temperature; pH; Electric Conductivity and chemical parameters during the period. A sociological survey was conducted concurrently to study the impact of two communities (tea factory line house and agricultural) living along the stream bank; on water quality. The lowest pH of near Th most upper catchment of the area is probably due to the large amount of household refuse that is discharged directly into the stream at this location. The study revealed the decomposition of organic matter produces CO₂; which dissolves in water as carbonic acid; thereby lowering the pH values. The study further reveled that the major health problems in the lower part of the basin due to unplanned settlements; direct discharge of effluent from factories and urban waste to the river; and negative impacts of water tapping for mini hydropower projects.

Electric Conductivity; GIS; pH; sociological survey; temperature

Water Resource Management in Chhattisgarh State of India: Strategies for Sustainable Development

Dr. Soni P

Asst. Professor; Dept of Chemistry; Govt. G.N.A. P.G.College; Bhatapara; Chhattisgarh;India; preetis419@gmail.com

Abstract

Water is one of the most valuable natural resources gifted by nature to mankind. Out of the 3 percent fresh water available globally; 77.2 percent is stored in glaciers; 22.4 percent is ground water and just 0.4 percent is distributed among lakes; swamps; rivers and streams. World water demand doubles every 21 years; but the volume available is the same as it was in Roman times. Something has to be done urgently. According to UN and Stockholm Environment institute; statistics (1995) by the year 2025; two third of the world population will be affected by water scarcity. In such a situation our most valuable water resources are deteriorating; polluting and depleting day by day. Hence; each and every drop of rain water has to be conserved through various methods. In order to manage and conserve our precious water resources applying various scientific approaches; traditional method; technology and effective and relevant water policies of state government we may achieve the sustainable development of water resources in the state. In Chhattisgarh state about 80 percent population is rural and mainly dependent on agriculture. The biggest effect of PWC influence on state policy has been the three principles – location Specificity; decentralization and multipurpose water resources development. Instead it is replaced by state sponsored groundwater exploitation; which is underutilized is also most fragile in Chhattisgarh hydrological setting. A sustainable strategy for management of water resources is must to make aware masses for conservation of water and make the best use of our water by water saving programs; by capturing rain water from roof top. An attempt has been made in the present research paper to suggest the relevant strategies for the management of water resources. The aim of the research paper is to highlight various programs & policies of state government to manage and conserve the water resources of the state.

A Methodology Study of Watersensitiveurban Design Based on the Polder Buffering System

—A Case Study about the Urban Design of Mengjin River Basin in Changzhou

Zhu Jiawei¹, Zhu Yingying²

¹Southeast University, China, 690889096@qq.com

²Tongji University, China

Abstract

Nowadays, ecological patches in the area with lakes and rivers are gradually destroyed with the development progress of urban construction land-use. As a result, some environmental problems such as flood disaster and water pollution occur. Under the circumstances, domestic researchers use a WSUD method recognized by International Water Association to solve these problems. WSUD method is a new urban planning approach respecting urban water circulation and ecological progress. The article analyzes the water security grid and ecological network from a macroscopic angle by using GIS spatial analysis and confirms the ecological base line of Mengjin River basin. Based on these analysis, land-use and landscape design in the polder area can adjust to the environmental situation. By learning and researching the characteristics and key point of WSUD, the article aims to help the areas with lakes and rivers solve water ecology and security issues on urban planning level.

Evaluation of Rural Water Resources System Vulnerability in Hengyang Basin Based on the GIS&RS

ZOU Jun, YANG Qin

College of city and tourism, Heng Yang Normal University, Hengyang, 421002, P. R. China, zoujun4@163.com

Abstract

In order to study the dynamic evolution of the vulnerability of rural water resources system in Hengyang Basin, collecting required data of the research through RS, constructing the spatial model, and conducting the spatial analysis with GIS, this essay has constructed the mathematical model to extract the changing information and generated the changing layers about vulnerability of water resource system in Hengyang Basin to analyze the spatial-temporal characteristics of vulnerability of water resources system and the changing trend during recent two decades. The conclusions as below: 1) the water resource system in Hengyang Basin has become much more vulnerable in recent two decades. 2) Vulnerability of rural water resources system in Hengyang Basin shows "low around and high in the middle, north strong and south weak" of the distribution pattern. 3) in the study period, the overall vulnerability has increased, spatial differentiation significantly. 4) The spatial differentiation of Vulnerability index changes can be divided into four types. 5) Trends from the vulnerability changes, the vulnerability of rural water resources system with no change for the main types, two types of monotonic change very little. 6) The variation period of vulnerability index has presented a typical character of sharply increasing, especially in the ending period of 2005-2010.

Spatiotemporal Variability in Water Quality of the Poyang Lake and Its Relation to Hydrological Conditions

LI B, Yang GS, Wan RR

Nanjing Institute of Geography and Limnology, Chinese Academy of Sciences, Nanjing, 210008, P. R. China,

libing9133@126.com

Abstract

A study of the spatiotemporal water quality patterns and the factors that impact these patterns is crucial for lake water quality maintenance and managements. For this purpose, a combination of nutrient and geochemistry concentrations from 15 sampling sites during 2009-2014, as well as hydrological data was used for visualization, principal component analysis and density analysis. The nutrient indicators examined included total nitrogen (TN), total phosphorus (TP), ammonia nitrogen (NH₃N) and chlorophyll-a (Chla). Results showed that the water quality did not demonstrate significant spatial variations except for stations near the outlets of tributaries, however the water quality of sites in the northern waterway connecting the Poyang Lake and the Yangtze River is influenced by different environmental parameters compared to sites in central lake, especially for Chla concentration. While significant temporal variations, especially seasonal variations were found. Furthermore, the nutrient indicators experienced substantial changes between river phase and Lake Phase, the latter of which showed great possibility of excellent water quality. Future research is required in order to ascertain the specific impact of discharge from tributaries to give a reliable advice for improvement and maintenance in the Poyang Lake.

² University of Bucharest, Centre for Environmental Research and Impact Studies, Romania

Abstract

The paper examines the impact of surrounding areas on groundwater sources (wells) situated in a rural village. Groundwater from private water wells is the major source of drinking water in rural and peri-urban areas. The current problems facing groundwater quality derive from spatial arrangement flaws that facilitate nitrate contamination. These originate from fertilizer application to agricultural lands and from biochemical reactions of untreated human and animal wastes. Water samples collected from wells in a rural area in Romania were analyzed using fluorescence spectroscopy and the cadmium reduction method for nitrates. Maps with the distribution of fluorescent organic matter and nitrates in the groundwater were created to understand the role of local planning in the quality of groundwater. Fluorescence data evidenced high quantities of microbial organic matter in the water sampled from wells located near sheepfolds and poor management of domestic/animal wastes. Nitrates concentration exceeded the maximum admitted limit in some wells due to soil infiltration from agricultural practices and animal wastes. The study has shown that groundwater is negatively influenced by animal sheds, local cemetery and natural pools. The effect is amplified by the area's geomorphological features, such as: soil type, altitude levels, hydrological and hydrogeological flows. The employed methods offer a rapid and sensitive evaluation of water quality in order to avoid health hazards for the population. Heavy Metals in Aquatic Systems of the Don River Delta

Tkachenko O.V., Tkachenko A.N., Lychagin M.Yu., Berdnikov S.V., Povazhnyi V.V., Sorokina V.V., Kleshchenkov A.V.

Faculty of Geography, Lomonosov Moscow State University, Moscow, 119991, Russia, tov1989@yandex.ru

Abstract

River deltas can be considered as the biogeochemical filters on the way of the pollutants flows from the land into the sea. Don is the largest river of the Azov sea basin. Landscapes of Don River have been influenced by agricultural and industry for a long time. A significant amount of heavy metals and other pollutants comes into the river annually. This paper is focused on the spatiotemporal analysis of the heavy metals (Fe, Mn, Zn, Cu, Ni, Co, Cr, Pb, Cd) in the water and bottom sediments of the Don River Delta.

The results are based on the field studies carried out in 2010-2015. Aquatic systems of the Don River delta have been sampled, and content of heavy metals identified. The research covered different seasons and characterize geochemical features of the aquatic systems for the spring floods, summer, autumn and winter low water periods. As a result, the seasonal change of the heavy metal inflow to the delta apex was determined and spatial diversity of metal content identified. A significant increase of the heavy metal flows downstream the big settlements proves the considerable anthropogenic impact on the aquatic systems of Don River delta.

Heavy metals; water pollution; river deltas; aquatic systems; geochemical flows

Optical Absorption Properties of Chromophoric Dissolved Organic Matter in Poyang Lake in Dry Season

Lizhen LIU¹, Qi Huang²

¹Poyang Lake Research Center, Jiangxi Academy of Sciences, Nanchang 330096, P.R.China. woliulizhen2007@126.com

²Key Laboratory of Poyang Lake Wetland and Watershed Research, Ministry of Education, Jiangxi Normal University, Nanchang 330022, P.R. China

Abstract

The optical absorption properties of chromophoric dissolvable organic matter (CDOM) of the waters in Poyang Lake including estuary, nearby waters in Nanjishan Wetlands, and main lake in dry season in 2015 was researched and its relationship with dissolved organic matter was discussed. The results showed that CDOM absorption coefficients in whole waters in Poyang Lake at 254, 280, 350, and 440 nm were in the range of 7.74—20.03 m⁻¹, 5.54—14.37 m⁻¹, 1.37—4.24 m⁻¹, 0.29—0.94 m⁻¹, respectively. M values which could reflect the molecule size ranged from 5.61 to 8.18. The order of CDOM concentrations was nearby waters in Nanjishan Wetlands > main waters > estuary, which indicated there was the large effect of wetlands on the waters in Poyang Lake. The M values (molecular size) in nearby waters in wetlands were significantly higher than other lake areas, suggesting that high proportion of humic-matters would lie in CDOM. Dissolved organic matter (DOC) ranged from 1.39 to 4.86 mg/L, with the mean value of 2.33 mg/L. The correlation between CDOM absorption and DOC concentrations at 254 nm was the best among the common wave lengths used, and the coefficient could reached up to 0.88. The liner regression equation between absorption coefficient at 254 nm and DOC concentration ($CDOM_{a(254)} = -0.53 + 0.27 \times DOC$ ($R^2 = 0.76$, $p < 0.01$)) showed that CDOM in Poyang Lake in dry season could be a promising tracer for the source of DOC.

Pollutant Dispersion Analysis of Lake Water Based on Hyperspectral Remote Sensing

lv jianjun, shen zongji

China University of Geosciences, Wuhan, 430000, P. R. China, 872196459@qq.com

Abstract

Water pollution monitoring for prediction of lake water quality trends and propose appropriate countermeasures is of great significance. In this paper, HJ-1A / 1B satellite hyperspectral imaging and inherent optical properties of the lake water, including characteristic absorption and scattering coefficients of the chlorophyll a, BOD, DO, TN, TP, etc. Analysis of Water reflectance measured or from the water radiation to estimate the concentration of the above water quality parameters, The spatial distribution and variation of water quality and the numerical simulation of pollutant dispersion are simulated based on the WASP water quality model of the convection diffusion equation and the water flow rate, the flow rate and the volume of the lake. The accuracy of simulation results are verified by the measured data of water quality parameters obtained from Honghu in 2010-2015, On the basis of this, analysis the spatial distribution and variation of water quality in Honghu and predicting the diffusion of pollutants.

The Bio-Degradation of COD in Unconventional Water Resources: A Case Study from Beiyun River in Beijing

Du Yi¹, Hu WeiXuan¹, WANG Xiaoyan^{1,2,*}

¹ College of Resources, Environment & Tourism, Capital Normal University, Beijing 100048, China

² Research Center of Aquatic Environment in the Capital Region, Beijing 100048, China

Abstract

Taken the Beiyun River in Beijing river basin (from Shahe Reservoir to Yangwa Dam) as the study area, 19 sampling sites were selected to monitor the water quality of Beiyun River in October, 2013. The types of pollution and temporal and spatial characteristics of COD were recognized. Based on activated sludge model (ASMs), combined with aerobic respiration measurement and physical-chemical method, biodegradation of component in Beiyun River was analyzed by using BM-Advance breathing apparatus. The result shows that there was no obvious trend of COD, and the water quality of most sampling sites was beyond class V. Biodegradable COD (BCOD) was higher than un-biodegradable COD (UBCOD). The bio-degradation of COD was not good. Based on the water pollution characteristics, the sampling sites were classified into 3 categories with system clustering method. Category 1 was located in the upstream and downstream of Beiyun River. The main component was the soluble inert fraction (S_I), Category 2 was near the dam and the main component was the slowly hydrolysable COD fraction (X_S). Category 3 was located in the midstream, and the main component was the particulate inert fraction (X_I). According to the PCA results, the first principal component of water quality involved TN、TP、 NH_3 -N. The second principal component included readily biodegradable COD fraction (S_S) and the particulate inert fraction (X_I). The third principal was heterotrophic bacteria (X_H) and the forth was the soluble inert fraction (S_I).

Beiyun River; COD fraction; biodegradability

The Regional and Structural Equilibrium Analysis of Grey Water Footprint in China Based on Gini Coefficient

Sun C Z, Bai T J

Center for studies of marine economy and sustainable development of Liaoning Normal University,
Dalian, 116029, P. R. China, suncaizhi@lnnu.edu.cn

Abstract

Based on calculating grey water footprint in 31 provinces of China from 1997 to 2013, we select the population and GDP as indicators, and use the Gini coefficient to study the spatial and structural equilibrium of the grey water footprint of China during 1998-2013 in this paper. The results suggest that (1) In terms of regional equilibrium, the balance of economic grey water footprint is worse, at the same time, the proportionality of the eastern regions in the economic grey water footprint and western regions in the population grey water footprint is relatively low; (2) In structural equilibrium respect, the equilibrium of economic grey water footprint has reached the "big gap" range, and the proportionality of economic grey water footprint of both agriculture and industry is poor, in the meanwhile, the equilibrium of the economic grey water footprint of the life has declined significantly in recent years; (3) From the point of view of the marginal effect, we could improve the overall equilibrium by reducing the grey water footprint of the heavily polluted regions of the West and the agricultural grey water footprint of each province, and promote the improvement of the equity of China's water environment effectively. At last, aiming at the concrete problems of the balance of the grey water footprint in China, we put forward some suggestions to reduce the grey water footprint and improve the equity of the water environment in China.

Analyzing and Simulating Response of Soil Moisture-Groundwater to Continuous Light Rainfall Events in a Lowland Paddy Field with Shallow Groundwater Table

Hai Yang, Chuanhai Wang, Jingbo Chen, Xiaohua Xiang

Hohai University, Nanjing, 210098, P. R. China, yhasan@163.com

Abstract

After long-term cultivation, artificial deposition, irrigation and leaching, paddy soil profile generally shows clear and unique layered structure with poor permeability and a high content of clay, which makes the regime of infiltration complicated. Additionally, the shallow groundwater table (GWT) affects the soil water transformation as water infiltrates through the soil profile. In such circumstances, the unsaturated zone and saturated zone should be regarded as a continuum. In this paper, the response of soil moisture and groundwater to rainfall is studied simultaneous based on the field data in the past two years in a lowland paddy field in Taihu Lake basin. To weaken surface ponding effect, several continuous light rainfall events with different antecedent soil moistures while similar GWT levels are selected. The results of four soil moisture profiles show that the response time of soil moisture at different depth differs greatly when the top 40cm height soil is very dry, which infers the presence of preferential flow paths in some surface layers and great variability of dry soil structure in the field. The GWT level rises when the surface layers are not saturated nor the soil moisture adjacent to the GWT responses. The trapping and compressing air in the surface layers may change the vertical pressure head distribution, pushing the capillary fringe water into the GWT. When the surface soil is relatively wet, the infiltration process seen from soil moisture response appears uniform while the GWT still rises in advance. Considering the effect of trapping air and capillary fringe transport, we modified the module in Hydrus-1D model to simulate the soil moisture-groundwater response. The results showed the modified version simulated better than the original one compared with the measured process.

soil moisture; groundwater; shallow groundwater table; paddy soil; capillary fringe; Hydrus 1D

Assessment of Ground Water Level for Future Use: A Case Study of Haryana, India

Mehtab Singh

Profesor of Geography, M.D.University, Rohtak, Haryana,India, msrana241@gmail.com

Abstract

Advancement of agriculture has led to peculiar situation in northern India. In some areas, ground water is depleting fast where as in other, ground water is threatening the very existence of crops due to rising of ground water. The present study has been carried out in Haryana which is one of the most agri-productive state of India. Some of the districts have witnessed a fall in the ground water level as much as 7 metres during last 10 years. At the same time , ground water level in other districts is with in 3 meters from the surface. Monitoring the quality of groundwater in agriculture intensive areas is as important as assessing its quantity. Uncontrolled extraction without commensurate recharge and heavy leaching of pollutants from pesticides and fertilizers has resulted in pollution of groundwater. Hence, The mapping of ground water level will help to understand the spatial variability over an area on the bases of such studies. Secondary data has been used to study the spatial patern of ground water level as well as the quality of ground water. The spatial distribution maps for level of ground water and quality of ground water were prepared in GIS environment using Quantam GIS.

Ground Water; Monitoring; pollutants; recharge

CFSv2-based Seasonal Meteorological Drought Prediction over the Low Latitude

Highland

Yang Lang

School of Resources Environment and Earth Science, Yunnan University, Kunming, China, 650091, langyang@ynu.edu.cn

Abstract

Drought in southwestern China, especially durative drought over the low latitude highland, will seriously affect the utilization of water resources and hydropower resources development in our country. Therefore, research on seasonal drought and flood prediction over the low latitude highland has very important significance and application value for flood control and drought relief, water resources planning and management. NCEP Climate Forecast System version 2 seasonal precipitation prediction is used to calculate six-month standardized precipitation index (SPI6), which is used as the primary drought indicator to measure the medium-term meteorological drought. To fully understand the potential and limitation of CFSv2 in predicting seasonal drought over the low latitude highland, this study investigated how the seasonal drought predictive skill varies with multiple lead-times and spatial scales. The predictive skill was then assessed by the correlation coefficient between observation-based SPI6 and CFSv2 forecast-based SPI6 during the period 1982-2008. Through this analysis, we will better understanding the capability of CFSv2 in seasonal meteorological drought prediction, which can help us to better manage water resource over the low latitude highland.

Changing Climate and Indigenous Community: An Odyssey of Leh's Water Scarcity to Stress

Singh, Devinder

Associate Professor, Department of Geography, University of Jammu, Jammu-180006, Jammu & Kashmir, India.

devinder_jmu@yahoo.co.in

Abstract

This work is concerned with the changing human nature relationship in the glaciated mountain ranges in Ladakh in Western Himalayas. By taking a case study of rapidly growing Leh town, located in the semi-arid Ladakh region and sustained largely by the glacier-fed small streams, it demonstrates how combined factors of climate and social change have been influencing the flow of water across urban landscape and reshaping human and nature relationships. The emerging relationship exhibits the ways indigenous community is treading the path vulnerable to unsustainability and water stress. The traditionally designed water networks are being replaced by technologically supported administrative networks. Historically, water resources fed by the glaciers have played a key role in the origin and spread of settlements in Ladakh region and indigenous society displaying human wisdom evolved indigenous sustainable water management system. This study assumes greater significance in the light of projections of water shortages in the world's glaciated mountain ranges (Bury, et.al, 2013) due the climate change and societal forces. Methodologically, this work draws upon both intensive and extensive methods. Besides, realizing the fact that water histories have enormous power and insight (Wescoat, 2013: 408), this inquiry employs historical geographic perspective to unfold how communities in different levels of cultural development organized their life around water in this fragile ecological setting.

Comparison of IDW and Physically-Based IDEW Method in Hydrological Modelling for Large Mountainous Watershed, Northwest China

Lanhui Zhang, Chansheng He, Jinlin Li, Yong Wang, Zhongfu Wang

Key Laboratory of West China's Environmental System (Ministry of Education), College of Earth and Environmental Sciences, Lanzhou University, Lanzhou, 730000, China

Abstract

Topography and spatial patterns of landscape significantly affect spatial distribution of atmospheric processes, and in turn hydrological modeling, especially in high elevation, mountainous watersheds of arid regions. This study incorporates a physically-based inverse distance and elevation weighted method (PBIDEW) and an inverse distance weighted method (IDW) into a distributed conceptual hydrological model, Distributed Large Basin Runoff Model (DLBRM) to assess the impacts of topography on hydrological modeling at watershed scale. The PBIDEW considers the impacts of topography using month-dependent parameters in its interpolation of meteorological variables while the IDW method doesn't. Both the IDW and the PBIDEW methods are evaluated and compared in hydrological modeling at different spatial resolutions in the upper reach of the Heihe River Watershed, Northwest China. Results show that the IDW method does not sufficiently account for the spatial variability of the precipitation as the PBIDEW method does. Considering the impacts of topography and using month-dependent physically interpolation parameters, the PBIDEW method seems more suitable in data lacking, high elevation, and topographically complex mountainous watersheds in arid area. In addition, it is important to evaluate the performance of interpolation methods at different spatial resolutions and finer temporal scales (e.g. seasonal or monthly) for more accurate hydrological modeling at watershed scale.

Dangerous Ice Phenomena on the Lowland Rivers of European Russia

FrolovaN.L. AgafonovaS.A., SazonovA.A. MagritskyD.V. KireevaM.B.

Lomonosov Moscow State University, Faculty of Geography, 119991, LeninskieGory, GSP-1, Moscow, Russian Federation;
frolova_nl@mail.ru

Abstract

In Russian climate, population and economy security is often limited by dangerous ice phenomena. It is not just ice jam floods, but also about the processes that lead to violation of operating conditions of various facilities (water intakes, roads, bridges) and damage hydraulic structures and fleet. Currently, the rivers' ice regime characteristics change under the influence of both natural (primarily climatic) and anthropogenic factors. Changes of these characteristics have been analyzed in detail on the basis of observations of 300 hydrological stations for the period from 1936 to 2013. Change of ice phenomena hazard is estimated. During high spring water on the rivers of the North of European part of Russia severe ice jams are regular occurrence. Our investigations showed that climatic changes of the last decades led to noticeable changes of the water and ice regime of the rivers. Now we often observe the long periods of freezing up which are followed by formation of sludge ice jam and coming to significantly later freeze-up at high water levels. Break-up during the winter period are now frequent. The last catastrophic flood in this area was observed in the spring of 2013. For an assessment of danger of the hydrological phenomena in the period of high waters and formation of ice jams on the northern rivers of Russia the questions connected with an assessment of probability of such events, calculation of duration and depth of flooding at various water levels with an assessment of the corresponding economic damage are considered. Modeling of formation of maximum water levels and flooding of the territory in the period of a high water and formation of ice jams was carried out by means of the Russian program complex "Flood" on the basis of the numerical solution of the two-dimensional Saint-Venant equations.

Abstract

Understanding and assessing the effects of extreme drought on agricultural ecosystems is a key step toward minimizing drought-related yield losses and impacts. In this study, we analyzed the spatiotemporal characteristics of drought in the North China Plain (NCP) based on the Standard Precipitation Evapotranspiration Index (SPEI) and also examined the impacts of drought on winter wheat and summer maize. An overall drought trend and a wetting trend were detected in Henan Province and Shandong Province, respectively, during the winter wheat growing season, whereas a wetting trend was dominant in the NCP during the summer maize growing season. Moreover, the drought episodes clearly revealed the evolution of drought from summer and autumn drought in the 1980s and autumn and winter drought in the 1990s to winter and spring drought in the recent decades. Our results also suggested that the year-to-year variations in the detrended SPEI could explain well the extensive fluctuations in the yields of both crops between the late 1990s and the earlier 21st century. However, considerable differences in the responses of the agricultural crops to different lags of the SPEI were observed, and the most correlated time scale increased with advancement of the winter wheat growth stage. In addition, the correlations between winter wheat yield and SPEI in three sub-periods were relatively stable, whereas all time scales except for a 1-month lag exhibited a substantial decreasing trend in the relationship between summer maize yield and SPEI in its growing season.

Environmental Analysis of the South Cubatão River Catchment through the Use of GIS and Geographical Categories

De Sá Motta Lima, Alex

Federal University of Santa Catarina, Florianópolis, Brazil, alex.geoufsc@gmail.com

Abstract

The South Cubatão River Catchment located in Santa Catarina, Brazil, is responsible to provide water for 700.000 inhabitants. Although the importance of this hydrological basis are known, the expansion of urbanism, agriculture, planted forests and pastures are affecting terrestrial ecosystems, presenting the greatest reduction of pioneer formations, riparian and the Atlantic forests, increasing the water flow and decreasing the water quality in the rivers of this region.

The dynamics of land use and land cover changes and its impacts in the water resources are being well explored through the use of geotechnologies (remote sense and GIS) combined with the water quality and hydrologic flow monitoring. This kind of work is justified by the growing need for natural resources management in the south part of Brazil. However these technologies are not enough to understand the complexity of the water problem.

Based on a national and international methodological framework, the main purpose of this work is to define few geographical categories and environmental management's skills to explore the water issue in this catchment. Is the possibility to join the human, physical geography and geotechnologies for better understading of the environmental problems. The present work was a final thesis presented in 2016 to obtain the bachelor diploma in Geography.

Abstract

North Caucasus is one of the most dangerous parts of Russia in terms of hydrological risks. During last decades a rise in frequency and intensity of river floods is observed in North Caucasus that is considered to be caused by recent climate change. On the one hand a rise in mean annual temperature provokes an increase in glaciers melt rate, and on the other hand a rise in precipitation sum contributes to the process through more frequent rain flooding. According to this in order to predict possible future trends in extreme hydrological events in the context of climate change it is essential to estimate contribution of different nourishment sources in rather complicated flow forming processes in the alpine part of North Caucasus.

A study was carried out for Djancuat river basin that was chosen as representative for Northern Caucasus during International Hydrological Decade. Simultaneous solution of water, isotopic and ion balance equations and energy balance modelling of ice and snow melt was used to separate Djancuat river hydrograph by such nourishment sources as ice melt, seasonal snow melt, rain precipitation, base flow. The study allowed to obtain new results on river runoff respond to glaciers melt regime, seasonal redistribution of melt water due to accumulation ability of the glaciers as a prerequisite of the formation of extreme hydrological events.

Abstract

The changing climate and future variations in floods and water availability across China during 2070-2099 under Representative Concentration Pathway 2.6 (RCP2.6) and RCP8.5 are studied. We analyze the discharge simulations from hydrologic models forced by the Global Climate Model (GCM) outputs of the Coupled Model Intercomparison Project Phase 5 (CMIP5). The outputs are provided by the Inter-Sectoral Impact Model Intercomparison Project (ISI-MIP). The results show that: (1) the intensities of floods increase during 2070-2099 under RCP8.5 relative to those during 1971-2000; (2) water availability decreases in southern China, and increases in northern China under RCP8.5, but changes negligibly under RCP2.6; (3) more intense precipitation extremes in the future cause more severe floods over China. The negligible change in mean precipitation and the increase in actual evapotranspiration bring about a decrease in the water availability in southern China; and (4) projections of increasing precipitation extremes are more consistent among different GCM outputs compared to mean precipitation.

Abstract

The Loess Plateau is located in the upper and middle reaches of the Yellow River valley. In this paper, our researches on hydro-ecology in the Loess Plateau over the past 10 years are briefly introduced, focusing on the water behaviors, ecological effects and optimal regulation. (1) Soil moisture characteristics in deep soil profiles and groundwater recharging processes by precipitation, in which the preferential flow played an important role. (2) The internal connection of crop production with water consumption and WUE was elucidated based on an elasticity index. (3) The water balance and its optimal management on rainfed cropland were studied, such as the components and coupling relations of precipitation use efficiency chain, the optimal crop-water-fertilizer coupling supplies, etc.. (4) The method of watershed hydrological assessment. Under the framework of the Budyko hypothesis, a modified formula of the first-order approximation for assessing the contribution of climate change to runoff, and a semi-empirical formula of the controlling parameter for water balance of a watershed were put forward. (5) The processes of watershed hydro-ecology and their responses to climate change and human activities. Results showed that river runoff volume in the watersheds was reduced significantly, in which the human activities played an important role; the watershed hydrological variability would be enlarged in the future due to intensified extreme climate events like rainstorm. Enhancing research on hydrological ecology is of significance in agricultural development and ecological construction in the loess plateau where water resources shortage has been considered to be a major restricting factor.

Hydrograph Separationmethod Issues for Different River- Station in Mongolia

Enkhtuya.M¹, Oyunbaatar. D², Soninbayar.J²

¹Institute of Geography –Geoecology, Mongolia, minenhee@gmail.com

²Information and Research institute of Meterology, Hydrology and environment, Mongolia

Abstract

This study aim was at understanding of separation of annual hydrograph into surface and groundwater components. Daily discharge data of different river-stations in Mongolia and different flow years are used to run the selected software and method. The Boughton's two-parameter filter algorithm and simple linear methods are used to separate groundwater component of annual hydrograph. Results of separation are discussed and compared to each other. The two-parameter filter algorithm provide physically better results in terms of temporal variation of groundwater components and percentage of the groundwater source expected to be higher than pervious linear estimation results by 10-20 percent. Further more detailed study and analysis are required with use of more comprehensive data in terms of spatial and temporal variation such long term annual hydrographs or selected river systems with different physio-geographic conditions. Also to improve the results of separation is needed to calibrate different parameters with local data set and under local condition.

Modeling Urban Floods in a Changing Climate: From Reconstructing the Past to Projecting Future Risks

ChangH, Hue D.¹, Helaire L, Talke S.A.²

¹Department of Geography, Portland State University, Portland, 97201, USA, changh@changh.pdx

²Department of Civil and Environmental Engineering, Portland State University, Portland, 97201, USA

Abstract

The city of Portland, Oregon, USA has historical records of flooding dated back to the mid-19th century. Located at the confluence of the Willamette and Columbia Rivers, the city has historically been exposed to large floods from both rivers. Climate change in the region is projected to bring more intense winter storms with higher temperatures, possibly leading to more intense flooding on the Willamette such as the 1996 rain-on-snow event. Combined with an earlier spring snow-melt on the Columbia (the largest river in the Pacific NW and 30th largest in the world), climate change may exacerbate flood risks in the future. Using archival river data and flood maps, we develop and calibrate two modelling tools, Delft 3D and HEC-RAS. The simulations allow us to re-assess present-day and historical flood risk. Next, using downscaled climate change scenarios from CMIC5, we project future changes in flood risks under different land management and climate scenarios. The integrated modelling approach offers potential synergies and trade-offs in urban flood risk management.

Pattern of Drinking water Availability and use in Assam, India: A Geoenvironmental Study

Kalita Nripendra Ram

Dept. of Geography, B. Borooah College, Guwahati-781007, Assam, India nrkgu@yahoo.co.uk

Abstract

The state of Assam covers an area of 78438 sq. Km and its population according to 2011 census is 31,205,576. Due to heavy rainfall in the sub-Himalayan region as well as in the valley portion, Assam is endowed with rich water resources potential carried by an elaborate river system consisting of the Brahmaputra, Barak and their large number of tributaries and as ground water reserve. The main source of drinking water for the people in the state is ground water. Here, annually replenishable ground resources occur in large alluvial deposits of the Brahmaputra and Barak river. In this paper an attempt is made to study ground water potential of the state and its spatio-temporal distribution and to estimate the present status as well as future scenarios. In order to estimate the status of water availability in the state, hydrogeomorphological studies based on satellite as well as conventional data have been carried out. The study related to water use will be primarily based on secondary data sources. The collected data is analysed using appropriate computer assisted analytical procedures. The analysed data will be presented through a series of maps, tables and graphs using appropriate cartographic techniques. The study is expected to generate considerable scientific data necessary for drinking water planning and development in the state. The study will help also help in understanding the problems and prospect of drinking water development and management in the state in the background of its unique geoenvironmental and socio-economic setting.

Key words:

Spatial Perspective of Drinking Water in Rural Haryana: A Case Study of Village Panghal, District Hisar

KULDEEP SINGH

Ph. D Research Scholar, Department of Geography, Panjab University, Chandigarh, kuldeepgeography@gmail.com

Abstract

The supply of safe drinking water, most important basic needs of life, is currently the major challenge before the governments in developing countries including India. Rapid growth of population, competing demands, pollution and depletion of water sources have posed serious problem before the policy-maker and planners in our country. After 73rd Constitutional Amendment (1992) and Swajaldhara programme (2002) the government gave the responsibility of management of drinking water to local bodies such as Gram Panchayats.

In Haryana, 65 per cent population live in 6642 villages (Census, 2011). Haryana is one of the foremost states to provide piped water supply to its all villages by 1992. But there is a significant change in sources of drinking water used by rural population. In 1981 a majority of rural households (53 per cent) use well water as a source of drinking water, whereas in 2011 main source of drinking water was tap with 63 per cent households (Census of India).

The objective of the present study is to find out the variation in drinking water sources among various caste groups and to find out temporal change in sources of drinking water from 2011 to 2016 and to study the determinants.

The study area of the present study, Panghal village, lies in Hisar district of Haryana. The climate of the district is characterised by its dryness and extreme temperature and scanty rainfall. According to Census of India (2011), 82 per cent households of village use tap as a source of drinking water but in 2016 it reduce up to 69 per cent. Whereas use of borehole increased up to 17 per cent from 0.5 per cent in 2011. The present study is based on primary and secondary data both. Arc map will be used to show spatial pattern.

Spatial-temporal Variation of Soil Moisture Based on In-Situ Observations and Remote Sensing Application in the Qilian Mountain, China

Bai X., Zhang L.H., Wang Y.B., He C.S., Liu G.H.

Center for Dryland Water Resources Research and Watershed Science, Key Laboratory of West China's Environmental System, Ministry of Education, College of earth and environmental science, Lanzhou University, Gansu Lanzhou, 730000, China, baix2010@lzu.edu.cn

Abstract

Soil moisture links the atmospheric precipitation, surface water, and groundwater, its spatial-temporal variability influences ecological processes and the river flow. We established the soil hydrological observation system with 36 in-situ soil moisture observation stations in the Qilian Mountain, Northwest China. Subsequently we analyzed the spatial-temporal variability of soil moisture in the study area, and results show that: 1) Significant differences existed in soil moisture content among the different vegetation types, particularly between shrubs and other types of vegetation's; 2) In the 0 ~ 70 cm layer, soil moisture increased first and then decreased with the depth, and the largest variability occurred on the surface layer; 3) on the daily scale, temporally soil moisture was low in the morning and higher in the afternoon; seasonally, soil moisture was highest in the summer and the lowest in the winter; 4) Spatial distribution of soil moisture was affected by rainfall and soil hydraulic properties. Then based on MODIS data, the improved ATI and TVDI model were used to calculate the soil moisture in the Qilian Mountain for each month, 2014. The results show that: 1) ATI and TVDI model for soil moisture inversion in Qilian Mountain looks feasible; 2) 10 ~ 20cm layer soil moisture inversion result expresses best; 3) During the rainy season, soil moisture is closely related to altitude, and varies from extremely wet to extremely arid, while in the dry season, soil moisture is low overall. These findings provide important information for eco-hydrological research in the Hexi Corridor, Northwest China.

Using Isotope Method on Determination of Groundwater Age for Feasible

Utilization of Water Resource in Arid Region of Mongolia

B.Erdenechimeg, G. Udvaltssetseg, M.Rinzaan, Z.Bayambasuren

Institute of Geography and Geo-ecology, MAS, Department of Water Resources and Water Utilization, Ulaanbaatar

15170, Mongolia, erdenechimegb@gmail.com

Abstract

The water resources can be distributed unevenly throughout the country depending on geological and topographical conditions of the country. Mongolia is situated in the southern part of the north hemisphere and plays an important role in originating natural water resource. However, the southern part of Mongolia lacks surface water resources and annually fourtimes lower than world's average. The amount of precipitation that fall in the South Gobi region of Mongolia is very limited thus only groundwater resources are used with very small recharge rate. If the consumption of the groundwater resources exceeds the ecological capacity, this will have a negative impact on this arid region.

This paper presented the results of research on determining groundwater origin, its age and recharge rate by using ^{18}O , ^2H , ^3H , ^{14}C isotope method. This was part of research "Evaluation of groundwater resources in large depressions in the Gobi region" and provided recommendations for an adequate utilization rate of water in the arid region of Mongolia. The isotope analysis was undertaken in the nuclear laboratory of Geological and Geophysical Institute of Beijing, China.

The result of isotope study showed that the groundwater age was between 11063-25900 years in the artesian well and deep borehole located in Sain-us and Bor huuvur depressions and recharge rate was lower than 0.7-2.1 mm/year, but the groundwater age was younger in the dug well, and recharge was 89.1 mm/year.

groundwater age; groundwater recharge; ^{18}O ; ^2H ; ^3H ; ^{14}C isotope method

WALRUS–Paddy Model for Simulating Hydrological Processes of Lowland Polders with Paddy Fields and Pumping Stations

Renhua Yan ^{1,2}, Junfeng Gao ^{1,*}, Jiacong Huang ¹

Nanjing Institute of Geography and Limnology, Chinese Academy of Sciences, Nanjing 210008, P. R. China, yrh036@163.com

Abstract

Simulating the rain-runoff process in lowland polder will lead to improvements to hydrological modeling of entire floodplain catchments. The lumped Wageningen Lowland Runoff Simulator (WALRUS) provides an efficient and reliable model for simulating the hydrological processes in lowland catchment with shallow groundwater. However, this model needs to be improved before being applied to Chinese polders, which have multiple land use types and pumping stations. This study proposes an improved version called WALRUS-paddy that accounts for the discharge from multi-sources, including drylands, paddy fields, residential areas, and water areas. A water management scheme is incorporated to control the irrigation and drainage operation in paddy rice fields and the groundwater flow between the paddy field and the adjacent dryland is considered. In addition, a new stage-discharge relation function is introduced to represent the discharge process of the polder with pumping stations and culverts. Then, the model is validated in the Jianwei polder of east China. The modeled results agree well with the observed discharge and show that the improved model can provide good estimates of the discharge in this polder district. Thus, the improved model is feasible and helpful for water resources management of Chinese polders.

lowland polder; hydrological processes; multi-type land use; paddy field; pumping station

Watershed Hydrologic Research in Arid Regions: Advancement, Opportunities and Challenges

Chansheng HE^{1,2}, Lanhui ZHANG¹, Baoqing ZHANG¹ and Juan GU¹

¹Center for Dryland Water Resources Research and Watershed Science, Key Laboratory of West China's Environmental System (Ministry of Education) Lanzhou University, Lanzhou, 730000, China, he@wmich.edu

²Department of Geography, Western Michigan University, Kalamazoo, MI, 49008-5424, USA.

Abstract

Arid areas account for approximately 41 percent of the global land surface, and support over 2.5 billion people. Understanding spatial and temporal distribution of hydrological process at the watershed scale is essential for effective management of water resources to ensure sustainable regional development in arid regions. This paper reviews recent advances in watershed hydrological research, particularly applications of remote sensing, GIS, and simulation models in estimating rainfall and snowmelt, evapotranspiration, soil moisture, groundwater, discharge and storage at the watershed scale. Subsequently, the paper discusses opportunities and challenges in watershed hydrological research and suggests that 1) long term, detailed spatial coverage, high quality in-situ observation data need to be collected and assimilated with current regional and local datasets to advance watershed hydrological modeling; and 2) regional/watershed hydrology and water resource models need to be developed to integrate components of climate, economy, ecology, and water consumptions through international collaborations to support water resource policy/decision making at the regional/watershed scale.

Analysis Drought Pattern in the Upstream of the Heihe Watershed by Palmer

Drought Severity Index

YANG L.X, HE C.S

Center for Dryland Water Resources Research and Watershed Science, Key Laboratory of West China's Environmental System, Ministry of Education, College of earth and environmental science, Lanzhou University, Gansu Lanzhou, 730000, China, yanglx2014@lzu.edu.cn

Abstract

Based on the meteorological data from the 4 meteorological station (Qilian, Yeniugou, Tuole, Sunan) in the upper reaches of Heihe basin during 1960-2009, the Palmer Drought Severity Index (PDSI) method is applied to calculate the annual, quarterly and monthly Palmer drought index at each station, respectively. And the drought frequency of annual and seasonal of each station is counted further. The results show that the PDSI in the upper reaches of Heihe basin has a changing trend of decreasing-increasing-decreasing in the past 50 years. According to the statistical analysis, the drought level in the upper reaches of Heihe basin is mostly concentrated in slight drought and medium drought. In the seasonal scales, the serious drought mainly occurred in summer and autumn. Compared the PDSI with the SPI at different time scale, it suggests that the SPI is easy to leave out some heavy drought processes, while the PDSI still accurately reflect some drought events. Therefore, the PDSI is more systematic and targeted than SPI to describe the drought in the upper reaches of Heihe basin.

PDSI index; drought evaluation; drought frequency; the Upstream of the Heihe watershed

Characteristic of Soil Moisture under Different Artificial Forestland in the Loess Hilly Regions of the Loess Plateau, Northwestern Shanxi

JunjieNiu

Research Center for Scientific Development in Fenhe River Valley, Taiyuan Normal University, Taiyuan 030012, China

Abstract

The northwestern of Shanxi Province as a typical arid and semiarid region on the Loess Plateau, is the ecological transition zone and fragile environment area. The special natural environment and climate conditions have led to a lot of ecological problems in the region, such as droughtland, and poor soil and fragile ecological environment. Soil water is the main source demand for vegetation growing water, is the main influencing factors for limiting the vegetation type, growth and distribution. The study area of artificial vegetation soil moisture has made great important scientific significance for soil drying causes. It can evaluate the soil reservoir, guide the rational configuration of vegetation in the area model and avoid the green desert environmental problems. This research adopts the field sampling and laboratory analysis, combines with a variety of statistical methods. It studies systematically soil moisture content of different soil depth in the northwestern Shanxi multiple county various vegetation types. Besides, it put forward the development of the area suitable for vegetation types of artificial vegetation types in the area of different soil drying and dry layer distribution. The study area of this topic is in northwestern of Shanxi, such as Wuzhai, Lanxian, Pianguan, Zuoyun, Youyu, Shechi, Kelan. Taking the local common seabuckthorn, *caragana korshinskii* and for comparison of populus *simonii*, larch, *pinus tabulaeformis*, elm, willow, abandoned, farmland as experimental samples, and using descriptive statistics analysis, variance analysis, correlation analysis and spatial variation analysis model, it analysis the differentiation characteristics of soil moisture content in the depth of 0-6 m and 0-10 m and the distribution regularity of soil dry layer in different vegetation types in different seasons. Studying the soil moisture content change of different age of *korshinskii* forest as a whole, it reveals the characteristics of vertical distribution and degree of soil drying and the relationship between the various levels of different age of *korshinskii*, soil moisture forest age *korshinskii*. It compared the soil moisture content change of different vegetation types in different depth of soil layer and factor correlation in northwest mining and non-mining area. And evaluate the effects of mining on different vegetation types of soil moisture. By building the appraisal model of soil water deficit, it quantitatively evaluate the deficit of soil moisture of different artificial forest land and reveals the relative stem characteristics of soil water deficit and drying of different layers in different artificial forests in the

northwestern of Shansi. It also studied the soil moisture of jujube and apple in depth of 4 m and analyzed the differences of available water resources and the type of availability soil moisture in Yanchuan county, Shaanxi province. And the soil moisture availability, dry soil layer and the water cycle, etc were analyzed. This topic research results had important scientific significance to find out the different artificial vegetation soil moisture vertical stratification in northwestern Shanxi in different parts of the thickness differences, water content and the cause of the different areas of soil drying and the change of farmland soil moisture content and the change of farmland temporary dry layer, and provided a basis for the regional ecological reconstruction and agricultural production and theoretical support.

Northwestern Shanxi Province; soil moisture; vegetation types; soil drying; ecological reconstruction

Climatological Characteristics of the 2013-2014 Water Crisis in São Paulo

Metropolis, Brazil

Muniz Miranda G, Reynard E, Milano M, Guerrin J

University of Lausanne, 1015 Lausanne, Switzerland, gmunizmi@unil.ch.

Abstract

São Paulo metropolitan region experienced an acute water crisis in the years 2013 and 2014, which resulted in interruptions of drinking water supply for some cities and industries. In the literature, this crisis is generally attributed to an exceptional decrease in rainfall coupled with high temperatures. After characterizing the regional climate, this study analyses the long-term evolution (1944-2015) of rainfall and flow rates in the Piracicaba River, one of the basins that supply water to the metropolis. Rainfall, temperatures and flow rates of the 2013-2015 period are then confronted to the climatic and hydrological norms, and the long-term evolution of climate and hydrology. The main conclusion is that the 2013-2015 period has indeed been relatively dry, but is not unique according to the past 70 years. The origin of the 2013-2014 water crisis is not only related to the climatic situation, other factors must be addressed.

Abstract

Population, the branches of economy, biocenosis in the mouths of rivers flowing into the Caspian Sea are very vulnerable and susceptible to the adverse effects of hazardous hydrological-morphological processes and ill-conceived economic activity. The results of long-term and comprehensive research show that inundations, low-water periods, water pollution, storm surges and wind-induced down-surges, water logging, rapid reformation of sea-coast line, riverbeds and degradation of lakes, storm waves threaten safety of peoples and its health, economic activity, ecological communities and natural objects in the mouths of Caspian rivers, especially the Urals, Volga, Terek, Sulak, Kura and Sefidrud. List of hazardous hydrological-morphological processes and their characteristics depend on the location, size and structure of the river mouth area, on the river regime. In addition, water management activities can regulate these processes. Large-scale and rapid sea-level fluctuations also influence the intensity of some of the processes. All of these issues are discussed in detail by the authors of the report, the patterns and characteristics of hazardous hydrological and morphological processes are defined.

Detecting spatial and Temporal Changes in flood Cycles within the Two Largest Freshwater Lakes of China from Time-Series MODIS Imagery

Hu Yanxia¹, Huang Jinliang², Du Yun²

¹Hubei University, Wuhan, 430062, P. R. China, yanxiahu@hubu.edu.cn

²Institute of Geodesy and Geophysics, Chinese Academy of Sciences, Wuhan, 430077, P. R. China

Abstract

Dongting Lake and Poyang Lake are the two largest freshwater lakes in China, and both are the most important regulation lakes of the Yangtze River. Hydrological regimes have appeared some changes in these two lakes after the impoundment of the Three Gorges Reservoir. This study was aimed at finding out the action mechanism of the Three Gorges Project on flood cycles in the two lakes. A methodology was proposed to detect spatial characteristics of flood cycles (including inundation areas, start dates, end dates, and durations of floods) based on MODIS imagery between 2000 and 2015. The estimated flood cycles were validated via comparisons with hydrological data, and there was excellent agreement between them. The results showed that annual inundation areas in the two lakes experienced a downward trend after the impoundment of the Three Gorges Reservoir. Specifically, inundation areas presented a decrease in flood periods but an increase in normal periods. Furthermore, annual start/end dates of floods and those in normal periods all occurred ahead of time, except for those in flood periods. These variations in flood cycles will probably break the present wetland vegetation pattern and lead to forward succession of wetland plants in the two lakes. This study enabled an understanding of seasonal and annual changes in the hydrologic environment of Dongting Lake and Poyang Lake from a global viewpoint, and can provide scientific guidance for the optimal scheduling of the Three Gorges Reservoir and the enhancement of ecosystem services of wetlands.

Abstract

Evapotranspiration (ET) is an important component of water cycle, but its measurement in high altitude mountainous region is quite difficult, resulting in the poor understanding of the temporal and spatial variations of actual ET in high altitude mountainous region. In this paper, a weighing lysimeter was used to measure the hourly ET in a grassland in the Pailugou Catchment, in the Upper Reach of Heihe River, northwest China. Based on the measured data, diurnal variations of grassland ET over different periods were analyzed. Results indicate: (1) snow and ice sublimation appeared during the freezing period, with a very different diurnal variation pattern: during the period without sunshine, the amount of snow and ice sublimation was nearly constant; when the highest global radiation and lowest relative humidity appeared in the same period, the amount of snow and ice sublimation increased a little. (2) The early growth period was a period when snow and ice started to melt, at which snowmelt evaporation and soil evaporation occurred at the same time. (3) The growth period had the highest evapotranspiration rate. Due to continuous rainfall events, maximum and minimum ET values appeared at the same hour. (4) The late growth period mainly produced on soil evaporation, producing 3 peaks in diurnal variation, which is different from only one peak in both the early growth and growth.

Key words:

Upper reach of the Heihe River; Weighing lysimeter; Grassland evapotranspiration; Diurnal variations

Observed Changes in the Frequency and Magnitude of Floods in the Eastern Part of Romania

Zaharia L., Ioana-Toroimac G., Costache R., Ciobotaru N., Neculau G., Minea G., Crăciun E.

University of Bucharest, Faculty of Geography, Bucharest, Romania, zaharialili@hotmail.com

Abstract

The study of floods is particularly important for flood risk management and sustainable development strategies design. This work aims to identify possible changes in the frequency and magnitude of floods in some watersheds located in the eastern part of Romania, a region heavily affected by damaging floods in the last decades. The considered watersheds are spread over different landform (mountains, hills, plains), and have surfaces varying from less than 100 km² to over 2000 km². They are more or less engineered.

The work is mainly based on the statistical processing (frequency and trends analysis) of monthly and annual maximum discharges data series, recorded between 1971 and 2010 at the gauging stations (belonging to the national hydrometric network) controlling the selected watersheds.

The results showed no significant trends in the magnitude of annual floods, but some cyclicity has been identified, including periods with high peak flows (before 1980, after 1990, and especially after 2000) and low peak flows (1980-1990). The decennial analysis of the frequencies and magnitudes of major floods (with the peak higher than the average of the annual maximum discharge) revealed a relatively heterogeneous situation. Nevertheless, after 2000, an increasing trend of peak flows and of the number of large floods has been identified, especially in the watersheds without dams and reservoirs.

Excepting the climate variability and the reservoir design, intensive deforestations performed after the fall of the communism period (starting with 1990) had an important role in the change of floods' features in the study area.

³Jiangxi Provincial Key Laboratory of Poyang Lake Comprehensive Management and Resources Exploitation, Jiangxi Normal University, Nanchang 330022, P. R. China

Abstract

In this paper, the spatial variation characteristics of Poyang Lake during the flood period and receding period were analyzed by using the 50 years' waterlevel data from the seven gauging stations of Poyang Lake, the area of Poyang Lake flooded area from year 2000 to 2013 was calculated by using the MODIS high time resolution characteristics, combined with the water level observation data of Poyang Lake, the difference of Poyang Lake water area between receding period and flood period in recent years and the difference characteristic of Poyang Lake flooding range before and after sandexcavation was both analyzed. The study indicates that: (1) The absolute value of Poyang Lake water level gradient decreased with the increase of the water level and it tended to zero when the water level arrived about 14 meters, the absolute value of water level gradient in flood period was greater than that in with precede water period within 14 meters of the water level; (2) The changes of Poyang Lake area was consistent with the changes of its water level, Poyang Lake area at the high water level was about 4 times greater than that at the low water level, the waters of Poyang Lake would have the corresponding changes in the form at different water levels. However, due to the complexity of Poyang Lake hydrological conditions, the water area of discrete degree at different water level segment was not consistent; (3) The difference of water area of flooding range in different water level segment during flood period and recede period was not the same when they were at a similar water level, this difference was affected by the incoming water, the Yangtze River backwater and the Poyang Lake and form; (4) The river channel become wider and the lake shore form become irregular in the main engineering area after the sand mining ship entering Poyang Lake for jobs, and these phenomena were more and more obvious with the pushing back of date.

NDVI; hydrological data; water level gradient; sand mining

The Evaluation of the Risk of Absolute Maximum Runoff of the Small Mountainous Rivers in the Republic of Armenia

Vardanian T. G.

Yerevan State University, Yerevan, Armenia, email: tvardanian@ysu.am

Abstract

Risk assessment is the determination of qualitative and quantitative indicators' change's degree of risk which are closely correlated with each other. Taking into account these approaches, the differences and similarities of assessment principles and final goals the quantitative method has been applied for risk assessment for absolute maximum runoff of rivers. The quantitative method of risk assessment is based on mathematical statistics and probability theories.

This paper explores the evaluation of the risk of absolute maximum discharges of the rivers in Armenia. The evaluation of the risk of the absolute maximum discharges of the rivers

in Armenia shows that a tendency of reduction of the risk level is observed, and this means that the degree of probability of disastrous floods makes up 0,1%, or they can repeat once per 1000 years. The values of coefficient of changeability or variation (C_v) of absolute maximum discharges of the rivers in Armenia fluctuate from 0,3 to 1,5. The mean value of the coefficient is 0,6. For the absolute maximum discharges of the rivers such values are rather small, in other words one could conclude that the absolute maximum discharges of rivers are quite stable, and they have relatively small risk values.

Abstract

As the most populous country, China has become the second largest economy, the largest energy consumer and producer in the world. Energy demand and consumption will continue to increase as a result of socio-economic development which will continue to be mainly driven by industrialization and urbanization in the coming decades. Water and energy are fundamental resources to economic growth and human life and their inextricably linkage termed as Water-energy Nexus has become a hot research and policy topic in recent years around the world. Energy production and electricity generation heavily rely on water and this is particularly a grand challenge in China with severe and uneven water stress across the country. This study applies the Virtual Water Approach to developing a comprehensive understanding of water use for energy in China at the provincial level, aiming to contribute to integrating water implications and constraints into energy policies and strategies.

As a dominant water user in China, the energy industry is only smaller than agriculture in terms of water use and the largest water user among all industrial sectors. Through a water-extended multi-regional input-output model (WATER-MRIO model), virtual water flows embedded in energy trade among provinces are evaluated. This study also illuminates energy development policies and water management policies and then builds five scenarios of electricity generation, presenting combinations of cooling technology upgrading, adjustment of power generation mix and change in the spatial distribution of thermal power plants. Finally, the study evaluates water use under various energy development strategies.

Exploring the Use of Deep Level Gold Mines for Underground Pumped Hydro Energy Storage in Karst Areas of South Africa

Frank Winde¹, Ewald Erasmus, Friederike Kaiser

Mine Water Re-Search Group, North-West University, Vanderbiljpark, South Africa, frank.winde@nwu.ac.za

Abstract

The paper explores the feasibility of using deep level gold mines in dolomitic karst areas of South Africa to install underground pumped hydro energy storage (UPHES) schemes which not only prevent the post-mining flooding of mine voids and the associated pollution of overlying karst aquifers but also generate much needed peak-demand electricity. Hosting the deepest mines in the world the identified study areas provide shafts of up to 4 km depth allowing to exploit a significantly larger hydraulic head than commonly utilised at surface schemes. Possible combinations with the storage of renewable energy (wind, solar) and the extraction of geothermal energy are also discussed. Apart from assessing the economic feasibility of the concept the paper also covers peculiarities of its design (e.g. sourcing feed flow from overlying aquifers), selected engineering aspects (e.g. dimensioning of the turbines, diameter of pipes etc.) and the required underground infrastructure (e.g. storage capacity). Given the generally conducive conditions and encouraging preliminary results it is strongly recommended to conduct an in-depth investigation to assess the feasibility of implementing a world's first UPHES in South Africa. The concept has the potential to prevent abandoned mine voids becoming costly, long-term liabilities by turning them into assets that generate clean water and energy as critical elements for sustainable post-closure development in a water- and energy stressed economy.

Fluctuations of Lake Baikal Level: Past Changes and Current Problems

Garmaev E.Zh, Andreev S.G., Ayurzhanaev A.A.

The Baikal Institute of Nature Management SB RAS, Ulan-Ude, 670047, Russia, garend1@yandex.ru

Abstract

In the report the results of dendrochronological reconstruction of Lake Baikal level from 1750 to the present are shown. In the Baikal region the trees (*Pinus Sylvestris* L.) are reliable proxies of total precipitation amount variability, which determines the change in lake level fluctuations. Reconstruction identifies periods of high lake levels (1775-1795, 1825-1835, 1852-1856, 1865-1870) and a sufficiently long period of low levels (1795-1805, 1840-1850), which are in good agreement with the available historical data. It is revealed that the Lake Baikal level fluctuations have a 30-year periodicity.

In the report the consequences of modern extreme fluctuations of Baikal level caused by the commissioning of HPP cascade on the river Angara and low water content of the rivers flowing into the lake are examined. The high level contributes to erosion processes of coastline, including the unique ecosystem of shallow waters in the northern Baikal. Low levels appear in a negative impact on the organisms living in the coastal zone, groundwater regime change, sprawl algae colonies, etc. It concludes with recommendations for the conservation of the lake level regime.

Projected Impacts of Climate Change on Hydropower Potential in China

Liu, XC, Tang, QH, Cui, HJ, et al.

Institute of Geographical Sciences and Natural Resources Research, Chinese Academy of Sciences, A11, Datun Road,
Chaoyang District, Beijing, China, tangqh@igsnr.ac.cn

Abstract

Hydropower is an important renewable energy source which is sensitive to climate change. Future changes and associated uncertainties in China's gross hydropower potential (GHP) and developed hydropower potential (DHP) are projected using simulations from eight global hydrological models (GHMs) forced by five general circulation models (GCMs) with climate data under two representative concentration pathways (RCP2.6 and RCP8.5). Results show that the annual GHP is projected to change by -1.7 to 2% in the near future and increase by 3 to 6% in the late 21st century. The annual DHP is projected to change by -2.2 to -5.4% and -1.3 to -4% for 2020-2050 and 2070-2099, respectively. GHP will increase in northern China, but decrease in southern China where numerous reservoirs and large IHCs currently are located. The area with the highest GHP in Southwest China will have more GHP, while DHP will reduce in the regions with high IHCs (e.g., Sichuan and Hubei) in the future. The largest decrease in DHP (in %) will occur in autumn or winter, when streamflow is relatively low and water use is competitive. Large ranges in hydropower estimates across GHMs and GCMs highlight the necessity of using multi-model assessments under climate change conditions. This study prompts the consideration of climate change in hydropower development and operations in China.

Abstract

Hydropower plants have been developed quickly to meet the demand of electricity and reduce of the carbon emission, especially in developing countries. When the dams are reconstructed, some trees, grass and soil will be submerged and the organic matters are decomposed and mineralized to CO₂ and CH₄ and emit to atmosphere. Despite the greenhouse gas emission from the water-air interface, large amounts of sediment deposit in the reservoir bottom and some amounts of carbon are preserved in the sediment. It is important to evaluate the carbon stock in the sediment deposits for the comprehensive understanding of carbon cycle in hydropower reservoirs. Xiaolangdi Reservoir, the last reservoir in the main Yellow River, was investigated in the current study. The volume of sediment deposition was up to approximately 3.07 billion m³ in October 2014 when the mainstream delta vertex moved to 16.4 km upstream of the dam. During the operation of water impoundment and sediment detention for the Xiaolangdi Reservoir, the particle organic carbon (POC) concentrations in the reservoir water body ranged between 0.43 and 693.75 mg L⁻¹. The spatial and temporal variations of carbon in the sediment deposits and water body increase the calculation uncertainty of carbon sequestration in the reservoir bottom. The large sedimentation volume and high POC in water body indicate a potentially big carbon sink in the Xiaolangdi Reservoir.

Sedimentation; Carbon Cycle; Particle Organic Carbon; Xiaolangdi Reservoir

Water Surface Temperature Variation for Large Lakes across the Tibetan Plateau Using MODIS Imagery

Song, K.S, Yuan Y, Ma J.H, Mu G.Y, Du J

Northeast Institute of Geography and Agroecology, CAS, Changchun, 130102, P.R. China, songks@iga.ac.cn; Tel: 86-431-85542364.

Abstract

Lake surface temperature plays a vital role for aquatic ecosystems in both ecological functioning and biogeochemical processes. Remote sensing provides a powerful tool for assessing lake water surface temperature (LWST) variation, particularly for water bodies located in remote areas. In this study, MODIS land surface temperature (LST) product were used to examine LWST of Tibetan lakes with area > 50 km². Altogether, 3620 daytime and 3720 nighttime imagery from MODIS/Terra and Aqua in clear-sky conditions from 2000 to 2015 were used. Qualified imagery data were built through visual inspection, and QA flags stored in the imagery products. In situ meteorological data and WST measured over lakes were used to validate the MODIS LST product, and the MODIS LST products matched well with in situ measured bulk lake water temperature ($R^2=0.91$). It turned out that the LWST ranged from 11 to 28°C for lakes across the Tibetan Plateau during hot month starting mid-July to mid-August in day time. Generally, large and deep lakes (e.g., Nam Tso) located at high altitude show low temperature, while these shallow ones (e.g., Gas Hure Lake) sitting at low elevation present high temperature. Likewise, large LWST variation was observed at night time, ranging from 1.5 to 20°C. Our results also indicated that large diurnal LWST differences were exhibited (4.2-14.8°C), where water bodies with large volume demonstrate small diurnal difference (around 4°C); on the contrary, shallow ones exhibit relatively larger diurnal difference (around 15°C). In addition, lakes showed large diurnal difference in spring (8.53°C) than that in fall (4.81°C) for all lakes investigated. In summary, lake elevation, morphology, water supply source, and local air temperature are the major factors regulating LWST variations for lakes across the Tibetan Plateau.

MODIS imagery; bulk temperature; Tibetan Plateau; water supply source

Reduced Energy Consumption in Wastewater Treatment Plants by Optimizing the Control of Effluent Quality

Elfrida M. Carstea, Gabriela Pavelescu

National Institute of Research and Development for Optoelectronics, INOE 2000, Magurele, Romania,
elfrida.carstea@inoe.ro

Abstract

Society faces an urgent need to adapt to reductions in energy consumption due to climate change, population growth, urbanisation and pollution. Wastewater treatment is an energy-intensive operation, caused by the vigorous aeration in the activated sludge process (ASP), contributing to over 55% of the energy costs associated with wastewater treatment. The quality of wastewater is generally assessed using biological oxygen demand (BOD), chemical oxygen demand (COD) and total organic carbon (TOC). However, these global parameters depend on expensive or time-consuming methods. Consequently, water utilities often over-aerate in order to ensure compliance with final effluent standards. This means that energy can be saved if an effective method is used for effluent quality monitoring. This study aims to use fluorescence spectroscopy as an innovative and robust method to monitor the chemical and microbiological quality of wastewater. The removal efficiency of OM in five wastewater treatment plants was investigated. Fluorescence was measured on samples collected from the inlet, primary settling tank, secondary settling tank and outlet. The measurements were correlated with BOD, COD and TOC. Moreover, the potential of using portable fluorimeters was explored in comparison to laboratory-based instruments. Good correlations were observed for wastewater samples between fluorescence intensity and BOD ($r = 0.78$), COD ($r = 0.90$) and TOC ($r = 0.79$). The results indicated that fluorescence spectroscopy could be used for continuous, real-time assessment of DOM removal efficiency in wastewater treatment plants. A Comparative Evaluation of Stone Spout Management systems in Heritage and non-Heritage Areas of the Kathmandu Valley, Nepal

TripathiMIRA, HugheyKEN, RennieHAMISHG

PhD student, Lincoln University, Christchurch, New Zealand, mira.tripathi@lincolnuni.ac.nz

Abstract

Management of water resources is a major challenge throughout the world and in many long-established societies people still use traditional water harvesting and management techniques. Despite often being seen as efficient and cost effective, traditional methods are in decline or have been abandoned in many countries. Nevertheless, traditional approaches continue to be useful in some countries such as Nepal. The extent to which such traditional measures, in this case via stone spouts, may survive modernization, while fulfilling socio-cultural and other needs is the focus of the research. The research develops an understanding of the socio-cultural and other values of stone spouts for the people of urban and peri-urban heritage and non-heritage areas of the Kathmandu Valley to help ongoing sustainable management of remaining spouts. Three research questions are addressed: the impacts of changes in social and cultural norms and values; development activities; and, the incremental and ongoing loss of traditional stone spout infrastructure. A meta-theory framework has been developed which synthesizes Institutional, Attachment, Central Place and Common Property theories, which form analytical lenses for the mixed-method research approach. From the exploration of the meta-theory approach, it was found that no spouts are in pristine condition but those in non-heritage areas are in better condition than those in heritage areas. "Utility value" is the main driver that still motivates people to conserve spouts.

Stone spouts; Meta-theory; Social and cultural norms and values

Applicability Evaluation of Climate Forecast System Reanalysis Data for Hydrologic Prediction: A Case Study in the Behe River Basin

Sheng Hu, Mingming Cao, Haijun Qiu, Jinxi Song, Jiang Wu

Urban and Environmental Science, Northwest University, Xi'an 710127, China, husheng198800@126.com

Abstract

In recent years, global reanalysis weather data has been used more often during the hydrology modeling around the world, but the results of simulation vary greatly. To discuss the applicability of CFSR (Climate Forecast System Reanalysis) data in the hydrologic prediction of watersheds, taking Bahe River Basin as a case, the paper uses two types of weather data (the conventional weather data and the CFSR weather data) to establish SWAT hydrologic model, and makes use of such evaluation methods as regression analysis, Nash-Sutcliffe Efficiency (NSE) and Percent Bias (PBIAS) to compare the simulation effect of both data. At last it puts forward CFSR weather data correction method. The research result shows: (1) although the quality of the CFSR weather data has some problems, it basically achieves a satisfactory result in the hydrologic simulation of Bahe river basin. The R^2 of the simulated results is above 0.50; the Nash-Sutcliffe Efficiency (NSE) is above 0.33; $|\text{Percent Bias (PBIAS)}|$ is below 14.8. (2) The simulated flow of the CFSR weather data is higher than the observed flow; the reason may be that there are more rainy days and the rainfall intensity is much stronger according to the estimation of day-to-day rainfall data by CFSR, which leads to the data will simulate a higher base flow and flood peak discharge in terms of the Water Balance. (3) The relation between the CFSR rainfall data and the observed rainfall data of Bahe river basin can be displayed by a power exponent equation: $y = 1.4789x^{0.8875}$ ($R^2 = 0.98$, $P < 0.001$); the fitted equation of each CFSR station varies slightly from others. The equation just lays the theoretical basis for correction of the CFSR rainfall data.

China and Trans-Pacific Partnership Agreement Members: Consideration under the Framework of Virtual Water Trade of Agricultural Products

Yu ZHANG, Jinhe ZAHNG, Guorong TANG, Hongsong PENG, Chang Wang, Huan Hu

School of Geographic and Oceanographic Sciences, Nanjing University, Nanjing 210023, P. R. China, zhangyu_0730@163.com

Abstract

Water scarcity has become increasingly severe in China. Virtual water trade is a useful tool to alleviate water shortage. China has a close relationship with Trans-Pacific Partnership Agreement (TPP) members. This paper focuses on a comprehensive study between China and TPP members from the perspective of virtual water trade of agricultural products and completes a diachronic analysis from 2001 to 2014. The results show that China was in trade surplus in relation to the virtual water trade of agricultural products with TPP members. The exported virtual water amounted to 7 billion m³/yr. while 63 billion m³/yr. was embedded in imported products. The trend that China exported virtual water per year was on the decline while the imported was on a rising trend. Virtual water trade between China and the TPP members generally conforms to the virtual water strategy, but with specific countries still need to adjust. The largest exported virtual water flow of China was to Japan while the largest imported was from Malaysia. Not all of the exported products had comparative advantages in virtual water content. Imported products were excessively concentrated on soya beans, palm oil and cotton. From the ethical point of view, TPP members were classified into four types in terms of “net import” and “water abundance”: mutual benefit countries; unilateral benefit countries; supported countries; and double pressure countries. Virtual water strategy can alleviate Chinese water shortage as well as TPP members, is beneficial for promoting water saving and adjusting trade structures.

virtual water; agricultural product; trade partner type; Trans-Pacific Partnership Agreement

Contribution of Recycled Moisture to Precipitation in Oases of Arid Central Asia Based on Stable Isotope Approach

Wang S, Zhang M

College of Geography and Environmental Science, Northwest Normal University, Lanzhou, 730070, P. R. China,
geowang@126.com

Abstract

Terrestrial moisture contributed by surface evaporation and transpiration, also known as recycled moisture, plays an important role in hydrological processes especially across arid central Asia. The stable hydrogen and oxygen isotopes can be used for water budget analysis to calculate the contribution of recycled moisture to precipitation between two locations along the moisture flow. Based on a three-component isotopic mixing model, the moisture recycling in oasis stations of arid central Asia during summer months is assessed. At large oases of Urumqi, the proportional contribution of recycled moisture to local precipitation is approximately 16.2%, and the mean proportions of surface evaporation and transpiration are $5.9\% \pm 1.5\%$ and $10.3\% \pm 2.2\%$, respectively. At small oases like Shihezi and Caijiahu the contribution of recycled moisture is less than 5%, and the proportion of surface evaporation is much less than that of transpiration. The vegetative cover in arid central Asia is generally sparse, but the evapotranspiration contribution to precipitation cannot be ignored at the widely distributed oases. The oasis effect shows great variability depending on locations and water availability for evapotranspiration.

French Rhone River and Its Basin Harnessing

Jean- Paul BRAVAR¹, Zongxia Cai²

¹Jean- Paul BRAVAR, Professor of Department of Geography, UNIVERSITE LUMIERE-LYON II; Hydrologist. Jean-paul.bravard @wanadoo.fr

²Zongxia Cai, Professor of Institute of Geographic Sciences and Natural Resources Research, CAS; Visiting professor of Department of Geography, UNIVERSITE D' ORLEANS. zongxia.cai@wanadoo.fr

Abstract

The Rhone has been a typical fierce river in European history. The untamed river, suffered from fierce currents, shallows, and floods, was a mythological symbol of force, power and ruthless. Then, the Rhone became a tame river that made great contributions to the recent industrial revolution and modern economic development of France. 20 hydropower stations were built along the 500 km river reach, which set a world record in cascade development of river hydropower station. However, the era of cascade development of river hydropower station ended when France shifted its energy policy to rapid development of nuclear power since 1980s. Claims of environmental protection grew heater and heater. The Rhone basin harnessing entered an age of sustainable development by restoring and protecting natural ecological environment. Dams and dikes were torn down; wetlands and floodplains showed up. Perception, policy and technology about river basin harnessing changed dramatically during development of complicated relations between human beings and rivers. The Rhone basin harnessing centered on a development strategy of healthy river and river health, which provides precious experiences for Chinese river basins harnessing.

Institutional Responsibilities to Recharge Ground Water, Need for Policy

Implementation: A Case Study of Banaras Hindu University Campus

Shakya C.

Department of Geography, Faculty of Science, Banaras Hindu University, Varanasi-221005, U.P., INDIA

chanchal.shakya@rediffmail.com

Abstract

In some large cities of India situated in the Ganga plains, one of which is Varanasi, 50% of water supplied is tapped from the ground and hence ground water levels are falling down deeper and deeper year after year. Besides a large military cantonment and a large manufacturing unit (Diesel Locomotive Works), there are three large universities one of which is Banaras Hindu University, in Varanasi City. These institutions draw groundwater to meet their various needs. Banaras Hindu University alone occupying about 1270 acres, accommodating about 20000 residents (students and staff) is drawing about 20.00 lakhs liters per day through its 20 boreholes. Of course, it doesn't take a single drop of water from Corporation's supply. Since, it is extracting enormous volume of water every day; it should harvest rain water to recharge the ground water. Just as there are many policies/guidelines for individuals, there are policies/guidelines for institutions to tap ground water as well as responsibilities to recharge ground water. The current study emphasizes on, how much its campus can harvest out of the rain it receives and on the structures to impound the harvested water for some campus uses as well as recharge sources. Surface water yield is worked out and measures are suggested to take harvested water into the recharge structures.

Groundwater; Extraction; Recharge; Institutional Responsibilities

Landscape-Hydrological approach to Water Management of Lake Baikal Catchment

Area

Olga Gagarinova

Sochava Institute of Geography SB RAS, Russian Fed, whydro@irigs.irk.ru

Abstract

The development of any area is related to water resources supply, which is a topical issue at the moment. The water reserves of Lake Baikal are a strategic resource for the Asian region and that makes the urgency of environmentally oriented development of its catchment area.

Water management, including the water resources use and water protection measures do not provide conditions for reproduction and preservation of high quality of natural waters, as they are directed primarily at preventing and eliminating the effects of negative water and environmental situations.

Previous studies on the Baikal Natural Territory show that the river basin management should be based on knowledge of the laws governing the formation and transformation of natural waters in the context of internal changes and external influences.

Landscape-hydrological approach to the research of the Lake Baikal catchment area reveals hydrological properties of individual landscapes, especially the formation of water-resource and hydro-ecological potentials of the territory. Analysis of the physical and geographical conditions, combined with environmental and socio-economic features of the territory makes it possible to identify the areas that are most important in the formation of qualitative and quantitative characteristics of natural waters, show the areas experiencing the greatest burden on the environment, identify areas with different resistance to human and natural impact. Functional zoning is the basis for the development schemes of water resources use and protection, the general development direction of the Baikal Natural Territory according to the water factor.

catchment; surface water; landscape; hydrological processes; ecology

Machanism of Groundwater Recharge Using Hydrochemical and Isotopic Methods in Guanzhong Basin, China

Kong, F.H.¹, Song, J.X.^{1,2,*}, Zhang, Y.¹, Xue, Y.¹.

¹College of Urban and Environmental Sciences, Northwest University, Xi'an 710127, P. R. China,

²State Key Laboratory of Soil Erosion and Dryland Farming on the Loess Plateau, Institute of Soil and Water Conservation, Chinese Academy of Sciences, Yangling 712100, P. R. China, Feihek@stumail.nwu.edu.cn

Abstract

Based on stable isotopic (δD and $\delta^{18}O$) and hydrochemical data, the sources of groundwater recharge and factors controlling them in the Weihe River basin in Shannxi province, China was demonstrated. Comparative analyzed isotopic values and hydrochemical data between surface water and groundwater of south tributaries, north tributaries and the main stream, it is found that the main hydrochemical pattern of the study area is $HCO_3^- \bullet SO_4^{2-} - Ca^{2+} \bullet Na^+$ and precipitation is the main recharge source of groundwater. For the west area of Jinghe River of Weihe River basin, the dominate ions are HCO_3^- , Ca^{2+} and Na^+ , and in autumn the groundwater recharges from surface water while in winter the groundwater mainly accept the recharge from precipitation. For the east area, the pattern of groundwater recharging from the surface water and groundwater discharge into surface water exist in different place. For the south tributaries, in autumn the water type is $HCO_3^- \bullet SO_4^{2-} - Ca^{2+}$ while in winter the water type is $HCO_3^- - Ca^{2+} \bullet Na^+$ and the groundwater recharges mainly from the surface water in downstreams of south tributaries; and the groundwater recharges from the surface water seepage and precipitation infiltration occur in upstreams. For the main stream, the water type is $HCO_3^- \bullet SO_4^{2-} \bullet Cl^- - Na^+ \bullet Ca^{2+}$ and the recharge relationship is complicated and frequent.

Key words:

groundwater recharge; hydrochemistry and isotopes; the Guanzhong basin

Patterns of Natural and Anthropogenic Changes in Runoff of the Rivers Flowing Into the Seas in the Russian Arctic

Magritsky D.V., Frolova N.L.

Lomonosov Moscow State University, Faculty of Geography, 119991, Leninskie gory, GSP-1, Moscow, Russian Federation; magdima@yandex.ru

Abstract

Climate change together with water use generates changes in the runoff, morphological processes, hydro-ecological conditions, hydrological hazards, etc. Large-scale changes in the runoff of large rivers may affect the regime of the seas, and possibly the processes in the atmosphere. Runoff of the Arctic rivers is particularly prone to the current changes. Long-term fluctuations of annual runoff of such rivers in Russia have been established to contain alternation of periods with different runoff, upward trends. The trend exists due to increased runoff since the late 1980's - mid 1990's. As a result, the average runoff of most of the major rivers increased by 5–10% in 1976–2013, in comparison with 1935–1975. In the rivers of the North European part and Yakutia (except Kolyma), runoff increase is observed in all seasons. The volume of runoff in spring-summer flood increased on average by 2.5–7%. In the Ob and Yenisei, regulated by reservoirs, runoff reduction is observed over the entire period of open channel, in the Kolyma – only in the flood season. All the rivers demonstrates positive winter runoff dynamics, especially Ob (+17.9), Yenisei (+68.4), Lena (+46.3) and Kolyma (+169%). Water consumption in the Arctic river basins does not affect the fluctuations of river inflow in the Arctic seas, whereas the operation of large reservoirs has changed the regime of the rivers in the Kola Peninsula and in Karelia, as well as of the Ob, Yenisei, Lena and Kolyma rivers. The studies were performed due to RSF (No.14-37-0038).

Spatial Patterns and Driving Factors of Conversion Coefficients for Free Water Surface Evaporation of the Two Different Pan Evaporation in China

Li yanzhong

Institute of Geographic Sciences and Natural Resources Research, CAS, China, liyz_egi@163.com

Abstract

Pan evaporation measurement is considered as the most practical, stable and reliable method to estimate free water evaporation. Determining the conversion coefficient (K_p) among various pans evaporation is necessary for scientifically detecting and comparing evaporation trend. Using the evaporation data of the 20 cm pan ($\phi 20$) and the E601B from 541 Chinese meteorological stations from 1998 to 2001, this study estimated monthly variation and spatial distribution of K_p for the two pans evaporation, and explored its possible underlying mechanisms. Results showed that (1) the two pans evaporation shared similar spatial patterns, and exhibited good correlation. The K_p , with a great deal of geospatial heterogeneities, varied prominently from 0.46 to 0.92 with mean of 0.60 in warm season across China and 0.49 to 0.81 with mean of 0.66 in cold season in humid regions. Higher and lower K_p were detected in the southeast and northeast regions of China in warm season (May-September), while in southeast and east of humid area in cold season (October to April). Moreover, the K_p differed significantly by month, characterized by increase trend in warm season for all regions, and a continued increase to December or January and then decrease to April for humid regions. (2) The net radiation was the dominant climatic factor accounting for K_p variation with better correlation and stronger explanation power in most of regions, followed by the relative humid and vapor pressure deficit. The combined explanation rate was 23.1% with regional difference. (3) Although we found the overwhelming control of climate on K_p spatial variability, the climatic factors employed in this study explained a much smaller fraction, indicating more complicated mechanisms underlying the distribution of K_p , including pan area, water depth, installation. (4) Compared to global typical pans (Class A, GGI-3000, $\phi 20$), the E601B exhibited a better performance in depicting the free water evaporation and was recommended for estimating reference evapotranspiration and hydrological studies.

The Assessment of Ecological Restoration Effect of Comprehensive Treatment of Shiyangriver Basin Based on Gis

——As the Spatial and Temporal Variation of Groundwater Level in Minqin Oasis for Example

Hao YY, Xie YW

College of Earth Environmental Sciences, Lanzhou University, Lanzhou, 730000, P. R. China, xieyw@lzu.edu.cn

Abstract

Ecological restoration effect evaluation not only is the important way to judge the effect of ecological restoration, but also one of the hot spots of current research. Comprehensive Treatment of ShiyangRiver Basin (CTSRB) is one of the important measures for ecological restoration in Shiyang river basin, its main purpose is to restore the groundwater level in the Minqin oasis. In this paper, we used geostatistics and spatial analysis methods to study the spatial and temporal variation of groundwater level from 2000 to 2015. The results illustrate that in the study area, the groundwater level in Minqin oasis was declined sharply, which the largest drop of 5.15 m and the “water funnel” appeared and expanded gradually before CTSRB (2000-2005 a); afterwards, the groundwater level continue declined sharply and remarkably, which the largest drop even up to 34.82 m and thus that the “water funnel” deepening and expanding rapidly at the preliminary period of CTSRB (2006-2010 a); but by the later period of CTSRB (2011-2015 a), the groundwater level began to slowly rebound, which the highest rise up to 8.45 m and the area of the “water tunnel” began narrower more and more gradually. Thus it can be seen that CTSRB has a certain positive role about recovery of the groundwater level in Minqin oasis, but this impact has certain hysteresis effect and will be more pronounced in the coming years.

Using Different Parameterization Schemes to Assess the Changes and Variability of Seasonal River Flow in the Main River Basins of European Russia

Kireeva M., Frolova N., Rets E., Efremova N., Ezerova N., Dzhamalov R., Juk V. Evstigneev V.

Lomonosov Moscow State University, Moscow, Russia kireeva_mb@mail.ru

Abstract

New intelligence on the mechanism of seasonal and occasional flood formation has been achieved. Based on data for the period 1946-2015 yy. Changes in the coefficient of natural runoff regulation were identified. It is shown that the transformation of spring flood type is closely related to the other phases of the water regime. Mostly it connected with the changes in the characteristics of occasional floods in different seasons (spatially winter thaws). Statistical analysis shown, that these changes are various in different geographical regions. The role of peak flow increase in the central and in the southern sub regions, while on the north it decreases. Through the author's original program, based on the genetic daily hydrograph separation, according to the methodology of B.I. Kudelin, the calculations of seasonal flood characteristics were done. After that the parameterization scheme of these changes was created. The main selected parameters include maximum to the 5-day minimum ratio, seasonal peak in compared to flash flood maximum, the minimum flow during summer and winter for the annual. It is shown that, the most of the rivers is characterized by reduction in these rates exponentially. Series of the inequalities describing the state and variability of water resources have been developed.

The study was supported by the Russian Science Foundation (grant No. 14-17-00155) in data and materials and Russian Foundation for Basic Research (grant No. 16-35-60080) in methodology and calculations.

Abstract

Limited water resources are available for human use within a certain time and space. In this study, system dynamics (SD) and geographic information system (GIS) were combined to establish an evaluation index system. GIS method performs qualitative analysis from the perspective of space and SD method performs quantitative calculation about related water security problems from the perspective of time. We established a water security system model for Guizhou Province, China to analyze influential factors, main driving factors and system variation law using SD method. We simulated the water security system from 2005 to 2025 under four scenarios (Guiyang model, Zunyi model, Bijie model and concerted development model). The results demonstrate that: (1) The water resources of the three cities is secure in Guizhou Province. Four cities are situated in the basic security and two cities are situated in the insecurity from the space dimension of GIS through water security synthesis. (2) The major driving factors of the water security system in Guizhou Province include the agricultural irrigation water demand, soil and water losses area, ratio up to the Standard of water quality and the investment of environmental protection. The concerted development model is the best solution for water security system by 2025 in Guizhou Province under the four scenarios from the time dimension of SD.

Application of the Satellite System of the Earth's Gravity Field Measurement (GRACE) For the Evaluation of Water Balance in River Catchments

Frolova N.L., Zotov L.V., Grigoriev V.Yu., Sazonov A.A., Magritsky D.V.

Lomonosov Moscow State University, Faculty of Geography, 119991, Leninskie Gory, GSP-1, Moscow, Russian Federation;
frolova_nl@mail.ru

Abstract

Space-based Earth observing systems provided a substantially large amount of information to the scientific community in recent decades. One of the most important contributions of these data sets is their use to study Climate Change. Cumulative effects of redistribution of masses in the Earth system can be seen in the changes of the gravity field of the Earth. Gravity Recovery and Climate Experiment (GRACE) satellites, launched 17.03.2002 from Plesetsk, provide a set of monthly Earth's gravity field observations. GRACE data is very useful for hydrological and climatological studies, especially over large territory, not completely covered by the meteorological and hydrological networks, like Russia. Possible application of the satellite gravity survey data obtained under the GRACE for solving various hydrological problems is discussed. The GRACE-based monthly gravity field data are transformed into the maps of water level equivalent and averaged for the catchments of the largest rivers of Russia. The temporal variability of the parameter is analyzed. Possible application of the GRACE data for the evaluation of particular components of water balance within the largest river basins of the European part of Russia is discussed. After averaging over 15 large Russian rivers basins annual component shows amplitude increase since 2009. Trend component grows until 2009 and then reaches a plateau. It is mostly dominated by Siberian rivers. Map for the trend show gravity field increase in Siberia, at Black Sea and decrease over Caspian Sea since 2003. The studies were performed due to RSF (No.14-37-0038).

Estimation of Stream Flow Responses to Land Use Change in the Yan River Using SWAT Model

Yang K.J., Lu C.H.

Key Laboratory of Land Surface Pattern and Simulation, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, yangkj.12s@igsnrr.ac.cn

Abstract

This study quantified stream flow responses of the Yan River to land use change. As a key area of the Grain for Green Project implemented in 1999, the Yan River Basin, located on the Loess Plateau, has experienced substantial land use changes since then, and could induce a change in stream flow.

Firstly, the Soil and Water Assessment Tool (SWAT) model was parameterized and the modelling performance was evaluated by the Nash-Sutcliffe efficiency and Coefficient of Determination. Then, two land use maps in 1999 and 2010 were used to simulate the effect of land use change on stream flow. With same climate records of 1999-2010, annual stream flow was simulated under land use condition of 1999 and 2010, respectively; then the average value of annual stream flow was calculated and analysed. The results show that 1) SWAT model has relatively satisfactory modelling performance in the Yan River; 2) Land use change during 1999-2010 has induced a 1.52 mm stream flow decrease in the Yan River as well as reduction of the inter-annual stream flow variability indicated by decrease of the Coefficient of Variation from 0.42 to 0.39; 3) The differences of annual stream flow between two scenarios show negative linear correlation with annual stream flow amounts with coefficient of 0.86. Results of this study indicate that land use change have not only reserved more water but also enhanced the inter-annual dampening capacity of the hydrologic system in the Yan River.

stream flow responses; land use change; SWAT modelling; inter-annual variability

Integrated Assessment of Water Bodies in the Kharaa River Basin as a Prerequisite for IWRM Planning

Karthe D and the IWRM MoMo Project Team

Helmholtz Centre for Environmental Research, Magdeburg, Germany; daniel.karthe@ufz.de

Abstract

The Kharaa River Basin in Northern Mongolia was selected as the study region for a project aiming at the conceptualization and implementation of a model framework for integrated water resources management in Mongolia and neighboring regions of Central Asia. In this context, a multidisciplinary study on hydrology, hydro-morphology, climatology, water quality and aquatic ecology was conducted between 2006 and 2013. The results allow, for the first time in this region, the development of a science-based water management concept.

Key findings include the following:

- Climate change will most likely not have a major effect on the available water quantity. However, land use changes are likely to modify regional hydrological cycles. Deforestation in the headwater regions is specifically relevant in this regard.
- When compared to water bodies in other parts of the world, the water quality in the Kharaa and its tributaries is good to moderate. However, high fine sediment loads caused by grazing pressure in the floodplain and resultant riverbank erosion in the floodplains, and heavy metals released by mining activities and energy production are problematic.
- Ecologically, the river system is in a good to moderate state, but with a clear longitudinal gradient. Nutrient levels are increasing and elevated downstream of urban wastewater influxes. The accumulation of heavy metals in sediments and aquatic biota indicate that water pollution has reached levels that are relevant for aquatic ecology and potentially public health.

These findings are currently being introduced into river basin management planning in the region.

Abstract

The standardized FAO56 Penman–Monteith model, which has been the most reasonable method in most climatic conditions, provides reference evapotranspiration (ET_o) estimates for planning and efficient use of agricultural water resources. Response analysis is important to understand the relative importance of climatic variables to the variation of reference evapotranspiration. And more variables are used to analyze response of reference evapotranspiration, more helpful to cognition of ET_o response to climate change. In this study, a non-dimensional relative sensitivity coefficient was employed to analyze responses of ET_o to perturbations of five climatic variables in the watershed between Yangtze river and Huaihe river China. A 35-year historical dataset of daily air temperature, sunshine duration, wind speed, saturation vapor pressure deficit and atmospheric pressure in the watershed between Yangtze river and Huaihe river was used in the analysis. Results have shown that daily sensitivity coefficients exhibited large fluctuations in a year, and saturation vapor pressure deficit was the most sensitive variable in general for the watershed, followed by atmospheric pressure, air temperature, wind speed and sunshine duration. In the recent 35 years, variations of yearly sensitivity coefficients were more stability. Among all sensitivity coefficients, the average yearly sensitivity coefficient of wind speed and atmospheric pressure showed larger spatial variability. Uniform distribution of sensitivity coefficients for air temperature, saturation vapor pressure deficit and sunshine duration was also found, which was similar to the distribution of the three climate variables.

A New ‘Hybrid Complexity’ Approach to Modeling Changes in Estuary Hydrodynamics and Extreme Flood Levels at 10 to 100 Year Timescales

French, JR, Burningham H, Thornhill G

UCL Department of Geography, University College London, Gower St, London WC1E 6BT, UK, j.french@ucl.ac.uk

Abstract

The risk of extreme coastal flooding is expected to increase with climate change, especially in estuary floodplains susceptible to inundation during tidal surges. Estuary hydrodynamics are well understood but propagation of surges and extreme water levels can be modified significantly by changes in estuary morphology. We currently have only a limited ability to predict morphological change at time scales relevant to management of flood risk under climate change. Conventional (‘reductionist’) hydrodynamic and sediment transport models often perform poorly at longer timescales and estuary morphodynamics are increasingly modelled using ‘synthesist’ approaches that capture behaviour that emerges naturally at broader time and space scales. However, non-linear interaction between tidal hydrodynamics and morphology means that it is useful to retain some hydrodynamic complexity in models of estuary morphological change over 10 to 100+ year timescales. We present a novel approach to mesoscale estuary morphological evolution that combines 1D simulation of tidal channel hydrodynamics, parameterised 2D representation of tidal flat dynamics driven by fetch-limited waves, and more empirical representation of 2D variation in salt marsh morphodynamics. We use this in combination with a full 2D shallow water equation model to simulate changes in extreme flood levels at 100 year timescales that include the effect of changes in estuary morphology due to sedimentary processes and realignment of flood defences to accommodate sea-level rise.

Debris Flow Hazards Emergency Assessment Method and Its Application

Yan YAN, Peng CUI

Institute of Mountain Hazards and Environment / Key Laboratory of Mountain Hazards and Earth Surface Processes,
CAS, Chengdu, 610041, China, pengcui@imde.ac.cn

University of Chinese Academy of Science, Beijing 100049, China

Abstract

Emergency assessment is extremely useful in urban hazard reduction and post-hazard reconstruction at hazard prone region. It is also imperative to the development of sustainable society at mountainous countries. In this paper, we have developed a debris flow emergency hazard assessment method and its application. This method was based on the analysis of the unmanned aerial vehicle aerial photography data. From the aerial photographs, the information on sediment thickness and diameter of the large particles in debris flow deposition zone were extracted and analysed. This information allowed us to retrieve flow path, and dynamic parameters of debris flow including velocity, impact force, and momentum of debris flow. The availability of these debris flow parameter can be used to derive a quantitative analysis of destructive degree due to debris flow in its deposition area, as well as to carry out the rapid assessment of hazard. This proposed method could carry out dynamic inversion for specific location over the whole area, and make a quantitative analysis of the damage within the debris flow deposition zone after the hazards. The application of this method will be very instrumental for the post hazards relief and reconstruction operation. As a case study, the method is applied to the quantitative analysis of a specific debris flow event in Wenchuan earthquake area.

Geoarchaeology: Man and Environment in Past Times

De Dapper, M.

Ghent University, Department of Geography, Ghent, Belgium, morgan.dedapper@UGent.be

Abstract

The term 'Geoarchaeology' was first used in 1973 by BUTZER, a geomorphologist who did important research on archaeological sites in Egypt.

There are numerous definitions for Geoarchaeology and its related terms: 'Archaeometry', 'Bioarchaeology', 'spatial archaeology', 'Archaeological geology', 'Environmental Archaeology', 'Landscape Archaeology'. They are all formulated from a different point of view, giving away as much about the authors and time spirit of the definitions than about geoarchaeology itself. However, all of these definitions have in common the combination of geo-sciences and archaeology.

Geoarchaeology has often been described as a one-way relationship between the geo-sciences and archaeology. The 'geologic' arsenal is treated as mere 'auxiliary' tools which are only 'at the service' of archaeology. It is a 'one way' definition which does not stress the mutual interest between geo-sciences and archaeology. Indeed, Man himself is an important actor in the complex human-environmental relationships. BUTZER expresses this very well: "Human populations have always interacted with their environment in multiple ways, using it, shaping it, and devising alternate ways to bend its constraints – but also abusing it and sometimes degrading it. At the core of human history is a long tradition of persistence in the face of adversity and resilience in the throes of crisis". This statement will be illustrated by examples from research in Italy, Syria and Egypt.

Geoarchaeological research; Italy, Syria; Egypt

Geomorphic Constraints to Urban Development in National Capital Territory of Delhi (India)

Singh, Naveen Chandra

Department of Geography, M.M.H. (PG) College, Ghaziabad, Uttar Pradesh, India, 201009,

naveenchandrasingh@gmail.com

Abstract

Geomorphic setting, which plays a vital role in urban planning and development, is regrettably ignored in planning of most of the Indian cities. Town planners and policy maker are sufficiently unaware whether the land, which has been chosen for urban development, is geomorphologically suitable or unsuitable. Consequently some of the urban land shows a mismatch between adopted land use and geomorphic setting. The proper realization of the effects of geomorphic setting and surface processes may be helpful in classification of suitability of land for different urban uses. Delhi, which has an ancient origin, has been destroyed and built several times. Rapid population growth especially during last six decades has led to physical expansion of the city. Despite physiographical, topographical, hydrological and seismic constraints, Delhi continues to expand towards its periphery and much of the suburban area has been added into its urban limit. These constraints have become even more critical as the rate of urbanization increases. Therefore it becomes essential to analyze the geomorphic constraints to urban development of Delhi in order to measure the geomorphic capability of the area. The present paper attempts to find out topographical, physiographical, geological and hydrological constraints to urban development of Delhi by applying geomorphic information.

Human Adaptation Technology to River Bank Erosion in the Jia Dhansiri River, Assam, India: A Case Study of Five Villages

Sarmah, RANA

Department of Geography, Pandu College, Guwahati-12, India, ranasarmah2@gmail.com

Key words: Human Adaption, Bank erosion, Jia Dhansiri River

Abstract

This study is an attempt to examine the human adaptation technology to river bank erosion in the Jia Dhansiri River at five villages during a period of 15 years 2000-2015. The study adopted the method of superimposition of bank lines of variously dated maps and satellite imageries for examination of the bank erosion hazard and interview method through personal household survey using a questionnaire for examination of human adaption technology. It is found that more than 60% and 81% land area of the villages under study are engulfed by the river during 2000-'06 and 2000-'15 respectively. Thus, river bank erosion is found to be an extremely dominant fluvial hazard in the Jia Dhansiri River at five villages under study. This study reveals that bank erosion affected families living based on crops grown in own agricultural lands has been decreased from 89% to 65% during 2000-'06 and 65% to 45% during 2006-'15. Families living through earnings from paid agricultural labour has been increased from 6% to 21% during 2000-'06 and 21% to 22% during 2006-'15. Families who have opted secondary occupation after losing their lands on bank erosion has been increased from 7% to 13% during 2000-'06 and 13% to 32% during 2006-'15. It is also found that there were no families living based on tertiary occupation during 2000-'06, which has been increased to 2% during 2006-'15. It is examined that people of the five villages under study has responded to bank erosion hazard mostly by changing their occupation.

Abstract

Disaster risk reduction involves complex processes not only to mitigate, but to avoid the creation of new risks. Landslide disaster risk is particularly multifaceted since landslide controlling factors can be both, natural and human induced. Aiming at establishing risk communication strategies, in the municipality of Teziutlán, Puebla, Mexico, an area that has been historically affected by landslides, landslide risk perception analyses have been carried out. Such analyses were undertaken in Juárez and Xoloco, two neighbourhoods highly exposed to landsliding. Risk perception surveys were constructed by conducting in-depth interviews, followed by the application of a pilot study derived from in-depth interviews, and preparing the final version of the questionnaire accordingly. Questionnaires comprised more than 200 questions and covered five major topics: (1) Landslide experience; (2) Landslide risk awareness; (3) Exposure; (4) Preparedness; and (5) Risk communication and trust. In addition to risk perception analyses, field recognition and survey in both neighbourhoods was carried out by using an unmanned aerial vehicle (UAV), a DJI-Phantom 3 drone, in order to map the different degree of exposure to landslides. Results of the potential linkages between risk perception, particularly of exposure, and actual landslide exposure conditions, derived from the survey are presented in this paper.

Mapping of Global-Scale Landslide Susceptibility Based on GIS and Method of Logistic Regression

Lin L., Lin Q., Wang Y.

Academy of Disaster Reduction and Emergency Management, Beijing Normal University, Beijing, 100875, P.R. China,
linle@mail.bnu.edu.cn

Abstract

Using a self-built database of global landslides, this paper proposes a quantitative model for mapping landslide susceptibility based on logistic regression. After investigating explanatory factors for landslides in the existing literature, five factors were selected to model landslide susceptibility: relative relief, extreme precipitation, lithology, ground motion and soil moisture. When building model, 70% of landslide and non-landslide points were randomly selected for logistic regression, and the others were used for model validation. For evaluating the accuracy of predictive models, this paper adopts receiver operating characteristic (ROC) curve method. Logistic regression experiments on six datasets found all five factors to be significant in explaining landslide occurrence on a global scale. During the modelling process, percentage correct in confusion matrix of landslide classification was approximately 80% and the area under the curve (AUC) was nearly 0.90. During the validation process, the above statistics were about 80% and 0.85, respectively. Experimental outcomes for all six datasets were similar, which indicates that the model has strong robustness and stable performance. Existing studies of landslide susceptibility mapping have generally used qualitative methods based on expert knowledge and semi-quantitative methods. The accumulation of global landslide data makes it practical to mapping landslide susceptibility quantitatively. This quantitative assessment found that at a global scale, extreme precipitation dominates the occurrence of landslides and topographic factors are secondary. Soil moisture, which has not received much attention in quantitative studies, has a significant contribution on landslide occurrence.

Key words:

global scale; mapping; landslide susceptibility; explanatory factor; logistic regression

Risk Monitoring: Dynamics of Exposure to Mountain Hazards

Keiler M, Fuchs S, Röthlisberger V, Thaler T, Zischg A

University of Bern, Institute of Geography, Bern, Switzerland, margreth.keiler@giub.unibe.ch

Abstract

Disaster risk is continuing to increase, main drivers are environmental change influencing hazard processes, but also greater numbers of vulnerable people and assets located in exposed areas. Techniques to monitor risks and the effects of the risk reduction instruments are essential for improving disaster risk management. This study takes as starting point for risk monitoring a co-evolutionary perspective to understand the dynamics of exposure to mountain hazards in the European Alps. A spatially explicit object-based temporal assessment of elements at risk to mountain hazards (river floods, torrential floods and debris flows) in Austria and Switzerland is presented for the period 1919-2012. The assessment is based on two different datasets, (a) hazard information using legally binding land use planning restrictions, and (b) information on the building stock/residential buildings combined from different spatial data available on the national level. We discuss these dynamics trans-disciplinarily and focus on economic, social and institutional interdependencies and interactions between human and physical systems. The results show that some regions have a strong increase in assets exposed to hazards over the monitoring period, while other regions are characterised by a below-average development. The results indicate stable hot spots, which mirrors the topography of the countries, but also the different economic activities and political settings within the different regions. A co-evolutionary framework widens the explanatory power of multiple drivers to changes in risk and risk monitoring enables to support a change in natural hazard management from a structural, security-based policy towards an integrated, risk-based management system.

Spatial-temporal Dynamic Monitoring of Vegetation Recovery after the Wenchuan Earthquake

YANG W.¹, QI W.²

¹School of Water and Soil Conservation, Beijing Forestry University, Beijing, 100083, P. R. China, yang_wentao@bjfu.edu.cn

²Beijing Aerospace TITAN Technology Co., LTD, Beijing, 100070, P. R. China, qiww@otitan.com

Abstract

Major earthquakes can be important disturbances to mountain ecosystem. The spatial and temporal influence of such disturbances to post-seismic vegetation is unclear. This paper uses 16-day interval MODIS NDVI time series from 2000 to 2014 to track vegetation recovery processes after the Ms. 7.8 Wenchuan earthquake. To assess vegetation conditions, Savitzky-Golay filter and cross-correlogram spectral matching (CCSM) were used to overcome cloud and phenology influences. Then, change vector analysis (CVA) was applied to measure post-seismic vegetation recovery conditions for each year. Finally, trend analysis is carried out to classify post-seismic vegetation conditions into three recovery types: recovering, fluctuating and deteriorating. Spatial analysis shows that low elevation and southern slope aspects are favorable for post-seismic vegetation recovery, whereas vegetation at higher elevations above 3000-meter experience difficult recovery processes. These results demonstrate that major earthquakes may have long and important influences on high mountain vegetation, and more care should be taken to these locations after mountain disasters.

Abstract

Many small watersheds have been took measures of comprehensive control to reduce flood disaster and soil loss in recently years in Guangdong province. Now that was a problem how to evaluate the benefit of control. This paper reviewed construction rules of indicator system of benefit assessment for comprehensive management in small watersheds in China. Then according the characteristic of small watershed in Guangdong province, 4 benefit types (flood protection and disaster reduction, ecological, economic and social benefit) and 21 indices were chosen to evaluate the benefit of comprehensive control of soil and water conservation of Guangdong, using national standards, frequency in references, theoretical derivation, and selection of specialists. The study gave the method of data standardization and built the fuzzy comprehensive evaluation model. The model was used in a small watershed named Yao'an of Guangdong province. The result showed that: (1) chosen indices system and evaluation model can present the comprehensive benefit of soil and water conservation of small watershed, were suitable in the region of Guangdong province and the similar zone, and also the scientific basis of policy decision for government department. (2) Comprehensive whole benefit and four single benefit improved to varying degree from 2007 to 2013 in Yao'an small watershed, with the most increase in flood protection and disaster reduction benefit and economic benefit.

Changing Pattern of Channel Morphology of Alaknanda River in Srinagar Valley (Garhwal Himalaya), India

Chauniyal Devi Datt and Dutta Surajit

Department of Geography, HNB Garhwal University Srinagar (Garhwal), Uttarakhand India.

Chauniyal_devidatt@yahoo.co.in

Abstract

Srinagar is a famous cross road town along the Badrinath NH 58 of the Garhwal Himalaya, located at the left bank of Alaknanda River. The Alaknanda River is a most significant tributary of Ganga and forms an 8 km long and 3 km wide valley locally known as the Srinagar Valley. The purpose of the present study is to highlight the recent landform changes in the Alaknanda channel course after Kedarnath disaster 2013.

The disastrous Kedarnath flood completely changed the channel morphology of the Alaknanda river. The river changed its course at Srikot, SSB and Sriyantra Tapu. The lower terraces were silted by sands at Ranihat, SSB, Bhaktiyana and Sriyantra Tapu. A new depositional terrace is also formed just opposite of Sriyantra Tapu. New lateral channel bars, braided channels, back swamp, rapids, pools and river souls are identified in the channel course of the river. Shifting of channel course at Chauras is a very serious problem to the Garhwal University Campus. The river undercut the terrace scarp which is still in process. About 2-5 m silt was deposited on the lower terrace at SSB, and ITI. At Srikot river bed was upgraded to 4.60m during 2013 flood. Shifting of channel course of the river arises many problems in the valley. Out of these the natural landforms are changing into anthropogenic landforms. Urbanisation, sand and boulders mining, construction of dams, road, hydroelectric canal, etc are the prominent examples.

Distribution of Landslides on Each Landforms Unit Based on Geomorphological Approach in Merawu Sub-Watershed, Indonesia

Utama Gerry, Mardiatno Djati

Faculty of Geography Universitas Gadjah Mada, Yogyakarta, 55281, Republic of Indonesia, gerry.utama@mail.ugm.ac.id

Abstract

The Merawu Sub-Watershed is a part of Serayu Watershed located in Central Java Province, Indonesia. Exogenous processes that occur is very intensive such as rainfall, weathering and the arrangement of topography with steep slope and thick soil material to trigger the occurrence of landslides in this region. This study aims to 1). Identify the types of distribution of landslides that occurred on each unit of landforms, 2). Determining the level of potential landslides occurrence based on the density of landslides.

The research method is done by census aims to collect distribution of landslides data and types of landslides. Measurement of the thickness of soil by conducting transect method. The analysis is done by descriptively to explain the relationship between the distribution of landslides using geomorphological aspects morphology, morphogenesis, morphochronology, and morphoarrangement.

The results of this study showing a link between landforms and distribution of landslides. High potential for landslides on steep slope conditions, and soil characteristics is thick. Landuse evolved into one of the factors that influence the occurrence of landslides in Merawu Sub-Watershed.

landslides; geomorphological approach

Early-Warning Model for Clusteringshallow Landslides Induced Byextreme Rainfall in Southern Mountain Areas of China

Qinghua Gong, Guangqing Huang, JunWang

Guangdong Open Laboratory of Geospatial Information Technology and Application, Guangzhou Institute of Geography,
Guangzhou 510070, China

Abstract

Extreme rainfall-induced landslides usually gathered in a small watershed caused great harm in South China. Those landslides formation mechanism are essentially different from general rainfall pattern of landslides. Geological environment has a unique regional characteristic in South China. In this study, the river basin was selected as the basic unit to deduce landslide processes and mechanisms under different rainfall intensity conditions. The rainfall threshold will be calculated by couple the landslide hydrological model and landslides stability model. Through the analysis of the response mechanism of slope for the heavy rains insouth china, coupledthe hydrological model and the landslide stability modelusing a deterministic approach based on the SINMAP model.Suitable FS thresholds forlandslide warnings are proposed for each slope unit in the watershed area.Based on DEM data, the slope units were automatically partitioned on GIS platform. Based on GIS spatial analysis, hydrological analysis and map algebra, a set of suitable framework and method of landslide disaster warning system was put forward. TyphoonFanapiin 2010 was selected as a simulation scenario to calibrate the efficacy ofthe cumulative rainfall thresholds derived in this study.The results show that the result of model is more ideal.

Examining the Zuru Gullies of Kebbi State, North-West Nigeria (1994-2014)

Dr Abubakar, Sheikh D.

Department of Geography, Faculty of Natural Sciences, Ibrahim Badamasi Babangida University, Lapai,

sheikh.abubakar@udusok.edu.ng

Abstract

The menace of gully erosion is widespread in Nigeria, particularly in the savannah ecological zone within a broad East-west belt from the Eastern highlands to the edge of Sokoto basin (Ologe 1986). The aim of this study is to empirically examine the characteristics of the gullies in Zuru and project the extent of the land loss for 10 years. The study identified and classified the gullies into zones to be able to determine the rate of change that occurred between 1994- 2014 and used surface Analyst tools of ArcGIS software, using Digital Elevation Dataset from Shuttle Radar Topographical Mission (SRTM) to determine the topography and terrain of the area. Using the elevation datasets created from the Digital Elevation Model (DEM), a raster of flow direction from each cell to its steepest down slope neighbor was generated. The data were used to determine the rate of change that occurred between 1994- 2014. Furthermore, the area measurements obtained for each gully prone areas were then taken to Microsoft excel 2007 to have outline result into a series of graphs. The rate of change was calculated using Change rate ($D = B - A$). It might be argued that the growth and decline from one area to the other within this period on the gully formation can be attributed to changes in external factors in the gully areas. From the evidence derived in the direct field measurement of the sites (2014), it has been noticed that the external factors especially man's activities have greatly contributed to the changing flow of the runoff channels.

Geomorphic Expression of Paleo-Earthquakes on the Minle-Damaying Fault, Middle of the Hexi Corridor, Northwest China

Youli Li, JianguoXiong, Weilin Xin, ZhiyueZhong

College of Urban and Environmental Sciences, Peking University, Beijing, China, liyouli@pku.edu.cn

Abstract

The Minle-Damaying Fault (MDF) is a segment of the north frontal fault of the Qilian Mountains, and the southern boundary fault of the Zhangye Basin in the middle of the Hexi Corridor, a foreland basin system in the northern margin of the Qinghai-Tibet Plateau. Based on field investigation and topographic survey, it is found that the river terraces of a tributary of the Dongdahe River were vertically offset by the MDF around 15m, 10m, 7.5m, and 5m from older to younger, respectively, indicating at least 4 faulting events. A trench on the lowest terrace reveals 2 paleoseismic events, each with an around 2.5 m vertical dislocation. Radiocarbon ages of the terraces are 12.7 ± 0.7 ka (T6), 10320 ± 80 cal a BP (T5), 5838 ± 30 cal a BP (T4), 3138 ± 78 cal a BP (T3), 2807 ± 52 cal a BP (T2) and 1360 ± 50 cal a BP (T1). These ages are used to limit the periods of paleo-earthquakes, and calculate the average vertical slip rate of the fault. It is found that the vertical slip rate of the fault is around 1.2mm/a-1.0mm/a, and the paleo-earthquakes have different recurrence intervals.

Key words:

River terrace; slip rate; paleo-earthquake; Minle-Damaying Fault; Hexi corridor; Qilian Mountains; Tibet Plateau

Influences of Exogenic and Endogenic Processes on Landslide Orientation

Chen YC., Chang KT. Huang JC.

Department of Geography, National Changhua University of Education, Changhua Country 50007, Taiwan, China,
yichinchen@cc.ncue.edu.tw

Abstract

The genesis of landslides is essentially ascribed to exogenic and endogenic processes. These processes produced systematic or random orientation patterns and redistributed on rugged topography, resulting in different landslide features on slopes of different aspects. Previous studies have noted that landslides were active on some specific slope aspects, which were also regarded as an important landslide predictor. The causes included sunlight, weather and climate, geological structure, seismic wave, etc. However, current explanations were only applicable in a small or specific case, and the influences of exogenic and endogenic processes on landslide orientation were still overlooked. This study used regional, island-wide landslide inventories triggered after the 1999 Chi-Chi earthquake and Typhoon Morakot in 2009 in Taiwan and a set of small basin-wide, multi-temporal typhoon-triggered landslide inventories. By systematically examining orientations of landslides and processes, we attempted to clarify the mechanism of genesis of landslides. The results showed that earthquake-triggered landslides tend to occur on slopes opposite to the approaching seismic waves. Typhoon-triggered landslides were constantly active on the eastern and south-eastern slopes that were uncorrelated with the main direction of wind during the typhoon events. This suggests that endogenic, tectonic factors are a fundamental control on the orientation of mass movement.

Key words:

landslide; orientation; exogenic and endogenic processes; earthquake and typhoon

Landslide Dams on Large Chinese rivers: An Under-estimated Hazard?

Higgitt, D.L., Zhang, X.B., He, X.B., Liu, W.M.

School of Geographical Sciences, University of Nottingham Ningbo China. david.higgitt@nottingham.edu.cn

Abstract

Landslides forming natural dams across rivers have been described from numerous mountain environments. Such features pose considerable hazards particularly the risk of catastrophic flooding after dam failure. The topic has received increasing attention in recent years. In China, documentary records of large earthquakes and river blocking landslides have enabled inventories to be compiled. However, the remote and rugged terrain shelters evidence both of recent landslide dams which escaped the attention of official records and of ancient landslides which occurred before documentary records. Recognition and interpretation of palaeo-landslides and their lake impoundments is vital to extend understanding of the frequency-magnitude and spatial characteristics of landslide dams. Evidence of a previously unrecognized ancient landslide which dammed the main stem of the Yangtze River, China (crest height 200 m; lake volume $11.4 \pm 1.3 \text{ km}^3$) indicates that very large rivers have – and can be – impacted by persistent river-blocking landslides. Combining geospatial techniques with field evidence of sediment deposited in landslide dams lakes, identifies a number of candidate sites in the large rivers of the Upper Yangtze basin where river blocking may have occurred. It is argued that the potential for large earthquakes to generate enormous river-blocking landslides may be underappreciated as a mega-hazard.

Landslide dam; flood hazard; large rivers; Yangtze River; China.

Morphological Dynamics of River Bank Erosion: A Case Study of Brahmaputra River System in Assam; India

Roy N. , Pandey B. W.

Department of Geography, Delhi School of Economics, University of Delhi, Delhi-110007, India, nikhilroy21@gmail.com

Abstract

River Brahmaputra has been regarded as the lifeline of Assam. However, this life giving river is also the harbinger of disasters. In 1950, Brahmaputra valley was the epicentre of an 8.7 magnitude earthquake that raised the North East section of the valley by 3-4 meters that caused severe flooding in Assam. The earthquake caused extensive landslides and rock falls on hill slopes, subsidence and fissuring in the valley and changes in the course and configuration of several tributaries as well as the main course. Post-earthquake, the river has been eroding land along its banks at an alarming rate. While in 1920s, the Brahmaputra River occupied an area of 4000 Km² in Assam; today, it occupies more than 6000 Km². This study tries to assess the morphological changes of river Brahmaputra in Assam by examining three LANDSAT images of 1995 (TM), 2005 (ETM+) and 2015 (OLI). In this study, it is endeavoured to assess the morphological changes of the river channel actuated by stream bank erosion process. The braiding indicators such as Plan Form Index (PFI) and Flow Geometry Index (FGI) have been adopted in the study to analyse the braiding behaviour. This study aims to quantify the human tragedy and minimise its adverse effects by trying to develop a quantitative model to assess the callous hazard on the one hand, and finding solutions to mitigate the issue on the other hand.

Key words:

Brahmaputra; Erosion; Plan Form Index; Flow Geometry Index

Potential Risks of Natural Hazards in Kayseri Region, Central Turkey

Abstract

Either in historic or prehistoric period, human beings have experienced a wide variety of natural hazards including flood, volcanic activities and earthquakes. Since the frequency of extreme events of such phenomena is low, the historic records of severe natural hazards often lack in ancient periods, but there may be some suggestions in archaeological records for such events. Here we explore the geomorphological and geological records in Kayseri region, central Anatolia where many archaeological settlements (mainly B.C. 3000 – A.D. 1000) are located under potentially hazardous environmental settings with presence of floodplains, volcanoes and faults. We started our field survey by acquiring detailed topographic data of the study sites using recent technologies of high-definition topographic measurements such as laser range measurement, global navigation satellite system and structure-from-motion multi-view stereo photogrammetry with a small unmanned aerial vehicle. We also performed on-site geological or sedimentological recordings. From our investigations of landforms including floodplain, alluvial fans, fault scarps and hummocks in debris avalanche deposits, it was found that there are several potential risks of natural hazards in the area with regard to flooding in basins, sector collapse of volcanic mountain body and earthquakes by normal fault displacements in the Holocene period. The geomorphological and geological data, including a regional geomorphological map, will be further analyzed to explore spatiotemporal relationships of archaeological settlements and landform developments. Learning from the past, the hazard risk assessment will also be applied to the modern city.

Sedimentological Characterization and Microsurface Texture influence on Slope Instability, Garhwal Himalaya (India)

Pandey V K*, Sharma M C

Center for the Study of Regional Development, Jawaharlal Nehru University, New Delhi 110067 INDIA

*Presenting author's e-mail: vkpandey@jnu.ac.in

Abstract

This paper describes the sediment characteristics and influence of geomorphic process that induces slope failure. Sediment samples were collected from five active landslides to understand the role of grain size composition of landslide slip zone. In order to understand the instability mechanism; grain size distribution, mineral composition and micro-surface texture have been carried out. X-ray diffractometry of fine sediments was done to analyse mineral composition, crystalline structure and lattice strain of slip zone. The composition of grain size and minerals significantly relate to volume and types of landsliding in the area. Quartz was abundant mineral, with a higher concentration in the debris fall and rock slide, particularly in the Lesser Himalayan metasedimentary silicate rock groups. Microsurface features of quartzite rock with higher composition of quartz mineral, lesser strain, little 'd' spacing within molecules show high shear strength and greater resistant to slope failure. Surface microtextures presents on the quartz grains provide significant insight to geomorphic process and depositional history of clastic sediments. The prominent surface features that are established to sedimentary process are grain outline, types of edges, steps, pits, crystal overgrowths, ridges etc. The surface features are mainly related to the transportation mode, run-out distance and time, and often the size of particle. But features are equally a function of the original grain shape of the particle in the parent material. Significant relationship between types of landslide and volume of displacement related to grain size and mineral compositions exists in each of the slope failure investigated.

The Space Distribution of Houses at Debris Flow Prone Area and Its Role in Disaster Risk Reduction

Yu LEI, Peng CUI,

Institute of Mountain Hazards and Environment / Key Laboratory of Mountain Hazards and Earth Surface Processes,

CAS, Chengdu, 610041, China, pengcui@imde.ac.cn

University of Chinese Academy of Science, Beijing 100049, China

Abstract

Geomorphological hazards impose great potential risk towards the human settlements at mountainous region. For countries like China, mountain terrains covered large portion of its territory, therefore, reduce the risk from mountain hazards is imperative to the development of a sustainable community. Due to the space limitation at mountain terrain, human settlements normally concentrated at alluvium fan or river bank, which happened to overlap with the high risk zone of mountain hazards such as debris flow or flash flood. By conducting field investigation of damaged houses after several debris flow events, information on the structure type, space distribution, failure mode and degree of damage for 197 houses were recorded. The space distribution model for houses was constructed using quantified parameters which described the relationship between houses and debris flow gully. Distance ratio and angle ratio were used to quantify the relationship between the houses and debris flow gully while spacing between different houses were used to describe the inter-houses relation. Afterward, the space distribution model was correlated with the records of houses damage to develop a vulnerability chart for houses at debris flow prone area. This chart gives guideline to the authorities when conducting housing planning at debris flow prone area since it indicates the potential damage of houses when debris flow occurs. This study also provides an alternative solution to disaster risk reduction which could be put in place at the housing planning stage.

Ainterpreting Physical Landscapes – Challenges at Viewpoint Geomorphosites

Migoń P, Pijet-Migoń E

Institute of Tourism, Wrocław School of Banking, ul. Fabryczna 29-31, 53-609 Wrocław, Poland,
edyta.migon@wsb.wroclaw.pl

Abstract

Viewpoint geomorphosites are specific geosites which allow one to see, interpret and understand a wider landscape rather than show an individual landform from a close distance. Moreover, other than providing a viewpoint, they may not be of any particular geomorphological value. Nevertheless, they may play a key role in geotourism and geoeducation, being also much more attractive to casual visitors than geosites *sensu stricto*. It is therefore important to realize not only opportunities provided by viewpoint geomorphosites but challenges as well. These can be divided into a few thematic groups, i.e. selection, criteria of evaluation, maintenance, access and suitability for tourism, and interpretation. In contrast to other geomorphosites, their success as site of geomorphological interest is very much weather-dependent. Access may be technical difficult and not for everyone, especially for hilltop locations. In warm and humid areas, with vigorous growth of vegetation, regular clearance is necessary to sustain the scenic values which may generate conflicts with biological conservation. Being often exposed locations in the landscape, any facilities for tourism (shelters, rest places, information panels) are at risk to spoil the scenic quality of the viewpoint and careful decisions have to be made how such facilities should be erected. Finally, the level of interpretation usually varies from simple naming of geographical spots through identification of specific features, explanation of rock-landform relationship, to storytelling about how the particular landscape evolved. The latter is most exciting, but also most challenging, requiring considerable skills in showing such a story in pictures.

Artificial Landform Extraction and its Water and Conservation Effect

--A Case Study of Terraced Field in Loess Plateau of China

Jiaming Na, Xin Yang, Hu Ding, Hanqing Zhao

Key Laboratory of Virtual Geographic Environment (Nanjing Normal University), Ministry of Education; Jiangsu Center for Collaborative Innovation in Geographical Information Resource Development and Application; State Key Laboratory Cultivation Base of Geographical Environment Evolution, Nanjing, 210023, P. R.China, najiaming@qq.com

Abstract

With the increase of human activities, artificial landforms become one of the main terrain features with special geographical and hydrological value. Terraced field, as the most important artificial landscapes of the loess plateau, plays an important role in conserving soil and water. With the development of digital terrain analysis (DTA), there is a current and future need in developing a robust, repeatable and cost-effective research methodology for terraced fields. In this paper, a novel method using bidirectional DEM shaded relief is proposed for terraced field identification based on high resolution DEM, taking Zhifanggou watershed, and Shanxi province as the study area. Firstly, 1m DEM is obtained by low altitude aerial photogrammetry using Unmanned Aerial Vehicle (UAV), and 0.1m DOM is also obtained as the test data. Then, the positive and negative terrain segmentation is done to acquire the area of terraced field. Finally, a bidirectional DEM shaded relief is simulated to extract the ridges of each terraced field stages. The method in this paper can get not only polygon feature of the terraced field areas but also line feature of terraced field ridges. The accuracy is 89.7% compared with the artificial interpretation result from DOM. And additional experiment shows that this method has a strong robustness as well as high accuracy. Moreover, the influence of terraced field on LS factor in Revised Universal Soil Loss Equation (RUSLE) is discussed, which shows that terraced fields may reduce the average capability of carrying sands, but may have larger detriment at the high-slope position.

Beach-Barrier Dynamics under Rapid Sea-Level Fall

A.Kakroodi, Kiavarz. M. Yazdanpanah, Q

Faculty of Geography, Department of Remote Sensing and GIS, University of Tehran, Iran, a.a.kakroodi@ut.ac.ir

Abstract

The Caspian Sea is well-known for its rapid sea-level changes. This can help us to observe rapid coastal evolution which may take a millennium in oceans. Between 1929 and 1977 the level of the Caspian Sea fell down around 3 m and rose back in the former sea level in 1995. Again it started falling with a minor sea level rise in 2005. Afterward up to now, 2016, based on satellite data altimetry, its level is decreasing and rapid sand progradation is dominated. This real observed record allow us to detail all characteristics of sand facies including grain size, thickness and its progradation under rapid sea level fall. Considering the lack of tide in the Caspian Sea the most controls of this process which appeared as beach-barrier, spitare rapid sea-level change, sand supply and wave dominated coast respectively. By using high satellite images we estimate sand progradation and its behavior during this period of sea-level fall.

Cave Dwellingcultural Heritage in Plateau Geomorphology (SE Tunisia)Ben Fraj T¹, Boukhchim B², Reynard E³¹University of Sousse, Sousse, Tunisia²University of Kairouan, Kairouan, Tunisia³University of Lausanne, Lausanne, Switzerland, emmanuel.reynard@unil.ch**Abstract**

South-East Tunisia is known for different types of cave dwellings developed for centuries on the Matmata-Dahar plateau. Their shaping takes into account the geological and geomorphological context of the sites. They thus provide an interesting example of geoheritage on which was developed an important cultural and architectural heritage. An interdisciplinary research – crossing geomorphological and archaeological approaches – was carried out in two sites: Haddej and GuerMESSa. Haddej site belongs to the Matmata area and its surroundings located in the northern part of the plateau. It is characterized by cave dwellings dug deep into Quaternary aeolian silt accumulations that are filling the valleys that dissect the plateau surface. GuerMESSa site belongs to the Tataouine region, located in the southern part of the plateau. It is characterized by troglodyte dwellings dug laterally in alternations of limestone, clay, marl and dolomite layers of Cenomanian and Turonian age. These alternations are the backbone of buttes still partially attached to the front of the cuesta.

Both sites offer favourable conditions for geomorphological study. They exhibit a wide range of structural landforms within the monoclinic structure, and their surroundings present a variety of shapes and Quaternary formations allowing the study of the geomorphological and palaeoenvironmental changes that happened during the Quaternary in this now arid region. These geosites were assessed using the method developed by the University of Lausanne, which allowed us to assign them a strong scientific, aesthetic, cultural, educational and tourist value. Proposals for their tourist promotion were then proposed.

Key words:

geoheritage; geomorphosites; cultural heritage; cave dwellings

Identification and Assessment of the Desert Geosites**(Case Study: Lut Desert in Iran)**Maghsoudi M¹, Moradi A²¹Associate Professor, University of Tehran, Tehran, Iran, maghsoud@ut.ac.ir²Candidate, University of Tehran, Tehran, Iran, anvar.moradi@ut.ac.ir**Abstract**

The Lut Desert is located in the southwest of Asia and in the southeast of Iran. This Desert, with the unique landforms, is a perfect laboratory for geologist and geomorphologist. This desert represents an interesting scene of the integrated performance of geomorphic and geologic processes and climate changes. The Hydro-Aeolian erosional and depositional landforms in the area can be seen widely. The wind processes are the most dominant formative processes affecting the landforms. This desert with the staring scenes of the highest and longest yardangs (Kalut) of the world presents interesting scenes of different forms of yardangs (Kalut). Unique landscapes of the Yallan Sand Sea (Rig-e Yallan) have the highest sand dunes of the world and a variety of landforms. The area has also the highest nebkhas of the world. Playa, desert pavements and Hamada, gypsum crusts, salts and salt weathering, cavernous weathering forms, ventifacts, desert varnishe, desert karst, lake basins with palaeo shorelines, ephemeral stream channels, badlands, inselbergs, sand ramps, dark lava irregular basalt pavement and other related landforms identified in the study area . According to field work, images and aerial photos 58geosites were identified in study area. Assessment of geomorphosites was done using a suitable model for the study area. According to the assessment model 8 areas were selected for development of tourism activities.

Key words:

Iran; Lut desert; Kalut; Geosite assessment; Desert landform

Landscape Connectivity Evolution Responses to Landcover Changes in Dryland Environments, Serra Talhada, Pernambuco

Souza, J. O. P.¹

Federal University of Paraíba, João Pessoa – PB, Brazil, jonasgeoufpe@yahoo.com.br

Abstract

The present work has as a goal to analyze the dryland fluvial dynamics to Saco Creek Watershed, Serra Talhada, Pernambuco, focusing the change probability in the fluvial structure and landscape connectivity. At the end, the methodology will be applied to identify the response of behavior transmission due to natural and anthropogenic changes in the landcover, and how these changes could cause adjusts in the fluvial structure. The local hydrologic behavior was detailed, as well the precipitation distribution by altimetric zone, and the detailed, using soils and land cover data, runoff behavior. After the landscape connectivity and effective catchment area were defined, and were created logical scenarios of landcover changes, based in the social economical dynamic of the region. There are two major scenarios planned by the planning department, one to expand the agricultural areas in sub humid zone, and the second one with the increase of removal of semiarid vegetation. In the first scenario the landcover change leads to an increase in the gully processes and induce canal aggradation, locally decreasing the landscape connectivity, holding a bigger amount of sediment. In the other hand, the second scenario leads to a major increase in the runoff and in the peaks of stream power, and this induce a riverbed vertical incision, removing the channel sediments and increasing the landscape connectivity. Lastly, the proposed methodology proved to be adequate to initial analyze about the transmission hydrosedimentological responses to processual and structural changes scenarios, natural and/or anthropogenic.

³College of Earth and Environmental Sciences, Lanzhou University, Lanzhou 730000

Abstract

In the alpine sand area of china, the wind-sand movement is peculiar for its long wind seasons, strong wind velocity and changeful wind directions, great wind-sand hazards need urgent controlling measures to stabilize the moving sand dunes and recover the ecosystem. Through field experiments of different artificial controlling measures and a continuous investigation of soil erosive depth, wind-sand flow, and topography monitoring from 2009~2014, an artificial controlling model of stabilizing sand dunes was concluded and reflected by its morphology transformation. The model went with three periods: paving straw checkerboards with small or middle norms in the first year, transplanting saplings for afforestation in the second year, and then resetting the straw checkerboard barrier with large norm in accordance with a measure of direct seeding afforestation in the following 2~3 years; Relatively, the sand dune structure would suffer different changes with controlling steps, the depositional intensity increased to 83.8~120.6 kg·m⁻², the erosive intensity in the top of sand dune decreased to 37.2 kg·m⁻², the height fall has reduced to almost 1m per year, and the length of the windward slope was equated with the backward slope. Additionally, the monthly moving speed of the sand ridge line changed from 5.2m to less than 0.5m, the primary crescent shape turned symmetrical and oblate. In consequence, the methodical artificial controlling model contributed to convert the original form of the sand dune, reduce wind-sand hazards, and improve desert ecosystem. Otherwise, the morphology change reflected the scientificity and availability of the artificial controlling model.

Shaping Distinct Landscapes by Dynamic Fluvial-Aeolian Interaction Processes

Liu B.¹, Yan P.², Li X.³, Wu W.².

¹College of Environment and Ecology, Xiamen University, Xiamen, 361102, P. R. China, baoli.liu@outlook.com

²State Key Laboratory of Earth Surface Processes and Resource Ecology, Beijing Normal University, Beijing 100875, P. R. China

³Tourism and Environment College, Shaanxi Normal University, Xi'an, 710062, P. R. China

Abstract

Although the interaction between fluvial and aeolian system have been noticed in many studies, very few of them have focused on the dynamic interaction process and the implication on geomorphology. Liu and Coulthard (2015) have classified six fluvial-aeolian interaction types after a global inventory. However, these are based on static satellite images which could not allow the generation of information relating the specific physical processes occurring within each of the systems being mapped.

As such, in the current study, preliminarily investigations into the geomorphologic characteristics as well as dynamics of four distinctive fluvial-aeolian interaction landscapes in China are undertaken. The dominant processes at the four sites are namely Fluvial dominant (F), Mostly Fluvial (MF) dominant, Balanced (B) and Mostly Aeolian (MA) dominant interaction, respectively, according to Liu and Coulthard (2015)'s classification.

By contrasting the fluvial/aeolian regime at each location, and mapping the resulted landscape characteristics, this study provides in situ field monitoring data to test the theory of fluvial-aeolian interaction classification and further numerical modelling work. The results have the potential to inform our understanding of the ways in which humans in dynamic fluvial-aeolian environments are at risk through both internal systems and natural landscape evolution processes. Given the changing patterns of flooding occurring globally it is apparent that a more nuanced understanding of these environments is fundamental to future risk management strategies in many areas.

Fluvial-aeolian interaction; geomorphology; sand dunes; river

Study of Landscape Changes after the 2012-2013 Tolbachik Fissure Eruption (Kamchatka, Russian) Based on Remote Sensing Data

Mikhaylyukova P.G., Tutubalina O.V., Sazonov A.A.

Lomonosov Moscow State University, Moscow, Russian Federation, esquiruello@gmail.com

Abstract

Volcanic eruption is one of the primary planetary resurfacing agent. Lava post-emplacement deformations and formation of surface of lava flows still need to be explored. Remote sensing data and its increasing availability allows to explore lava flows and landscape changes in different period of eruption with high periodicity.

According to seismic data the 2012-2013 Tolbachik Fissure Eruption started on November 27, 2012. Landscape of TolbachinskyDol was strongly changed. Three new lava fields were formed with a total area is about 36 km². The scientific and touristic infrastructure was damaged. Two scientific bases had been destroyed by lava flows. The road to TolbachinskyDol was blocked. The full picture of landscape transformation was analyzed on the basis of remote sensing data.

Remote sensing data (optical and radar imagery) were regularly acquired during the whole eruption period. These series of radar interferometric pairs, optical imagery, digital elevation model (DEM) and results of fieldwork provide valuable information for complex thematic mapping. A series of thematic maps were created as a result of the study. They show dynamics of lava flow areas during eruption, provide complex maps of lava flow formation and describe landscape changes.

The Formation of the Yangtze River. And Assessing Zheng Hong Bo's Pre-Miocene birth of the Yangtze River

Yang Liankang

The Ministry of Land and Resources*. P. R. China, Beijing, 100035, China, Yanglkk@pku.org.cn

Abstract

Early in 1959 and 1960, the author attended the investigation of the Yangtze Gorges evolution. He also surveyed the Yangtze River from its source to mouth on foot with 6300 km for 750 days during 1982-1984, which is the first time in Chinese history. Since then he made his conclusion and published in 1985, 1990, 1991, 1995: the Yangtze has been largely linked up in Miocene based on his evidence which discovered separately at upper reaches (Dege County, Hutiao Gorge), middle reaches (Sichuan Basin, Three Gorges) and lower reaches (Jiangnan Basin, Nanjing) of the Yangtze [*The Formation of the Yangtze River*. Abstracts XIV INQUA etc.].

This conclusion is 28 years earlier than *Pre-Miocene birth of the Yangtze River* (Zheng Hongbo et al. PNAS 2013.4). The following is Zheng's respond to author's statement above: "Our understanding is an affirmation of your early cognition" in 2015. However Zheng didn't provide any direct evidence (gravel, sand etc.) showing the Yangtze ran through the sites around the Three Gorges and above it with 4500km in Miocene, his article is obviously not rigorous and questionable. And to confirm the Upper-Mid Yangtze's waterway with 4500 km and to draw out its map in Miocene (Zheng's Fig 4) is simply impossible just according to Zheng's evidence in Nanjing. Its hasty publishing is irresponsible for science and needs to be corrected by geographers.

Yangtze River; formation; Miocene; survey; discover; evidence

Geomorphology of Punpun River System

Lal Keshwar Prasad Singh

University Professor of Geography, Patna University, Patna, Bihar 800005, India, lal_keshwar@yahoo.com

Abstract

The Punpun river rises in the lower reaches of the highlands of Palamau district of Jharkhand state in India. Its course is nearly 200 km and discharges its water into the sacred Ganga river near the small town of Fatuha of Bihar state. The river flows northward almost parallel to the east of the Sone river and to the west of the Phalgu river. The Sone and the Phalgu rivers have shallow depth in their river courses. However, the Punpun river has a deep course, in between the shallow courses of the Sone and the Phalgu rivers. The Punpun river course is 40' to 50' deep throughout its extent, except in its 15 km upper reaches. The river forms many sharp meanders throughout its course. At many places, water is sweeping out in its course from the bed. Thus it is a perennial river. The entire length of the river is sand free.

The present paper addresses the following pertinent questions to be answered:

1. Why the river is so deep, despite being flown over plain areas?
2. Why does the river create many sharp meanders?
3. Why does the water often sweep out of the bed of the river?
4. Why the river bed is sand free?

The entire work is based upon the field work and explanations have been drawn through statistical and cartographic calibration.

Key words:

geomorphology; river system

Assessing Geometric Configuration of Son Alluvial Fan System Using Srtm Dem: Implications for Delineation and Evolutionary history

Manish K. Pandey^{1,2}, K. N. Prudhvi Raju², U. K. Shukla³, Aman Arora⁴

¹Centre for the Study of Regional Development, SSS-III, J.N.U., New Delhi-110067, manish07sep@gmail.com

²Department of Geography, B.H.U., Varanasi-221005

³Department of Geology, B.H.U., Varanasi-221005

⁴Department of Science and Technology, Govt. of India, New Delhi-110067

Abstract

Alluvial fan surface profiles are least studied and poorly understood elements of the fan systems. This study is an endeavor to fill this gap by analyzing cross & radial profiles of the Son Alluvial Fan System (SAFS) in order to: 1) understand fan boundary extent, and 2) interpret gradational history. SAFS is a megafan formed by coalescence of the Son fan and a number of small alluvial fans deposited mainly by the Son River and some of the right bank tributaries of the Ganga River. Reclassified SRTM DEM was used to enhance fan boundary and various fan components' appearance as well as to calculate cross and radial surface profiles along and across the SAFS. Radial fan profiles show concavo-planar form from proximal to distal part of fan with maximum surface slope ranging from 0.4% to -1.2% and average surface slope from 0.0% to -0.1%. Radial altitudinal variation from apex to distal part of the fan along various profiles is from 458m to 75m to western most part whereas it ranges from 458m to 42m to eastern most part of the fan. Cross sectional slope (max slope 0.7% to -0.0%; avg. slope 0.2-0.0%) and altitudinal variation (ranging from 408m-51m) gives the fan SE-NW orientation. Concavo-planar shaped long profiles along SAFS indicate that there is not sufficient sediment supply which may be due to effects of interplaying factors like changing climate, basement fault movements, and changing base level of the Ganga which acts as temporary base level for the Son River.

Son Alluvial Fan System (SAFS); SRTM DEM; Radial fan profile; Cross fan profile

Automatic Recognition of Loess Landform Integrating Terrain and Texture Features

Wufan Zhao, Guo'an Tang, Xiaoli Huang, Hu Ding, Qinghui Lu, Xiaoling Wu

Key Laboratory of Virtual Geographic Environment (Nanjing Normal University), Ministry of Education; Jiangsu Center for Collaborative Innovation in Geographical Information Resource Development and Application, Nanjing, 210023, P. R. China, wufan_zhao@163.com

Abstract

Automatic recognition of landform is one of the hotspots in modern geomorphology. This research presents an automatic method for loess landform recognition which integrating terrain and texture features based on the digital elevation models (DEMs) data. Small watersheds of loess plateau, which have high homogeneity in topographic features, were divided as analysis units to extract geomorphic information. Terrain features such as average slope gradient, elevation range and texture features such as slope gradient contrast, elevation variance were used to quantify characteristics of landforms. By taking advantage of Random Forest algorithm, the recognition achieved a good result. Experimental results show that the highest recognition accuracy based on the fusion features is 92.06%, which is higher than that of single-class feature data set. Meanwhile, the terrain features made more contribution to the recognition processing than the texture features. In addition, among the selected seven typical types of loess landform, loess terrace and loess mid-mountain obtained the highest accuracy while the precision of loess hill, loess hill-ridge and loess sloping ridge is relatively low. Further, compared to the CART trees and TreeNet Gradient Boosting Machine classifier, Random Forest performs better in features extraction and recognition process.

Key words:

Landform Recognition; Feature Fusion; DEM; Random Forest; Loess Landform

Beach-Barrier Dynamics under Rapid Sea-Level Fall

A.Kakroodi, Kiavarz. M. Yazdanpanah, Q

Faculty of Geography, Department of Remote Sensing and GIS, University of Tehran, Iran, a.a.kakroodi@ut.ac.ir

Abstract

The Caspian Sea is well-known for its rapid sea-level changes. This can help us to observe rapid coastal evolution which may take a millennium in oceans. Between 1929 and 1977 the level of the Caspian Sea fell down around 3 m and rose back in the former sea level in 1995. Again it started falling with a minor sea level rise in 2005. Afterward up to now, 2016, based on satellite data altimetry, its level is decreasing and rapid sand progradation is dominated. This real observed record allow us to detail all characteristics of sand facies including grain size, thickness and its progradation under rapid sea level fall. Considering the lack of tide in the Caspian Sea the most controls of this process which appeared as beach-barrier, spit and rapid sea-level change, sand supply and wave dominated coast respectively. By using high satellite images we estimate sand progradation and its behavior during this period of sea-level fall.

Coupling of the Channel Downcutting Rate at the Heishan Gorge and Sedimentation Rate in the Yingchuan Plain of the Upper Yellow River since 700 Ka B.P.

Suiji Wang

Key Laboratory of Water Cycle and Related Land Surface Processes, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, wangsj@igsnr.ac.cn

Abstract

In order to analyze the historical variation trend of the sedimentation rate and their influence factors in the Yinchuan Plain of the upper Yellow River, this work based on bore columnar section to estimate the sedimentation rate. The results show that the sedimentation rate has an inapparent increase trend during the time period from 700 ka B.P. to 200 ka B.P. while a distinct increase trend since 200 ka B.P. The peak value of the sedimentation rate was 3.43 cm/a. The channel downcutting rate at the Heishan Gorge which located upwards the Yinchuan Plain showed a similar variation trend with the sedimentation rate. Furthermore, there is a good linear relationship with a correlation coefficient of 0.995 between the sedimentation rate and the channel downcutting rate. Apparently, the increased sedimentation rate in the Yinchuan plain was mainly influenced by the increased channel erosion rate in the upper stream basin. The increased channel erosion rate resulted by climate change as well as the tectonic rise in the upriver basin. Since 200 ka B.P. the climate of the upper Yellow River basin has changed to more arid which could diminish annual precipitation and enhanced accident of rainstorm. Accordingly, vegetation coverage reduced and rainstorm erosion enhanced gradually in the upriver basin. The tectonic rise in the upstream basin would increase sediment supply to the Yinchuan Plain. These factors consequentially resulted in increased sediment delivery to and increased sedimentation rate in the Yinchuan plain.

Distinguishing Desert Landscapes Base on Eco-geomorphic Thresholds

Abdollahzadeh S, SepehrA, RashkiAR

Dept of Desert and Arid Zone Management, Ferdowsi University of Mashhad, Mashhad, Iran,

abdollahzade.sara@gmail.com

Abstract

The resilience of an ecosystem determines recovery time after pressures as well as ecosystem resistance. Short recovery time and high erodibility can be used for distinguishing sustainable and unsustainable ecosystems. A transitions zone can be considered as a critical threshold in non-equilibrium state, where is emersion of heterogeneous patterns of vegetation, soil and bare rock. To distinguish desert ecosystem base on transition zones, the approach was applied in Khorasan Razavi province in north-east of Iran. To determine ecogeomorphic threshold in transition zones of semi-arid ecosystems, the spectral and morphological algorithms were implemented in remote sensing images of MODIS surface reflectance. The spectral angle mapper analysis was applied for surface conditions (vegetation, bare soil and rock) and the mathematical morphology algorithm of dilation was used for identifying potentials erodibility and recovery in heterogeneous patterns. Detailed assessment of this mappingwas achieved by implementation an iterative self-organized clustering technique (ISODATA) and calculation of separability of formed typologies classes using application of transformed divergence algorithm. Several desert threshold were detected in susceptible ecosystems to desertification in KR under the influence of natural and anthropogenic factors. Some of intrinsic thresholds were crossed due to influences of ecogeomorphic factors, such as formation, lithology, soil, land cover and geomorphology. Some of them are crossing under the anthropogenic disturbances, because of the high rate of disturbances over the ecosystem resilience. Meanwhile, in prone areas which have the high potential to desertification like KR, ecosystem reach to the tipping points and will cross over into the desert state.

Abstract

The topographic evolution of an active orogenic belt derives from the interactions of tectonics and surface processes. However, the relative role of tectonism and climate in the recent topographic evolution, especially terrace formation, remains an issue of debate. The Tian Shan and its foreland basins provide such an excellent natural laboratory to probe this scientific question. In the northern Chinese Tian Shan foreland, transverse rivers northward flow across the piedmonts and incise into the anticlines. We focus on the range front of the Sikeshe River, where the Tuostai anticline develops. Well-developed terrace staircase and alluvial fans display along the course in the range front. Further work is needed to better understand the geomorphic processes forcing river incision and terrace formation. In order to better understand the driving force behind terrace generation in the range front of the Sikeshe River, we have measured several terrace cross sections and defined the types and distributions of terraces and their correlations with alluvial fans. From these, we have dated seven samples using ¹⁰Be-derived cosmogenic exposure age and optically stimulated luminescence (OSL) dating methods. The goals of this work are (i) to describe the sequence and distribution of fluvial features, and (ii) to evaluate the possible contribution of tectonics and climate change to river incision and terrace formation. Our results suggest that climate change during the transition of late Quaternary and Holocene promoted the river incision and the formation of main terraces in the range front of the Sikeshe River.

Abstract

Analysis of temperature fluctuations is significant to understand the local and regional trend of climate change and variability in the Himalayan Cryosphere. In the present study two glaciers have been selected to analyse the temperature fluctuations at micro as well as regional scale. Moderate Resolution Imaging Spectroradiometer (MODIS) LST onboard Terra (MOD11L2) satellite product, with 500m spatial and daily temporal resolution for the period 2001-2015 was used in the study. After extracting day and night bands separately for the entire period, the data products are stacked and processed using MODIS tool in ArcGIS10.2. Temperature information derived in kelvin has been exported for 5 random points for each glacier, two points from accumulation zone, two from ablation zone and one from terminal zone. Temperature variability in both the glaciers was analyzed using co-efficient of variation (CV). The land surface temperature indicates slightly declining trend for Menthosa glacier; whereas a negligible rising trend is noted for Gangtang glacier. The temperature within the accumulation zone varied from -9.11°C to -10.72°C in Menthosa glacier. However, the ablation zone temperature has been recorded as -5.41°C in 2002 and declined to -7.15 °C during 2013. The terminal zone also indicates high variability in temperature as it varies from -4.13 °C to -6.43°C. Gangtang glacier also has shown high variability in the temperature of accumulation and ablation zones. In the accumulation zone it varied from -9.23°C to -11.38°C and in the ablation zone it ranges from -11.09°C to -12.73°C. The analysis has been validated with temperature data from meteorological observatory (Keylong).

Abstract

Vouraikos basin, which is located in Kalavryta area, in the northern part of Peloponnesus in Greece, flows from Priolithos to Diakopto, in the Corinth gulf, which is one of the most active tectonic areas in Europe. Its valley is characterized of a diverse relief, which is dominated by a variety of landforms. This is the result of a mixture of different processes and complex geology, along with intense tectonic activity (uplift rate 1,3mm/year) which dominates the area of the Corinth gulf. The geomorphology of the basin is a result of fluvial processes, the tectonic uplift of the north Peloponnesus and the last Glaciation during Pleistocene of the Chelmos Mountain. To detect and analyze the processes affected the relief, sophisticated methods for geomorphological mapping were used. Specifically, a semi-automated method was selected in order to interpret and analyze the Digital Elevation Model from National Cadastre, to construct aspect, hill shade and slope models, with cell size 5 meter, through the software Arc GIS v. 10,3 and remote sensing data. From the automated models (Slope, Aspect), the principal landforms can be depicted. The results were evaluated through the fieldwork and the use of remote sensing data. The geomorphological map, scaled 1:25.000, presents, with symbols derived from the literature review, the principal landforms, which specify the dominant processes, such as canyons, knick points, cliffs, alluvial fans, cirques, U shaped valleys etc., of the present landscape and indicate the evolution of the relief.

Geomorphological Mapping of Colima Volcano, Mexico

Zamorano-Orozco, J.J., Figueroa-García, J.E.

Institute of Geography, UNAM, Mexico, zamojj@yahoo.com.mx

Abstract

The Colima Volcano is a late Pleistocene composited cone, built by overlapping lava (andesite), pyroclastic flows and fallen material (ash). This structure, as part of a mountain range oriented N-S, was created by the intersection of three other volcanoes: El Cantaro, Nevado de Colima and Colima, all located in the western sector of the Mexican Volcanic Belt. The origin of the Colima Volcano is associated with complex tectonic dynamics, in which the subduction of the Cocos Plate under the North American Plate and the triple point formed by the *Rifts Tepic-Zacoalco, Colima and Chapala* interact. The Colima Volcano had an explosive and effusive activity, which explains its complex and heterogeneous morphology. In this investigation, we documented and analyzed landforms associated with volcanic dynamics and represented them in a detailed geomorphological map (1:25 000), which is our main research contribution. The methodology we followed included the interpretation of aerial photographs to identify the volcanic relief, and the representation of the morphologies in a plain (cf. Bashenina, 1977). As for the classification of the relief, we used the genetic parameters proposed by Simonov (1985). In sum, this geomorphological study reveals the particular characteristics of each morphological unit of the aforementioned volcano.

Abstract

A geomorphological survey for a roman age settlement in Farasan island (Saudi Arabian coast, Red Sea), resulted to sea level estimation during Roman times (approx. 2000 yrs BP). A multi-proxy methodological approach including, processing of remote sensing data, such as Shuttle Radar Topography Mission (SRTM) and ASTER GDEM (2009) obtained digital elevation models DEM; old Russian maps have been georeferenced, digitized and processed through the software ArcGIS v. 10.2. In addition, geomorphological mapping and hand drilled core at a depth of 3,5m have been performed. The samples collected, were micropaleontologically analyzed for their benthic foraminiferal content and dated using AMS C¹⁴ method. A rocky planation surface has been identified, comprised of fractured and karstified reef limestones of late Pleistocene, displaying cliffs of various heights (1-3m) at its borderline. The planation surface neighbours with the main Wadi Matar valley, featued by downcutting erosion, and the presence of an alluvial fan at its end. Uplifted notches and residual wave cut platforms were also discovered along with a playa at the northwest part of the study area. The paleoenvironmental study of the drilled sediments in the interval between 0 - 1.18 m (Unit I), revealed only rare marine, mostly broken/reworked foraminiferal specimens, which are considered mainly transported. Therefore Unit I is evaluated as a paralic environment. From 1.18 till 2.40 m depth (Unit II) the microfauna findings suggested high energy conditions at nearshore environments. The rest of the core (2.40 - 3.20 m; Unit III)) presented high foraminiferal density and low ratio of broken/reworked foraminiferal tests, indicating a shallow marine paleoenvironment.

The Lambeck's glacio-hydro-isostatic model along with the ratio of the sea level rise in this area and the correlation with paleo-shoreline indicators resulted that the coastline was uplifted about 3m the last 5.000yBP (uplift rate 0,6mm/year) due to the diapirism of underlying layers of Miocene evaporites.

Geomorphology of Punpun River System

Lal Keshwar Prasad Singh

University Professor of Geography, Patna University, Patna, Bihar 800005, India, lal_keshwar@yahoo.com

Abstract

The Punpun river rises in the lower reaches of the highlands of Palamau district of Jharkhand state in India. Its course is nearly 200 km and discharges its water into the sacred Ganga river near the small town of Fatuha of Bihar state. The river flows northward almost parallel to the east of the Sone river and to the west of the Phalgu river. The Sone and the Phalgu rivers have shallow depth in their river courses. However, the Punpun river has a deep course, in between the shallow courses of the Sone and the Phalgu rivers. The Punpun river course is 40' to 50' deep throughout its extent, except in its 15 km upper reaches. The river forms many sharp meanders throughout its course. At many places, water is sweeping out in its course from the bed. Thus it is a perennial river. The entire length of the river is sand free.

The present paper addresses the following pertinent questions to be answered:

5. Why the river is so deep, despite being flown over plain areas?
6. Why does the river create many sharp meanders?
7. Why does the water often sweep out of the bed of the river?
8. Why the river bed is sand free?

The entire work is based upon the field work and explanations have been drawn through statistical and cartographic calibration.

Abstract

The aim of this study is the analysis of the processes that have affected the relief and thus the glaciation of Mt Chelmos. Several glacial landforms have been recognized, such as moraines, cirques, and tillites, indicating its quite extended glaciation during Middle and Late Pleistocene. Two ground moraines located at 2000m and 1850-1900m within the Ano Loussoi basin, have been dated using the OSL method. These ages indicate a Late Pleistocene phase of glacier advance/stabilization during MIS 3, which is in consistence with the well established stratigraphical framework of Northern Pindos. These findings come to widen our understanding of the late Pleistocene glacial history of Mt Chelmos, which up to now has been limited to the identification and dating of two distinct glacial phases at 40-30 ka and 13-10 ka respectively. The basin of Ano Loussoi is a Polje created by the chemical dissolution of limestone and by the still active tectonism with an uplift rate of approximately 1,3mm/year. Along with the Polje many different Karstic landforms can be identified such as karstic springs, caves, potholes and hums. A sophisticated semi-automated method was used in order to analyze the Digital Elevation Model from National Cadastre, and to develop aspect, hill shade and slope models. The developed models were created with commercial software Arc GIS and additional Aster satellite images. The detailed presentation of the driving forces of the relief evolution as well as of the karstic and glacial landforms allow for their direct comparison and correlation on an explanatory base.

² TunceliUniversity , Department of City and Regional Planning, 62000 Tunceli

Email: cihanbyr@istanbul.edu.tr

Abstract

Akdağ, Barla, Dedegöl, and Beydağları Mountains are subjected to Pleistocene glaciations in Western Taurus. Lithologically all the mountains are substantially formed from limestones. Even though glaciated mountains in Western Taurus have similar elevations and climate characteristics, there are significant discrepancies as to the extent and style of Pleistocene glaciations and the size of landforms and their spatial distributions created by glaciers. Litho-stratigraphy is the main factor affecting this situation. Western Taurus mostly consist of carbonate rocks and the karstic evolution has started in Anatolian landmass surfaced above the seas; even though it has been affected by tectonic activities and climatic changes the karstic evolution has continued so far. Karstic evolution in Western Taurus has developed in distinct courses in the sections of autochthons and nappes. Due to the complex lithological units resulted from the Lycian (Teke) nappes, shallow surface karstification (epikarst) is dominant in Akdağ where soluble and permeable carbonate rocks are surrounded by the ophiolites and insoluble rocks from the bottom or round of the mountain. On the other hand, endokarst is dominant in Mount Beydağları and Mount Dedegöl where thick and continuous carbonate rocks consist of a thousand meters vertical extent. These conditions have affected development and extent of the Pleistocene glaciations. Therefore, both on these mountains polygenic landforms have been produced by karstic and glacial processes. In Western Taurus wherever epikarst prevailed, Pleistocene glaciations developed as an icefield style occupying paleo-karstic depressions above the equilibrium line altitude, while areas wherever endokarst prevailed above the equilibrium line altitude, older cave systems were destructed and transformed into steep walled cirques and glacial troughs by glaciers. As a result, litho-stratigraphic formations have significantly affected the development of glaciations and the distributions of glaciated areas in a different manner even those areas are closely situated in western Taurus and created a polygenic topography peculiar to its own. In this study we try to explain how paleo-karstic features affect the Pleistocene glaciations in Western Taurus. Geographic information systems, morphometric analysis were used in this study.

Landform Planation Index Extracted from DEMs—A Case Study in Ordos Platform of China

Qian Yeqing, Li Jilong, Xiong Liyang, Tang Guoan, Tao Fei

Key Laboratory of Virtual Geographic Environment, Nanjing Normal University, Ministry of Education, Nanjing 210023, China; State Key Laboratory Cultivation Base of Geographical Environment Evolution, Nanjing 210023, China; Jiangsu Center for Collaborative Innovation in Geographical Information Resource Development and Application, Nanjing 210023, China

Abstract

Planation surface is the consequence of the denudation and planation processes under a tectonic stable condition. The quantitative expression of the characteristics of planation surface plays a key role in reconstructing and describing the evolutionary process of landforms. In this study, Landform Planation Index (LPI), a new terrain derivative, was proposed to quantify the characteristics of planation surface. The LPIs were calculated based on the summit surfaces formed according to the clustering results of peaks. Ten typical areas in the Ordos Platform located in the central part of the Loess Plateau of China are chosen as the test areas for investigating their planation characteristics with the LPI. The experimental results indicate that the LPI can be effectively used to quantify the characteristics of planation surfaces. In addition, the LPI can be further used to depict the patterns of spatial differentiation in the Ordos Platform. Furthermore, the characteristics of the planation surfaces can also reflect the original morphology of the Ordos Platform before the loess dusts deposition process evolved in this area. The statistical results of the LPI show that there is a gradually increasing tendency along with the increasing of slope gradient of summit surface. It indicates that the characteristics of planation surfaces vary among test areas with different landforms. These findings help to deepen the understanding of planation characteristics of the loess landform and its underlying paleotopography. Results of this study can be also served as an important theoretical reference value for revealing the evolutionary process of loess landform.

Late Quaternary Alluvial Cone Formation and Climatic Change in the Konan District, Koriyama, Northeastern Japan

Funabiki, A and Seto, M

College of Engineering, Nihon University, Koriyama, Japan, bickey@mech.ce.nihon-u.ac.jp

Abstract

A new 30m-long drilling core was obtained from in the Konan district, Koriyama, northeastern Japan. The location is on the small alluvial cone formed at the foot of the Oumountains, which was formed by old debris flows from mountains.

The core consists of the alternations of gravel and peaty silt layers, with some volcanic pumice layers accumulated during the late Quaternary. Gravel layers are poorly sorted and contain much plant fragments and wood pieces. We carried out radiocarbon dating, tephra analysis, and pollen analysis. These results enabled us to consider the environmental change of the Inawashiro basin, surrounded by the Oumountains, during late Quaternary period.

In this presentation, we will discuss the age of the debris flows at the drilling point. Furthermore, local environment changes in this region during the late Quaternary will be discussed.

Late Quaternary Glacial Landform Evolution and Paleoclimatic Implications of the Tien Shan Mountains

Gengnian Liu, Jing Xiao, Zhenyu Nie, Yixin Chen

College of Urban and Environmental Sciences, Peking University, Beijing 100871, China, Liugn@pku.edu.cn

Abstract

The Tien Shan Mountains are located in arid, mid-latitude regions in Central Asia, with abundant glacial geomorphological and depositional phenomena. However, Late Quaternary glaciations and their climate implications in Tien Shan are lack of attentive discussion. Based on previous glacial landform and chronological studies, and modern landform analyses, we select 7 typical study areas where glacial landform and chronological data are available in Tien Shan, to discuss the Late Quaternary glacial history and the paleoclimate change. The temporal and spatial characteristics of glacial landforms in Tien Shan show that from MIS 4, through MIS 3 and MIS 2 to Holocene, the climate of Tien Shan area gradually dried. The great glacial expansions in MIS 4 and MIS 3 are related to more moisture brought by westerlies from ice-dammed lakes formed by Eurasian Ice Sheet. Since MIS 2, the gradually strengthened Mongolia High and decrease of moisture brought by westerlies might be reasons for glaciers becoming smaller and smaller. The local reliefs also play an important role in glacier size.

Tien Shan; Last Glacial; climatic change

Luminescence Dating of the Minjiang River Terraces and Its Geomorphological Implication

Yesong Han, Zhijiu Cui, Gengnian Liu, Jiafu Zhang*

MOE Laboratory for Earth Surface Processes, Department of Geography, College of Urban and Environmental Sciences, Peking University, Beijing 100871, P. R. China, yshan@pku.edu.cn

Abstract

The river terraces of Minjiang located at the east margin of the Tibet Plateau have been used to investigate the tectonic history of the region during the late Quaternary. However, the chronology of the terraces has not been well constructed due to the lack of suitable materials for dating. In this study, we investigated the river terraces in the upper reaches of the river in Songpan, a total of five terraces were identified in the field. 21 terrace samples were collected for optically stimulated luminescence (OSL) dating. The results showed that some samples were not well bleached at the time of deposition. Based on the equivalent dose (D_e) distribution and the value of the overdispersion, a minimum age model (MAM) was used to calculate the D_e values of the samples. The minimum ages obtained are considered to represent the true burial ages of the samples, and then the formation ages of the river terraces. The five river terraces were thus dated to ~ 3.3 , ~ 7.2 , ~ 12.7 , ~ 40.9 and ~ 55.4 ka, respectively. Based on the terrace ages and their elevations above the modern channel, the river incision rates were calculated to be 0.90-1.49 mm/yr, which reflect the differential uplift rates during the past ~ 55 ka. In addition, the terrace ages are also compared with the ages of moraine deposits located in the Xuebaoding Mountain close to the Minjiang River. The factors affecting the formation of the terraces were discussed, including the uplift of the Minshan and Longmenshan mountains.

Minjiang river terrace; Luminescence dating; Minimum age model; Tectonic uplift

Modeling Geomorphic Processes and Simulation of Virtual Landform Changes for the Future 120ka Shown as Animations

NOGAMI, Michio

Emeritus Professor, Tokyo Metropolitan Univ. Japan, mnogami@h07.itscom.net

Abstract

A versatile simulator of landform changes was built up in Windows® computer. All parameter values are designed to be obtained from a separate list file. Initial conditions are a DEM of an island in this case and corresponding digital map of rock types. The simulator is adaptive to (s-1) wearing down of slope, (s-2) intermittent collapse of loose layers on steep slopes, (f-1) fluvial erosion of bed rocks, (f-2) sediment transportation with progressive abrasion of gravels downstream, (m-1) storm-originated sea-cliff collapses, and (m-2) wave erosion and sediment transportation above the surf-base.

Sea-level as an independent condition of the simulation is designed to be selectable from prepared change curves, for example, the curve from the last interglacial (mis5e) to the last glacial maximum (mis2). The climate types "inter-glacial", "moderate" and "glacial" are classified according to sea-level heights in the curve. Coefficient values of diffusion models for slope and fluvial processes depend on the climate types, and determine speed of landform changes. The other intermittent events like as river flood and sea-cliff retreat will occur after probabilistically determinative equations.

Almost all parameters of geomorphic processes are unknown numerically in Geomorphology. But specific numerical values of them are required to run the simulator. The more than one hundred values in the list file were given after repeating trial and error observing animations of landform changes compiled from time-serial DEMs of the simulator output. The simulation is suggestive for understanding basic geomorphologic concepts that landform change, that is, height change is equivalent to difference between material in-flux and out-flux measurable for the simulation, and that different parameters of rock properties and climate types make different landforms through time.

Key words:

simulation; landform change; modelling; animation

Modern Methods for Studying Exogenous Processes OT the East European Plain

AydarSharifullin

Kazan Federal University, Kazan, Russia, luleo123@mail.ru

Abstract

The role of exogenous processes in the formation of sediment load is poorly investigate. The processes are not just change relief of the Earth, but they have more influence on agriculture, construction of hydropower. In the last decade the exogenous processes are studied by satellite data, 3D scanning and radioisotope methods. This study examines the modern methods of studying exogenous processes. For assessment the intensity of their makes vast-scale geomorphological map. It is used field data, results of identification of satellite images. On the satellite images identified landforms (areal and linear) and determined channel sediment storage inside small watersheds. Finally, we propose that geomorphological maps and data of intensity of exogenous processes can estimate the total volume of transported sediment.

Old Landslide Deposits and Formation of Block Stream in Mt. Maneo, South Korea

Seto M., Kim S-H., Nakamura Y. and Tanaka Y.

Fukushima University, Fukushima, JAPAN, msyk_seto@nifty.com

Abstract

This study revealed that formation processes and period of slope deposits include block stream near Mt. Maneo, South Korea. In this study, we examined slope deposits including a block stream on Mt. Maneo. When examining the plan view and incline of the block stream, we observe that in the central section of the block stream becomes wider, and the incline becomes gentler. The contour lines indicate the presence of a valley in the upper half of the block stream and a ridge in the lower half. We found some spring water at the upper end and lower end of block stream. These general geomorphological and hydrological characteristics mean that this block stream was formed by landslide. Outcrop shows a silt layer mixed with weathered gravel of biotite granite below the block stream. There are three silty layers. These layers contain weathered gravel and AT (ashfall). The weathered gravel and AT are scattered throughout the three silt layers, but never form their own layers. The results can be summarized as follows: On Mt. Maneo, after the AT descent around 26 to 29 ka, slope deposits consisting of weathered gravel and AT were mixed. At some point after this mixing period, a large-scale landslide that reached the weathering layer occurred. This was followed by the removal of fine-grained material from the landslide block by flowing water, which led to the formation of a block stream.

Sedimentary Environments of Terrace Gravel Layers of the Qingyi River along the Jingxian Basin, China, Based on a Combined Analysis of Gravel Fabric and ESR Dating

Chunsheng Hu, Youpeng Xu, Chenqi Hu

Anhui Normal University, Wuhu, 241000, P. R. China, huchsh03@163.com

Abstract

The Qingyi River, which issues from the northern fringe of Mt. Huangshan, is an important tributary of the lower Yangtze River. Field investigation focuses on the natural outcrops along the Qingyi River in the Jingxian Basin, where a well-preserved sequence of three terrace gravel layers is present. Based on the gravel fabric analysis and ESR dating, this paper tries to discuss the sedimentary environments of the terrace gravel layers. The results show that: (1) The gravels are mainly medium and coarse in diameter, showing the hydrodynamic conditions were strong in the formation periods of the terrace gravel layers when the maximum flow velocity could be up to 3.5 m/s; (2) The gravel orientations in the gravel layers of the T3 terrace and T2 terrace are 191° and 250° , respectively, pointing to SSW and SWW, similar to the present current; (3) The gravels are mainly sub-round or round in shape, implying these gravels should have been transported over a long distance from their provenances; (4) The terrace gravel layers contain mainly quartz sandstone, sandstone, vein quartz and quartzite, showing the change of the provenances was not significant; (5) The gravel layers of the T2 terrace and T1 terrace are typical fluvial sediments, whereas the gravel layer of the T3 terrace might be a product of the superimposition between debris flow deposits and fluvial deposits to some extent; (6) The ESR dating of the T3 terrace suggests that the Qingyi River has developed in the Jingxian Basin since about 0.9 Ma B.P., as a response to the MPR when the 0.1 Ma cycle began.

Spatial Association between Valley Density and Environmental Factors over the whole of Conterminous China

Xuezhi Cang, Wei Luo

Northern Illinois University, Dekalb, IL60115, USA, xcang@niu.edu

Abstract

The density of valleys is a quantitative parameter which describes the degree of land surface dissection. This research analyzes the valley density and environmental factors which include three types of environmental factors (geology, climate, and terrain). Previous research found contradictory results about the controlling factors in different research areas. We hypothesize that the dominant controlling factor, or the interactions between factors, vary from region to region due to differences in each region's local characteristics and geologic history. This hypothesis is tested by using the geographical detector method to conterminous China's three levels of physiographic divisions. The geographical detector method computes the power of determinant that quantitatively measures the affinity between the factor and valley density. Our results show that the factors, with the largest determinant value, or their interactions, with the largest determinant value, are different between physiographic divisions. For example, lithology dominates in mountainous regions, relief dominates in plains. We compared this result to a similar research over the entire conterminous United States

Spatial Association between Valley Erosion Degree and Mineral Factors over the Global Mars

Xuezhi Cang, Wei Luo

Northern Illinois University, Dekalb, IL 60115, USA, xcang@niu.edu

Abstract

Valley networks are the evidence of the fluid process that existed on ancient Mars. Their spatial pattern and erosion degrees vary from region to region. The main contributors to their difference are 1) ancient climate factors and 2) geological factors. The Mars' valley networks were mainly formed in Noachian period (3.1-4.7 Gya). The high resolution and high accuracy ancient climate distribution is hard to estimate from the existing data because of lack of in situ data. The terrain and geologic factors may have been changed over time, however they are more stable and easier to estimate than climate, because of low temperature, lack of liquid water and weak tectonic plate process. The valley networks have been modified by re-surfacing processes and the impacting of craters, however their depths and boundaries could be extracted from terrain data. The terrain data was provided by Mars Orbiter Laser Altimeter (MOLA), which covered Mars' global surface, and High/ Super Resolution Stereo Colour Imager (HRSC) which covered 50% of the surface. The mineral endmember data was provided by the OMEGA Mars global maps which used an infrared mineralogical mapping spectrometer. These maps provided six types of endmember on the Mars surface. This research used different resolution digital elevation model (DEM) data to estimate the erosion degree and analysed the relationship between erosion degrees, mineral endmembers, and terrain factors by applying the geographical detector method to the Mars geological divisions. The results showed that the factor, or their interactions with the largest determinant value, is different for geological divisions.

Study of Glaciers in Drass Basin and Mass balance of Machoi Glacier in Kargil district, J&K–India

Davinder Singh¹, Rajinder Singh²

¹Ph.D Scholar, Department of Geography, University of Jammu- J&K, India-180006

²Cartographer Department of Geography, University of Jammu, Jammu -J&K, India Email id: manhasgis@gmail.com

Abstract

The Himalayan Glaciers comprise nearly 30% of glaciers outside the polar region and cover an area of 20 times the glaciers of Alps (Weismann, 1959). Drass is one of the coldest places in India and second in the world. It extends from Gumri (Close to Zojila pass) on National highway in the west to Kargil district. Drass sub-basin holds special geographical significance for the study of snow cover changes in the light of climate change phenomena. The study region has cold sub-arid type of climate with long chilly winters (Oct. to May) with minimum temperature ranges from (-15°C to -25°C) and strong snow storms, and a short mid summers (June to Sept.) with maximum temperature varying from 10°C to 25°C. Drass in western Ladakah is located at the altitude of 3230m in the Kargil district of Jammu and Kashmir. From the last ten years Drass basin glaciers have shown slight changes in snout position and 40% retreat and 60% advance. Overall the glaciers positive and negative balances thus indicate that glaciers are having secular retrial with large percentage of steady state.

Tectono – Morphic Analysis of Sundor Basin in Chhattisgarh, India

Ahamed Sk Nasib

Research Scholar, Raipur, India, 492010, nasibahamed@gmail.com

SOS in Geography, Pt. Ravishankar Shukla University, Raipur, Chhattisgarh.

Abstract

Tectonic activities shape the terrain. Topography is the surface expression of the earth surface motored by tectonic deformation which encourages the denudation process. Rivers are the most powerful agent among all denudation agents. Tectonic activities play an important role for developing drainage system and controlling the river behaviour. In the present study morphometric analysis has been carried out in Sundor basin with the help of geospatial technology. Morphometric analysis helps to understand the tectonic incidents as well as the present condition of the basin. Various geomorphic indices of active tectonics (GAT) are measured in Arc GIS environment using SRTM DEM and topographical sheet. Lithologically the area is homogeneous in character (mainly granite rock) which gives birth the dendritic drainage pattern and all the rivers are monsoon fed. The geomorphic indices reveal that the Sundor basin is in old stage or monadnock stage where recent tectonic deformation is not found. Some portion of the upper basin indicates the late youth and early mature stage but it has happened due to the hardness of rock (granite) and lack of erosive agent (water). Over the entire basin is tectonically stable in condition. This study demonstrates the importance of geomorphic study as well as geospatial technology to evaluate the tectonic sensitivity.

The Progress of DEM based Terrain Texture Research—A Novel Perspective of Digital Terrain Analysis

Xiaoli Huang, Guo'an Tang, Kai Liu, Wufan Zhao, Jiaming Na

Key Laboratory of Virtual Geographic Environment (Nanjing Normal University), Ministry of Education; Jiangsu Center for Collaborative Innovation in Geographical Information Resource Development and Application, Nanjing, 210023, P. R. China, xiaoli_yanyee@vip.163.com

Abstract

Existing digital terrain analysis is mostly based on the neighborhood or track analysis to get terrain factors. Obviously it is hard to reflect the characteristics of the topography in a macroscale. To solve this problem, we did a lot of works on DEM textures. In some particular spatial scales, natural terrain texture distinctly shows the similarity of similar landforms and the difference of different landforms. Unlike the satellite images texture, DEM terrain texture expresses pure terrain without surface mulches. Some major achievements were: (1) Proposed conceptual models of DEM texture and its basic attribute, influencing factors, internal mechanism and external appearance. Besides, built a mathematical model for describing it. (2) Hu Invariant Moment model, spatial Gray-level Co-occurrence Matrix model (GLCM), improved three dimensional lacunarity model (3D-LCA) and Daubechies-4 wavelet decomposition model are selected and improved to quantify the morphological and spatial structural features of landform. (3) Discussed the application of DEM texture by two examples: recognition of the mare and lunar highland; recognition of typical landforms in the Loess Plateau. On the basis of the above research, we explore a new research method of landform morphology cognitive, analysis, quantization and application based on texture analysis. The results show that texture analysis starts from human vision perceptive mechanism can effectively analyze and quantify the morphological and structural characteristics of terrain surface at multi levels of terrain morphology. Texture based digital terrain analysis methods can better explore and recognize the spatial distributing characteristics and the nested hierarchical structure characteristics of landform morphology.

Three-Gorges Dam: A Gigantic Mechanism for All-Year-Round Riverbed Erosion of Yangtze River

Daowei YIN, Xiaohe LAI, Zhongyuan CHEN

State Key Laboratory of Estuarine and Coastal Research, East China Normal University, Shanghai, 200062, P. R. China,

dwyin@geo.ecnu.edu.cn

Abstract

Three-Gorges Dam (TGD) play an important role on the adjustment of the runoff and sediments from the upper Yangtze to the estuary. This adjustment strengthens the stream power and accelerates the incision of the middle Yangtze channel. Although previous studies predicted the evolution of the Yangtze after the construction of the TGD, the limitation of the incision is still unclear. This study aims to investigate the potential of incision of the middle Yangtze in order to understand the recent mechanism of the river bed evolution by using the hydrological data from nine main gauging stations (from 1950s to 2010s). The preliminary results demonstrate that after the construction of the TGD, (1) the mechanism of the erosion and deposition alters from “non-flood-deposition and flood-erosion” to all-year-round erosion; (2) the closer to the TGD, the worse the relation is between the discharge and sediment concentration; (3) erosion is resisted by the gravel armour layer at upstream of the Shashi Station and the channel between the Shashi and Jianli Station currently suffers from the most intensive erosion in accordance with the grain size analysis; (4) the channel downstream the Jianli Station still has potential to be eroded based on the carrying capacity calculation. Briefly, this study indicates that the middle Yangtze River is under the all-year-round erosion and is experiencing an adjustment from an unsteady stage to a new steady stage. The next goal of our study is to discover the temporal and spatial limitation of the influence of the TGD.

Yangtze River; Three-Gorges Dam; River bed erosion; Carrying capacity

Topographic Mapping of Large-Scale Tidal Flats Using Waterline Method

KANG Yanyan, DING Xianrong, ZHANG Chuangkuan, GE Xiaoping

Hohai University, Nanjing, 210098, P. R. China, kangyanyan@hhu.edu.cn

Abstract

Tidal flats, considered as a natural ecosystem and landscape style, have an important environmental function and significant resource potential, especially in terms of land. Remote sensing has become an established technique for the measurement of topography over tidal flats; of such methods, the waterline method is particularly effective for constructing a digital elevation model of intertidal areas. Based on this method, this paper concentrated on obtaining a topographical map of tidal flats on Radial Sand Ridges in the southern Yellow Sea, using optical remote sensing images (HJ-1 and TM) and a high-precision hydrodynamic model based on measured water level data. From December 2013 to May 2014, 21 waterlines under different tidal conditions were extracted from satellite images. A hydrodynamic numerical model was established and run to simulate the tide level for every position of the waterline at the time of image acquisition. Five new tide stations were built for both monitoring the variation of tidal level and accurate validation of the numerical model. The points from every waterline were given the synchronous tide level values calculated from the model. The DEM was then generated using the natural neighbourhood interpolation method based on the height attribute of 21 waterlines. In this paper, a DEM covering an area of approximately 1900 km² was constructed using the waterline method. The height accuracy of the DEM was within 20 cm. This method offers the clear advantage of being able to construct an intertidal DEM over large areas cost effectively and efficiently.

Abstract

The ancient mounds are the area of human activity in the near and far past. These places may be the ruins of remainders or transit camp of a village or town. This study examines the archeology of ancient mound of Meymanatabad by using granulometry, geochemical and micromorphological methods. Natural and cultural characteristics of the samples taken from Meymanatabad site were studied and finally, the abandonment of settlements or their shift to another place was examined. In general, the results of the study showed that residents were strongly influenced by changes in water flow and river course changes on the alluvial fan of Karaj River and its tributaries like Shadchay River. Since the youngest sediments of Shadchay River terraces are sedimentologically bimodal, it represents the theory of flow rate and its impact on the residents. Based on micromorphological and clay mineralogy results before the entrance of settlers, warm and wetter conditions than present predominated over the region. According to the cubic _ microscopic structure that is characteristic of the natural samples of region, a period lack of establishment from section E to section D has occurred. Section C is the last stage of culture and after this section cultural heritage is not present. The results show that flooding was the main reason of disappearance and abandonment of the civilization from the Shadchay River bank which resulted in the loss of civilization in this region.

Abstract

Identifying the provenance of aeolian sediments in the Ordos deserts is of great importance for understanding the responses of earth surface processes to climate change and the linkage with the Yellow Rivers which is still controversial. We investigate the major, trace and rare earth element composition of sandstones, lacustrine sediments and aeolian sands collected in the Ordos deserts. Our result shows that the aeolian sands in the Kubq Desert have experienced multiple sedimentary cycles. They derived primarily from the north Tibetan Plateau by the Yellow River rather than from the sandstones underlying Aeolian sands. No obvious genetic linkage between the Helan Mountain, the Yinshan Mountain and the aeolian sands in the Kubq Desert. The lacustrine sediments and sandstones are the main sources of aeolian sands collected in the east part of the Mu Us Sandy Land, but they may not contribute much to aeolian sands in the west part of the Mu Us Sandy Land, especially the lacustrine sediments. Aeolian sands collected in the west part of the Mu Us Sandy Land have been transported by rivers according to the grain size distribution and trace and rare earth element composition. Further study still needed to determine which contribute more on transporting sands, either the Yellow River or small rivers developed in the Mu Us Sandy Land.

Abstract

The Arabian Gulf is characterised by important sea level glacio-hydro-isostatic fluctuations during Late Pleistocene and Holocene. Between Late Glacial Maximum and 6 000 years BP, the Gulf basin is relatively quickly flooded, through an important post-glacial marine transgression. So far, researches has considered this sea level drop as globally homogeneous. However, coastline lateral geometry variations are much more complex, especially because of uplift processes and diapiric dynamic.

Holocene human occupation of Western Abu Dhabi coastal areas remains still quite poorly known, in spite of archaeological survey and excavation programs. Reconstructing these coastline local variations become thus a key issue to characterize coastal palaeo-environments during Holocene and identify the spaces settled by human populations.

In order to adress theses issues and bring elements of response, we relate geological, geomorphological and archaeological data, by using ArcGIS10.1. A review of the archaeological sites of the region, allowed us to define the spatial and temporal indicators of human coastal occupation. On the other hand, a fieldwork has been conducted in specific coastal places, identifying coastal geomorphological landforms (beachrocks, beach ridges) as sea level indicators during Holocene. Selected samples were dated by 14C AMS method.

Crossing and relating all theses data allow us to model relative sea level variations, comparing with the glacio-hydro-isostatic model of Lambeck, and determine the evolution of western Abu Dhabi coastline area and its human occupation through Middle to Late Holocene.

Abstract

Clay dunes, characterized by a higher content of silt and clay commonly occurred on the lee side margin of closed-basin in arid and semi-arid areas, are important component of aeolian landform and extensively identified in most of continents on the Earth. While little is known about its development and distribution in Asian continent. Our field investigations firstly identified the occurrence of clay dunes in the Alashan Plateau Desert, north China, an important part of arid central Asian. Clay dunes occurred in three isolated lowland areas of the SHT Basin are of barchans, hooked barchans, asymmetrical barchans, linear or seif dunes in morphology, which are different to most of the well-studied clay dune in Australian, African and American. These differences may be main attributed to the asymmetric bimodal wind regime, prolonged droughts and physical nature of sediment. Based on the history of the SHT lake-basin evolution and climate change, we inferred that the landscape of modern clay dunes in Alashan Plateau Desert could not predate to the MIS 5, and probably formed since late Holocene. Evidences from characteristic of particle size distribution and trace and rare earth elements, combining geomorphological characteristic, indicate that source sediment of the clay dune are main derived from the local Cretaceous and Quaternary red fluvial-lacustrine mudstone and sediment, and the ultimate source is the weathered and denuded products of granitoids from East Altay Mountains. Comparison of the shapes and alignments of clay dune with the pattern of winds tends to support Tsao's model of transitions in dune shape from barchans to seif or linear dunes. Seif and linear dunes laterally migrated and elongated, and the northeastward lateral migration was about 20~40 m and 100~200 m between 2003 and 2013 with a rate of about 2~4 m/year and 16~20 m/year, supporting the idea that seif and linear dune could migrate laterally, although the migration rate is very low.

Landscape Sensitivity, Climate Change and Land Use Change: Learning from the Past

Michael E Meadows

Department of Environmental & Geographical Science, University of Cape Town, South Africa,
mmeadows@mweb.co.za

Abstract

The concept of climatic geomorphology developed to explain apparent relationships, mainly at large geographical scales, between landforming processes and climate. Although there are clearly some problems of applying this idea to a direct understanding of the impact of climate change, there are situations whereby the dynamics of climate in the past, most particularly in the late Quaternary, can be shown to have impacted on geomorphic processes. Such evidence may be usefully employed in assessing the potential degree of landscape sensitivity to projected climate change in the future. Geomorphic process response to successive climate shifts in the late Quaternary is demonstrated, in the case of the Kalahari of southern Africa, to have been both substantial and widespread. Other case studies from southern Africa indicate the potential of land use change, coupled with climate shifts, to induce land degradation. It is concluded that a perspective from the past is useful in estimating landscape sensitivity to both climate and land use change in the future.

Abstract

On the basis of interpretation of satellite imageries and field investigations, we studied the distribution patterns of sand dunes in the Maowusu (Mu Us) Sandy Land in the southern Ordos Plateau, northern China. Our research questions included: which parameters are critically responsible for the landscape spatial pattern? How is the relative importance among various factors? Our initial analysis was enhanced by applying a new approach, i.e., the Geographical Detector that has been developed for geographical spatial analysis, and being now increasingly used in the epidemiology in China. Using the combined methods of the Geographical Detector, digital image processing, field investigation and Normalized Difference Vegetation Index (NDVI) spatiotemporal analysis, our work aimed to contribute to a better understanding of the causal relations between landscapes' distribution and variations of geographical factors within this Sandy Land and beyond. The findings of this study highlighted that the climatic potential productivity, local relief and river system are the first order of important factors in shaping the landscape spatial pattern. In addition, landscapes' distribution at different spatial scales is controlled by different predominant driving factors. Owing to different climatic backgrounds and land use histories, the responses to external forcing change between western part and eastern part of the Maowusu Sandy Land are out-of-step. We conclude that the desertification of the eastern part of Maowusu Sandy Land has been mainly caused by unecological human activities while the western part is governed by natural factors.

Landscape-Scale Geomorphic Evolution Constrained by OSL Dating: An Example around Taosi, an Archaeological Site in Eastern Loess Plateau of China

Zhou L.P., Feng J., Mo D.W.

Department of Geography, Peking University, Beijing, 100871, China, lpzhou@pku.edu.cn

Abstract

Reconstruction of landform evolution at landscape-scale is important for both geomorphological and archaeological studies. Previous attempts to constrain the chronology of the Earth surface processes of such a scale have been impeded by the lack of precise dating techniques. In this study, we apply optically stimulated luminescence (OSL) dating method to reconstruct geomorphic evolution at a relatively small scale around Taosi, an archaeological site in the eastern part of the Loess Plateau. The present landscape of Taosi area is a loess platform cut by several large deep gullies. It has been a mystery how the landform of such an area in the heart of an ancient capital has changed over the last few millenniums. Fluvial sediments samples at ten sites were collected and quartz extracted was dated with blue light OSL measurements. The OSL ages obtained vary from 0.9 ± 0.1 ka to 22.5 ± 2.1 ka. These new data provide not only chronological constrain on the evolution of the fluvial systems in the Taosi area but also clues for the connection between human activities and Earth surface processes during the last twenty thousand years.

Abstract

The history of the civilizations of the oasis of Bukhara and Qaraqol (south-eastern Uzbekistan) since the Neolithic in link with environmental changes is study by the French/Uzbekistan Archaeological Mission in Bukhara¹ in the continuity with pioneer Russian studies². Using a methodology tested in Afghanistan, the geoarchaeological side of the program focused on the drawing of a regional geomorphological map then on the identification, mapping and dating of the paleochannels of the river Zerafshan. We established the chronology of several fluvial channel generations by association with archaeological settlements of different eras (Early Neolithic, Neolithic, Bronze Age, Iron Age, Islamic period) and with optically stimulated luminescence dating carried out on alluvium deposits. Based on preliminary results of these OSL dates we propose and discuss a regional reconstruction.

Sediment Grain-size Analysis of the Niya Drainage Area in the Taklamakan Desert, Northwest China

Qida Jiang, Xiaoping Yang

Key Laboratory of Cenozoic Geology and Environment, Institute of Geology and Geophysics, Chinese Academy of Sciences, Beijing, 100029, P. R. China, jiangqida@mail.iggcas.ac.cn

Abstract

Sediment grain-size closely relates to sand migration, and the Niya drainage area is a representation in the Taklamakan desert, which sand migration is governed by aeolian and fluvial process. Therefore, we study the grain-size distribution of the Niya drainage systematically to explore mechanisms of aeolian and fluvial transport and to identify grain-size characteristics of internal drainage systems of the Taklamakan desert. In this study, grain-size parameters of 29 aeolian and fluvial samples from the Niya drainage area were analysed. The main composition of the Niya drainage area is very fine sand and fine sand. Sorting improves as mean grain-size decreases, sand become progressively symmetrical-skewed as sorting improves and become progressively mesokurtic as grain-size decreases. It indicates that the main loss of particle composition is coarser grains during sand migration in the desert. Combining topography, wind and hydrological data, our result shows an obvious different relationship between grain-size and sorting in cases of along the river and increasing distance to the river, indicating spatial variability of aeolian and fluvial transport. And a high difference of particles of the same latitude between adjacent drainage areas, implying restricted sand migration in the east-west direction. We herein conclude that grain-size parameters change regularly along the Niya river and others from the edge of the desert into the interior, and the two transports work variably both parallel and perpendicular to the rivers.

dzhang@mail.iggcas.ac.cn

Abstract

The grain-size distributions (GSDs) pattern of aeolian sands of an individual dune may contain information about fluctuations of wind regime and vegetation cover. While some earlier studies were focused on the response of GSDs to aeolian processes and source area, research of the effect of bi-modal wind regime and vegetation cover on GSDs is still rare. In this paper, grain-size parameters were determined for bulk sand samples along the longitudinal profile and crestline of a transitional (barchan-to-parabolic) dune. Along the longitudinal profile, the grain-size and sorting pattern is characterized with the finest sands and the worst sorting occurring on the middle of stoss face, and the coarsest sands and the best sorting occurring on the crest. Under the effect of spatial variation in vegetation and dune slope, the grain-size and sorting vary along the dune crestline, which is characterized by a decrease in grain-size and improvement in sorting toward two horns. Decomposition analysis of the bulk sand samples indicate that the modern aeolian dune sands contain a bimodal distribution with a coarse reptation and a fine saltation component. Our results show that each component in sand samples have different responding level to bimodal wind regime and vegetation cover. The coarse component, comprising the main part of the dune sand, has pronounced kurtosis and is well sorted, which is interpreted to be the product of sand transport generated by near-surface strong northwesterly winds. Conversely, the fine component has a wide grain-size range and is poorly sorted. Its modal size and sorting pattern suggest that it can be readily transported by near-surface weak southeasterly winds. It appears that temporal variation in dune-scale factors, such as wind regime, rather than vegetation, is responsible for the grain-size variations on a barchan-to-parabolic dune, and thus for its transformation.

Abstract

Over the past five years, the authors have conducted a geoarchaeological survey in Northern Henan Province, China, to test three hypotheses of regional and global significance. First, many Chinese archaeologists consider this area void of archaeological remains. Based on our data, the majority of the archaeological material in Northern Henan is far below the surface - approximately 5 to 8 meters. Our preliminary results suggest that an area over 50km² was buried by Yellow River flood deposits, preserving a great variety of archaeological and geological features, including roads, towns, fields, lakes, and buried soils, capable of answering many questions concerning the subsurface archaeological record of the region. We have found human disturbance in nearly all stable land surfaces dating from the Bronze Age to the Song dynasty. Some archaeologists argue that buried soils are a marker bed for the Anthropocene. The stratigraphic sequence in Northern Henan contains buried soils from as early as the Pleistocene and as late as the Song dynasty, making this an ideal area to test if buried soils do reflect changes in land use. Our preliminary results suggest that the deep sedimentary record of Northern Henan can reveal much about the intricate inter-relationship between human behaviour and environmental change.

The Geoarchaeology and Geomorphology of Maya Wetlands from the Late Holocene to the Anthropocene

Tim Beach

Geography and Environment, The University of Texas at Austin, United States, beacht@austin.utexas.edu

Abstract

Based on many field studies from 2000 to 2016 in Central America we present models of the natural and human factors of wetland agroecosystems. We start with the broader context by considering Pre-Columbian wetland agriculture in the Americas and in ancient China. Next, we consider multidisciplinary evidence for the formation of ancient Maya wetland agriculture. Evidence ranges from hundreds of field excavations to the lab with many radiocarbon dates, pollen, soil and water chemical analyses, and remote sensing including Lidar in 2016. We then consider the natural and human altered formation of wetland fields, what crops grew in the fields, and when they were active. We synthesize older models with new findings from three distinct wetlands field complexes on three chemically diverse river systems in Belize. Each system has slow rates of aggradation before the Maya Preclassic, about 3000 BP. After the Maya Preclassic, sedimentation increased, and multiple proxy show the expansion of cultigens like maize, cassava, and fruit trees. The Maya built field and canal systems in these wetlands over periods of drought and rising water tables in the Late to Terminal Classic from 1500 to 1000 BP, and the canals became traps for sedimentation after Maya abandonment about 1000 BP. Based on remote sensing, we next consider the extent and importance of wetland agriculture to Mesoamericans. Lastly, we consider what these agroecosystems tell us about adaptation and resilience to climate change but we question whether they provide a successful model for development and restoration.

Abstract

The initial formation of the current desert landscapes in northern China and the environmental changes in these regions since then have been a big question mark although deserts account for about one third of Chinese land territories. On the basis of detailed geomorphological and sedimentary studies and OSL chronologies of various sedimentary sequences, we suggest that the dune landscape of the Hunshandake Sandy Land in eastern Inner Mongolia has been initially formed about 4000 years ago, much younger than assumed earlier. The palaeoenvironmental proxies indicate that the currently desert-like areas were occupied by forest with different species of trees, and with dense occurrence of wetlands and rivers. Although the abrupt aridification of the regional climate ca 4200 years ago was crucial to this shift, we found out that geomorphological and hydrological processes had played a significant role in the change. The headward erosion of the Xilamulun River reached the sandy land also ca. 4200 years ago, drained the water via groundwater sapping and caused ca. 30 m decrease in groundwater table. The loss of water via groundwater sapping is still going on, and impacts the environments and human society even today.

Abstract

Understanding how aeolian sediment systems respond to internal and external forcing factors is important to evaluating their significance as an environmental proxy. Comparison of granulometric characteristics between aeolian and fluvial sediments in the Ejina Basin was conducted in this study aiming to examine the textural response of single-process systems in desert environment. Sediments studied were collected from four geomorphological units, i.e. river channel (fluvial), foredune (palaeo-alluvial), interdune and dune crest (aeolian). Most of the dune-crest sands are of unimodal distribution with medium to fine sand. The interdune sands are generally bimodal to slightly polymodal with medium and fine sand. The foredune and riverbed sediments are greatly polymodal with wide size classes. All Mz values of aeolian, fluvial and alluvial sediments tend to decrease from southwest to northeast, but in different SD patterns, indicating a general grain-size variation but different sorting processes between wind-dynamical and water-dynamical sediments at the basin. Aeolian sediments are relatively coarser and worse-sorted in comparison with other deserts, implying closer sources for the Ejina dunes. Detrital-sediment transportation modal analysis suggests that sources of aeolian sediment for the most part are the distal palaeo-alluvial fan deposits (foredune) rather than the modern fluvial sediments. The Ejina dunes is unlike so-called 'mature' sands (e.g., central Namib Sand Sea), which lie at some distance in space from the original sources of sediment, indicating that the availability of particle sizes in source area exerts a strong influence on the formation of aeolian dunes in the Ejina Basin.

P7), 1 rue Jussieu, 75238 Paris, Cedex 05, France**Abstract**

In sand seas submitted to multi-directional wind regimes, star dunes exhibit crests with various orientations giving rise to a huge variety of shapes. Using numerical modelling, we show that stationary star dune patterns may be the result of simultaneous growth in both the bed instability and the fingering modes. As the central part grow in height from the local sediment source, arms may extend in multiple directions. Thus, distinct sediment fluxes may coexist as the result of the speed-up effect in multidirectional wind regime, i.e., the apparent dune aspect ratio is not the same for each wind. We also find that star dune morphodynamics is not only related to the period of wind reorientation but also to the specific sequence of wind directionality. Starting from a flat sand bed, star dune fields may develop as individual dunes collide with one another and exchange sediment through their arms dynamics. Then, star dune size is not entirely controlled by the depth of the flow even if they need to remain voluminous (i.e., few times the elementary length scale for dune formation) to combine a variety of superimposed bed forms.

Geohistorical Analysis of Fluvial Landscape Evolution near A Roman *Villa* in Western Switzerland

Capt M¹, Reynard E¹, Dubois Y²

¹Institute of Geography and Sustainability, University of Lausanne, Lausanne, Switzerland

²Institute of Archaeology and Sciences of Antiquity, University of Lausanne, Lausanne, Switzerland,
emmanuel.reynard@unil.ch

Abstract

In the Menthue catchment (Western Switzerland) archaeological remnants of a Roman *villa* are investigated in a rural area, near Neuchâtel Lake. Aerial photographs, taken in particular during dry years (e.g. 2003), show traces of former meanders of the Menthue River close to the villa location. In order to study the Menthue River former channels and the former lake shorelines, a geohistorical analysis was carried out, combining several methods: (1) High-resolution (2m) Digital Terrain Models (DTM) processing; (2) Analysis of historical maps dating back to 1722 AD; (3) Analysis of vertical aerial photographs of the Swiss Topographic Service (swisstopo) dating back to 1934; (4) Analysis of oblique aerial photographs using the WSL-monoplotting tool. Processed images and documents were included in a Geographical Information System (GIS).

The various analyses allowed us: (1) to reconstruct palaeo-channels of Menthue River and palaeo-shorelines of Neuchâtel Lake; (2) to map a maximum space of river divagation; (3) to show a fluvial metamorphosis (from a braided river to a meandering river); (4) to show possible links between former meanders, an possibly artificial watercourse and the villa. Nevertheless, the absence of sedimentological investigations and absolute dating – which are the next step of the study – only allowed us to reconstruct a relative landscape evolution.

Heavy Metal Contamination of Agricultural Soils in the Low Reaches of the Yellow River

LIU Ziting, ZHANG Baohua, CAO Jianrong, TANG Qingxin, TAO Baoxian, DONG Jie

School of environment and planning, Liaocheng University, Liaocheng, 252000, China, zitingliu@126.com

Abstract

Heavy metals are potentially harmful contaminants that can accumulate in the tissues of organisms and cause severe environmental damage. Thus it is necessary to assess the accumulation degree of heavy metals in agricultural soils. In this study, surface and profile soil samples in agricultural fields were collected from the low reaches of the Yellow River. The concentrations of trace elements were measured using the inductively coupled plasma-mass spectrometry (ICP-MS). The results show that the concentrations of heavy metal elements such as Cr, Ni, Cu, Zn and Pb in most samples are lower than the recommended values of the Environmental Quality Evaluation Standards for Farmland of Edible Agricultural Products (HJ/T 332-2006), but the Pb concentrations in the roadside soils are higher than the standards. The chondrite-normalized rare earth elements (REE) of soil samples are characterized by similar distribution patterns. Based on the distributions of trace elements data, we suggest that the abundances of Pb, Cu, Zn, Ni and Cr in the agricultural soils from the low reaches of the Yellow River were mainly sourced from natural species, but the positive anomalies of Pb were derived from human activities.

Holocene Landscape History of Lower Yellow River Valley: A Geoarchaeological Approach

Lee, Jinok

University of Texas, Austin, US, jlee8295@gmail.com

Abstract

The region of the Yellow River valley has experienced significant climate and geomorphic change through time. Since the broad floodplain of the Yellow River and its tributaries is very sensitive to hydrological changes caused by climate and human land-use, the sedimentary archive of the Yellow River system provides valuable information on the long-term alluvial history of the catchment. In this poster I present results of Geoarchaeological and archaeobotanical investigations I conducted in multiple locations in Shandong Province, including Rizhao, Heze, and Qufu. The research focuses on ca. 6000 years in the region, from the early Neolithic to the Han Dynasty. Using geomorphological and archaeobotanical data, I reconstruct local-level environmental history and land-use practices, to demonstrate that farming communities had sophisticated adaptation strategies to cope with environmental variations.

Provenance of Aeolian Sands of Dune Fields in Northern China, Inferred from Geochemical and Sedimentological Data

LIU, Ziting¹, YANG, Xiaoping²

¹School of environment and planning, Liaocheng University, Liaocheng, 252000, China, zitingliu@126.com

²Key Laboratory of Cenozoic Geology and Environment, Institute of Geology and Geophysics, Chinese Academy of Sciences, Beijing, 100029, China

Abstract

Identifying provenances of aeolian sediments in dune fields is of great importance for understanding the formation of dune fields, surface processes and dynamics of aeolian sand systems. By using the published geochemical and sedimentological (mainly grain size) data of aeolian sands from the Hunshandake Sandy Land, the Badain Jaran Desert and the Taklamakan Desert in northern China, we compared and investigated the sediment sources in the desert belt of northern China. The trace elements data show that the sources of the coarse- and medium-sized dune sands, the major component of aeolian sands, change distinctly among the various dune fields, suggesting diverse sources constrained by local geology and geomorphology. Trace elements and grain size features suggest that aeolian sands should be sourced mainly from the surrounding mountains initially via fluvial processes.

Abstract

The coastal and marine area surrounding the Attica Peninsula and the southwest Euboea Island has a high geoarchaeological potential, since intense human activity has been ascertained from Neolithic. This region has played an essential role in Bronze Age cultural interactions and the subsequent evolution of the classical Greek civilization. However, few studies have combined the cultural growth with the landscape changes caused by the Holocene fluctuations of the sea level. During Early Bronze Age, the sea level was about 5 m lower than its present-day position, and therefore, the Greek mainland had a greater surface area. Nowadays, the locations of the paleo-shoreline are detected by a variety of archaeological and geomorphological indicators, such as the submerged ancient constructions in Delfinion (pier), Sounion (walls), Pountazeza (Public building with ashlar marble blocks), Anavyssos (coastal settlement), Daskaleio (mole) and Marathon Plain – Nea Makri (remains of settlement), as well as the submerged beachrocks in Aghios Nikolaos – Thorikon, Sounion, Aghios Nikolaos – Anavyssos, Aghios Nikolaos – Kalyvia and Eretria. The presence of the aforementioned sea level indicators is crucial for identifying not only the local climatic conditions during Holocene, but also the relative vertical movements (uplift of subsidence) due to tectonic activity. The present study collects, analyzes and assesses the available geological and archaeological information that focus on the gulfs of eastern Saronikos, western Petalion and Euboean, as well as it reconstructs the paleo-shoreline since Early Bronze Age. Landscape changes seem to be related with shifts in settlement patterns, resource exploitation and engagement of ancient civilizations with the sea.

Shallow Landslide Study and Mapping in Volubilis Archaeological Site (Morocco)

Rouai M, Dekayir A, Qarkory Kh

My Ismail University, Faculty of Sciences of Meknes, PO box 11201, Zitoune 5000, Meknes, Morocco,
mohamed.rouai@gmail.com

Abstract

Volubilis is an important and famous Roman archaeological site in Morocco. Founded in the 3rd century BC, the site holds fine monuments and beautiful Roman mosaics, and is classified as world cultural heritage by Unesco.

Volubilis is located 400m height on the south-western hillside of Jbel Zerhoun mount, with 10% average slope, the most part of the city lies on marls of Miocene age, overlying calcareous Jurassic terranes.

A field study showed obvious soil instability, consisting mainly of a superficial gravitational creep. This landslide phenomenon affects some precious Roman mosaics, and threatens to ruin ancient house walls. The marls mineralogical composition and the geotechnical characterization showed a high swelling potential of these expansive soils.

In the north-eastern quarter of Volubilis, measurements of the whole house walls inclination using a dipmeter device have been carried out, leading to determine the magnitude and direction of soil displacements and to perform statistics.

The study has led to draw quantitative mapping of marly soil movement, mapping both the direction and intensity of displacement, and to determine the most vulnerable zones and walls under the threat of fall over.

The establishment of database maps under a geographic information system (GIS) will be an important tool for monitoring the landslide phenomenon and the proposed solutions for risk mitigation, contributing to the protection and conservation of this universal human heritage.

A Case Study of Nujiang Prefecture: Construction of Ecological Security Pattern in Alpine-Gorge Area

LI Yi-min

School of Resource Environment and Earth Science, Yunnan Institute of Geography, Yunnan University, Kunming 650091, Yunnan, China, 648119611@qq.com

Abstract

As part of our national security, correlational research on ecological security must be given high attention. Aiming at the importance of ecosystem services, such as biodiversity protection, water and soil conservation etc., scholars focused on building up ecological security pattern based on ecological principles. Many factors must be considered when build up ecological security pattern in alpine-gorge area for its prominent and complex ecological security issues. Take Nujiang Prefecture, a typical alpine-gorge area, as study area, this program will build up ecological security pattern based on the characteristic of seriously water and soil erosion, geological disaster susceptibility and the human settlements environment vulnerability. 3S technology, hydrological analysis model and methods of landscape ecology were applied to this research to identify the key “source land”. Then build up ecological security pattern of Nujiang Prefecture based on resistance surface constructed by the factors of ecological security assessment, elevation and slop with the MCR model. After that, identify the corridor and node, then set key node in the eco-fragile region to improve the landscape connectivity.

Assessment of Geo-hazards Induced by Gorkha Earthquake Sequences in Nepal

Koirala, H. L.

Central Department of Geography, Tribhuvan University, Kathmandu, Nepal, Koiralah@ntc.net.np

Abstract

Nepal experienced a major earthquake with magnitude of 7.6 on 25 April, 2015 and was followed by more than 30,000 aftershocks out of which 400 were greater than magnitude of 4.0. The district level database produced by the National Planning Commission had recorded 8,800 casualties and over 22,000 injuries and displacement of more than 100,000 people as the overall earthquake disaster affect. There were lack of information on the damage and loss from the earthquake induced geo-hazards. However, literatures have identified that the high magnitude earthquake followed by many aftershocks results a number of geo-hazards particularly in mountain areas. The present study is an attempt to explore the earthquake induced geo-hazards and its losses within seven severely affected districts. The study is based on secondary data collected from different sources such as national daily newspapers; Google Earth Images; available reports; District offices and primary data generated through case studies at local level. The study identified altogether 1654 landslides covering a total area of 3121.68 hectare. The results produced different clusters of districts in numbers of pre-existing landslides and landslides induced by the earthquake sequences. The study found that the analysis on local level are more useful than the district level in representing ground realities on the damages and loss from the earthquake as well as geo-hazards induced by earthquake sequences.

Abstract

Debris flows are one of the common natural hazards in the mountainous area. They often cause devastating damages to the lives and property of local people. The construction of drainage channels in the discharging area is considered to be a useful method for hazard mitigation. Due to the lack of energy dissipation, large scale debris flows often lead to serious abrasion on the channel surface. In order to prevent drainage channels from scouring by debris flows, a new type of debris flow channel with stepped dissipaters was proposed. Debris flow patterns under different types of drainages (Rectangular channel, Dongchuan channel, and channel with stepped dissipater) were investigated. Variation of flow velocity and debris flow depths along the drainage channel was measured. The mechanism of energy dissipation was also analysed for the new type of drainage channel. The results indicated the drainage channel with stepped dissipater had higher energy dissipation than that of other types of drainage channel. With decreasing the debris flow scales, the energy dissipation rate for the drainage channel with stepped dissipater increased gradually.

Abstract

Due to the ecological vulnerability and the strengthening of economic activity as well as the interaction between them, the human-land relationship of the Upper Minjiang River Basin become worse which restrict the sustainability of the basin. So we choose it as study area to explore characteristics, change and sustainability strategies of human-land relationship.

This research includes four parts. Firstly, it quantitatively analyzes the element of human-land system and explains the relationship and interaction between each system. Secondly, it quantify human activity intensity and ecological vulnerability from spatial aspect, and builds a comprehensive discriminant model to explain spatial pattern of human-land relationship. Thirdly, it analyze the change and development trend of human-land relationship by matter-element model and Grey model. Fourthly it provides suggestion for human-land system sustainable development.

The result shows that: (1) the settlement distribution and mountain disaster distribution is highly overlapped, due to the contradiction between the space limitation and increase of construction demand, the human-land relationship is intension; (2) When the altitude is lower than 2300m, human-land relationship is the worst, meanwhile the juncture of Wenchuan county, Mao county and Li county is cool point which means the contradiction of human-land relationship concentrate in these area. (3) The human activity index and resource-environment carry ability index respectively increase from 0.141, 0.172 to 0.502, 0.298 from 2000 to 2010. If keep the same way of development, the two index will increase from 1.24, 0.36 to 8.43, 2.18 from 2015 to 2025. The human-land relationship will become worse and worse.

Abstract

The areas affected by landslides in the earthquakes correlated with earthquake magnitude and other factors. Some empirical formulas just discuss the main factor magnitude with areas. However, the terrain can have a great effect on the landslide areas. In this study, we use the database of earthquake-induced landslides and digital elevation model to establish a modified correlation by terrain. The result indicates different places have different terrain, the former empirical formulas can be modified by calculating the terrain prominency. It can also increase the relevance of landslide areas and magnitude.

Dynamic Analysis and Numerical Modeling of the 2015 Abandoned Soil Landslide in Guangming New District, Shenzhen, China

Ouyang, chaojun

Institute of Mountain Hazards and Environment, CAS, #.9, Block 4, Renminnanlu Road, Chengdu, China,

cjouyang@imde.ac.cn

Abstract

As amounts of underground and slope excavation work is done with the urbanization process, a rising number of abandoned soil sites are built between the ravines around in the cities. Analysis of its mobility and risk of this kind of landslide is crucial for city managers. In this paper, the recently occurred abandoned soil landslide in Guangming new district, Shenzhen, China in 2015, which caused 69 deaths and 8 losses, was investigated. In spite of no high rainfall and antecedent rainfall, about 2 million cubic meters abandoned soil traveled over a gentle terrain more than 1.0 km. It indicates its landslide mobility index ($H/L \approx 0.1$) is much lower than general designed value and value in most other cases. The depth-integrated continuum method and a MacCormack-TVD finite difference algorithm and discrete element method (DEM) were both adopted to numerically analyse this landslide. It is indicated that a Coulomb friction model with consideration of the pore pressure effects could well reproduce the dynamic process. Sensitivity analysis shows that the high pore pressure plays a significant role in its mobility is the key factor to its severity.

Ecosystem Service Function in Recovering Process of Desertification Grassland Since 1995 in Zoigê, China

Shui Wei, Bai Jianping, Jian Xiaomei

College of Environment and Resources, Fuzhou University, Fuzhou, 350116, China, shuiweiman@163.com

Abstract

Zoigê Plateau is not only the important ecological function area but also the environmental sensitive area in China. Specially, grassland desertification has happened at different degree under the dual influence of global climate change and unreasonable human activities. Large-scale vegetation restoration has been initiated by the central government over the past decades to improve ecosystem services, and ecological restoration benefit of desertification grassland is widely focused at home and abroad. The plant samples and soil samples were collected from five desertification grasslands of different managed year (including 1995, 2007, 2009, 2010, 2011 years) in Zoigê County. According to spatio-temporal eco-geographical process, the investigation and experiment was used to analyze the changes of ecosystem services from water and soil conservation, carbon sequestration and maintenance of biodiversity. The results show that along with the managed time increasing, community succession and soil physico-chemical property of the desertification grassland was gradually improved, and the function of soil and water conservation and carbon sequestration capacity was also enhanced. Overall, ecosystem service function was increased at different degree. Based on the above results, the research of ecosystem services can provide basic data for the government achievement of grassland desertification under the background of global climate change, and also provide a realistic basis for the further improvement of Zoigê desertification grassland management and the study of ecological restoration.

Experimental Study of the Impact Force and Superelevation Features When Debris Flow Passing Channel Curves

HUAN yuanhong^{1,2,3}; Zhaojinheng^{1,2}; HU Kaiheng^{1,2}; LI Pu^{1,2,3}

¹Key Laboratory of Mountain Hazards and Earth Surface Processes, Chinese Academy of Sciences

²Institute of Mountain Hazards and Environment, Chinese Academy of Sciences & Ministry of Water Conservancy

³University of Chinese Academy of Sciences

Abstract

Through conducting flume tests focused on the impact force and superelevation of debris flow when passing channel curves, we derive the following conclusions: 1. The impact force obviously increased in the outer flank and the eccentric degree of the impact load show positive correlation with the velocity of debris flow; 2. The peak values of the impact force of debris flow were treated with dimensionless analysis, and we obtain an effective formula to evaluate the space distribution of eccentric load; 3. The separation of solid and liquid phase when diluted debris flows passing channel curves is quite apparent while in the case of viscous ones, the separation of the two phases is hard to detect. In the same experimental conditions, the superelevation of the diluted debris flows is greater than that of the viscous ones; 4. The position of the superelevation peak value varies with the density of debris flow. It is in the intersection angle 75° of the curved channel for diluted debris flows, and in the intersection angle 45° of the curved channel for viscous debris flows.

³School of Geography Science, Nanjing Normal University, Nanjing 210023, China

Abstract

The eastern margin of the Qinghai-Tibet Plateau is one of the four most active landslide and debris flow regions in China. The previous research points out that the Late Quaternary rapid uplift and deep incisions of valleys control the occurrence and distribution of landslide. The purpose of this study is presented the approach for the analysis of distribution characteristics and modeling of the multi-temporal landslide considering the regional geomorphic evolution. We combine the landslide causative factors, elevation-area integral value, and drainage branching ration to the eastern margin of the Qinghai-Tibet Plateau of the geomorphic evolution. The pre-Holocene to recent landslides (include fossil landslides, rainfall triggered landslide and the WenChuan Earthquake induced landslides) inventory are built up based on the previous papers, these geological hazard investigations documents, field investigation, monoscopic manual interpretation, image classification and texture analysis using SPOT 5 and ALOS remote-sensing image data. The landslide causative factor database was constructed, digital elevation model (DEM, 30×30m and 90×90m) and derived topographical parameters (e.g. altitude, slope, aspect, profile curvature, plan curvature), geology (the map scale of lithological properties and fault is 500,000), land use (the map scale is 100,000) and further different environmental layers including road network and rivers. The trigger factors include the Peak Ground Acceleration, Peak Ground Velocity, Modified Mercalli Intensity of WenChuan Earthquakes and rainfall data from 600 weather stations in China include the study area available for the investigations.

Mountain Disaster Risk Management during Emergency Avoidance Process in Country Resort Area of Western China

CHEN Rong, CUI Peng

Key Laboratory Of Mountain Hazards and Earth Surface Process, Chinese Academy of Sciences, Institute of Mountain Hazards and Environment, Chinese Academy of Sciences, Chengdu, 610041, P. R. China, rongchen@imde.ac.cn

Abstract

Emergency avoidance is one of the most important mountain disaster mitigation measures at mountainous region, which directly influence the severity of casualties. Country resort area is highly populated with tourists whose consciousness and behaviors against mountain hazards are unpredictable, which has made it very difficult to organize and manage the risk when mountain hazards occur. This study focuses on this issue and concentrates on mountain disaster risk management during the emergency avoidance process in country resort area. Based on analysis of recent mountain disaster events and semi-structured interviews with 70 local people in country resort areas of western China, we identified the whole process of emergency avoidance and the potential risks, and found that the owners of farmhouse and the monitoring personnel play great roles in emergency avoidance process. The evacuation model led by monitoring personnel was summarized and feasible measures to reduce loss of mountain disasters were proposed and applied in empirical research of Longmenshan town, Pengzhou County. The results of this study will improve the mountain disaster risk management during emergency avoidance process and provide scientific support of hazard prevention and mitigation at mountainous region.

Mountain Hazards: A Case of Nepal Himalaya

Narendra Raj Khanal

Central Department of Geography, Tribhuvan University, Kirtipur, Kathmandu, Nepal, nrkhanal.geog@gmail.com

Abstract

Nepal is a mountainous country. It comprises series of mountain ranges extending from the west to the east. Those are Chure (Siwalik) Hills, Middle Mountain, High Mountain and High Himal (Greater Himalaya). A combination of factors such as highly rugged topography, active tectonic and highly concentrated monsoon precipitation has made this area highly susceptible to a wide range of hazards such as earthquakes, landslides, debris flow, landslide dam and its outburst flood, avalanches, glacial lake outburst flood, drought and epidemics. Recent global warming and subsequent increase in extreme precipitation events and rapid melting in snow and ice has been exacerbating the occurrence and magnitude of water induced hazards in these mountains. Moreover, the rapid growth in population, subsistence based economic activities and mass poverty have resulted the country most vulnerable to these hazards. So, the country has both high exposure and high vulnerability to natural hazards, thereby creating high risk of loss of life and property. Nepal is one of the 20th most disaster-prone countries in the world. It is ranked 11th in terms of risk from earthquake, 30th in terms of flood risk, and 5th in terms of risk from the impacts of climate change. A World Bank study in 2005 classified Nepal as one of the global “hot-spots” for natural disasters. This paper discusses the types of mountain hazards occurring in the country, the loss and damages from those hazards, and vulnerability context; and identify the gaps in disaster risk management efforts for sustained development of the country.

Probability Prediction of Rainfall-Induced Shallow Landslides Based on a Coupled Physically-Based Model

LI Xiu-zhen^{1,2}

¹Key Laboratory of Mountain Hazards and Surface Processes, Chinese Academy of Sciences, Chengdu 610041, China

²Institute of Mountain Hazards and Environment, Chinese Academy of Sciences, Chengdu 610041, China,

Lxzljt@imde.ac.cn

Abstract

Rainfall-induced shallow landslides not only have extensive distribution and high occurrence frequency, but also will often cause loss of lives and serious damage to infrastructure. Therefore, landslide space-time prediction is an important issue for human lives, urban planning and infrastructure management.

This study presented an efficient probabilistic method for predicting the space-time change of rainfall-induced landslides, based on a coupled physically-based stability model: Transient Rainfall Infiltration and Grid-based Regional Slope-stability analysis (TRIGRS) and a probability assessment model: Rosenblueth's point estimate method for Bayi gully in the Sichuan province of China. In the study, we collected a lot of data of the study area, including investigating and sampling data on the spot and relevant research reference data. We determined a line relationship between the wetness index and soil thickness of the study area based on powerful ArcGIS platform. We set a kind of rain scenario: 20-year rainfall at 24 hours recurrent period. The space-time change characteristics of landslides in the study area were deeply analyzed based on the coupled model of the TRIGRS model and Rosenblueth's point estimate method.

The research results were compared with the historical rainfall-induced shallow landslides in the study area and showed that the probabilistic analysis had better performance than the deterministic analysis. In addition, the results showed that TRIGRS model is an effective tool for rainfall-induced shallow landslides and proper understanding uncertainties of rock-soil mass plays an important role in accurately predicting space-time change characteristics of shallow landslides.

Rapid Weathering Processes of a 120-Year-Old Chronosequence in the Hailuoguo Glacier Foreland, Mt. Gongga, SW China

Jun ZHOU, Haijian BING, Yanhong WU*, Zijiang YANG, Jipeng WANG, Hongyang SUN, Ji LUO, Jianhong LIANG

Key Laboratory of Mountain Surface Processes and Ecological Regulation, Institute of Mountain Hazards and Environment, Chinese Academy of Sciences, Chengdu 610041, P. R. China, zhoujun@imde.ac.cn

Abstract

Knowledge on the initial stages of weathering at the decadal time scale is limited. Our aim is to reveal the weathering processes and influential factors in a 120-year-old chronosequence in southwest China. Soil and water samples were collected from 6 sites with different exposure ages. Mineral compositions were determined using X-ray diffractometry, and four mineral pools were separated using a sequential extraction method. The results reveal that the soil particle sizes of $< 2 \mu\text{m}$ in the A horizons increased and the particle sizes of $20 - 2000 \mu\text{m}$ decreased with time. The weathering can be generally divided into two stages: the first stage was dominated by the weathering of carbonates and was present at sites with an exposure age of ≤ 52 years; the second stage was characterized by the intense weathering of biotite, hornblende and apatite and was present at the 80- and 120-year-old sites. The rapid weathering was a result of the interactions of the lithology, rapid vegetation succession and climate in the Hailuoguo Chronosequence. Fine silt was produced in large quantities by the strong glacial abrasion and freeze-thaw cycles, providing rich materials for the subsequent chemical and biogeochemical weathering. The decarbonation and the rapid establishment of the conifer forest due to relatively high temperatures and precipitation promote mineral weathering by decreasing soil pH. The high permeability of the soil horizons due to the high content of rock fragments and abundant precipitation allows water and organic acids to infiltrate and dissolve mineral soils above the impervious bedrock.

Roads and Agricultural Terraces in Mountain Areas of the World: Their Geomorphological and Hydrological Role

Tarolli, P

Department of Land, Environment, Agriculture and Forestry, University of Padova, Agripolis, viale dell'Università 16,
35020 Legnaro (PD), Italy, paolo.tarolli@unipd.it

Abstract

Humans are among the most prominent geomorphic agents, causing direct consequences on natural processes (e.g. soil erosion, surface runoff) through agricultural practices, road network construction, and urbanization (Tarolli and Sofia, 2016). High-Resolution Topography (HRT) derived from the recent remote sensing technologies (e.g. lidar, low cost Structure from Motion photogrammetry) allows for a better understanding of the interaction between anthropogenic elements and the geomorphology of a landscape (Tarolli, 2014). The present research shows the effectiveness of HRT to highlight the influence of anthropogenic topographic signatures on hillslope processes in mountain areas. The first analysis is related to agricultural terraces. Agricultural terraces are among the most evident and extensive human fingerprint on different landscapes of the world. Terraces are generally built to retain more soil and water, to reduce erosion, and to support irrigation. They reduce the slope gradient and length, facilitating the cultivation on steep slopes, and they increase the infiltration of water in areas with a moderate to low soil permeability, controlling the overland flow and velocity, with positive effects on agricultural activities. If poorly designed or not properly maintained (e.g. terraces subject to abandonment) a terrace system can progressively increase gully erosion and cause landslides. The second analysis discusses about the role of agricultural and forest roads on surface erosion and landslides. The construction of these anthropogenic features can have deep effects on surface water flows and sediments. The long-term consequences of road-associated landslides and surface erosion are still an open question in the Earth science community (Sidle and Ziegler, 2012). The results show how anthropogenic elements have crucial effects on sediment production and sediment delivery, also influencing the landscape connectivity. Thus, the availability of HRT can help in understanding and mitigating anthropogenic hillslope processes. The results presented here may be used for rural development planning, provide useful guidelines for sustainable land use planning, and they might help guiding future research directions for development-based watershed studies.

Rock Fall Hazard and Risk Assessment along Araniko Highway, Central Nepal Himalaya

Amar Deep Regmi, Cui Peng, Megh Raj Dhital

Institute of Mountain Hazard and Environment, Chinese Academy of Sciences, Nepal, amardeep_regmi@yahoo.com

Abstract

Rock falls are frequent along the steep slopes of highway cuts in mountainous areas like Nepal. Araniko Highway is a major highway connecting Nepal and China that has suffered from several instability problems. Recent earthquake activity in Nepal has generated many landslides, including rock falls along the highway, mostly between Lamosangu and Liping. These landslides have deposited huge piles of debris along the highway, as well as in the hill slope above, which has increased future risk of rock fall. Here, we have tried to analyze the distribution of rock falls along the highway, their mode of failure and the associated hazard and risk. The analysis shows that most of the rock falls are concentrated along steep rock cliffs and are of wedge and plane failure type. For the rock fall hazard and risk assessment of the highway, we have slightly modified the original Rock fall Hazard and Risk Assessment (RHRA) method to fit the condition of the Araniko Highway. The developed hazard and risk map effectively indicates various levels of rock fall hazard and risk along the highway. Thus, based on the level of hazard and risk, the maintenance and inspection work can be carried out. In addition, the study reveals that this system can be effectively used to prioritize the severity of potential rock falls along other highways with similar geological and morphological settings.

Simulating Mountain Resource City Expansion Based on Ecological

Resistance Surface Model: A typical Chinese City Case Study

Jifei ZHANG, Wei DENG

Institute of Mountain Hazards and Environment, Chinese Academy of Sciences, Chengdu, 610041, P. R. China,
dengwei@imde.ac.cn

Abstract

Urban expansion is one of the core contents for urban studies. Using expansion model to simulate urban spread has been a highlight of the world. As a useful tool for exploring urban expansion, minimum cumulative resistance (MCR) model has been given much attention in recent decades. However, there are two main problems when directly applying the MCR model to simulate mountain resource city expansion: not considering the levels of different urban expansion sources and overlooking the existence of absolute ecological constraints (such as natural reserves, basic farmland etc). Hence, the reliability of urban expansion simulation is greatly reduced. In this paper, we view the expansion of mountain resource city as a process that city landscape spreads by surmounting ecological resistance. Based on MCR model, the resistances of different levels of ecological sources and the inflexibility restriction of ecological barrier on city expansion are incorporated. The mountain resource city ecological resistance (MRCER) model is constructed and applied to the growth simulation of Dongchuan District, one of the most typical mountain resource cities in China. The results illustrate that the ecological resistance surface produced by the MRCER model comprehensively reflects the ecological resistance of the city expansion and its spread trends. Compared with MCR model-based simulation, the simulation results derived from MRCER model are more reasonable for guiding territorial development (city expansion) in mountain resource area. The proposed model may have significant implications for mountain territorial development study.

Sustainable Livelihood Approach to Poverty Reduction: A Geo-Empirical Analysis of Mizoram, the Eastern Extension of the Himalaya

SATI Vishwambhar Prasad

Department of Geography and Resource Management, Mizoram University, Aizawl – 796004, INDIA; Email:

vpsati@mzu.edu.in

Abstract

Mizoram characterises primitive economy where livelihood of people depends on production of biomass based agriculture system, livestock rearing and on use of forest products. Meanwhile, output from these activities does not meet the food requirement and thus, the people suffer from chronic poverty and malnutrition. This paper examines sustainable livelihood approach to poverty reduction in mountainous region of Mizoram. We conducted a case study of sixteen villages of eight districts of Mizoram. Total 1527 households were surveyed through random sampling method (76% sample size). An analysis of all livelihood assets – natural, human, physical, financial and social/institutional was carried out and vulnerability context was assessed. Our study reveals that about 53% population in the study villages is engaged in agriculture and related activities. About 51.3% populations live below poverty line and out of it, 17.6% live under chronic poverty. Mizoram also suffers from malnutrition and natural hazards. At the meantime, it characterises plenty of natural resources – land, water and forest – the life sporting layers and human assets. In terms of financial and institutional support, it lags behind. We concluded that development of all livelihood assets, social and institutional support and coping with malnutrition and natural hazards will enhance livelihood and will reduce poverty.

The Quality and Sustainable Use of Soil in Mountain Areas, Southwest China

Cui J.-F., Tang X.-Y.

The Institute of Mountain Hazards and Environment, CAS, Chengdu, 610041, P. R. China, jfcui@imde.ac.cn

Abstract

In mountain areas, soil is vulnerable by being exposed to wind and water runoff, and mountain hazards. Compared to traditional definition of soil quality, in mountain areas, it is more proper to define soil quality in a way that stresses functionality in a broad context, involving soil not only as a medium for agricultural production but also as an important reservoir for water storage, as a buffer for the filtration, transformation and neutralization of pollutants and as a pool for carbon storage, which smooth the challenges caused by climate change. Correspondingly, the sustainable use of soil in mountain areas, should meet the needs of agricultural development, but also the enhancement of overall environmental quality and of the natural resource base. This paper reviews the soil quality in mountain areas, Southwest China, and how it functions in relation to water quality. This paper also discusses the role of soil as a “bio-filter” in reducing the load of pollutants (i.e. heavy metal, antibiotics and pesticide, etc.) to aquatic environment, through various physical, chemical and biological processes.

Key words:

Soil quality; sustainable use; mountain area; bioreactor

The Varieties of Mountain Hazards and Human Resilience in Koshi Trans-Boundary Basin of Himalaya

Ningsheng Chen

Institute of Mountain Hazards and Environment, Chinese Academic of Sciences, Chengdu, 610041, P. R. China,
chennsh@imde.ac.cn

Abstract

Koshi trans-boundary basin enjoys the largest elevation difference in the world, where mountain hazards, including mountain torrent, debris flows, landslides and GLOF is frequent, whereas disaster characteristic and the mitigation measures are quite different among China, Nepal and India, respectively in the upper, middle and lower part of Koshi basin. In China, landslides and GLOFs is the prime disasters with large magnitude and low frequency and the transformation disaster chain can significantly influence large domain. The government leads the disaster mitigation efforts through spending money on the high standard mitigation measures such as engineering, monitoring and warning works. In Nepal, debris flows and landslides are the major hazards with medium magnitude and low frequency and the disaster chain can pose bad effect to a certain area. The local residents lead the disaster mitigation efforts under government's suggestions, and community based warning is the primary measure, followed by the flexible engineering works. In India, torrent is the main type, covering a large area with high frequency and large magnitude. The government, non government organization and local residents work together and conduct limited flexible engineering works and partly non-structural warning system. Research suggests in the analogous basin, the scientific disaster mitigations should cover the whole basin falling in different countries to make a scientific plan and the utilization of water resource in disaster mitigation. Besides, the resilient alleviation model among different countries requires corporation from all the countries.

wangyaping0410@163.com

²Institute of soil and water conservation, Chinese academy of sciences, Yangling, Shanxi 712100, china

Abstract

Subsidence is one of the serious geological disasters in well mining area. More than 20 published papers were synthesized using meta-analysis method to assess quantitatively the influence of coal mining subsidence on the vegetation changes in the Shenfuyu area. The results show that: The vegetation coverage shows a decreasing trend in the early stage of subsidence, then it increases and gradually exceeds the level before the collapse. The constructive species change little after mining subsidence, but the number of species increases after 1-2 years of subsidence. The new plant species mostly belong to ephemeral or ephemeroid plant after collapse interference, such as *Agriophyllum squarrosum* (Linn.) Moq. and *Incarvillea sinensis* Lam. The change characteristic of vegetation in the subsidence area displays the important role of natural restoration in vegetation construction. The ecological construction measures that the natural recovery is major and complementally adopts artificial restoration should be carried out in the Shenfuyu mining area and even the whole Loess Plateau.

The Space Distribution of Houses at Debris Flow Prone Area and Its Role in Disaster Risk Reduction

Yu LEI, Peng CUI

¹Institute of Mountain Hazards and Environment / Key Laboratory of Mountain Hazards and Earth Surface Processes, CAS, Chengdu, 610041, China, pengcui@imde.ac.cn

²University of Chinese Academy of Science, Beijing 100049, China

Abstract

Geomorphological hazards impose great potential risk towards the human settlements at mountainous region. For countries like China, mountain terrains covered large portion of its territory, therefore, reduce the risk from mountain hazards is imperative to the development of a sustainable community. Due to the space limitation at mountain terrain, human settlements normally concentrated at alluvium fan or river bank, which happened to overlap with the high risk zone of mountain hazards such as debris flow or flash flood. By conducting field investigation of damaged houses after several debris flow events, information on the structure type, space distribution, failure mode and degree of damage for 197 houses were recorded. The space distribution model for houses was constructed using quantified parameters which described the relationship between houses and debris flow gully. Distance ratio and angle ratio were used to quantify the relationship between the houses and debris flow gully while spacing between different houses were used to describe the inter-houses relation. Afterward, the space distribution model was correlated with the records of houses damage to develop a vulnerability chart for houses at debris flow prone area. This chart gives guideline to the authorities when conducting housing planning at debris flow prone area since it indicates the potential damage of houses when debris flow occurs. This study also provides an alternative solution to disaster risk reduction which could be put in place at the housing planning stage.

Diversity and Conservation of the Endangered Species, *Cercidiphyllum Japonicum*, and Its Communities in the Shennongjia Reserve, Central China

Jin-Tun Zhang¹, Bin Zhang¹, Xunzhi Zhu²

¹College of Life Sciences, Beijing Normal University, Beijing 100875, China, E-mail: Zhangjt@bnu.edu.cn

²School of Biology and Chemical Engineering, Jiangsu University of Science and Technology, Zhenjiang 212003, China

Abstract

Cercidiphyllum japonicum is an endangered and nationally protected plant species; its conservation is important and urgent. Fifty-eight 10 m × 20 m quadrats of *Cercidiphyllum japonicum* communities were randomly set up along an altitudinal gradient in the Shennongjia Nature Reserve, Central China. Data for species composition and environmental variables were measured and recorded in each quadrat. To investigate the community variation, two-way indicator species analysis (TWINSpan) and canonical correspondence analysis (CCA) were conducted. Moreover, species diversity indices were used to analyze the relationships between species diversity and environmental variables. The results showed that there were eight types of *Cercidiphyllum japonicum* communities. Each community had its own compositional, structural and environmental characteristics. The variation in *Cercidiphyllum japonicum* communities was significantly related to elevation and slope; aspect and litter thickness were also related to community variations. Elevation and slope were revealed as important factors that influence community distribution and diversity. Species diversity showed a quadratic and negative correlation with elevation. The importance values of *Cercidiphyllum japonicum* also showed a quadratic and negative correlation with species diversity. For conservational purposes, species diversity should be maintained within a reasonable range.

³The Center for Excellence in Tibetan Plateau Earth Sciences, CAS, Beijing, 100101, China

Abstract

Under rainfall or earthquake conditions, karst accumulation bodies on the slopes were easily triggered and transform into landslides which may lead to major disasters. Huluqiao landslide, occurred in Longtoushan mountain before Ludian 8·03 earthquake, went through obvious deformation process, did not cause any casualties of residents or passing vehicles due to the success of early warning. Based on field investigation and lab analysis, this landslide was identified as a progressive failure type according to the characteristic of its slope deformation vs. failure time curve. Steep slope, loose structure and low intensity of the accumulation horizon provided favorable environment for landslide formation. Long duration rainfall with high intensity caused the rock and soil particles to flow and rupture inside the sliding area at micro scale. At the same time, the flow and micro rupture play imperative roles in the macro deformation and failure of slope. The rainfall infiltrated into landslide along the surface of the accumulation mass, formed conflux transfixion at the interface between the soil and rock where backwater was formed. The backwater reduced the soil strength and introduced dynamic uplift force in the landslide. Meanwhile, with the rainfall filled in the cracks and the weak structural planes, the dynamic expanding force was induced and the tension crack was enlarged. As a results, the deformation of the accumulation mass was intensified. Revealing the mechanism of such landslide provided support to the slope stability assessment at regions with similar geological condition and laid the guideline for early warning of such landslides.

Numerical Study of the Particle Segregation Effect on the Flowing Mobility of Granular Debris Flows

Gordon G. D. ZHOU^{1,2}

¹Key Laboratory of Mountain Hazards and Earth Surface Process, Chinese Academy of Sciences, Chengdu, China, E-mail: gordon@imde.ac.cn

²Institute of Mountain Hazards and Environment, Chinese Academy of Sciences & Ministry of Water Conservancy, Chengdu, China

Abstract

Granular debris flows are of great concern because they often cause catastrophic disasters due to the long run-out distance and large impact forces. Based on the field investigation, the particle segregation can be always observed inside the deposited debris flows and it occurs both parallel and perpendicular to the flow direction no matter there is pore fluid or not. To investigate the mechanisms of particle segregation and its influence on the debris-flow mobility, granular debris flows with grains of mixed sizes are numerically modeled and the contact behavior of solid particles is fundamentally studied using the discrete element method (DEM). Compared to granular flows with uniform solid particles, the effect of segregation on granular flowing mobility is investigated. It is found that reverse segregation can significantly influence the flowing mobility and the flowing regimes in the front head of the granular body. The development of solids segregation needs certain traveling distances, which depend on the slope inclination. This research illustrates that the segregation for debris flows is usually completed before the flows become inertial flows.

Key words:

granular debris flow; segregation; mobility; DEM

Soil Moisture and Vegetation on Slope in the Shenfu Coal Mining Area as Affected by Collapse Fractures

Li Chao¹, Liu Wenzhao^{1,2,*}, Song Xiaoqiang³

¹Institute of Soil and Water Conservation, Northwest A & F University, Yangling, Shaanxi 712100, China, 915902219@qq.com

³Soil and Water Conservation Bureau of Shaanxi Province, Xian, Shaanxi 710004, China

Abstract

Soil bulk density, soil moisture and vegetation on two sides of collapse fractures in the Shenfu coal mining area were investigated and analyzed in order to explain the effects of collapse fracture occurrence (two years after collapse) during coal mining on slope vegetation and their characteristics. Research showed that (1) the collapse fracture occurrence made surrounding soil loose and thus resulted in a decreased soil bulk density nearby. (2) In the case of fracture strike at right angle or close right angle to slope, the fractures had effects on soil moisture about 3 m below fractures. Water status in the lower part of the fractures became worse due to intercepting effect of the fractures on runoff. In the walls of the fractures, soil water content on fracture slope was much lower than that on slope without fracture because of strong evaporation effect. (3) Without considering other factors, fracture occurrence worsened the soil moisture status within fracture and in the lower part of slope and further inhibited the growth of vegetation.

Abstract

The stability of gravel soil slope is an important problem for disaster prevention and mitigation in China's mountainous west. Danba JiaJu landslide, Danba Suopo landslide, Lixian Xishan village landslide in Sichuan province and Wushan landslide in Chongqing are selected as typical examples to study the physical properties of slip soils of gravel soil landslide. The study methods are field investigation and sample testing. The results showed that slip soil of gravel soil slope is wide grading and gap grading, and the content of grain smaller than 2mm is less than 10%; The mineral composition of slip soils are mainly White mica, Sodium feldspar, Kaolinite, Calcite and Quartz, but lack of clay mineral with strong swell-shrink such as Montmorillonite; The surface area of soil sample is small and most of nitrogen adsorption is occurring in macropore; The shear strength increase firstly and decrease secondly as the moisture content increasing. The slip soil of Wushan landslide has some characteristics as follows: high content of carbonate minerals, large specific surface area and low shear resistance. The characteristic confirmed that Wushan landslide is much more likely to occur suddenly under groundwater than three other landslides. The analysis results were consistent with true situations.

Key words:

gravel soil landslide; slip soil; grading; mineral composition; specific surface area; shear resistance

Abstract

Named by Chinese geologists, Danxia landforms refer to an erosional landscape developed on red beds and featured by scarp slopes. As a representative of red beds distributed in the western United States, Zion National Park is characterized by a geomorphic combination of plateau and canyons in arid climate. Based on field investigation and lab analysis of rock samples, this paper looks at the developmental mechanism of landforms in Zion. In terms of geologic structure, Zion is a fault block on the western margin of the Colorado Plateau, a regional network of oriented fractures controlled the development of canyons in the park. The major rock strata exposed in Zion belong to red beds, which were mainly deposited in the Jurassic within a variety of environments, including near shore/shallow sea, streams, lakes, and deserts. In terms of lithological features, most red beds in Zion are fine-grained sandstones and siltstones. Among them, the spectacular cliffs in Zion are made of eolian quartz sandstones. However, due to cement differences of each rock member, there are remarkable diversities in rock strength and colors. Moreover, this study also found that rock hardness values do not positively correlate with mountain slopes in Zion. Finally, in terms of exogenic forces, fluvial incision plays a dominant role in the formation of cliffs and canyons in Zion, followed by lateral erosion and sapping process. As controlling factors for landform development in Zion are similar to Danxia landforms in China, they may be ranked as Danxia.

Abstract

Base on the distribution in the world, Cretaceous system is one of the most important example among the divisions of the Phanerozoic, and the same in China and Russia. Distribution of complex facies (marine, continental, lagoon, volcanogenic) in Russian Cretaceous system is presented in various kinds of sedimentary, igneous and metamorphic rocks with different colors on the Russian plate and their boundaries, especially the Late Cretaceous with high-carbonate are widespread. Meanwhile, continental Cretaceous system is an important part in China which Red Bed has been one of the most attractive topics in Cretaceous research in the last several years. In the aspect of paleoclimate the temperature east-Europe, Siberia, the Far East where located at the subtropical zone was less than 18-20°C while the average temperature in the blocks near to the coast was almost 19-23 °C. At the same time, the average temperature in some blocks of China was a bit higher than most territory in Russia and the strata became to red cause the salt accumulation and dry weather.

In Russia some nice monocline and folds exist on the Cretaceous stratigraphic, and furthermore the outstanding Danxia landforms develop on the Chinese Red Beds. It is also noticed that there are deposits of energy, chemical, engineering-building materials preserved in Russian Cretaceous stratigraphic.

Key words:

Cretaceous stratigraphic; volcanogenic; monocline; paleoclimate

Abstract

Danxia landform was first named in China and then well known all over the world. Though great progress has been made in Danxia landform research and discipline construction in recent 30 years, the theoretical construction of Danxia landform is far behind other disciplines of rock geomorphology. Normative regional investigation has not been carried out on Danxia landform resources, and weak basic geological research and environmental geology issues are also very serious. Based on previous investigation on the basic theory of Danxia landform and tourism development for many years, the following main development directions of Danxia landform research are proposed. Firstly, the normative investigation and database construction of regional distribution of Danxia landform resources. Secondly, the basic geological research on Danxia landform, including formation conditions, dynamic mechanism, evolution process and systematize classification, especially the relationship between different landscape formation mechanisms, sedimentary facies and the development of Danxia landform. Thirdly, the rockfall landscape survey, detection and prevention programs research. Fourthly, biodiversity and human landscape research and construction of scientific tourism and research base. Finally, the subject and theoretical system of Danxia landform should be perfected.

Abstract

Late Cretaceous continental redbeds, the Guifeng Group of the Yongchong basin in South China have been investigated to link alluvial stratigraphy to paleoclimate change. The Guifeng Group is divided into the Hekou, Tangbian and Lianhe formations in ascending order. The Hekou conglomerates are typically polymict, moderately sorted with erosional bases, cut-and-fill features, normal grading and sieve deposits, representing rapid shifting and abandonment of stream-flow dominated fans during the incipient stage of the basin infill. The Tangbian Formation, however, is characterized by structureless fine-grained sediments with dispersed coarse clasts, recording a change to a quiet playa environment with occasional ephemeral stream flooding, thus indicating a basin expanding stage. The Lianhe conglomerates are disorganized, poorly sorted, lack of erosional bases, and a wide particle-size range from clay to boulders reflect mud-rich debris-flow process on fans, likely related to reactivation of faulting along the northwestern mountain fronts during a post-rift stage. The depositional system changes from stream-flows up through playa to debris-flows during the accumulation of the three formations are attributed to different source rocks and climatic conditions. The fluvial-dominated fans of the Hekou Formation were accompanied by a subarid to subhumid paleoclimate. The dominant subarid climate during the Campanian Stage produced abundant fine-grained sediments in the Tangbian Formation. A climatic change from subarid to subhumid during the latest stage was probably favourable for high deposition rate of coarse clasts in debris-flow dominated fans of the Lianhe Formation.

Mechanisms of Escarpment Retreat in Sedimentary Tablelands

Duszyński F, Migoń P

Institute of Geography and Regional Development, University of Wrocław, pl. Uniwersytecki 1, 50-137 Wrocław, Poland,
filip.duszynski@uwr.edu.pl

Abstract

Sedimentary tablelands, including Danxia tablelands, are distinctive regional geomorphic landscapes and may be found within every continent. In the long term, their areal extent is reduced due to retreat of their marginal escarpments, whilst they may also become fragmented due to fluvial incision into the plateau level and dissection of escarpments. In consequence an array of mesas, buttes and pinnacles may originate at the expense of a once uniform plateau. Hillslope processes are thus crucial in understanding the patterns and efficacy of long-term landscape evolution of tablelands. A variety of mechanisms is involved in escarpment retreat, depending on geological structure, lithology and environmental setting. They include preparatory physical and chemical weathering, followed by mass movements. Rock falls and avalanches, rockslides, topples, landslides, debris flows, and lateral spreading phenomena may occur. Groundwater sapping has been recognized as an important prerequisite to rock slope failures. Bedding caves are valuable indicators of sapping and locations of future collapses. In all these cases escarpment retreat is episodic and catastrophic. Non-catastrophic scenarios are also possible and particularly applicable to sandstones. They involve subterranean detachment and removal of sand grains by groundwater flow. In effect, massive caprock compartments lose support, disintegrate and settle, producing 'blocky chaos' instead of a regular cliff line. This mechanism applies to both frontal escarpments and backslopes, where canyons may develop. Mechanisms and patterns of escarpment retreat are typically inferred from landforms and correlative deposits, hence the value of landform recognition and mapping in the study of tablelands.

²Institute of Geographic Sciences and Natural Resources of Research, CAS, Beijing 100101, PR China

Abstract

To estimate the tectonic uplifting rate, geomorphic age, cliff retreating rates and erosion rates and so on, this paper presents four simple formula proposed by author after sever years field-test. In order to obtain a more accurate rate of the tectonic uplifting, the gravel samples of the bottom of riverbed in the bedrock seated terrace must be obtained form various locations at the same level terraces far away from the river. The age of the oldest gravel samples can be taken as basis for calculating the rate of tectonic uplifting. This improved sampling method can improve the accuracy of quantitative research on Danxia landform process. These quantitative research methods for the study on Danxia landform processes can be used to reflect more truly that the fluvial terraces are formed on the condition of intermittent tectonic uplift, to calculate geomorphic ages, cliff retreating rates and erosion rates of Danxia landforms more reasonably, and also can be applied in non-Danxia landforms areas to resolve quantitative measurement of above-mentioned issues.

Key words:

Danxia Landforms; tectonic uplifting rate; geomorphic age; cliff retreating rates; erosion rates

Morphometric Analysis of Danxia Landform in Longhushan

Abstract

Morphometric parameters are found a useful statistical study of the Earth's surface for understanding landform evolution. This research applied dimensionless morphological parameters to quantify the erosional stage of the Danxia landform in Longhushan, and the tectonic/lithological controls in the formation of the local topography. In this paper, Longhushan, an archetypal Danxia landform site, is selected to conduct the morphometric features, using DEM- and GIS-based analysis. Geomorphologic parameters are adopted including normalized stream length-gradient index (SLK), hypsometric integrals (HIs) and hypsometric curves (HCs) as well as river longitudinal profiles. SLK anomalies for the seven streams across the study area are found to positively correlate with the presence of faults and changes in rock erodibility, reflecting tectonic and lithologic controls on the formation of topography. Hypsometric analysis of the 26 subwatersheds in Danxia landform areas yield low HIs (<0.42 , mean=0.21) with concave up hypsometric curves, suggesting Danxia landforms in Longhushan are in an old erosional stage. The findings in this research are in accordance with the previously proposed, but invalidated, old geomorphic stage of Longhushan that is based on estimated eroded land mass. This work is an attempt to quantify the erosional status of Danxia landforms at basin scales and for validating lithological and tectonic controls on its topography in relation to bedrock channels. The parameters used in this research are dimensionless, thus can be applied in other Danxia landform areas for future comparison.

Key words:

Danxia landform; Longhushan; Hypsometric analysis; SLK; Erosional stage

On Danxia Culture and the Cultural Heritage Value of Danxia Landscapes in China

Zhang Renshun

School of Geographical Science, Nanjing Normal University, Nanjing 210097, China, danxiahj@126.com

Abstract

Danxia landform is a highly artificial landform. The color and landscape of Danxia landform is so close to people's life. The colour of the rocks accord with Chinese auspicious red, so often temples and caves are built in the Danxia areas. Many religious architecture and their residence and domicile choose in the caves of Danxia landform. Difficult to climb, Danxia landscapes often become the old society, the local residents escape banditry and war-torn fortress, and even become a military defense heavy. Red sandstone with a solemn auspicious red and easy to carve, the Danxia landforms often associated with the grottoes together, such as Sichuan, Leshan Giant Buddha, Anyue sculpture carvings, Chongqing Dazu rock carvings. Especially the ancient Silk Road more closely associated with caves. In Gansu, such as Maijishan, Daxiangshan, Binglingsi, Tiantishan, Matisi and so on, all is the soul of the Silk Road treasure. In the red sandstone rock, and cliff stone calligraphy close companions, many Danxia Landform Scenic Area, different degree left very high level of cliff stone calligraphy, adequately the brilliance of the art of calligraphy in China. The magnificent Danxia landform and the rich cultural landscape together, often become famous scenic spots. This paper system analysis including ancient myths, cave cliff, religious books, landscape poetry, famous celebrities, construction drawing, College site selection, and so on, describes the color of the landform trends of human aesthetic value. Deeply research the original psychological mechanism of the color preference. It is possible to apply for the landform investigation, heritage protection and tourism development, and provide multi-disciplinary field of academic support basis and reference for further improvement Danxia culture and aesthetics building.

Peculiarity Morphology, Genesis and Age of the Formation of the Landscape within the Reserve Longhushan

Morozova E.B., Chernyatieva A.P.

Institute of Earth Sciences St. Petersburg State University, Universitetskaya nab. 7/9, Saint Petersburg, 199034, Russia, nastya250@mail.ru

Abstract

Jiangxi Province is one of the most widely spread areas of danxia landform. The new research the distribution, formation mechanism and comparative study at home and abroad, in particular, the study of the sedimentary facies and structure of red beds have injected new vigor into the study of Danxia landform in China.

To reveal the morphological features of the relief is possible to use techniques "the principle of elementarisation" relief proposed by A. N. Lastochkin (Lastochkin, 1987, 1991). This technique is allows exclude subjectivity in the analysis of the relief. Morphological studies because of the enormous possibilities of computer technology have become one of rational method.

We planned basic geological research on Danxia landform, including formation conditions, dynamic mechanism, evolution process and systematize classification, especially the relationship between different landscape formation mechanisms, sedimentary facies and the development of Danxia landform.

Danxia landform appropriate place to develop an algorithm of morphological analysis of dynamic topography as a basic operation of landscape planning and definition of the specificity of the method in terms of different types of landscapes, as well as in the territories of different dimensions, character and degree of development. Morphological study of the relief can be regarded as one of the traditional part of its study.

Morphology; genesis; the principle of elementarisation; continental redbeds

Rill/Lithology Interaction in Arid/Semi-Arid and Humid Badlands

Kasanin-Grubin, M., Yan, L.B., Peng, H.

University of Belgrade, Institute of Chemistry, Technology and Metallurgy, Njegoseva 12, 11000 Belgrade, Serbia,
mkasaninrubin@chem.bg.ac.rs

Abstract

Badlands are areas in which soil cover has been eroded and a wide range of erosional processes are governed by lithological properties and climate. They are therefore ideal locations to study rill/lithology interactions. This study will focus on rill characteristics in three badland areas to ensure the range of lithologies and different climatic conditions. Dinosaur Park badlands, Canada, mean annual precipitation 350mm, are developed in the Upper Cretaceous sandstone and smectite-rich mudrocks. Chinguacousy badlands, Canada, mean annual precipitation 885mm, are developed on the Ordovician illite/chlorite-rich shale. Red-bed badlands in Nanxiong basin, China, mean annual precipitation 1560mm, are developed in illite-rich sediments. Total of 1200 rill depth and width measurements were taken on 80 slopes. Weathering profiles were examined and unweathered samples were collected for the weathering experiment by rainfall simulation or water immersion. The surface weathered layer on smectite-rich sediments was 2cm, on illite-rich sediments 1cm, on sandstone 0.5cm thick. Slope angles varied in a wide range 17-54° regardless of the lithology. Rills width/depth ratio showed statistically significant variation depending on the lithological unit. Rills on sandstone had the width/depth ratio 1.3, smectite-rich sediments 1.6 and illite-rich sediments 2.7. Weathering experiment has shown that the physical breakdown was dominant for illite-rich sediments, while dispersion and sealing was dominant for smectite-rich sediments. Sandstone sample completely dispersed after 2h immersion in water. This study proves that rill morphology is controlled by lithology and not by climate. Higher climate control is expected regarding other hillslope processes, but that remains for future studies.

Key words:

badlands; rills; lithological properties; clay minerals

The Role of Structural and Climatic Processes in the Formation of the Relief on the Territory of Nature Reserve Longhushan

Sitina I. A.

Institute of Earth Sciences St. Petersburg State University, Universitetskaya nab. 7/9, Saint Petersburg, 199034, Russia,
i.sitina@yandex.ru

Abstract

Jiangxi Province is one of the most widely spread areas of danxia landform.

To reveal the morphological features of the relief is possible to use techniques "the principle of elementarisation" relief proposed by A. N. Lastochkin (1987, 1991). This technique is allows exclude subjectivity in the analysis of the relief.

Works based on the experience of Russian scientists in the field of relief as the foundations of morphodynamic landscape (landscape envelope component).

Traditionally, as a basic (initial) operation of landscape mapping method was used "relief sculpture", first developed and tested in the practice of drawing up geomorphological maps. According to the method of relief sculpture first on the topographic base stand and river erosion Network (are outlined by river valleys, ravines, gullies). Land between the rivers are divided into the surface with different exposure, slope, concavity or convexity of the slope profile and plan. It is expected that the selected contours correspond to certain landscape units as well as the nature of landscape processes controlled relief, in each circuit is the same as the uniform relief

Of greatest interest is advanced by A. N. Lastochkin geotopological concept postulates the leading role in the differentiation of the relief sculpture of the landscape envelope, and offering rigorous, mathematically based approach to elementarizatsii landscape structure. In general, the meaning of the operation morphodynamic analysis is to identify within geomorphological surfaces elementary surfaces (EP). In the role of elementary geomorphological boundaries or structural characteristic line (SL) contouring EP top bottom and side stand.

As a formalized method morphodynamic analysis eliminates the factor of subjectivity and largely impartially resolve emerging conflicts in progress in landscape planning, making, thus, this procedure is not only advisory and auxiliary (secondary), and, above all, a major Engineering Design procedure with conclusive findings and recommendations.

Key words: Nature Reserve LonghuShan; morphology; the principle of elementarisation.

The Significance of the Extension of China Danxia Research to the Redbed Issue

Peng Hua

School of Geography and Planning, Sun Yat-sen University, Guangzhou 510275, China, eesph@mail.sysu.edu.cn

Abstract

In May 2009, the first international academic conference on Danxia Landform was held at Danxiashan in Guangdong Province. In July, 2009, at the 7th International Association of Geomorphologists (IAG) conference in Melbourne, Australia, the IAG Council approved the establishment of the IAG Danxia Geomorphology Working Group, which symbolized that Danxia research had risen to the international stage. In October 2011, six famous Danxia landform sites representing “China Danxia” were included on the World Natural Heritage list as a type of landform, which brought much attention from the rest of the world. Now, we are thinking on how to orient the future research of Danxia landform as China Danxia research further reaches across the globe.

Concerning the research of Danxia landform in recent years, we find that there is a lack of attention from international geoscientists to redbeds and the study of redbed landforms. Also the approach to the redbed issue from different disciplines lacks integration, and is especially lacking attention on the land degradation and ecological problems of redbeds, which are a special and fragile geographical unit. The Southern China humid region is one of the areas with a concentrated distribution of redbeds. In most of the redbed areas, there exists serious geomorphological hazard and soil erosion problems, even as far as “redbed desertification”. In addition, the deepening of study of Danxia landform demands us to deeply analyze the features of redbeds. So, we intend to extend the research of Danxia to the redbed landforms and redbed issues. The “Geographical Society of China Redbeds & Danxia Research Working Group” was founded with the approval of the Geographical Society of China in 2011. Then at the 8th IAG conference in Paris, France, the IAG made the necessary adjustment to the “Danxia landform working group” according to China’s conditions. The name of the working group was changed to “IAG Redbeds and Danxia Geomorphology Working Group”. This was not just a change of name, but a qualitative promotion and extension of the research field, showing that the research field was extending to the redbed landform and redbed issues. The qualitative promotion means the transition from landscape and form research to a comprehensive study of underground-surface-above ground which blends geology, geomorphology, and ecology. The extension also indicates the development from landscape research to the comprehensive study of the geological environment, geomorphological hazards,

ecological security, and land conservation. Also it increases the interaction between the national economy and the people's livelihoods, and the discipline's room for development. So the redbed issue is not only a geomorphologic issue, but a comprehensive scientific issue of Earth surface systems, a large issue of comprehensive physical geographical systems which covers the relationship between rock features and geomorphological evolution, rock features and geohazards, rock features and weathering-erosion and soil erosion, the water in weathered crusts and soils, special organisms and the ecological structure, land degradation in redbeds and environmental protection. We propose an interdisciplinary comprehensive research of redbeds, in line with the thinking of system dynamics, for pursuing the measurement of environmental optimization and desertifying land.

Key words:

Redbed; Redbed issue; Danxia landform; Extension

Danxia Landform and Redbeds in Southwest United States – A Comparison Study

Simonson S, Peng H, Pan ZX, Yan LB, Chen Z

School of Geography and Planning, Sun Yat-sen University, Guangzhou, China, scotw1t@gmail.com

Abstract

The worldwide distribution of redbeds has long been of interest to geomorphologists. Within China, the study of a particular type of redbed landform, Danxia landform, has been advancing since the 1920s. Danxia landform scholars desire to promote their study on an international level. One method for this is to create direct comparisons between Danxia landform in China and redbeds found elsewhere in the world. Once the language barrier is overcome, the next difficulty for this type of study is to gather enough information from international scholars to be able to make said comparisons. This research focuses on understanding the availability of literature to a student in China, how much literature can be collected, and ultimately will attempt to create a substantive comparison between Danxia landform in China and redbeds located in the Southwest United States.

Due to limited database access, the literature used for this study derives mainly from free-to-view journal articles found via Google Scholar searches. The literature found ranges from early 20th century geologic surveys to 21st century scientific research. This research intends to make substantive comparisons between Danxia landform and redbeds in the southwest United States on categories such as: genesis; depositional environment; lithology; stratigraphy; tectonics; and geometry. Data for Danxia landform will come from recent national surveys performed by Danxia scholars.

Key words:

Danxia; redbeds; Southwest United States; comparison

Definition and Classification and Distribution of Danxia landform in China

Abstract

Danxia landform is a special continental red beds landform which is characterized by red scarp slope. Danxia landform as a new rock landform types is named by Chinese geologists. A great amount of work has already been done by Chinese scholars on Danxia geomorphology more than 80 years of history. Up to now, 1061 Danxia landform sites have been discovered in 28 provinces in China. In this paper, we make a brief overview on the field of China Danxia geomorphologic study, including the definition of Danxia landform, types and distribution of Danxia landform in China, internal and external forces of landform processes, Danxia landscapes tourism development and its protection aspects. The authors regard that eighty percent of them are distributed in the crust uplifting red basins formed in Mesozoic and Cenozoic fault basins. Altitude from sea level to 5,000 meters, from semi-arid and arid areas to semi-humid and moist zones, fourteen climatic regions have Danxia landform distribution. It is estimated about one fifth of national scenic spots is Danxia landscapes in China. Danxia landform is one of natural rock scenery. They are human's wealth and the earth heritage. Some endangered and famous Danxia scenic sites must be protected.

On Landscape Characteristics of Danxia Landforms in Arid Area of Northwestern China

Chen Zhijun¹, Qi Deli²

¹Department of geology Science, Lanzhou University, Lanzhou, 730000 China, danxiahj@126.com

²Institute of Geographic Sciences and Natural Resources of Research, CAS, Beijing, 100101 China

Abstract

Danxia landform is widespread in the arid and semiarid areas in Gansu, Qinghai, Ningxia, Xinjiang and others region of north-western China. Danxia landforms in Gansu has confirmed 116, ranks the 3rd in China, located in the the Yellow River Valley plateau, Hexi Corridor, Qilian mountain, Longnan and Liupan mountains. The climate situation in Gansu province is complex, generally Jingning-Weiyuan-Lintao-Huajialing-Linxia line for the community, divided into the south semi humid region, the north arid humid area, and semi-arid area. Danxia landforms are very developed in arid areas and many arid types of Danxia landform is named here. This paper intends to explore the landscapes characteristics of Danxia landform in arid area of Gansu, including its types, characteristics and difference between Danxia landform with Colourful hills and Yardang landform. The paper analyses some fundamental conditions, characteristics, categories, evolutionary processes and hypogene /exogenic action of the Danxia landform in arid and semiarid areas. Additional it is Interesting research on the relationship between Danxia landform and caves alone Silk Road in north-western China.

Peculiarity Morphology, Genesis and Age of the Formation of the Landscape within the Reserve Longhushan

Morozova E.B., Chernyatueva A.P.

Institute of Earth Sciences St. Petersburg State University, Universitetskaya nab. 7/9, Saint Petersburg, 199034, Russia, nastya250@mail.ru

Abstract

Jiangxi Province is one of the most widely spread areas of danxia landform. The new research the distribution, formation mechanism and comparative study at home and abroad, in particular, the study of the sedimentary facies and structure of red beds have injected new vigor into the study of Danxia landform in China.

To reveal the morphological features of the relief is possible to use techniques "the principle of elementarisation" relief proposed by A. N. Lastochkin (Lastochkin, 1987, 1991). This technique is allows exclude subjectivity in the analysis of the relief. Morphological studies because of the enormous possibilities of computer technology have become one of rational method.

We planned basic geological research on Danxia landform, including formation conditions, dynamic mechanism, evolution process and systematize classification, especially the relationship between different landscape formation mechanisms, sedimentary facies and the development of Danxia landform.

Danxia landform appropriate place to develop an algorithm of morphological analysis of dynamic topography as a basic operation of landscape planning and definition of the specificity of the method in terms of different types of landscapes, as well as in the territories of different dimensions, character and degree of development. Morphological study of the relief can be regarded as one of the traditional part of its study.

Preliminary Study on the Relations between Danxia Landform and Traditional Culture of Mt. Longhushan

LI Zhiwen, GUO Fusheng, SUN li, Ye Changsheng

College of Earth Sciences, East China Institute of Technology, Nanchang, 330013, P. R. China,

zhwli@ecit.cn

Abstract

Based on the field investigation and summarizes previous research results, We hold that there are strong internal relations between Danxia landform and Traditional Culture of Mt. Longhushan. As for Taoist culture: the red color of Danxia landform agrees with cultural psychology of Taoism which advocates the color of red and purple, and the combined landscape of clean water surrounding red Danxia landform caters for the ideology of Taoism which regards harmony between human and nature as the best. Secondly, the sites in front of the Luxi River and surrounded by mountains with a large plain, according with the Geomantic Theory of Taoism. Thirdly, various exquisite Danxia microlandforms provide many inspirations for Taoism myths. As for Cliff tomb culture, Firstly, the red color of Danxia landform agrees with cultural psychology of the ancient Baiyue ethnic which advocates the color of red and enlighten to God. Secondly, the image of mother modeling in cliff of fairy according with their thigh which want their body back to mother. Thirdly, the flat Danxia sandstone cave provide a natural place for the Cliff tombs which near the mountain and the river. As for Poetry culture, various exquisite Danxia microlandforms, and the strong religious flavour breath, and their mysterious customs attract believers and literati select Mt. Longhushan for preaching, practice austerities and sightseeing, and then create lots of poems and songs which becomes immensely popular. These traditional Culture with deeprooted and originally long become treasure of cotemporary culture, and made Mt. Longhushan become a well-known mountain of culture.

Mt. Longhushan; the characteristics of landform; Taoist culture; Cliff tomb culture; Poetry cul-ture

The Developmental Conditions and Landscape Characteristics of Danxia Landform at the Northern Slope of Dabie Mountain

Guangsheng Zhang^{1,2}, Run Huang¹, Lixia Hao¹, Lvgui Tan¹, Linli Mo¹

¹College of Resources, Environment and Tourism Management, West Anhui University, Lu'an, 237012, P. R. China, zhanggs@wxc.edu.cn

²School of Resources and Environmental Engineering, Hefei University of Technology, Hefei, 230009, P. R. China.

Abstract

At the northern slope of Dabie Mountain, some typical Danxia landforms are distributed in this region. They are Wanxi Rift, Dabie Mountain Grottoes and Songliaoyan. Through the research methods of field statistics, document retrieval and experimental geomorphology, we had analyzed geological background and landscape characteristics of Danxia landform in this region. The results showed that the Dabie Mountain Orogenic Belt driving mechanism, the tectonic basin and Fenghuangtai Group red sandy rock are the basic conditions for the development of Danxia Landform. The Danxia landform in this area is composed by the conglomerate (maximum particle size reaches 60 * 50cm) and fine sandstone interbed at the bottom of Wanxi Rift, and the gritrock and siltstone interbed on the top of Songliaoyan strata. On this basis, through the study of the formation mechanism and landscape classification of the Danxia landform, we had found Danxia landform in this region is adolescence (Wanxi Rift), postadolescence (Dabie Mountain Grottoes) and topographic old age (Songliaoyan) complex developmental stage. From the Danxia landform landscape, it is mainly manifested in the rift valley, steep cliff, horizontal trench, cave and monadnock, etc. The characteristics of Danxia landform at the northern slope of Dabie Mountain are determined by sedimentary phases, the diversification of development stage, the features of landscape composition and the micro structure with the lens. Furthermore, the Danxia landform at the northern slope of the Dabie Mountain can be contrasted with Danxia landform in other regions in China, which had been assessed as World Natural Heritage.

The Geomorphological Formation and Sedimentary Characteristics of Danxia Landform of Zuixian Lake in Nancheng County, Jiangxi Province, China

Yang QK, Luo Y, Liu D, Huang BH

East China University of Technology, Nanchang, 330013, P. R. China, 197267245@qq.com

Abstract

There are giant thick red beds of the Hekou formation widely distributed in early cretaceous in southeastern Nancheng county, Jiangxi province, China. They are divided into small groups by the Zuixian lake, and become the landscape of Danxia Landform. By the study, we find that: 1) There were mainly the braided rivers in the study area in cretaceous period, and developed braided river deposition, no flood deposition; 2) The different sedimentary facies in Southern China play a certain restrictive role in the formation of Danxia landform, for example, the red beds of alluvial fan facies mainly formed landforms of the rock fort, rock dyke, and rock pillar; the braided river(alluvial plain) facies developed the rounded mountain landform, and the lakeshore or deep lacustrine facies usually can not form the Danxia landform; 3) According to the different characteristics of Danxia Landform in Southern China, we think that there are three genetic types: ① Sedimentation and sedimentary environment. ② Exogenic geological processes (water flow erosion and corrosion, and other different weatherings). ③ Endogenic geological processes (fault, cleftiness); 4) The formation and evolution of Danxia landform in Nancheng county are the result of interaction of exogenic and endogenic geological processes, however, each genetic type of Danxia landform usually is controlled by a magisterial geological process, and the other exogenic and endogenic geological processes just remold the Danxia Landform.

Abstract

a typical Danxia pillar stone Leipishi I in world natural heritage Mt. Langshan, collapsed on Sep 2, 2009. In order to throw some light on the mechanism of Leipishi I rockfall, experimental analyses of uniaxial compressive strength, tensile strength, resistance against sulfuric acid, and freezing and thawing properties were performed on 44 sandstone and conglomerate cores collected from Lanlong Formation, the unique formation in Mt. Langshan. In addition, 4 rock slices were collected for analysis under a polarizing microscope. The detailed reconstruction and rockfall process of the pillar stone geometry and of the actual restraint conditions acting before the rockfall permitted an estimation of the stress state by using 3D finite element code. The results show that the rapid retreat of soft intercalated rock layers due to weathering can profoundly change the stress state of rock body, and create compressive or tensile stress over its compressive or tensile strength in certain part of rock body, and cause part collapse or rockfall in unity. the compressive stress will decrease rapidly when it was put in acid solution, so the failure may related to the weakness of the rock body and the weakness of rock relate to the long term effect of the acid rainwater and freezing and thawing in winter. The acid rainwater and cold weather in winter caused the cycles of wetting and drying, and acid erosion, which accelerate the weathering of soft intercalated rock layers underneath. Geological setting often control the general shape of the dangerous rock, and may create discontinuity cracks, long term of fatigue the cracks continuous develop, decrease the strength of rock body, causing part collapse of rock body. Stress concentration happened in the edge of soft layer caused the part compressive stress which is over compressive strength, longtime acid rainwater and development of cracks on the top of the rock caused the decrease of tensile stress lower than the tensile strength. The two reasons may be two main triggering of rockfall.

The Protection of Zhejiang Red-Beds and Danxia Landforms and the Construction of Environmental Education Model

Wang Shaohua

Hangzhou Normal University, Hangzhou, 310000, P. R. China, huahua1205@163.com

Abstract

The distribution of Zhejiang red-beds and Danxia landforms has a high degree of correlation with the tectonic basin.

The low and undulate red-beds landforms develop in the center of basins, while Danxia landform which the crest is flat, steep slope, slow foothill develops in the edge.

By relevance analysis and the analysis of internal and external power to landforms forming, we can get the spatial distribution of red-beds and Danxia landforms, and know the protection scope of the site with typical value to establish corresponding protective measures.

Based on the red-beds and Danxia landforms (Jianglang Mountain) and the resources of science, technology, culture and education, we can build a stereoscopic environmental education model which is virtual and real (the New Media Communication and entities exhibition) with domestic and foreign partners (the comparison, communication and cooperation at home and abroad), with official and civil institutions (the communication and complement between the management and the folk organization), with the harmonious of red-beds landforms and sustainable ecology (humanistic ecology), with the combination of fashion, innovation and tradition.

By establishing the environmental education and training demonstration base to improve the red-beds landforms and protect Danxia landscape, we can raise public awareness and attention of the formation environment, geomorphological characteristics, ecological environment and the heritage protection of red-beds and Danxia landforms.

We need to conscientiously do the work of protecting ecological heritage protection and rouse the public's consciousness of natural environment. It's our duty to treat world natural heritages well while making moderate use of them.

The Research Progress of Jiangxi Danxia Landform

JIANG Yongbiao, GUO Fusheng, HUA Lin

School of Earth Sciences, East China University of Technology, Nanchang, Jiangxi, 330013, P. R. China, ybjjiang@ecit.cn

Abstract

Jiangxi Province is one of the most widely distributive areas of danxia landform with 203 concentrated distribution area so far, and also is one of the provinces that have the highest scale of kind of danxia landform in national wide. The earliest research of danxia landform in Jiangxi Province could be traced back to the Tang Dynasty, many poets and scholars had written a lot of poems and articles to describe the beauty of the danxia natural scenery. Xu Xiake, the geographer of the late Ming Dynasty, had got a more comprehensive investigation to Jiangxi danxia landform from east to west, and left the famous travel notes of the Right of the Rive. The modern studies on Danxia landform in Jiangxi started in 1930s, Chen Guoda et al., the first generation of geologists in China, had given the name danxia landform to the landscapes developed in the red beds after researched the Cretaceous red beds of Gongshui basin in Jiangxi. Since 1960s, Huang Jin has investigated and studied successively many times to 175 distributive areas of Danxia landform in Jiangxi Province. Since the end of last century, especially in the last 10 years, many studier have used technological means including 3S Technology, IRSI, electron probe etc to research the distribution, formation mechanism and comparative study at home and abroad, in particular, the study of the sedimentary facies and structure of red beds have injected new vigor into the study of Danxia landform in China.

The Role of Subsurface Erosion in Shaping Sandstone/Danxia Landscapes

Migoń P, Duszyński F

Institute of Geography and Regional Development, University of Wrocław, pl. Uniwersytecki 1, 50-137 Wrocław, Poland,
piotr.migon@uwr.edu.pl**Abstract**

Geomorphological evolution of sandstone terrains includes an important subterranean component, associated with groundwater movement along discontinuities and through the pores. Groundwater is capable of dissolving cement and detaching sand grains, being also able to carry this sand load to the surface. In this way, material is removed not only at the surface, but also in the subsurface, as in karst terrains on soluble rocks. The combined action of subsurface processes has various consequences for both the patterns of landscape evolution and the inventory of erosional and depositional landforms in sandstone areas. Small-scale depositional landforms below the cliff lines are most evident and take the form of sandy cones and sheets, grading into a veneer of sandy deposits draped over the mid- and lower slope. More spectacular are landforms indicative of material removal such as closed depressions (similar to karst dolines), troughs, open clefts and tunnel caves extending from cliff faces into the rock. However, the effects of subsurface erosion may also be spread over larger areas if removal of material along subterranean drainage lines is particularly efficient. In this way rock mass compartments above lose support and gradually settle into enlarging voids and cavities, rotating and disintegrating due to too high tensional stress. Chaotic boulder fills of channelless valleys are interpreted as the record of sand evacuation that was accomplished primarily in the subsurface. Examples of landforms and deposits resulting from these processes will be provided from the Stołowe Mts, Central Europe, and elsewhere.

Ecological Marginalization and Farmers-Pastoralists Conflicts in Drylands of West-Africa

Umar, A., Adamu, I. A.

Department of Geography, Federal University, Birnin-Kebbi, Nigeria, adanmalam@yahoo.com

Abstract

Most of farmers-pastoralists-conflicts' (F-P-C) researches in drylands of Nigeria and Niger, West Africa are thematic in nature. There is need for a holistic approach in conducting research on conflicts essentially the one that focuses on the conflicts causality, generalizability and prediction which will help in proffering effective mitigation measures. The aim of this paper is to review and synthesize fragmented F-P-C works in drylands of Nigeria and Niger with a view of establishing trends in climate change, ecological marginalization and F-P-Cs as-well-as causality, generalizability and prediction of F-P-Cs. The findings of the research revealed an increasing drought, and aridity in the study area from 1970s to 1980s and 1990s. These trends helped by ecological degradation, political and socio-economic systems decay culminated into ecological marginalization which threaten the survival of farmers and pastoralists who prior were co-existing in a symbiotic living. These factors were responsible for the increasing trend in F-P-Cs as a mal-adaptive strategy from farmers and pastoralists to deteriorating environment. Finally we recommend that addressing ecological marginalization; increasing pastoralists' access to land, empowerment rural dwellers enhancing their participation and curbing corruption are some strategies of ameliorating the F-P-Cs in the study area.

Establishment and Application of Human Settlements Composite Index Based on Raster Data——A Case Study in Beijing-Tianjin-Hebei Region in China

Xue Yang

Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing, 100101, P. R. China, yangxue_r@126.com

Abstract

In order to evaluate regional human settlements environment more comprehensively, this article selects relief amplitude, climate index, hydrology index, vegetation index, night lighting index, air quality index and traffic access degree to construct human settlements composite index (HSCI) at provincial scale based on raster data. Then use HSCI to analyze the spatial distribution laws of natural environment, humanistic environment and composite index in Beijing-Tianjin-Hebei region. Finally, the relationship between population distribution and the human settlements environment has been discussed. The results show that: (1) the natural suitability decreases gradually from southeast to northwest in Beijing-Tianjin-Hebei region. On the other hand, areas with better social and economic conditions are all construction areas and the humanistic environment in urban district becomes worse gradually from center to periphery. Similarly, it shows that high-grade administrative regions are better than lower ones. (2) HSCI value presents a descending series from southeast to northwest in Beijing-Tianjin-Hebei area and the east of Taihang mountain is more human-friendly than the west. Besides, built-up areas are more preferable than uninhabited areas, and core is better than outside as well as high level administrative regions are better than the lower ones. (3) The population distribution has the strongest correlation with night light index while it has the weakest relationship with air quality index. Furthermore, about 70% of the population live in areas with HSCI value greater than 0.72. Equally important, HSCI value in the most densely populated areas is 0.74, which shows a remarkable regularity of negative skewness distribution.

human settlements composite index; grid; Beijing-Tianjin-Hebei region in China

Research on Cooperativity and Spatial Heterogeneity of Human-Land System in

Hubei Province

Wang Zhanqi, Yu Li

School of Public Administration, China University of geosciences, China, zhqwang@cug.edu.cn

Abstract

The population change in Hubei province has several extremely obvious characteristics, as the sustained rapid growth, the higher the level of urbanization and a very uneven spatial distribution. With increase in the city, township of the reduction in the trend of changes in the number of features is obvious. Population of industrial distribution by the "one-two-three" optimized to the "three-two-one", the number of the first industry declined rapidly, and secondary and tertiary industries increased clearly. Research proposed by introducing elastic coefficient, pressure index, contribution index and load, on Hubei Province with population density of the spatial differentiation, types of quantity change and spatial distribution of employment structure change and land use patterns, for collaborative research. According to the research results, the study area can be divided into three kinds of areas, namely the highly cooperative area, the progressive collaboration area and the contradiction area. By measuring and analyzing the driving factors of the human earth system, put forward the relevant policy recommendations based on the research.

Key words:

Cooperativity; spatial heterogeneity

Spatial and Temporal Changes of Traditional Salt Making Activities and Environmental Adaptation in Coast of Jiangsu Province, China

Abstract

Sea salt production is important way of coastal resources use, which has a long history in China. The observation of the evolution history of sea salt production is a helpful perspective for studying the change of coastal human-earth relationship and environmental adaptation within global change research framework. In the present contribution, we use the historical archives/documents and adopt multidisciplinary methods, to reveal the historical evolution process and characteristics of salt making activities, and dynamic mechanism of its spatial and temporal changes in different coastal region of Jiangsu Province. The study indicates that Jiangsu coastal salt industry included three typical stages: leaching-brine and decocted salt, leaching-brine and solar salt, evaporated-brine and solar salt; from the 13th to 19th centuries, in distribution of the salt making technology, the decocted salt coexisted with solar salt for a long time, and formed a basic pattern that decocted salt making distributed in south coast but solar salt making in north, and there were different evolution stage of sea salt production in different coastal region; the production center migrated gradually from Huainan coast to Huaibei. Meanwhile, coastal natural environmental changes and economic policies were the main driving factors of the distribution changes and environmental adaptation of coastal salt production, especially the management policies for salt industry were the most important driving force which influenced the spatial and temporal variation of coastal salt making activities in the Ming and Qing Dynasties.

The Effect of Elevated Temperature on the Interspecies Competition between *Phragmites Australis* and *Spartina Alterniflora* in the Salt Marsh of the Yangtze Estuary, China

Chao Zhang, Kaiyun Wang, Wei Gao

The School of Geographical Sciences, East China Normal University, Shanghai, 200062, P. R. China,

zhangchao@geo.ecnu.edu.cn

Abstract

The effect of global warming on the invasiveness of invasive plants is now a high spot in the field of global change. *Spartina alterniflora*, a C4 species, is widely distributed in the Chinese coastal salt marsh, it put a high pressure to the native *Phragmites australis* (C3 species). Whereas little is known about the interspecies competition pattern between *Phragmites australis* and *Spartina alterniflora* under global warming? In this work, *Phragmites australis* and *Spartina alterniflora* in the salt marsh of Yangtze estuary were chosen, then open-top chambers were used for the elevation of temperatures (2 °C, 4 °C). We investigated the physiological traits, morphological traits, biomass accumulation, clonal growth and sexual reproduction parameters of these two species under elevated temperatures at monoculture and mixed community. We choose some biomass and reproduction parameters to quantitatively identify the interspecies competition pattern under elevated temperatures. Then physiological and morphological traits under elevated temperature were compared between these two species to understand the mechanisms behind the competition pattern. This work could provide basic data with respects to the population dynamics of *Phragmites australis* and *Spartina alterniflora* in the salt marsh of Yangtze Estuary under global warming, and provide scientific basis for the adjustment of present wetland management to adapt to the predicted global warming.

Abstract

Satellite-derived normalized difference vegetation index (NDVI) data have been widely used to monitor vegetation photosynthetic activity at various scales. Several methods for time series analysis have been proposed, however, most of them may not effectively reveal the nonlinear and nonstationary vegetation changes. In this study, by using the multidimensional ensemble empirical mode decomposition (MEEMD) method to analyze the NDVI satellite data from 1982 to 2011, we diagnosed the evolution of global vegetation activity trend during this period. And it was the first trial to apply this method in the area of remote sensing. According to the intrinsic trend extracted by the MEEMD method, we found that although global vegetation generally experienced a greening process during the entire study period, the trends in NDVI were spatially and temporally non-uniform. Global vegetation greening/ browning rates in 1986, 1990, 1994, 1998, 2002, 2006 and 2010 were mapped, showing that the vegetation activity trend and its rate in many places significantly changed over time. The area with monotonic greening and browning trends account for 26.9% and 3.6% of the total vegetated area respectively. For nearly 70% of the vegetated area, trends were found to change between greening and browning. The mid-high latitudes of the northern hemisphere experienced extensive greening-to-browning reversals from the late 1990s to the early 2000s, and the browning-to-greening reversals mainly occurred in low latitudes of the southern hemisphere from the late 1980s to the mid-1990s.

Key words:

global greening and browning; trend shift; time series analysis; MEEMD method; NDVI

Impacts of Protected Areas on Local Livelihoods in China

DUAN Wei, WEN Yali

Beijing forestry university, Beijing, 100083, P. R. China, bluewei0099@163.com

Abstract

Given the debates about whether PAs exacerbate local poverty or might contribute to poverty alleviation, there is a critical need for evidence to examine the impacts. In this study, we have conducted a household investigation of 712 rural households in 7 PAs of Sichuan province of China. We used matching method to value impacts of Protection Areas (PAs) on local livelihoods. The results showed that compared to the Average Treatment Effect (ATT), the results of traditional regression model exaggerate the negative impacts of the protected area. However, we should notice that the overall impact of PAs on local households' wealth was still negative. Households inside the PAs had more Non-timber Forest Products (NTFPs) gathering income, non-farm income and compensation, but fewer crop production income and forestry income. Better conservation policies need to be initiated to realize the harmonious and concurrent development of ecological objectives and livelihood objectives.

Abstract

Examining the change in freeze-thaw processes triggered by climate warming is a crucial issue in further assessing variations of permafrost, alpine ecosystem and engineering infrastructure *etc.* However, the quantitatively systematic research is still lacking on effect of the warming on freeze/thaw index (FI/TI), soil hydrothermal properties, soil freeze-thaw processes (SFTPs) and active layer thickness (ALT) in the permafrost regions of the Qinghai-Tibet Plateau (QTP) up to now. Thus, the experimental warming using open top chambers (OTCs) was manipulated in alpine swamp meadow and alpine steppe ecosystems in the permafrost regions of the Beiluhe Basin of the central QTP during 2009-2011. Results showed that under OTCs treatment, T_a significantly increased in the daytime and decreased in the nighttime, whereas obviously increased at the mean daily, monthly, seasonal and annual scales. Meanwhile, diurnal and annual T_a range significantly enhanced, and mean annual T_a increased by $\sim 1.4^\circ\text{C}$. Owing to the experimental warming scenarios, mean annual T_s at the depths from 5cm to 40cm was increased by approximately $0.2\text{--}0.7^\circ\text{C}$ in alpine swamp meadow and about $0.3\text{--}1.5^\circ\text{C}$ in alpine steppe. It showed that increase amplitude of T_s was greater in alpine steppe than in alpine swamp meadow, especially at 5-10cm depths. In addition, mean annual SM at 10cm depth decreased by $\sim 1.1\%$ and $\sim 0.8\%$, and mean annual SS at 10cm depth significantly increased by $\sim 0.3\text{g}\cdot\text{L}^{-1}$ and $\sim 0.1\text{g}\cdot\text{L}^{-1}$ in alpine swamp meadow and alpine steppe, respectively. Further, FI was significantly decreased by $\sim 410.7^\circ\text{C}\cdot\text{d}$ while TI was significantly increased by $\sim 460.7^\circ\text{C}\cdot\text{d}$. Likewise, the onset dates of shallow soil thawing at 5-40cm depths were advanced by 9 and 8 days while the onset dates of freezing were delayed by 10 and 4 days in alpine swamp meadow and alpine steppe, respectively. Moreover, soil frozen days were significantly decreased by ~ 28 days and ~ 16 days, but thawed days were increased by ~ 18 days and ~ 6 days, and frozen-

thawed days were significantly increased by ~10 days and ~10 days in alpine swamp meadow and alpine steppe, respectively. Furthermore, ALT had been significantly increased by ~6.9cm and ~19.6cm in alpine swamp meadow and alpine steppe ecosystems, respectively. However, the response differences in two types of alpine grasslands may be mainly controlled by vegetation coverage.

Key words:

freezing/thawing index; soil freeze-thaw processes; active layer thickness; experimental warming; Qinghai-Tibet Plateau

Study of Time-Space Evolution of Social-Ecological System Vulnerability of Hubei Province

Liguo Zhang, Zhanqi Wang

China University of Geosciences, China, 465533186@qq.com

Abstract

This paper use the municipal administrative region of Hubei province as research units, utilize PSR model, from two dimensions of Social System and Ecological System, building Social- Ecological System(SES) vulnerability analysis framework of Hubei province, to explore the fragility of the space-time distribution pattern and driving mechanism in various areas of Hubei province from 2000 to 2014. The results show that parts of Hubei province SES vulnerability showed a trend of rising and regional vulnerability gap larger. As the drive mechanism, human economic activities, policies and other social factors are the main driving factors, at the same time, regional climate conditions also play an important role. According to the analysis of results, this paper discusses each period's stage of SES adaptability circulation of different regions. Then put forward practical adaptive management countermeasures, to provide references for Hubei province's economic, social, ecological balanced and sustainable development.

Hubei province; Social-ecological system; Vulnerability; Drive mechanism; Adaptive management

The Vulnerability Evolution and Simulation of the Social-Ecological Systems in the Semi-Arid Area Based on the VSD Framework

J. Chen, X. Yang, S. Yin

College of urban and environmental sciences, Northwest University, Xi'an 710127, China, dongdongbj2010@126.com

Abstract

As an important proposition in the field of sustainable science, vulnerability assessment of social-ecological systems (SEs) still has obvious defects in the lack of effective framework and quantitative measurement methods. Taking the semi-arid area of the Loess plateau in Yulin City as an example, this paper improves the vulnerability assessment methods and techniques on the county scale using VSD (Vulnerability Scoping Diagram) assessment framework. Firstly, the vulnerability indexes were screen out by the SERV (Spatially Explicit Resilience-Vulnerability) model. Secondly, utilizing the space technology of RS and GIS, this study measured the spatial differentiation characteristics and evolution trend of the social-ecological systems in Yulin City during the period of 2000-2011. The results are as following: (1)The spatial pattern of Yulin City's SEs vulnerability is "high in northwest and southeast and low along the Great Wall", although the degree of system vulnerability reduced significantly during the period of 2000-2011 and the system development trend is better, there is a sharp distinction in the spatial distribution between the system vulnerability and exposure risk; (2)The evolution of system vulnerability is influenced by the risk factors of exposure, and the regional vulnerability and the spatial heterogeneity of exposure risk are affected by the social sensitivity, economic adaptive capacity and other factors. Finally, the future scenarios of regional vulnerability are simulated under different decision risks by taking advantage of the OWA multi criteria algorithm. This research will have significant implications for decision making of sustainable development.

Key words:

Social-ecological systems (SEs); VSD assessment framework; vulnerability; Yulin City

An Analysis of Growth Drag from Water and Land in China

Xue Junbo, Mengzhen Zhao

Institute of Policy and Management, China, jbxue@casipm.ac.cn

Abstract

Resource is the necessities for human survival and development. According to the hypothesis of Romer's theory, growth drag is caused by the limitation of resource and land in fact. This paper considers the influence of excessive water using on Chinese economic and farther analyses the economic growth drag of China. The results show that the growth drag value for the water resource being excessively exhausted is 0.001397, and that for the land resource being excessively exhausted is 0.013201, and that for the water and land resource being excessively exhausted is 6 times as much as that of America. The growth drag is so strong, so we must rely on technology progress in order to plan human and nature as a whole and to realize the goal of economic growth. And technology progress is the only approach to resolve the question to the growth drag.

Key words:

Growth Drag; Land Resources; Balanced Growth Path; Technological Progress

Exclusionary Urban Growth and the Specter of Premature Deindustrialisation with Specific Reference to India

Amitabh Kundu

Institute for Human Development, India, akundu.jnu@gmail.com

Abstract

Urbanization process in the Global South in general and South Asia in particular has been in favour of metropolitan and larger cities, with small and medium towns tending to stagnate. It is, therefore, not surprising that researchers here have looked at urban processes mostly through the prism of large cities. In fact, urban research on the entire Global South remains generally located in these cities. This is more so in South Asian countries where the share of cities with population above 5 million is 23 per cent compared to the global figure of 17 per cent only. In India, the figure is even higher.

The present paper attempts to make a departure from the paradigm of metropolis based urbanisation. This, it does primarily by shifting the focus of analysis to small and medium towns and *rurbanisation*. It is indeed true that a large part of contemporary urban growth occurs outside of the hegemonic power structure of globalisation, both politically and geographically. Therefore, instead of confining urban research to global and national market, state level institutions, formal programmes, missions and legal systems, the paper attempts to build a history of urbanisation from below. It is an attempt to put together the evidences from smaller places and construct a new narrative through an analysis of situations and processes that are considered of marginal importance within the framework of metro centric urbanisation. It is argued that simple dualistic models postulating categories such as rural and urban, small and big cities etc. are inappropriate to understand the dynamics of urban development in India.

Given the fact that Indian urban reality and its diverse manifestations stand up robustly as a refutation of the global models of explanation and prediction, the present paper begins by probing into the conceptual prism used for analyzing industrialization and urbanisation. It analyses the trend and pattern of urbanization in India, identifying the metropolitan bias in the dynamics of development. It then presents three alternate strands of urbanization, taking place in the country. In particular, it examines urban transformation processes operating around large cities. Subsequently, the dynamics of development or their absence in and around small and medium towns have been analysed. Finally, the process of rural urban transition in the distant rural hinterland is discussed. An attempt is made to analyse if the economic geography of urban growth in India simply reflects the hegemony of the global capital. To conclude, it speculates on the relevance of the thesis of premature deindustrialization in India, as evidenced in many countries in Global South.

How Do Regions Evolve in a Transitional Economy?

He, CF¹, Zhu, SJ²

¹College of Urban and Environmental Sciences, Peking University, 100871, Beijing, China, hecanfei@pku.edu.cn

²Department of Geography, Swansea University, UK

Abstract

Regional diversification emerges as a path-dependent process as a region often branches into industries that are related to preexisting industrial structure, whereas industries that are not closely related have a high probability of exiting the region. This paper contributes to the ongoing debates on path dependence and path creation with a new analytical framework that emphasizes the need to bring in a wider range of factors. It suggests that regional industrial dynamics are not only conditioned by preexisting regional capabilities and technological relatedness, but also by the ways in which technological relatedness is interconnected with industry attributes and more importantly region's institutional context. In order to better understand regional industrial evolution particularly in a transitional economy like China, it seeks to incorporate a new strand of literature into current EEG literature—i.e., literature on China's constantly changing, variegated and fragmented institutional contexts, including local state corporatism, market preserve federalism, political tournament and regionally decentralized authoritarian system theories. Based on a firm-level dataset of China's manufacturing industries during 1998-2008, this paper has studied regional industrial evolution in China by examining the entry and exit of 4-digit industries at the prefectural level. By using a measure of co-occurrence based technological relatedness, this research shows that regional industrial development is a path dependent process in China, one that is also inflected by industry attributes and institutional embeddedness. Our results imply that EEG would profit from incorporating insights on institutional change and economic transition in explanations of regional industrial evolution.

Hsinchu Technopolis: A Socio-technical Imaginary of Modernity in Taiwan?

Jinn-yuh Hsu

Taiwan University, Taiwan, China, jinnyuh@ntu.edu.tw

Abstract

The Hsinchu Science-based Industrial Park (HSIP), or labeled as “a Silicon Valley of the East (John Mathews 1997)”, was established by Taiwanese government to host high-technology firms in 1979. To attract the experienced engineers and entrepreneurs back, the HSIP constituted the production facilities and even residential amenities as “the-world-as-exhibition”, an imitation after the Silicon Valley. The HSIP became a social-technical imaginary which was supported by the advance of technology to offer a publicly performed vision of desirable futures of employment and even lifestyle, or a dreamscape of modernity. But the success of the HSIP brings forth social and urban contradictions to the neighboring areas. To meet the challenge of “harmonization” between the old villages and the new technopolis, the government proposes successively the “Hsinchu Science City” (HSC) plan and the Unpolished Jade Project (UJP) to integrate the neighboring counties with the development of the HSIP. The socio-technical imaginary of modernity bred by the HSIP project engendered two critical issues for the future development. On the one hand, land speculation burst out under the imaginary of spread effect of the HSIP, even the housing bubble evaporated after the 2008 economic crisis. On the other hand, the desires of development, or the Utopia of modernity, that were both evoked and betrayed by the successive actual regional development projects among the local people had to be taken serious in the debates on the HSIP’s future. This paper concluded that instead of victimizing local people, the positive thinking of the desire of modernity could ethically take advantage of the development projects which could not deliver the long-lasting promise of equal development, and explore possibilities to move the region forward “real” but never realized socio-technical imaginations.

Modernity; special economic zone

Spatial Organization of the Electronics Production Network in East Asia and Its Impact on Regional Development

GONG Peiping, LIU Weidong, TANG Zhipeng, YIN Guoqing

Institute of Geography Sciences and Natural Resources Research, Beijing, 100101, P. R. China, gongpp.11s@igsnrr.ac.cn

Abstract

For recent decades, the electronics industry has witnessed dramatic change in its spatial reconfiguration and the formation of a highly integrated regional production network in East Asia. In this regard, lots of work has been done with the perspective of global production network. While providing important insights into the mechanisms behind the reconfigurations of global production networks, the research above performs poorly in quantitative analysis and provides us lots of 'fragments' rather than a systematic macro overview of the networks. In this paper, we apply the multi-regional input-output model to relook into the electronics production network of East Asia in quantitative way. Specifically, by compiling a multi-regional input-output table of East Asia in 2010, we demonstrate the spatial linkages within the electronics production network in East Asia and evaluate their impacts on regional development with value-added trade measures. The results illustrate that regions in charge of the two ends of value chains, like Taiwan China, Korea and Japan, benefit the most from the current spatial organization of the regional electronics production network, while regions responsible for assembly production benefit the least. As the calculation results of value-added trade show, Taiwan, Korea and Japan are destinations of net inflows of valued added while the southern coastal region and eastern coastal region of mainland China are the main source of net outflows. We believe the proposed approach will have significant implications for strengthening quantitative analysis in global production network-based research.

Key words:

electronics production network; value-added trade; multi-regional input-output model, East Asia

The Rational Particularities of Chinese ODI

Lei Z, Weidong L, Yi L

Institute of Geographical Sciences and Natural Resources Research, University of Chinese Academy of Sciences, Beijing, 100101, P. R. China, zhengl.11s@igsnrr.ac.cn

Abstract

In 2014, Chinese outward direct investment (ODI) surpassed its FDI and Japanese ODI, which made China an economy with a net capital outflow as well as the world second largest FDI investor just behind America. It is still a wonder to achieve that in no more than 15 years after China's "go abroad" strategy, despite of Chinese miraculous economic development. Subsequently, the rapid expansion of Chinese ODI caused fear and fever. Alarmists warn of another version of economic colonization, while realists see opportunities for dividend and interests. It also arouses doubts and debates among researchers, as exemplified by Chinese companies' lack of general ownership advantages, perverse reaction to risk, and hyperbaric role of government.

Therefore, this study firstly aimed to summarize unique features of Chinese ODI, including its spatial pattern of destinations and impact factors of location choice such as resource endowment, institutional environment and so on. Then we focused on the rationale of these particularities based on China's governance mode and its game against globalization. We concluded that Chinese ODI has significant natural resources-seeking and financial freedom-seeking but not reverse technology-seeking features, and imperfect institution of host countries and close bilateral government relations would enhance Chinese ODI. However, the impacts of these factors varied in space. The current achievement is consequent of domestic accumulative ODI demand and institutional profit. The characteristics of Chinese ODI are shaped by domestic governing logic which is featured by powerful government and regulated market and bargains with host countries.

Key words:

Chinese ODI; spatial-temporal pattern; determinants; governance structure

Unpacking China's Belt and Road Initiative

Weidong Liu, Michael Dunford

IGSNRR, Chinese Academy of Sciences, China, liuwd@igsnrr.ac.cn

Abstract

In a world of significant geo-economic competition and collaboration, China's Belt and Road Initiative (BRI) is a result of the rise of China as a global economic power and its desire to demonstrate that it is a responsible stakeholder in a global multi-lateral system on the one hand and of its need to reform its development model and encourage development in potential markets/sources of goods and services on the other. The BRI highlights the role of the Silk Road as a shared part of the cultural heritage of many countries and civilizations and draws on it to promote mutually beneficial co-operation, while also reflecting the unsustainability of China's export-oriented growth model, its energy and resource needs, the rise of China as an outward investor and the role of infrastructure in creating the foundations for growth in less developed parts of the world.

Key words:

silk road; globalization; the Belt and Road Initiative

International Research Initiative in the Russian Arctic (ISIRA)

Tishkov Arkadiy

Institute of Geography, Russian Academy of Sciences, Moscow, Russia, tishkov@biodat.ru

Abstract

After the collapse of the USSR and economic crisis, the extent of research and possibilities for monitoring of natural and social change in the Russian Arctic decreased. An issue about the scientific cooperation expansion in the region and the establishment of technical and financial conditions for this has arisen. In early 1990s here a sharp decline in the number of scientific expeditions, disrupting transport links to remote villages took place, some weather stations and research stationeries were closed. In addition, long-term series of observations of various components of the Arctic environment that previously were characteristic for the Russian Arctic science were interrupted.

After significant easing of requirements for the visit for foreign scientists to the Russian Arctic in the 1990s the real opportunities for planning international research projects and expeditions took their start. The idea of creating the International Arctic Science Committee (IASC) Working Group ISIRA was born in 1993, when an experience of bilateral contacts between scientists on the Arctic themes and plans for joint research in different areas of the Russian Arctic appeared.

25 years ago the priorities of the ISIRA have been identified:

- Initiating international research programs and projects;
- Search for partners in the countries - participants of the working group ISIRA;
- Prompt achievement of new knowledge and the avoidance of duplication;
 - Assistance of the ISIRA for foreign counterparts to participate in scientific research in the Russian Arctic;
- Consulting in the area of research financing and organization.

The first projects supported by ISIRA, were successful. Special attention to international initiatives in the Russian Arctic has arisen during the period of IPY 2007-2008, and after him. On the one hand, it is clear that there are those countries, scientific organizations and scientists for whom the internationalization of research in the Russian Arctic is a real way to study its nature, for the fruitful cooperation and win-win experience. On the other hand, the stories, when calls for scientific cooperation does not carry a positive start, are not aimed at useful for both scientific cooperation partners also took place. Unfortunately, this results in a few joint publications, in missing important for any joint research final stage of the synthesis. And after the fieldwork

their results (collected data) are in arms of foreign counterparts and the Russian partners do not have access to them. Therefore, our task is to make IASC and its working groups, including ISIRA, to be a platform for the development of mutually beneficial scientific cooperation in the Arctic. Arguments in favor of this thesis are as follows:

- Key role of scientific research in the Arctic for geopolitical security of the country and its security interests;
- Defining their role in strengthening and development of the resource potential of the Russian economy;
- Outstanding perspectives for the international use of the Northern Sea Route as one of the main infrastructure elements in the Arctic;
- Support of the global biosphere functions (climate-regulating, global carbon balance, biodiversity and habitat of indigenous peoples).

All this formed the basis of the tens of scientific international and hundreds of scientific projects in recent years after the IPY implemented in the Russian Arctic, primarily by the RAS institutes and Roshydromet. Currently, in the Russian Arctic 80 - 120 international projects involving more than 20 countries are come to practice every year. In addition to the eight Arctic states, South Korea, Japan, China, Spain, France show the activity in collaboration in Arctic. Also a number of Arctic countries (e.g., Finland, Norway, USA, and Germany) formed a special state program of expansion of bilateral scientific cooperation in the Arctic. Their perspectives and priorities could be the subject of discussion at the "round table" in the IGU in Beijing.

Key words:

Russia, ISIRA, Arctic cooperation, China

New Silk Road and the Northern Sea Route: Is China Able to Combine Them?

Konyshov, V.

Professor, Saint-Petersburg State University, Russia, konyshov06@mail.ru

Abstract

China and Russia achieved significant progress in mutually beneficial cooperation in the Arctic. However, given the emphasis on land transport corridors via the Central and South Asia as well as on southern maritime routes that the New Silk Road concept makes, it is unclear whether China still has an interest in the Northern Sea Route? And if yes, is China able to combine these transport projects? It is an ambition of this paper to demonstrate that in spite of refocusing of China's transport development strategy on the New Silk Road project the Northern Sea Route still remains a high priority for Beijing. Russia and China develop a number of joint projects in the Arctic Zone of the Russian Federation (for example, LNG plant on the Yamal Peninsula) that requires development of shipping via the Northern Sea Route. The Polar Code, recently adopted by the International Maritime Organization and which enters into force on 1 January 2017, on the one hand, provides both Russia and China with some additional incentives to jointly exploit the Arctic sea route, and, on the other, introduces some measures to protect the Arctic fragile marine environment. From strategic point of view, the Northern Sea Route provides diversification of the Chinese transport infrastructure given the prospects for the rise of competition or confrontation between China and the U.S. in the Asia Pacific region. There is also another project with Chinese participation that aims to connect - by railroad - the new deep water port near Archangelsk with the Ural industrial complex, Central Asia, and China.

Key words:

The Northern Sea Route; Silk Road; China; cooperation

On The Problem of Biodiversity Conservation of the Russian Arctic

E. Belonovskaya, A. Tishkov, N. Sobolev

Institute of Geography RAS, Moscow, Russia, belena53@mail.ru

Abstract

Russian Arctic occupies nearly 1/3 of the Circumpolar Arctic territory -21, 2 billion km², of which the terrestrial part is only 7, 2 billion km².

Here one can see all main arctic types and variants of tundra, shrubs, meadows ecosystems, soils and plant communities. Great variety of landscapes and ecosystems are the habitats for the unique arctic terrestrial flora and fauna. There are 2300 species of vascular plants, 900 mosses and 1600 lichens. 60 species of mammals, nearly 200 birds and 400 fishes are met in Russian Arctic.

Recently because of the increasing of the economic activities in the region anthropogenic impact on the extremely vulnerable arctic ecosystems are strengthen. That's why biodiversity conservation is one of the priority problems in the Russian Arctic.

There are nearly 450 federal and regional Specially Protected Natural Areas (SPNA), which is 13,1% of the whole area of the Russian Arctic region (94,6 billion ha). Conservation of rare and endanger of plants and animals species, and also ecosystems is carried out on these areas. Kamchatka, Yakutia, Murmanskaya oblast, Komi republic are notable for the quantity of the protected areas. Krasnoyarskiy krai and Yakutia are notable for the total area of SPNA.

Nowadays within the joint Program of the Council of Europe and European Union on the Pan European biological and landscape conservation strategy implementation of the Pan European ecological network development (so called Emerald network) is at work. The main purpose of this Program is to guarantee the adequate conservation status for species, ecosystems and landscapes of the European value. Russia is invited for the Program and nowadays 34 Areas of Special Conservation Interest (ASCI) were proposed for the Emerald Network in the European part of the Russian Arctic. In the future the process of ASCI's revealing is supposed to be prolonged for the arctic regions of Asia. Besides Eastern European tundra, Chukotian one, North- Uralian and West-Siberian forest-tundra, mountain pine thickets of North-Eastern Siberia could be considered as priority ecosystems for the Ecological network creation.

Sino-Russian Cooperation on the Arctic: Problems and Opportunities

Sergunin, A.

St. Petersburg State University, St. Petersburg, Russia, sergunin60@mail.ru

Abstract

The paper aims at examining the Sino-Russian relations on the Arctic. It argues that, on the one hand, Russia is interested in China's investment in the development of the Russian North's energy and mining sectors, Northern Sea Route's (NSR) infrastructure as well as in promoting cooperation with the PRC on the Arctic research (climate change, ice dynamics, environment, etc.). On the other hand, there are some residual areas of contention, such as Russia's reluctance to provide China with a privileged status with regard to the NSR, debates on financial conditions surrounding specific projects in Russia's Arctic sector, Moscow's concerns on a potential mass Chinese migration, etc. Moscow faces uneasy choices between the need to keep cooperative relations with its 'strategic partner' and protect its national interests in the Arctic when they diverge with those of the PRC.

Abstract

Globalization and global consensus is one of the main themes of 33rd International Geographical Congress. Internationalization of geography education can play a key role in promoting global consensus. To accelerate the development of geography and facilitate communication and cooperation among scholars and professionals of geography worldwide, this forum will focus on internalization of geography education. This forum is hosted by School of Geography and Planning, Sun Yat-sen University, located in Guangzhou, China. The School is originated from Department of Geography, established in 1929 as one of the oldest geography departments in China. It has recently become International School of Geography, as part of a new internationalization initiative of the Ministry of Education and State Foreign Expert Bureau of China. The goal of the School is to explore a mechanism for making geography education in China more online with that of the international mainstream.

Mapping a Bright Future: Building Capacity for Internationalization in Geography

Bednarz, S.W.

Texas A&M University, College Station, Texas, United States, s-bednarz@tamu.edu

Abstract

As president of the American Association of Geographers, I have focused on ways geography departments can thrive in a time of great disruption in higher education, both in the United States and globally. One of the key disrupters is the denationalization of post-secondary education, driven by the market forces of globalization. It is now a global marketplace for students, faculty, researchers, and key resources. Geographers seek ways to adapt to this condition and to enhance our contribution to the internationalization of our campuses. This paper focuses on strategies geographers may develop and adopt to maximize the opportunities presented by the globalization and internationalization of higher education. First I will present an overview of the evolving drivers for internationalization using the framework proposed by Biles and Lindley (2009). Next I will discuss the opportunities and challenges of transnational higher education. To conclude I will examine the unique position of geography as a discipline in this enterprise and highlight the advantages we have to capitalize on internationalization both educationally and institutionally.

Abstract

In this study we develop a luminescence chronology for the S₁-L₁ loess palaeosol sequence at Niuyangzigou, south of the Horqin dunefield in northeastern China. We report standard quartz SAR OSL and post-IR infrared (IR) stimulated luminescence (post-IR IRSL; pIRIR₂₉₀) measurements made on sand-sized quartz and K-feldspar extracts, respectively. The quartz OSL characteristics are satisfactory. Over the dose range of interest, the measured pIRIR₂₉₀ D_e's do not vary with the first IR stimulation temperature between 50 °C and 260 °C, so all measurements were made using a first IR stimulation temperature of 50 °C. Extensive pIRIR₂₉₀ dose recovery tests were performed by adding doses on top of the natural dose. We found that the dose recovery ratios improve significantly when a large test dose is used (e.g. >20% of the measured dose) and good dose recovery can be obtained up to ~800 Gy. When small test doses (up to 10% of the measured dose) are used the dose recovery ratio is >1.10, and the D_e values also depend on the test dose size; we conclude that the effects of the size of the test dose should be routinely considered in pIRIR dating. Long term laboratory bleaching experiments show that a constant residual pIRIR₂₉₀ signal is reached after ~300 h; it corresponds to 6.2±0.7 Gy. Quartz OSL and feldspar pIRIR₂₉₀ ages are in good agreement at least back to ~70 ka. Beyond this limit the quartz ages begin to underestimate.

A Typhoon-induced Flood, Sediment Characteristics and Heavy Metals: A Case Study from Yaojiang River Valley, Zhejiang Province, East China

DAI X. R.^{*}, SHI Y. X., WU Z. Y., ZHENG J., XI Y. J.

School of Geographic Sciences, East China Normal University, Shanghai, 200241, P. R. China, xrdai@geo.ecnu.edu.cn

Abstract

Induced by the 'Buffett' typhoon that happened on the October 7th, 2013, an extra-ordinary flood occurred in the lower Yaojiang river valley, Zhejiang province, east China. This flood was determined to have broken through the historical record of water level and caused a huge economic loss. Flood sediments along riverbanks and also in Yuyao city were taken to analyse the grain size, magnetic parameters and heavy metals. Results show that the sediments are composed mainly of silts (58.72%), clay (about 23.27%) and fine sand (18.01%), and their frequency curves were featured with twin peaks or multimodal peak, and positive bias, and the probability cumulative curves were relatively flat. These features seem much similar to the 'yellow silt' collected from the adjacent Hangzhou floodplain. Magnetic parameters show that the magnetic minerals in the sediments were mainly composed of ferri magnetic minerals. The heavy metal analysis showed that the average value of Cu, Zn, Cr, Cd, Pb, Ni, Mn, Fe were 175.2mg·kg⁻¹, 400.7mg·kg⁻¹, 145.3mg·kg⁻¹, 0.8mg·kg⁻¹, 43.7mg·kg⁻¹, 32.1mg·kg⁻¹, 564.3mg·kg⁻¹ and 4.4%, all beyond the local background values. The heavy metals also showed an increasing trend from upstream to downstream due to urban anthropogenic input. This work was supported by project of National Natural Science Foundation of China (No.41071134).

Abstract

Streamflow and sediment discharge response to rainfall intensification under global warming is poorly discussed due to the limited data length and human alteration, particularly in the small mountainous watersheds. In this study, the historical runoff and sediment export from the Taiwanese rivers are investigated to illustrate the changes of both runoff and sediment export. Results showed that both rainfall and runoff in the 99.9-percentile have been significantly increasing in terms of frequency and intensity over the past four decades. The medians of the runoff depth and sediment yield extremes (99.0–99.9 percentiles) among the 16 rivers increased by 6.5%-37% and 62%-94%, respectively, reflecting the disproportionately magnified response of sediment export to the increased runoff. Taiwan is facing increasing event rainfall intensity which has resulted in chain reactions on magnified runoff and sediment export responses. As the globe is warming, rainfall extremes, which are proved to be temperature-dependent, very likely intensify runoff and trigger more sediment associated hazards. Such amplification should be a warning for other regions with significant rainfall intensification. Appropriate strategies are indispensable and urgently needed to maintain and protect the development of societies.

Global warming; rainfall-runoff; rainfall intensification; sediment discharge

Channel Planform Dynamics Monitoring and Channel Stability Analysis in Zhoushui River, Taiwan

Kuo, CW, Chen, CF

Center for Space and Remote Sensing Research, Central University, Taoyuan City 32001, Taiwan, China,

cwkuo@csr.sr.ncu.edu.tw

Abstract

Patterns of river channel planform dynamics reflect a variety of flow and sediment regimes. Recurrent flood events induced by typhoons are powerful agents to modify channel morphology in Taiwan's rivers. Frequent channel migration reflect highly sensitive valley floors and increase the risk of infrastructure and residents along rivers. Therefore, monitoring channel planforms is essential for analyzing channels stability as well as improving engineering design. This study analyze annual channel migration along Zhoushui River in Central Taiwan, from 2008-2015 based on satellite images of FORMOSAT-2. Channel area were digitized from mid-catchment to river mouth (~ 90 km). Channel stability for reaches were assessed through analyzing the changes of river indices including net channel change, channel activity, braid index and active channel width. The boundaries of reaches were decided according the confluences of tributaries and changes of valley confinement. Data of flow discharge and sediment load were incorporate into analysis to understand the magnitude and effectiveness of flood events. In general, channel activity and braid index increase as valley width expands whereas braid index decreases slightly close to river mouth. This downstream pattern was interrupted by river weir which resulted in limited changes downstream the weir due to the lack of water and sediment supply. Typhoon Morakot in 2009 induced great changes (mostly erosion) in Zhoushui River. This study shows that satellite image monitoring accompany river indices analysis could be an effective tool to evaluate spatial and temporal changes in channel stability in highly dynamic river systems.

Abstract

Chinese deserts and sand fields are regarded as an important dust source in Asia. In this study, 400 optically stimulated luminescence (OSL) ages and more than 100 depositional records in the Chinese deserts and sand fields were obtained; on the basis of these data, we reconstruct spatial distributions of the deserts and sand fields during the last glacial maximum (LGM, 26-16 ka) and Holocene Optimum (HO, 9-5ka). Our results show that the sand fields of Mu Us, Hunshandake, Horqin and Hulun Buir in northern and northeastern China had expanded 25%, 37%, 38% and 270%, respectively, during the LGM; the sand fields of Gonghe in the northeastern Qinghai-Tibetan Plateau had expanded 20%, and the deserts of Badain Jaran, Tengger in central northern China had expanded 39% and 29% separately during the LGM; the deserts of Taklimakan, Gurbantünggüt and Kumtag in northwestern China had expanded 10%-20% respectively, compared to their modern areas. On the other hand, all of the sand fields were nearly completely covered by vegetation during the HO; the deserts in northwestern and central northern China were reduced by around 5%-20% in area during this time. We use a model of present as an analogue to calculate dust emission in the LGM and HO, the results show a significant change of dust emission under the natural climatic changes.

Abstract

Mt. Taibai is the highest mountain in the eastern mainland China. It is a typical region for dendrochronology study. Several researches have been conducted on the relationship between tree-ring indices and climatic factors using traditional statistical methods. However, few physiological analysis of tree growth has been reported on the dendroecological studies in Mt. Taibai. In this paper, the response of tree growth of *Larix chinensis* to climatic factors are discussed in the upper tree-line area of Mt. Taibai based on the process-based VS-Lite model. The conclusions are obtained as follows according to the analysis of *Larix chinensis* tree-ring samples that collected from both northern and southern slopes of Mt. Taibai with the elevation of 3000-3400 meters.

(1)Both elevation and aspect have influences on the simulation results of VS-Lite model of *Larix chinensis*. The optimal simulation is shown on the elevation of 3200m approximately. While the correlation of the simulated value and measured value is higher on the southern than on the northern slope. (2) The main climate factor limiting the *Larix chinensis* growth in Mt. Taibai is the temperature of the growing season during May to August. (3)The VS-Lite model has a better simulation result in Mt. Taibai area and provides more biological information of tree growth than the statistical methods.

Coastal Geomorphologic Evolution and Human Impacts - The North Jiangsu Plain

Coast as an Example

ZHANG Yongzhan

The Key Laboratory of Coast & Island Development of Ministry of Education of China, School of Geographic & Oceanographic Sciences, Nanjing University, Nanjing 210023, China, zhangyzh@nju.edu.cn

Abstract

The geomorphologic evolution is mainly controlled by the river-sea interactions in the North Jiangsu Plain coast along the South Yellow Sea, triggered by the sea level changes during the post glacial period. However, the human activities have still shown the dramatic impacts to it during the historic period.

In 1128 AD, to prevent an invasion from northwards, the lower bank of the Yellow River was excavated, which caused the Yellow River captured the local Huaihe River, shiftily entered into the South Yellow Sea as a disaster for more than 350 years. By the strong artificial flood control engineering since 1494 AD, the Yellow River flowed straightly into the Yellow Sea till 1855 AD. A large scale delta covered 7,160 km² area above the water level and even huge area underwater, called the Abandoned Yellow River delta (AYRD) was built. As the result, it formed a promontory in the coast, and the Jiangsu coast changed into the tide dominated tidal flat coast from the wave dominated sandy barrier bar – lagoon coast. Furthermore, the landscape along the coast has been totally changed, an artificial large lake, Hongzehu Lake with the surrounding lowland was formed, and a broad North Jiangsu Plain was built.

On the contrary, after the Yellow River returned back to enter into the Bohai Sea at 1855 AD, lost the huge sediment supply suddenly, the coastline of AYRD began to retreat rapidly suffering from the severe erosion. The high dyke along the coast was built with series engineering in 1970s, such as offshore breaks with groins. Even the regressive progress of the coastline stopped, the underwater part of the AYRD is still adjusting fast. The offshore slope is getting steeper changed from convex shape into concave shape, and -5 m and -10 m even -15 m isobaths regressed landwards paralleled. The wave dynamic process is becoming more and more active in the nearshore area. Meanwhile, -10m~-15m deep tidal channels have also been formed in the offshore area along the both sides of the AYRD. Obviously, the whole coast of AYRD is adjusting controlled by the wave and tide dynamics under the extreme condition without any terrigenous sediment supply. Because of the salt farmland reclamation and natural extending of the spartina along the coast, the coastline at the both ends of the AYRD stopped to retreat, but became to progress seawards.

Abstract

It has been argued that alluvial fan morphologies, especially fan slopes are influenced by variety factors, such as the lithology, climates, the basin relief, fault activities and depositing processes. In explain this complicated system, much more efforts and work should be done and then a suitable dynamic model might be composed. In this study, we present the results of in-situ investigations of fan morphologies in the Hexi Corridor, NW China, and how the basin properties control fan slopes and fan channel hydraulics. We firstly chose 47 alluvial fans that draining 5 different mountain regions around the Hexi Corridor, including eastern Qilian Shan, middle Qilian Shan, western Qilian Shan, the Yumu Shan and the Longshou Shan, to extract their radial fan profiles, slopes, drainage basin areas and reliefs from DEMs and satellite images, and extracted lithology distribution for each drainage basin from local geology maps. By preliminary comparisons of fan slopes from different regions, we obtained similar power law relations of fan slopes with drainage areas as previous studies. Furthermore, we found that most of the fans have concave-up longitudinal profiles, and the slope is linearly decreasing downstream for all the fans. Another outstanding characteristic with the fan longitudinal profiles is that fans have different concavities in different regions, that the fans in Longshou and Yumu Shan have high concavities, the fans in middle Qilian Shan have relatively lower concavities, and the fans in eastern and western Qilian Shan have lowest concavities or close to straight longitudinal profiles.

In order to find out the controlling factors on this characteristic, we conducted field observations on 10 typical fans respectively distributing in front of the 5 mountain regions. Obtained field data include fan channel grain sizes, hydraulic radiuses, fan deposition properties, fan surface trenching information and old fan surfaces distributions. By comparisons on these characters and fan slopes, we found that the grain size has limited influence on the fan slopes, while the downstream fining of grain sizes is mainly controlling the hydraulic radiuses. With the fans draining granite rocks, fan heads have high medial grain sizes and downstream fining is significant, that hydraulic radiuses decreasing fast downstream; While with the fans draining sedimentary and meta-sedimentary rocks, fans have low medial grain sizes and downstream fining is weak, that hydraulic

radiuses slightly decreasing downstream. Other than grain sizes, the fan slope may be greatly controlled by the relations of water flux and sediment flux. The calculating results of bed load fluxes using the sediment transport model also indicate that the downstream decreasing rate of bed load fluxes are different with fans in different regions. For the eastern Qilian fans and large river fans, which formed single river channel on old fans by Holocene river incision, the fan slopes are weakly decreasing downstream, affecting that sediment fluxes are not decreasing downstream. For the fans with low concavities in western Qilian Shan, the slow decreasing of fan slopes is to adjust the decreasing of water flux caused by fast water infiltration on fans, at where the drainage basins have extremely low rainfall (<100 mm/yr). For the fans with high concavities in Yumu and Longshou Shan, where the rainfall is around 200 mm/yr, the downstream decreasing of fan slopes is corresponding the decreasing of sediment flux with lower water infiltrations. Thus, we can conclude that the fan slope change is the result of changing relations of water flux/sediment flux, but not sediment grain sizes.

³Department of Geography, University of Wisconsin-Madison, Madison, Wisconsin, USA

⁴Division of Atmospheric Science, Desert Research Institute, Las Vegas, Nevada, USA

Abstract

Northern China, encompassing spacious desert, sandy land and gobi, is one of the key sources of global dust emission, while the estimations of the total emission and contribution to North Pacific are still much disputed. In this study, a preliminary approach is made to estimate the total PM₁₀ (i.e., particle matter with aerodynamic diameter equal to or smaller than 10μm) emission flux from Tengger Desert and Mu Us Sandy land, through integration of observed data by PI-SWERL (standing for Miniature Portable In-situ Wind Erosion Laboratory) and ambient meteorological stations, with WESTDC 1.0 land cover product. During the observation, the gross PM₁₀ emission fluxes of Tengger Desert and Mu Us Sandy land lie in a range of 10³-10⁴ ton/day, and the former is higher. Moreover, the potential of PM₁₀ emission from six common landforms in these regions has been investigated, including sand dunes, coppice dunes, dry lakes, dry washes, fluvial and grassland. The results indicate that the emission flux of coppice dunes is highest, followed by fluvial and sparse grassland, whereas that of the rest is relatively low. The spatial and temporal heterogeneities in different landforms of dust emission are greatly dependent on the surface characteristics, especially vegetation and soil moisture.

Himalaya Evolution at Paleogene-Neogene Boundary Unraveled by Zircon Age Spectrum from Arabian Sea Sediments

Feng H, Lu H, Zhang H

School of Geographic and Oceanographic Sciences, Nanjing University, Nanjing, P. R. China, fenghangeo@163.com

Abstract

Although virtually all the intensive orogenic activities of Himalaya occurred in Neogene, the tectonic evolution of this high mountain range in Paleogene is poorly understood. Investigations of tectonic change pattern at Paleogene-Neogene boundary are important to better understand the interaction between mountain building and climate evolution. Here we present new U-Pb ages of zircon grains from Indus Fan sediments to constrain the orogenic history of Himalaya at Paleogene-Neogene boundary. 11 samples between late Oligocene and early Miocene from ODP 117 cores are dated by the zircon U-Pb technique. We calculate relative contributions of potential sources by counting zircon grains for each sample, and the quantized results indicate Himalaya contributed sediments to the coring site, and an extremely high input from Great and Tethyan Himalaya during late Oligocene-early Miocene. Four samples in Pleistocene are also dated for comparison, which indicates that high proportion of Lesser Himalaya has contributed to the sediment in Pleistocene. Our results suggest that the high contribution of Great and Tethyan Himalaya at Paleogene-Neogene boundary might correlate with the beginning of activity of MCT and extension of STD with leucogranite intrusion along Himalaya, which give rise to the extensive Great Himalaya exhumation. Our study demonstrates that zircon U-Pb dating technique is a good tool to reconstruct erosional history of mountain building on a tectonic timescale.

Landcover Change and Its Implication on Coastal Flood Hazards, Xiamen Island, China – An Analysis Based on Historical Photographs and Satellite Imageries

Y.T. Lin, S.M. Shen

Department of Geography, Taiwan Normal University, Taiwan, 162, He Ping East Road, Section 1, Taipei, Taiwan, s09930312@gmail.com

Abstract

Xiamen island, a strategic port city along the southern Fujian Province coast, has developed dramatically since designated as one of the six Special Economic Zones in 1980 under China's Reform and Open Door Policy. Along with the rapid economic growth, the area of island has increased from 132.5 to 172 km² through land reclamation projects, led by the authority. Under the threat of the extreme climate regimes, this implies the increasing of coastal flood risks. Thus, this study intends to detect the coastline change and its landcover transformation and to reveal the hotspots under the coastal flood threats around the Xiamen island. Based on the analysis of aerial photograph taken in 1960 and the sequential Landsat satellite imageries from 1980 to 2016, it is found that the landcover/landuse has significantly intensified not only on the reclaimed land but also along the original coastline. Recent studies show that the extreme sea level and its frequency has risen around the Xiamen Bay (Feng et al., 2015 a, b); storm surges and typhoons will become more hazardous and increase coastal flood risks (Yu et al., 2015). Thus, those newly constructed villas standing just beyond the beaches may suffer the most during the extreme events. For mitigating coastal flood disaster, a comprehensive investigation of vulnerability along the coastline is essential.

Abstract

China is a key area of early human settlement in eastern Old World with numerous palaeolithic localities indicating an early Pleistocene presence of hominins both in north and south China. Many searches are devoted to possible migration routes for hominins linking the two areas and here we report the discovery of several loess-covered Paleolithic sites in the Hanzhong and Ankang Basin, along the Hanjiang River, in the southern piedmont of the Qinling Mountains, central China. A chronology was developed for these sections using a combination of detailed magnetostratigraphic analyses and pedostratigraphic correlation with the well-dated loess-paleosol sequence of the central Chinese Loess Plateau. The results indicate that the age of the oldest lithic assemblage at Longgangsi locality 3 Paleolithic site in Hanzhong Basin could be ~1.20 Ma, and thus this locality would be probably one of the oldest in central China. Furthermore, our works indicate that hominin occupied the Hanjiang valley at several stages around ~1.2 Ma, ~0.9 Ma, ~0.6 Ma, and ~0.1 Ma. As many sites corresponding to these different phases were also discovered north to the Qinling mountains, we propose that Hanjiang River Valley was a probable hominin's route ways through the Qinling Mountains, and its future study is important for contributing the early human migration route hypothesis between southern and northern China.

Neogene Uplift in the Korean Peninsula Linked to Small-Scaled Mantle Convection at Sinking Slab Edge: Implications on Earthquake Hazards

Shin, J.

Department of Geography Education, Gyeongsang National University, Jinju, South Korea, jshin@gnu.ac.kr

Abstract

This study provides quantitative constraints on Neogene uplift in the Korean peninsula using onshore paleo-shoreline records and seismic data. The eastern margin of Northeast Asia including Korea sits in the back-arc system behind the Western Pacific Subduction Zone, a complex trench triple junction of the Philippine Sea, Pacific, and Eurasian (Amurian) plates. An analysis of seismic data in the subduction zone shows that the pattern of uplift in the peninsula mirrors the extent of deep seismicity in subducting Pacific plate beneath. Combined with previous tomographic studies it is proposed that uplift is partly driven by asthenospheric upwelling caused by a sinking slab during the Neogene. In addition, the SH_{max} orientations of E-W and N-S trends in the peninsula are consistent with the prevailing *in-situ* stress fields in the eastern Eurasian continent generated by various plate boundary forces. The uplift in Korea during the Late Neogene is attributed, in part, to lithospheric failure relating to faulting movements, thus providing a link between dynamic effects of mantle upwelling at sinking slab edge and lithospheric responses driven by plate boundary forces.

Abstract

There is a huge loess deposition in Chinese Loess Plateau, but the origin or provenance is still hotly debated. In order to pinpoint the dust source, surface samples from the North Tibet Plateau piedmont, Gobi Altay Mountains piedmont and modern dunes from the Tengger desert and the Mu Us sand field were analyzed using detrital zircon dating method, aiming to study the provenances of the Chinese loess. In order to quantitatively discriminate content of different potential sources, zircon grains of different age are grouped into different origins according to the tectonic demarcation line. Zircon grains age at 542~1300 Ma are grouped as the North Tibet Plateau piedmont origin, grains at 0-145 Ma are grouped as Gobi Altay Mountains piedmont origin, grains age at 145- 542 Ma can be either from the North Tibet Plateau or Gobi Altay Mountains piedmont, or a mixture of the twos. Proterozoic and Archean zircon grains may be a mixture of the North Tibet Plateau piedmont, Gobi Altay Mountains piedmont or North China Craton. As evidenced by this calculation, sediment in the Tengger Desert, Mu Us sand field is mixture of the three origins. Sediment in the two deserts shows stark spatial variability in sources. Loess deposition in the CLP is also a mixture of sediments from the North Tibet Plateau piedmont, the North China Craton and the Gobi Altay Mountains piedmont, albeit with the North Tibet Plateau piedmont dominating sources. Our result, using the novel statistical provenance group analysis, shows that the loess deposit is a mixture from a broad area of north China.

Response Divergence of *Abies Fargesii* Tree-Ring Widths to Climate Variation in the Niubeiliang Nature Reserve of the Qinling Mountains

Na Gao, Shu-heng Li, Hong-ying Bai, Bo Liu, Jun Wang

College of Urban and Environmental Science, Northwest University, Xi'an, 710127, China, gong2012@163.com

Abstract

The heterogeneity characteristics between tree-ring width of *Abies fargesii* and climate change in the Niubeiliang Nature Reserve of the Qinling Mountains was analysed by dendroclimatological methods, for two time periods of 1969 to 1992 and 1993 to 2013. The results showed that a divergence problem exists in the radial growth responses of *Abies fargesii* relative to temperature indicators in the study area. The characterization of *Abies fargesii* radial growth chronology (RES) series was explored by correlation analysis and response function analysis. During 1969-1992, the tree-ring widths of *Abies fargesii* did not correlate with the mean annual and seasonal temperature but had significantly negative correlations with the mean temperature of March and September and the precipitation of February and April in the current year. In addition, the tree-ring width of *Abies fargesii* showed a significant positive correlation with the mean temperature of May in the current year. During the period of 1993-2013, the tree-ring widths of *Abies fargesii* showed a significantly positive correlation not only with the mean temperature of the previous fall, especially in the previous October but also with the precipitation in February of the current year. Moreover, the tree-ring widths of *Abies fargesii* were negatively correlated with the average rainfall in the last winter during the two time periods. This study indicated that the *Abies fargesii* radial growth for the response characteristics of climatic variables and response patterns are different in the two time periods in the Niubeiliang Nature Reserve of the Qinling Mountains in the context of global warming.

Storm response of sand waves in the Taiwan Shoal

Cai Feng, Bao Jingjing

Island Research Centre, SOA, Pingtan, 350400, P. R. China, fcail800@126.com

Abstract

Data from repeated multi-beam echo-sounder surveys were used to study the changes in sand wave profiles in the Taiwan Shoal immediately before, immediately after, and one-year after the storm “Talim” passed. The results showed that current speedup caused by storm wind stress at the sea surface enhanced the bottom stress over the Taiwan Shoal, disturbing the original dynamic equilibrium between currents and sand waves. Consequently, the shoal experienced significant erosion during the storm event. The pattern of sea currents determined the degree of erosion on both sides of the track of the storm center. After the storm event, the area with high erosion required more sediment to recover, and thus erosion hotspots were formed under the track of the storm center. The sand waves mainly experienced erosion of both crests and troughs during the storm event, and showed resuming into their normal conditions by crest reconstructing. When the sand source could not supply sufficient sediment to reconstruct the crest–trough system, self-regulation of deeply cut trough bottoms to reestablish the previous sand-wave crest height occurred over the whole sand wave system to maintain the equilibrium between sand-waves and currents.

The Geomorphology and Active Structures of the Longmen Shan Fold-and-Thrust Belt

Yiquan Li¹, Dong Jia²

¹ School of Geographic and Oceanographic Sciences, Nanjing University, Nanjing 210093, P. R. China,
yiquanli@nju.edu.cn

² School of Earth Sciences and Engineering, Nanjing University, Nanjing 210093, China

Abstract

The Longmen Shan shows the steepest relief in the Northeast margin of the Tibet plateau. Due to the little shortening measured by the geodetic and geological surveys, hot debate focuses on the cause of the topography. Two end member models are proposed, including the lower crust flow (Royden et al., 1997; Burchfiel et al., 2003) and the brittle upper crust shortening (Hubbard et al., 2009). The Wenchuan and Lushan earthquakes are the direct active manifestations of the shortening process. These related structures are the driver for the steep topography along the Longmen Shan thrust belt. We built the 3D co-seismic faults of these earthquakes and active structures in the adjacent Sichuan basin. The results show that the Yingxiu-Beichuan and the Pengguan faults are responsible for the Wenchuan earthquake and the Range Front Buried Thrust (RFBT) is responsible for the Lushan earthquake. In the 3D structural model, the differences between the southern and northern segments of the rupture are highlighted. The RFBT that generated the Lushan earthquake is linked to a detachment that extends into the Sichuan basin along the Triassic evaporite layer. The coulomb stress change simulation suggests that other faults linked to this detachment may have been loaded by the 2008 and 2013 earthquake, posing the risk of future earthquakes along the Longmen Shan and in the densely populated Sichuan basin. This study illustrates the importance of building 3D models to study active faulting and folding, as well as to assess earthquake hazard.

The Resilience of Natural Hazards under the Threaten of Climate Change in Taiwan

J. C Lin

Department of Geography, Taiwan University, Taipei 106, Taiwan, China, jclin@ntu.edu.tw

Abstract

Taiwan is a hazardous region caused by typhoons, earthquakes. The climate change may make Taiwan in more “difficult” situation to recover from extreme events because of fragile geological background.

It has been 17 years after the Chi-Chi earthquake of 1999. The loss of the Chi-Chi earthquake was tremendous. This paper tries to demonstrate the impacts of earthquakes and typhoons and the (environmental) resilience as well as the adaptation of the study area out of earthquake and typhoon damages.

The study tried to analysis the impact of climate change and access the resilience of Tachia river catchment of central Taiwan from series of typhoons. The landscape changing from the adaptation works along the Cross Island Highway since the Chi-Chi earthquake in 1999 is continuously monitored. It is found that the study area is still not stable from Chi-Chi earthquakes. In comparison with the Kobe earthquake in 1995, the sedimentation load went back to normal in five year time, Taiwan need longer periods for resilience from the damages. Continuously heavy rainfall events are the main factor to cause the unstable situation in more difficult situation.

Vegetation Variation in Sub-Humid to Humid Regions of China Recorded by Pleistocene Loess Deposit

Zhang HY, Lu HY, Li XS, Zhang WC, Lv AQ, Zhao LY

School of Geographic and Oceanographic sciences, Nanjing University, Nanjing 210023, China, hongyan@nju.edu.cn

Abstract

The sub-humid to humid region, located to the south of Chinese Loess Plateau (CLP), is characterized by densely farming and population. To understand relationship between the natural vegetation composition and the environment in this region help to ecological conservation and agricultural management. However, the vegetation composition changes in the past and its controlling environmental factors in this subtropical area remained unclear largely because of paucity of depositional records. In this study, we present $\delta^{13}\text{C}$ records of bulk organic matter from four loess deposition sequences across the sub-humid to humid region respectively at Shangzhou (since 600 ka B.P.) and Luoning (since 56 ka B.P.) in Eastern Qinling Mountains, and Zhenjiang (since 128 ka B.P.) and Xuancheng (since 800 ka B.P.) at lower reaches of Yangtze River, to predict the relationship between vegetation composition and the environment. Our results show that the landform and soil structure in addition to the glacial-interglacial climate changes played important roles on the grass and woody plant distribution during Pleistocene.

Abstract

The sediment in the central Japan Sea which lies the downwind of westerly jet(WJ), is composed mainly of silt, mixed sandy silt that is typical aeolian dust. The grain-size of silt fraction has similar pattern with environmentally sensitive grain-size which is extracted by standard deviation/grain-size method and is used to reconstruct the palaeoclimate change since the last glacial period. The grain-size is sensitive to response the path changes of the WJ during both the glacial-deglacial and stadial-interstadial periods. During the stadial, the WJ most frequently appeared to the south of the Himalayas but also influenced the north attaining to 50°N, whose extent was boarder and wind speed was high. During the interstadial, provenance of the aeolian dust was composed of Taklimakan Desert because WJ migrated northward and concentrated in narrow band at north of the Tibetan Plateau, when the GS of the dust was smaller than the stadial in which has shorter distance from the Mongolian Gobi than Taklimakan Desert. We found the multi-millennial time scales variations during DOI 8, 12, 14, 16 between LV53-23 and Zhaosu Poma loess in Ili Basin in central Asia based on the results of core MD01-2407. We noticed the lowest grain size during the coldest phases during the LGM, which confirmed the northward extent of the WJ during the spring is an important prerequisite for the windstorms in Mongolian Gobi.

Application of River Longitudinal Profile Morphometrics to a Small Block Mountain in South China

Han Z, Li X, Wang N, Chen G, Wang X, Lu H

School of Geographic and Oceanographic Sciences, Nanjing University, XianlinDadao 163, 210023 Nanjing, China,
zyhan@nju.edu.cn

Abstract

The stream power model was applied to Mt. Lushan in South China in order to verify its capability of interpreting the uplift of a small block mountain. On a log-log plot, the longitudinal profiles of 9 rivers derived from a 30-m DEM exhibit primary characteristics similar to those derived from a 5-m DEM; however, the 5-m DEM clearly reveals more minor knickpoints, and the positions of knickpoints are pinpointed more accurately. All of the studied rivers on the block mountain are in a transient state due to geological perturbations. Some of them exhibit two segments in steady state separated by a slope-break knickpoint. Such rivers generally develop in a longitudinal valley, which are less perturbed by substrate inhomogeneities. The similar heights of the slope-break knickpoints and the similar uplift rate indicated by the k_{sn} values demonstrate an almost simultaneous headward erosion induced by the fall in base level. This modelling result is consistent with the mode of formation of this particular block mountain. Our study demonstrates that the stream power model is applicable to a small tectonically-active massif only if the channel segments are in a steady state.

Extraordinary Flood Events Response to Holocene Climatic Variability along the Upper Hanjiang River Valley, Middle Yangtze River, China

Chun Chang Huang, Yongqiang Guo

Department of Geography, Shaanxi Normal University, Xi'an, Shaanxi 710119, P.R. China, cchuang@snnu.edu.cn (C.C. Huang)

Abstract

Regional hydro-climatic change in response to global warming causes serious disasters threatening human life and society. Flood data sets in a long-time scale are important in flood mitigation and hydrologic engineering. Extraordinary Holocene flood events recorded by slackwater deposits (SWD) were investigated by using an integrative approach of sedimentology, fluvial geomorphology, palaeoflood hydrology and chronology along the upper Hanjiang River valley. Palaeoflood SWDs, deposited at high stage from suspended sediment load in flood water, were found inserted in the loess-soil profile in the cliff riverbanks. They represent the geological records of actually occurred extraordinary floods during the Holocene and their peak stages and discharges could be reconstructed using hydrological models. The chronology of these palaeoflood events was established by OSL dating, archeological dating, and pedo-stratigraphic correlations with the other dated Holocene loess-soil sequences. The results indicate that these palaeoflood events occurred during the episodes of 3200–2800 a BP, 1900–1700 a BP and 1000–900 a BP, respectively, along the upper Hanjiang River valley. These extraordinary flood events occurred during storm-rains and the SWDs are sourced from the soil erosion induced by human land-using over the drainage basin during the climatic decline. This means the hydrological system are highly sensitive to climatic change over the Holocene. Climatic change has caused instability of the monsoonal climatic system over the region with both droughts and floods occur in a same episode. This study provides important insights into hydro-climatic changes and soil erosion in a long-time scale during the late Holocene.

Geomorphic Processes in the Mu Us Dune Field, Northern China in Response to Climate Change

Xu Z, Lu H, Mason J A, Yi S, Zhou Y, Vandenberghe J, Wang X, Han Z

School of Geographic and Oceanographic Sciences, Nanjing University, Nanjing, 210023, P. R. China,

zhiweixu@nju.edu.cn

Abstract

The Mu Us dune field located at semi-arid region of north China, near the northern limit of significant summer monsoon rainfall, is sensitive to climate change and currently undergoing widespread stabilization by significant increases in vegetation since the 2000s. Landscape evolution in the Mu Us dune field since the Last Glacial Maximum was investigated by abundant geological evidence, precise dating technique (optical simulated luminescence dating) and analysis of paleoenvironmental proxy indexes. Reconstructed changes in dune field activity were then linked with past climate changes, and mechanisms about climatic forcing of dune field variations were discussed. Geomorphic evidence for recent dune field stabilization since the 2000s was also presented.

Abstract

Environment of mid-latitude deserts in Central Asia is undergoing rapid changes, in which the Late Quaternary landform pattern was the most typical. What needs to be particularly emphasized is its geomorphogenesis. In this study, a geomorphological research in the LRHRB is carried out on the basis of climate geomorphology, with regard to identifying the landform characteristics and related geomorphic processes. Regarding to the recent five-decade climate data, the current LRHRB is dominated by physical processes such as desiccation-deflation and aeolian, while the observed landform system is controlled by variable structures under conditions by specific hydrodynamical processes that existed during glaciations. We infer an obvious linkage of desert gorges and pediments in the LRHRB to ancient humid phases, which provided high energy runoff for the formation of these landforms and were associated with erosional features under more humid and colder climate during the last glacial period. Desert plains and aeolian dunes are the related products of contemporary climate. This reflects the dynamics of landform evolution in the LRHRB are characterized by a very effective integration of tectonic and climate-driven morphogenetic processes. Landform inconsistency and landform instability are clearly presented in the LRHRB, implying the main geomorphic unit is experiencing transformation from alluvial plain to desert plain and then to aeolian dunes. The geomorphodiversity in the LRHRB should be a result of multiple surficial processes other than glaciation. Frost weathering, fluvial/alluvial action, desiccation-deflation and aeolian processes as well as climatic changes, have played important roles.

Interlinks Of Fluvial and Aeolian Processes in a Semi-Arid Environment, Recorded by Sediment Sequences of Yellow River Terraces during Last Glacial Period

Wang, X., Yi, S., Ma, J., Vandenberghe, J., Lu, H.

School of Geographic and Oceanographic Sciences, Nanjing University, Nanjing, 210023, China, xianyanwang@nju.edu.cn

Abstract

Sediment sequences of last glacial terraces of Yellow River in semi-arid environment was composed by the lower channel gravel and flood sand, the middle Aeolian sand dune and upper laminar flood loam. These sediment sequences dated by Optically stimulated luminescence (OSL) method, recorded the inter-link between fluvial and Aeolian process and their response to climate change. The channel gravel and flood sand deposited during cold period (e.g. MIS 4 and LGM). The river incised slightly during the transitions from cold to warm phases, and Aeolian dune developed over coarse grained cold phase fluvial deposits. After that, the floodplain accumulation continued and flood loam covered the Aeolian sand dunes during the subsequent warm period. Sediment structure and grain size analysis show the Aeolian dunes were formed by the deflation of local fluvial sands, while the regional dust silt provided a large material to thick flood loam units. The millennial-scale climate fluctuations related to SE Asian monsoon system during the last glacial period were the driving forces for the interaction between fluvial and Aeolian process, such as deflation of fluvial sands and the formation of aeolian dunes, in this semi-arid environment.

³University of Lagos, NIGERIA

Abstract

Land Subsidence defined as the vertical change in the surface of the Earth is usually caused by natural and human activities mostly in the coastal countries all over the world. Port Harcourt city is an administrative capital of River State, located in the coastal areas of Nigeria with massive oil and gas exploration activities and also high demand for underground water for industrials and domestics needs due to high population density. Interferometry Synthetic Aperture Radar (InSAR) which has the capability of detecting land subsidence in millimeter accuracy has been demonstrated in many countries of the world where land subsidence are occurring. This study applied Persistent Scatterer Interferometry (PSI) method to determine land subsidence rates over Port Harcourt city from February, 2007 to May, 2009. The measurements points delivered are derived from the analysis of 18 descending passes from the processing of ENVISAT data using a customized InSAR processing Software. The analysis revealed that more than 58.83 % of the Port Harcourt city is undergoing low subsidence velocity of between -2.5 to -5mm/yr, while 20.66% of the area is experiencing high subsidence velocity of values of more than -5mm/yr. 26.36% indicates a stable ground of velocity values between -2.5 to 2.5mm/yr. 0.12% of the study area revealed a low uplift velocity between 2.5 to 5mm/yr and 0.02% of the study area indicates a high uplift with velocity value of more than 5mm/yr. The study concludes that policy makers should provide a framework for the control of surface deformation and improves coastal management.

Landscape Patterns and Dynamic Landscape Connectivity of Urban Green Space at Wuhan City, Hubei, China

Huang, Q, Xiao, H, Guo, W, Dang, W.

Jiangsu Normal University, Xuzhou, 221116, P. R. China, dangwl@jsnu.edu.cn

Abstract

On the basis of the green space distribution maps derived from 1991 TM, 2002 ETM+ , 2007 CBERS-02 and 2013 ETM+ images and taking urban Wuhan, which is located inside the Middle Ring, as the study area, we analyzed the dynamic changes of pattern metrics of the green space from 1991 to 2013 with the help of GIS, RS and Fragstats software. The integral landscape connectivity index and the importance of individual urban green space patch to landscape connectivity, and the effect of urbanization on the urban green space were investigated by using Conefor Sensinode 2.2 software. The results show that the area of urban green space and the mean proximity index of green space patches decreased from 1991 to 2013. Large patches were the dominant landscape type in terms of area, and small patches had the largest amount in 2002 and tended to decrease recently while middle-sized patches had the tendency to increase, and large patches were of the first magnitude for landscape connectivity. The integral landscape connectivity indexes kept lower for three years and the connection between patches trended to weaken in some parts of the study area. The most important patches are located in areas surrounding East Lake, South Lake and the southwest part of Hanyang.

⁴Department of Geography, University of Calcutta, 35 Ballygunj Circular Road, Kolkata, West Bengal, 700 019, India

Abstract

We present here for the first time, quartz optically stimulated luminescence (OSL) ages from the western part of lower Gangetic plain (LGP) deposits and discuss its implications on the evolution of fluvial landscape. Ten OSL dates reported here are from the valley-fill and associated deposits. Luminescence ages are obtained by sampling the trenched section of Damodar (Barjora) and cliff section of the Ajay (Nelegarh) including drill core samples from some parts of the Ajay (Panduk) valleys. This has been supplemented by detailed field surveys, topographical analysis, geomorphometry data and shallow subsurface stratigraphic studies. Comparison with more than twenty published OSL or ¹⁴C dates from Bengal Basin and Ganga-Brahmaputra Delta (GBD) plain shows that the sedimentary records in this area are significantly older. In the western LGP sediments 10 m below surface, yield an age varying between 10 and 29 ka whereas those occurring at a depth of 15-20 m are mostly 69 to 86 ka old. The data also reveals that during 90-82 ka (end of MIS-5), the LGP and associated deltaic plain experienced aggradational fluvial activities due to higher sea level and frequent climatic fluctuations and continued till 74-64 ka. In addition, the area experienced dry climate in the strata between 31-27 ka and that in turn has prompted the formation of pedocal soil and caliche nodules in this area. This complex interaction between environmental change and earth surface processes provides an important framework for examining the influence of the dynamic parameters that leads to landscape evolution.

Abstract

Zhang River basin is located in the north margin of West Qinling in the northeast margin of Qinghai-Tibet plateau, which is a tributary of the Weihe River. Through the field detailed and DEM technique, the spatial distribution of the four terraces of the Zhang River are established. The depositional age of the four terraces were calculated using optically stimulated luminescence (OSL) dating of terrace sand. Fluvial incision rates were generated by integrating the terrace depositional ages with terrace heights.

The Distribution of REE in Different Particle Size Fractions of Xiashu Loess and Its Implication for Provenance Tracing

LI Xusheng*, HAN Zhiyong, LI Yang, CHEN Yingyong, YUAN Xiaokang

School of Geographic and Oceanographic sciences, Nanjing University, Nanjing 210023, China

*Corresponding author: lixusheng@nju.edu.cn

Abstract

Differences in Rare earth element (REE) content between Different Particle-size fractions of sediments make it more complex for geochemical tracing, thus affecting the reliability of using REE characteristics of a whole-rock sample as an indicator in provenance study. Moreover, by far the knowledge about geochemical characteristics of REE in loess relative to particle size fraction is very limited, and so is that about restraining factors of the particle-size effects, and influences and significance of the effects on and in tracing of the parent materials of loess in provenance. In this paper, systematic fractionation of the northern loess and the Xiashu loess samples collected separately in particle size was performed and REE contents of the samples were measured, so as to better understand REE distribution among different particle-size fractions of the loess and its affecting factors.

Samples of Xiashu Loess (XL) collected from Nanjing and Zhenjiang and loess from the Loess Plateau (LP) in Lingtai of Gansu Province were pretreated with the quiescent sedimentation method for fractionation in particle size, separately, into six fractions, i.e. $<4\ \mu\text{m}$, $4\sim 8\ \mu\text{m}$, $8\sim 16\ \mu\text{m}$, $16\sim 32\ \mu\text{m}$, $32\sim 64\ \mu\text{m}$ and $>64\ \mu\text{m}$, and then REE contents in the six fractions of loess soil and the whole-rock samples were measured.

Results show: 1) significant differences in ΣREE existed between the two types of loess soils and in REE content between fractions of the soils, which indicates that obvious particle-size effect does exist on REE distribution. In practical terms, the effect is the most obvious in the fractions $<4\ \mu\text{m}$ and $>64\ \mu\text{m}$. In LP, REE accumulates in Fraction $<4\ \mu\text{m}$, but not in Fraction $>64\ \mu\text{m}$, while in XL, it does in both fractions and particularly in Fraction $>64\ \mu\text{m}$; REE content does not vary much between the fractions in the middle, i.e. $4\sim 8\ \mu\text{m}$, $8\sim 16\ \mu\text{m}$, $16\sim 32\ \mu\text{m}$ and $32\sim 64\ \mu\text{m}$ and so the particle-size effect therein is not obvious; 2) the accumulation of REE in the fractions of $<4\ \mu\text{m}$ of both of the soils is characterized mainly by that of heavy REE (HREE), which is possibly governed by weathering-based soil formation and attributed to specific adsorption of HREE by Fe-Mn oxides in fine particles; and 3) in Fraction $>64\ \mu\text{m}$ of Xiashu Loess accumulates mainly LREE (light REE), which may be possibly related to the high content of titanite and some other minerals typical of nearby regions in the parent material of XL and suggests that the materials coarse in particle size in XL may come mainly from nearby regions through short distance transportation.

All the findings in this study suggest that Fraction $>64\ \mu\text{m}$ may be the most sensitive one that can be used to distinguishes XL from LP in REE content. Whether or not Fraction $>64\ \mu\text{m}$ has an apparent accumulation

of LREE is an effective indicator of the distinction. This study also demonstrates that the researches in the past used to analyze whole rock samples for REE, thus possibly glossing over the important tracing information, whereas REE analysis by fraction has a greater potential as indicator in provenance study of loess and therefore can be used to exposit in depth internal differences between particle size fractions and between heavy and light REE and to provide more accurate evidence for provenance study.

The Neotectonic Activity of Wanchuan Catchment in the Northeastern Tibetan Plateau, Reflected by Geomorphic Indices

Dai Y, Wang X Y, Wang S I, Li Y Q, Lu H Y

Nanjing University, Nanjing, 210023, P.R.China, xianyanwang@nju.edu.cn

Abstract

Wanchuan River, located in the northeastern Tibetan Plateau, is one of the tributaries of the Yellow River. This area has witnessed many earthquakes of magnitude 6 on the Richter scale. Based on DEM data, this paper discussed the characteristics of neotectonic activity by analyzing the drainage networks and calculating geomorphic indices. It turns out that the mountain front sinuosity index is between 1.03 and 1.18 to the north of Wanchuan River (NWR) and from 1.83 to 2.88 in Xinglong Mountain (XLM); while the valley floor height-to-width ratio index is about 0.36- 2.34 in NWR while it ranges from 0.55 to 13 in XLM. The values and distribution of the mountain front sinuosity index and the valley floor height- to-width ration indicate that neotectonics are still active in the study area, and the movements in the north of Wanchuan River catchment are more active. The abnormal AF index in the southeast part means that there should be tilted fault block and folds in the northwest of Wanchuan River catchment. There exists a strike- slip fault in the southeast of the northern Wanchuan River valley, indicated by analyses of the distribution of knickpoints and off- set valley.

Vegetation Succession and Climate Change Revealed by Loess Deposit in Western Henan Province and Human Adaptation since 20 Ka B.P.

Chen YY

College of Environment and Planning, Henan University, Kaifeng, 475004, P. R. China, chenyy@henu.edu.cn

Abstract

Western Henan province located in southern part of loess plateau, human activities since late pleistocene were very frequent, earth has experienced a mediaeval warm period and a extremely cold period in recently 20 ka. Further study of loess and environmental change in this area is helpful to understanding the relationship of human activity and environmental change. Loess organic carbon isotope composition has widely applied to paleovegetation and paleoclimate reconstruction. In this study, we sampling five representative loess sections in the western Henan province, then establish time scale by optically stimulated luminescence(OSL). Combined with investigations of organic matter $\delta^{13}C$, pollen, grain size, organic matter content and magnetic susceptibility we reconstruct the paleovegetation and paleoenvironmental changes since 20 ka. On this basis, we collection information of ancient human activities in this area, and comparative analysis with reconstructed paleovegetation and paleoenvironmental records. The results above provide theoretical basis for understanding the relationship between human activity and environment.

As Honey as Arsenic? Interpreting Value Production in China-Africa Encounters

XIAO HAN

University of Melbourne, China, hanx1@student.unimelb.edu.au

Abstract

Since the nation's going out, China has been increasingly significant in boosting Africa's infrastructure projects, particularly the building of railways, large dams, and airports. Thus a "China-Africa" complex has attracted multi-disciplinary researches. Yet little has been studied from the economic geographical perspective with on-site investigation. Not to question the projects' political rationality, this paper is firm-actor centred and enquires about Chinese corporate behaviour in Africa, illustrated with Chinese engaged Bui dam project in Ghana. It departs from a material accident during construction concerning "waste-or-commodity" which agitated especially the Chinese engineering-procurement-construction (EPC) contractor and local Ghanaian authorities, to unfold the nexuses of actors and their relations in processing the accident's dynamics. Embracing value theories in "waste" literature and the global production networks (GPN) frameworks, the paper argues first that multi-scalar frictions in not only actor networks but also intra-actor networks are playing critical roles in shaping value generation and transformation; second that to perform the firm-actor's capacity for value activities across temporal-spatial contexts, prior to the organization of production there must be integration and adaptation to heterogeneous but relational determinants - in the case study to technological recognition, transnational standardization and institutional influences in territorial governance hierarchies. The work is based on fieldwork in Ghana and China respectively, including on-site observations and interviews with a variety of Ghanaian and Chinese participants.

Production Network Knowledge as a Basis for Successful Resistance – Workers Influence on a Chinese Acquisition in Germany

Bollhorn, K., Franz, M.

Osnabrück University, Osnabrück, Germany, Martin.Franz@uos.de

Abstract

‘No Experiments’ (‘Keine Experimente’) or ‘No Sell Out’ (‘Kein Ausverkauf’) were slogans of the protest of workers against the potential carve-out of the rubber and plastics department of the German automotive supplier ZF Friedrichshafen AG to Chinese based Zhuzhou Times New Material Technology Co., Ltd. in 2013. Such acts of resistance are a response to the global phenomenon of a rising number of acquisitions by emerging market firms in developed economies. The paper analyses how workers in Germany’s automotive industry developed power in the process of the above mentioned transnational carve out. The workers council decided against a strategy of pure co-operative co-determination but implemented a strategy of resistance. The worker’s actions were successful because they used their production network knowledge to identify those spots in the production network where their collective action can have the strongest impact on the involved companies. We define production network knowledge as the specific knowledge about the architecture of a production network. The case study shows that production network knowledge can be utilized by the labor representatives to strengthen the impact of collective action also in those industries that are not consumer orientated. The study is based on qualitative interviews, participatory observations of workers events and a press analyses.

The Dynamic Relationship among the Central Government, Local Authorities and Firms in Strategic Coupling: A Case Study of the China's Automotive Industry

HUANG Jie, LIU Weidong

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, China, 100101,
huangj.14b@igsnr.ac.cn

Abstract

Since 1978, China has gone through the processes of open-up policy, decentralization of power and industrial restructuring which put forward its rapid economy growth. The 'obligated-embeddedness' theory effectively explains the role of strong state in strategic coupling of global production networks which is based on the study of geography of China's automobile industry before 2000. However, since 2000, the dynamic relationship among central government, local authorities and firms has become more complicated and should be studied further. As most transnational suppliers entering into China since 2000 and China becoming the first largest country of automotive industry, China is playing more and more important role in global production networks of automotive industry. By reviewing the central and local automobile industrial strategies in China since 2000 and studying the bargaining between local governments and firms, this paper discusses (1) how the central government sets policies of industry development, (2) how local authorities and different enterprises like joint ventures, exclusively foreign-owned enterprises and local enterprises react. And the top 10 largest provinces and municipalities including *Jilin, Hubei, Shanghai, Guangdong, Zhejiang, Jiangsu, Beijing, Chongqing, Anhui* and *Shandong* and the top 10 largest firms of suppliers and assemblers. The results showed that in except for the embeddedness of transnational corporations and deregulation by the Chinese government, the institutional innovation and the training of native enterprises are advanced as the new two major factors that shape the car industry's geographic distribution in China.

Transnational Labour Migration and the Reorganisation of Global Production

Networks – the case of a German automotive company in Turkey

Müller, Philip; Franz, Martin

Osnabrück University, Institute of Geography, Seminarstr. 19 a/b, 49074 Osnabrück, Germany, philip.mueller@uni-osnabrueck.de

Abstract

Even though labour has been an important research topic in the field of economic geography for many years, up to now, only little is known about labour migration of the highly-skilled in global production networks. Taking a German automotive original equipment manufacturer (OEM) as an empirical case, this paper analyses the role and the impacts of transnational IT-professionals in the reorganisation process of sophisticated IT-services. As many other multinational companies, such as General Electric and General Motors, the German automotive OEM has been moving away from extreme IT-outsourcing and insourced back a wide range of IT-services. We found that the new IT-strategy has been highly related to shifts in human resource management. To create an effective collaboration across Germany and the newly established offshore IT-centre in Turkey, a large number of German educated IT-professionals of Turkish origin were hired at the IT-centre in Turkey. Their personal societal embeddedness facilitated the reorganisation process by managing knowledge transfers between the German subsidiaries, external IT-suppliers and the Turkish IT-centre. The exploration of highly-skilled labour migration from a transnational perspective, contributes to the discussion about the role of labour in global production networks. The case study is based on qualitative interviews.

Key words:

transnational migration; labour; global production networks; knowledge transfer; information technology; automotive

Upgrading of Intermediaries in Fresh Food Supply Networks - Dynamics in the Emerging Economy of Turkey

Inka Gersch

University of Osnabrück, Institute of Geography, Osnabrück, Germany, inka.gersch@uni-osnabrueck.de

Abstract

The dynamics of the food retail sector in developing and emerging markets, driven by accelerating foreign direct investments, have caused deep modifications of the corresponding domestic production networks of fresh fruits and vegetables (FFV). Transnational retailers, and domestic retailers imitating their processes, increasingly coordinate and consolidate supply networks in order to improve cost efficiency, economies of scale and product quality. In this context significant challenges but also upgrading possibilities for supplier companies and market intermediaries open up. They can realize the modern retailers' high demands regarding quality, quantity and prices within often traditional and fragmented production structures. Using the example of the emerging economy of Turkey, the presentation analyzes upgrading processes of FFV suppliers and intermediaries, corresponding information and knowledge transfers as well as the transforming power relations in the context of retail "modernization". The analysis shows that, due to shortcomings of required products, retailers have significantly promoted upgrading of their FFV suppliers, includes functional upgrading. However, sourcing strategies of big retailers and power relations are recently changing. It can be observed that a (1) based-market form of coordination during the entry phase of the transnational retailers transformed into a (2) relational form of governance with mutual dependencies and is now becoming (3) increasingly captive. This shows that functional upgrading can lead to a mutual dependency of supplier and buyer in the middle term but a high level of dependency of the supplier on the lead firm in the long term, which is contrary to the assumption from the literature.

A Role of Japan-Korea-China Joint Conference on Geography

As The Communication for the Young Geographers

Masatoshi MOTOKI

Tokiwa University, Mito, Ibaraki, 310-8585 Japan, motoki@tokiwa.ac.jp

Abstract

Japan-Korea-China Join Conference on Geography intends to give geographers from these three countries a place of international announcement and academic exchange between scholars, and specifically emphasize the contributions and development of younger academics. The purpose of this study is to consider the significance of Japan-Korea-China Join Conference on Geography and its possibility. This conference doesn't have an immobilized secretariat, and is the unique conference the young geographers volunteer manages. It's interesting that the chance to talk with a researcher in China and Korea aggressively is being made with a Japanese young geographer. And, difference between the interest and the angle of the same generation is also offered in a round of inspection as well as an announcement at this meeting. This conference has a possibility that it's possible to build an exchange by the research aspect beyond the field by an Asian structure as a geography in this meeting. A study group exists a lot in a Japanese geography, and an exchange of art and science is developed. The chance to touch China and Korean researcher for the young geographers is limited, and it's difficult to expand a network. But an exchange beyond a university and a specialized field is becoming little in recent years. The participant who carries the next generation would like to expect that one utilizes a JKCC aggressively to make a geography develop in the structure called Asia from now on.

A Study of Push Car Railway—Evolution of Local Transportation System in Colonial Taiwan

HIRONO Satoko

Waseda University, Tokyo, Japan, s.hirono@aoni.waseda.jp

Abstract

The purpose of this research is to understand the Push Car railway system between 1910~1937 involved in tourism and transportation, and by analyzing the condition of its operation, background and process of its route, conclude and organize the overall context of the Push Car railway system at the time. After the preliminary analysis, handcar rails can be divided into three types. The first type is the connects between city streets or industrial railway stations to Taiwan Trunk Line Railway. The second type is an industrial railway to connect the plantation or sources of raw materials and factories to the Taiwan Trunk Line Railway. The third type is to connect local towns and/or cargo distribution areas to Taiwan Trunk Line Railway and make a local area transport network. In its early stages, almost all Push Car Railway trackage had been the first or the second types. Push Car Railway was a small capitalized business, so local gentries entered Push Car Railways business gradually and it had been a good relations with local economy or industry. Growing a local economy, Push Car Railway companies expanded Push Car Railway lines more locally areas and made a transport network. Although the use of Push Car railways has been declining after 1930's, many of the routes have been transformed to bus routes nowadays and are still in use. In conclusion of this research, it proves the significance of Push Car railways to local transportations and development in Taiwan during Japanese colonial period.

Analysis and Simulation on Metro Interchange: A Case Study of Zhujiang New Town Station

Zhang JB, Huang QY, Hu YQ, Chen YF, Jin ZB, Chen XY

Guangzhou University, Guangzhou, 510006, P. R. China, Jiabinzdd@163.com

Abstract

Public rail transportation such as metro system is playing an important role in urban public transportation system for citizens' daily traveling. However, problems such as crowding and congestion have been observed in many interchange station of Guangzhou. This paper tried to simulate and analyse passenger flow in the Zhujiang New Town Station, which is one of the largest interchange stations of Guangzhou metro system, using Anylogic Software based on the Social Force Model. Some improper arrangement was discovered according to the simulation results. The suggestions were also given for the improvement and optimization of the flow control of passenger in existing stations and the layout design and construction of future metro stations.

Analysis of the Source Area and Moving Path of Dust Storms in the China-Mongolia Border Area

Yong mei, Teri Gele, Bao Yuhai

College of Geographical Science Inner Mongolia Normal University, China, yongmei201101@gmail.com

Abstract

The Gobi desert area in southern Mongolia is an area with a high incidence of dust storms. It is also one of the key sources of dust storms in East Asia. Gobi and the desert area in the southern part of Mongolia represent a vast area with a fragile ecological environment and frequent natural disasters, which directly affect the northern region of China. Research on the cross-border movement path of sandstorms in this region is the common demand of disaster prevention, mitigation, and resilience, both in China and Mongolia. In this paper, which focuses on the period 1981–2014, data representing sandstorm days at 70 ground stations in the China-Mongolia border region was used. Spatial and temporal variation characteristics were statistically analyzed with sand/dust storms occurring at 5 sites, 10 sites, and 20 sites, which were divided into three different scales. The cross-border movement path and intensity of the dust storms in Mongolia were further discussed. The results show that in terms of temporal change, the frequency of dust storms in Inner Mongolia showed a decreasing trend during the period 1981–2014. The peak periods for the above two scales of five stations and 10 stations all appeared in the period of 1985–1988 and 2000–2006. Moreover, large-scale dust storms show an increasing trend. The number of dust storms of different scales in Mongolia are far greater than in Inner Mongolia, but there is no significant downward trend. In terms of spatial change, the high dust storm incidence area from 1981–2000 was Hai Li Su, in the west; 2000 years later, a high incidence of dust storms was concentrated in Hai Li Su, Guai Zi Hu, and Xilingol League. The number of sandstorms during 2000–2005 in the above three regions accounted for 90% of the frequency of occurrence, of which, 12 sites in Xilingol League's sandstorm days accounted for more than 50%. After 2000, all the sandstorms recorded in Xilingol League originated in the territory of Mongolia. This source area is mainly near the border between China and Mongolia Tooroi and Zamin-Uud, two high-incidence areas.

Key words:

dust storm; source area; moving path; China-Mongolia border area

Assessing the Impacts of Affordable Housing Policy from a Residential Satisfaction Perspective: The Case of Mei-He-Yuan Project in Beijing

Liu, Z., Cheng, X., Zhang, Y.

Renmin University of China, China, Beijing 100872, China, zhilinliu@tsinghua.edu.cn

Abstract

In the past decade, the Chinese government has dramatically expanded its affordable housing programs, with the aim to solve the housing difficulties for medium to low-income urban households. However, many affordable housing units were located in the urban fringe area with inconvenient access to services and amenities. Previous literature from the western context also has warned of the possible negative impacts of large-scale affordable housing projects in terms of poverty concentration and social exclusion.

This paper presents a case study of Mei-He-Yuan Community, the first affordable housing project constructed in Beijing since the major over-haul of affordable housing policy in 2007. We specifically investigated the change of quality of life (QoL) of medium to low-income households after moving into affordable housing units from a residential satisfaction perspective. Preliminary analysis found that, although medium to low-income residents did see significant improvement in their housing conditions after moving to affordable housing units, their overall level of residential satisfaction did not change significantly. In particular, whereas residents tend to be more satisfied with their housing conditions, they are less satisfied with other aspects of quality of life such as accessibility and neighborhood social interaction. We further conduct multivariate regression analysis to investigate the extent to which residential satisfaction of affordable housing dwellers is determined by the change in housing conditions, public service accessibility, distance of residential relocation, controlling for socio-demographic characteristics.

Key words:

Affordable housing; residential satisfaction; low-income households; Beijing

Characteristics of Employment Structure in Rural Inland Region of China: Case Study of Liangshan in Sichuan Province

Chen Lin

Graduate school of Letters, Hiroshima University, Higashi-Hiroshima, 7398522, Japan, chinlin20@gmail.com

Abstract

This paper aims to clarify the features of employment structure and agricultural land management in rural inland region of China. I selected a village in the southern region of Sichuan Province as a case study. This village located at a region where was considered as one of the poorest areas in Sichuan Province. Therefore, to understand the employment situations of villagers is an important approach to solve the poverty issue in the region. Through the field works conducted in 2015, we can conclude that the villagers are mainly engaging in four types of jobs. The first one is on-farm work that is been done by most of the villagers. They are playing very important role in maintaining the agricultural land in the village. The second one is family-operated businesses nearby the village. Those who engaged in this type of work have a tendency to leave farming or do farming only for self-sufficiency. The third one is informal off-farm jobs outside the regions. These jobs are mainly engaged by younger generation those have a low education background. It is very difficult for them to get urban *Hukous*. The fourth one is formal jobs such teachers and public workers inside or outside the region. These works are very various employment opportunities for villagers who belong to the elite group with a highest education background in the region.

Key words:

employment structure; rural inland regions; on-farm work; family-operated businesses; formal jobs

Cross-City Convergence in Urban Green Space Coverage in China, 2002-2012

Abstract

The paper explored the pattern of convergence in green space coverage (GSC) of a group of 285 Chinese cities over the period 2002-2012 by using the non-parametric estimation technique, unconditional β -convergence model, and conditional β -convergence model. The results indicate that (1) the GSC in most of cities has been substantially improved; (2) The regional variations amongst the eastern, central, and western cities reduced remarkably. (3) The most rapid increase in UGSC in the places with relatively low GSC levels, indicating a city-wide tendency towards convergence of GSC rates; (4) the more compact, faster sprawling and wealthier cities are likely converge to higher level of GSC; (5) the economic growth has very limited influence on the changes in GSC; the urban sprawling leads to the decrease in GSC; spatial scale expanding results in increase in GSC; compactness of city shows negative impact on GSC.

Key words:

Green space coverage; Cross-city convergence; spatial disparity; Socio-economic factors

Firm Migration Based on Agent Modeling

LIANG Yu-tian¹, Lulun Liu¹, LIU Lin^{1,2}

Abstract

Firm Migration is one of the common phenomena in regional economic development, and a large number of firm migration activities will reconstruct the spatial patterns of regional industry. Spatial decision of firm migration is a very complex system involving the interaction among companies, governments, geography environment and social economy. Aiming at the lack of traditional research of firm migration, this paper mainly discuss about the using of the firm migration theory, the industrial location theory, the territory functional theory and the complex systems theory in the spatial decision-making process of firm migration, propose a method based on multi-agents proceeding to the comprehensive integration of the firm migration's spatial decision-making theory, and built a spatial decision-making behavior analysis framework of firm migration based on the comprehensive integration of the firm migration's spatial decision-making theory, the simulation of computer, the model of multi-agents and geographic information science. And taking Guangdong Province as the study area, simulating Industrial spatial variation pattern of the firm located in the Pearl River Delta, which migrate to the east and west wings of Guangdong Province and the mountainous areas of northern Guangdong. The simulation results of spatial patterns are pretty close to the practical situation, the firm migration trend has gradient and hierarchy, the preferred locations of firm migration are the counties near the Pearl River Delta region and the municipal district in the province, the other counties in the mountainous areas of northern Guangdong hold the worst potential to undertake the firm migration. Modeling of using the multi-agents thought to analyze the spatial decision behavior of the firm migration, which can provide a new idea to simulate the firm migration spatial pattern, and provide a scientific basis for reasonable guidance of firms migration and policymaking of industrial transfer.

agent-based modeling; firm migration; spatial decision-making

Freshwater Fisheries under Changing Natural and Social Environment in Lake Kasumigaura

Yusa, S

University of Tsukuba, Tsukuba, 305-8577 Japan, yusa1222@geoenv.tsukuba.ac.jp

Abstract

It is obvious that changing natural and social environment in lakes have certain impacts on fishing industry. However, only a few attention has been paid to the relationship between structural changes of fisheries and environmental changes in recent decades. To better understand the transitional process of fisheries under changing natural and social environment, I focused on the fishery culture in Lake Kasumigaura Japan. By field interview survey to fishermen and statistics analysis, I found the characteristics of this process. The commercial fisheries of Lake Kasumigaura has faced environmental and social problems over a long period of time. The environmental changes have started in 1960s, with the construction of Hitachigawa-river floodgate. This construction changed the water quality from brackish water to freshwater. Also the population growth in the basin caused water pollution. Moreover, nonnative species, embankment and over-fishing have influenced the ecological system. Each of these changes lead to the decrease of the fish population. On the other hand, the development of transportation system brought social changes. Those systems facilitate the access to saltwater fish, causing a decrease of freshwater fish demands. The decrease of demands and the fish population resulted in a decrease of the fishermen number. However, some fishermen got through these problems by adopting a trawling method instead of a set-net fishing. Also, some of them have been trying to transform fisheries in a sixth industrialization. These findings suggest that environmental changes bring about selection and development of specific fishing technology on the fishery in Lake Kasumigaura.

Key words:

fisheries; environmental changes; nonnative species; lake Kasumigaura; Japan; fishing technology

Global Economy, Local Landscape: Compare the Ethnic Economies of Japanese and South Korean Expatriates in China

LIU Yungang, ZHOU Wenting, JEON Jiyoung

School of Geography and Planning, Sun Yat-Sen University, Guangzhou, China, 510275, liuyung@mail.sysu.edu.cn

Abstract

As economic growth in China, the number of Japanese and South Koreans who expatriate to China has soared during the last decade. China has become the second largest destination for Japanese Transmigrants (JTs) and the third largest destination for South Korean Transmigrants (SKTs). However, as a non-immigrant receiving country, China did not provide fundamental public services for these transmigrants, educational and medical services in particular. This study is done to find out how the transmigrants solve these problems so that they could adapt to the local society easier. Using Wangjing area of Beijing, Gubei area of Shanghai and Tianhebei area of Guangzhou as cases, this study examines the establishment and development of Japanese and South Korean ethnic economies in China. Based on the data collected through onsite surveys and interviews conducted from December 2007 to March 2015, we found that transmigrants started to cluster since the 1990s, and the ethnic enclaves have established in the 2000s and undergone ongoing expansion. The residents in these enclaves include not only high-skilled transmigrants, but also overseas businessmen, self-employed people and locally hired people. According to the survey, the businesses within the enclaves are mainly co-owned or co-operated by the expatriates, and their daily services are mainly provided by people have multicultural background, such as Korean-Chinese and the Chinese have experience of study or work in Japan. Compared to the ethnic economies of other foreigners in China, the Japanese and South Korean economies are unique because of the participation in these multicultural background people.

Abstract

The increased participation of women into labor market has abstracted extensive attention, leading to increasing interest in the conflict between employment and household responsibility by women in dual-earner household. There are a number of household strategies can be used to deal with these problems. However, most research has only focused on negotiating strategy in nuclear household whereas other strategies like getting extra help from extended family or domestic helpers are under-examined. Based on the concept of household strategy, this paper studies the influence of extra helpers on gendered activity pattern in terms of time use by distinguishing three household strategies including nuclear families, extended families, and families with hired helpers. Draws upon a dataset from a GPS tracking survey conducted in Beijing in 2012, this paper compares the gender differences in time use among the three household types. The findings indicate gender differences in the division of household labor can be reduced by living with extended family and hiring helpers. And getting extra helpers mainly help women to cope with the pressures of juggling paid employment and household responsibilities, thus helping them in labor market. The impact of household strategy on social-leisure activities are very limited.

Gender; Household strategy; Activity pattern; Household responsibility; China

International Migration of Skilled Labor in Cambodia~ the Case of ITC (Institute of Technical of Cambodia and P.P.S (Phare Ponleu Selpak) ~

Ayumi Shirai

The University of Tokyo, PhD. Candidate, 3-8-1 Komaba, Meguro-ku, Tokyo, Japan, siraiayumi@gmail.com

Abstract

In 2015, ASEAN (Association of Southeast Asian Nations) decided to admit that it would aim at realizing “ASEAN Community” and allow skilled labor to move freely within the regions of “ASEAN Economic Community”.

This announcement has reviewed the change which has happened to the international movement of natural persons by using the technical colleges and technical high schools in Cambodia as examples under the acknowledgement that the leading force of globalization has moved from developed countries to emerging countries around Asia since the beginning of this century.

As a result, it has been found 1) that there is a trend which the movement of human resources from Asia to European and American countries has gradually been replaced by the movement between Asian regions, 2) that the mismatching between supply and demand on the labor market has increasingly expanded and the movement between Asian regions has increased due to declining birth rates and higher academic backgrounds of Asian countries and that 3) the Japanese companies need the management reform to exploit active power of various human resources in Asia partly because of the structural differences between the Japanese labor market and the Asian labor market.

In addition, the enhanced trend which Asian human resources return from Japan in East Asia to Asian countries advantageous to economic growth and increase in employment opportunities has been viewed as a sign. At the same time, the number of international students moving from emerging countries in Asia to developed countries including Japan continues to be on the increase due to effects of declining birth rates and higher academic backgrounds developing in Asia.

Thus, Japan has to build the strategies to catch the information of the movement which human resources return from European and American countries to Asian countries, also induce human resources to return to Japan from European and American countries and make Japan a hub for development of human resources and movement in the regions while promoting the systematic economic integration in Asia-Pacific Region. Japan thereby needs the long-term efforts for that purpose because it is idealistic that Japan should collaborate with the economic partnership of Asia-Pacific and promote development and circulation of human resources in the regions.

Market Transition, Access to Housing and Home-work separation: Evidences from Low Income Neighborhoods in Beijing

Zhang Y.¹, Liu Z. L.²

¹The Institute of Beijing Studies, Beijing Union University, Beijing, 100101, P. R. China, yanzhang@buu.edu.cn

²School of Public Policy and Management of Tsinghua University, Beijing 100084, P. R. China

Abstract

In developed and developing countries alike, scholars have endeavoured to theorize and test the impacts of urban spatial restructuring on individual commuting and daily travel behaviour, especially for low-income residents. Based on a 492 household surveys of nine typical low-income housing neighbourhoods in Beijing, we specifically address that in the context of suburbanization, to what extent limited residential mobility may exacerbate the commuting burden of low-income residents? Firstly, we explored the residential mobility pattern of the low-income residents and identified five relocation types. Then we further compared home-work links, commuting pattern and subjective satisfaction evaluation of above low-income groups, using the measurement of home-work distance, commuting time as well as travel mode. Specifically, we uses regression models to examine the impacts of institutional factors (such as housing reform, affordable housing policy, and urban sprawl) on low-income residents' job accessibility.

The results indicate that those low-income residents who relocated only because of government housing programs tend to endure longer commuting distance and time. As we expected, those who relocated under the Work unit welfare housing allocation system seem to enjoy more home-work closeness. Yet, the impact of dilapidated redevelopment on the low-income resident's home-work link is inconsistent. Finally, we pointed out that the factors which caused the spatial mismatch in Chinese cities are quite different from U.S. cities. Mixed institutional and structural forces impact differently on jobs-housings mismatch of the urban poor. Special attentions should be paid to the spatial implications of low-income residents' job accessibility and employment outcomes after passive residential relocation.

Modeling Trade-Offs among Forest Structure, Biomass, and Timber Production under Long-Term Forest Management Alternatives for Plantations in South China

Wang, X. F., Dai E. F., Ge, Q. S., Xi, W. M., Tian, Q.

Key Laboratory of Land Surface Pattern and Simulation, Institute of Geographical Sciences and Natural Resources Research, Chinese Academy of Sciences, 100101, Beijing, China; University of Chinese Academy of Sciences, Beijing 100049, China, wangxf.12b@igsnr.ac.cn

Abstract

Forests are facing serious problems such as degradation on structure and function at global to local scales. Focusing on plantation ecosystems, it's useful to know how to achieve the most appropriate comprehensive benefits through a sustainable forest management approach. Setting the forest management scenarios under human influence, including forest protection, forest regeneration, timber production and sustainable forest management, the effect of different strategies will be investigated, to propose a more suitable management strategy for plantations. LANDIS-II model was adopted to simulate the dynamics of structure, biomass and timber production under four strategies that meet actual conditions. Then a standardized difference method was used to investigate trade-offs on different ecological functions. As harvest intensity increases, timber production increases at the same pace, while forest areas and aboveground biomass decrease. Harvest strategies will improve forest age composition. A sustainable approach can achieve the optimization of overall ecological benefits through trade-offs on timber production and biomass. To achieve sustainable forest management in the long-term, a strategy that is based on forest type classification showed an indispensable advantage. It can fulfil the requirement of timber production without damaging other ecological functions, especially on plantations in South China.

Key words:

Forest structure; aboveground biomass; timber production; trade-offs; sustainable forest management; plantations in South China

Mutual Construction of Resettled Rural Residents' social space and identity from the Perspective of Everyday Life

WANG Yuan¹, ZHANG Min²

Nanjing University, Nanjing, 210000, China, 729947815@qq.com

Abstract

With the development of China's industrialization, urbanization and the new urbanization, resettled rural residents, a borderline group, has received more and more attention. Resettled rural residents who have experienced great changes of their political identity, life and production mode generally face the reconstruction of identity; the social space based on the resettlement community become the main field to reconstruct their identity. Taking Pingchang New City in Zhenjiang, Jiangsu Province as the case, based on qualitative research methods including questionnaire survey, semi-structured interview and text analysis, this paper investigates the mutual construction relations between identities of resettled rural residents and the social space based on the resettlement community. This findings show (1) Drawing on the “my group and his group” theory in social categorization, resettled rural residents have produced multi-identity cognitive, including “the landless peasant identity compared with city people and country people”, “the local people identity compared with outsiders”, the non-agricultural labourers identity compared with traditional farmers” and “acquirements of the citizen identity towards urban lifestyle”. (2) Rooted in everyday life, living, work, leisure, consumption these four different kinds of social spaces selectively reinforce multi-identities of resettled rural residents. (3) The process of space reconstruction under multi-identity cognitive mainly displays in the spatial performance basing on multi-identity cognitive, the inclusion and exclusion of space, the resistance and negotiation of space, and the reconstruction of space meaning.

Regional Revitalization and Countryside Regression in Japan: A Case Study of Kamiyama Town in Tokushima Prefecture

Takayuki Oishi

Okayama shoka University, Okayama, Japan, oishi@po.osu.ac.jp

Abstract

Japan, from 2010, turned to population decline. And industry of decline in rural areas led to the outflow of the urban population in rural areas. These, to the problem of population decline and aging in rural areas, from 2014, "regional revitalization (*Chihou sousei*)" - policy to try to the creation of the autonomous and sustainable society that makes full use of the characteristics of the region- has come to be promoted in the government-led. Currently, Japan has been addressed a variety of activities related to regional revitalization. In particular, activities in rural areas is attracting attention. As a result, the younger generation of 20-30 years of age began to migrate actively in rural areas. Such a phenomenon, Odagiri (2014) is referred to as "countryside regression (*Den'en kaiki*)". This study takes the Kamiyama town in Tokushima Prefecture. This town was a significant area of declining population, but is migrants increased by NPO activities, social population began to increase in 2011. Whether this is seen as one of the "countryside regression, or should be interpreted in a different perspective? The purpose of this report, from activities in Kamiyama town, is to clarify the significance of "countryside regression".

regional revitalization; countryside regression; Kamiyama town; rural; urban

Research on City Square Space from the Human Living Environment Perspective

Jiaji Gao

Liaoning Normal University, China, 64127957@qq.com

Abstract

This paper mainly study squares in four downtown districts of Dalian, which analyzes the influence of urban square on human living environment from four aspects: the lifestyle, living environment, transportation and living way in the living environment. On this basis to design an evaluation index system to study the urban square space differentiation and its formation mechanism. Spatial differentiation is mainly by building a new index system, using ArcGIS Spatial Distinction platform for the analysis of the spatial differentiation, and finally comprehensively evaluate the city square combined with questionnaire survey.

Through the spatial differentiation and data analysis, the author deepens understanding of Dalian city square. Through the micro and macro aspects, combined with the nature of the landscape design of square function value and the law of development, promote square related facilities and the layout, this paper put forward countermeasures for square internal space and external environment construction, adjust good coordination with the surrounding areas, in order to better serve the society, and provides the reference basis for the urban construction in Dalian.

Key words:

Dalian; city square; human living environment; evaluation index system

Research on Wetland Eco-Environmental Early Warning of Nansihu Lake

Songbo Li

Liaoning Normal University, China, 0825lisongbo@sina.com

Abstract

Lake wetland eco-environmental early warning is the key to lake monitoring. It is the further work which is based on ecosystem vulnerability and health assessment as well. Remote sensing data, land use and environment monitor data in 1982, 1992, 2002 and 2012 were chosen as data base. Then, an index system combine of organization structure, whole function and social economic environment was established. Every index was divided in five grades which include non-alert, light alert, middle alert, heavy alert and giant alert. The fuzzy synthetically judgment model was used as assessment and the conclusions were as follows: (1) As chemical fertilizer and pesticide issue in agriculture activities and industrial emission were over the environmental capacity. Nansihu wetland was in heavy alert state in 2012; (2) The whole wetland has been deteriorating while the social economic environment indexes were getting even worse. In the coming 10 years, either indexes or the whole warning state is getting better because of the increasing investment in ecological restoration. (3) The degradation rate of nearly 10 years was slower than it of earlier 20 years while the social economic environment indexes always keep a high speed, which can be explained by the negative disturb from human beings activities. This research is significant to the environment management of Nansihu wetland.

Key words:

Warning; Lake wetland; Eco-environment; Fuzzy synthetically judgment model; Nansihu Lake

Structural Changes of Economy and Perspective for Industrialization of Agriculture in Japan

Toru SASAKI

Sapporo Gakuin University, Hokkaido, 0698555, Japan, tsasaki@sgu.ac.jp

Abstract

Since the mid-1990s, economic structure in Japan has changed. In terms of trends, the current account and trade surpluses have continued to shrink, while net foreign assets have grown, the interest derived from these expanding the income surplus. Therefore, Japan seems to be evolving from “immature creditor nation” into “mature creditor nation”.

In response to such structural change, Japanese agriculture has pressed for reorganization. The structural reorganization of Japanese agriculture into large-scale farming was planned so that agriculture could be established as an industry that increases its productivity through expanding the scale of individual operations. This directional movement of the reorganization has today become the mainstream. However, the characteristics of the development of large-scale farming are that, in addition to moving toward an expanded scale of cultivated farmland, it also moves toward consolidation by expanding investment in labor and toward increased diversified management by expanding the scale of operations. That is to say, Japanese agriculture is expected to improving productivity and creating of added value through promotion of industrial competitiveness.

The purpose of this report is to examine the characteristics of structural change in Japanese economy and to clarify status of agricultural problems it is currently facing. First, I analyze the changes of Japanese economy, including a look at the trends in Japan's trade balance and income balance, current account after 1990s. In the second, I explore the characteristics of Japanese agriculture, from the view point of labor productivity and land productivity. Finally, I prospect industrialization of Japanese agriculture from an investment trend to East Asia.

Key words:

Economic Structure; Japanese Agriculture; Productivity; Industrialization; East Asia

The Characteristics and Sustainability of Theatrical Drama Performance in Fukuoka City, Japan

Yamamoto K

Faculty of Economics, Kokugakuin University, Tokyo, Japan, kenta@kokugakuin.ac.jp

Abstract

This presentation reports the characteristics and sustainability of theatrical drama culture in Fukuoka City, Japan. The live performances typified by theatrical drama are dominantly agglomerated in metropolitan regions, Tokyo being the only such place in Japan. Nevertheless, there are some groups based in other urban centers and regional centers. What is sustaining their activities in these local cities?

In the case of Fukuoka City, a regional center, an affiliate organization of the city government leads promotion projects. Performance groups based in the city apply for a grant funding project and perform in the city. There are many more theaters other than those in regional centers, and a large proportion of them are sponsored by private enterprises. These theaters are concentrated around the central business district of the city because of accessibility to the market. However, the theaters are inadequate for the needs of performance groups in the city because of their excessive capacity and costly rent fees.

In Fukuoka City, enterprises operating the theaters also host a theatrical drama festival annually with a Non-profit Organization. Only groups screened on the basis of artistry or which are invited from outside the city to attract audiences can perform in the festival. Although groups based and acting in the city are generously supported by the public sector, groups without sponsors lack opportunities to perform in the city. The city will have difficulty developing a performance culture without considering the imbalance between these supports and practices.

Key words:

regional center city; patronage; cultural industry; urban culture; live performance

The Development of Mountaineering Booms in the Northern Japanese Alps

Yasuhiro INOMATA

University of Tsukuba, Tsukuba, Ibaraki, Japan, inomaty@geoenv.tsukuba.ac.jp

Abstract

In Japan, tourism oriented specific mountaineering has been gradually popularized since around 1900. For the last two decades, as there is the mountaineering boom among old and middle aged people, it becomes much popular than before. This study clarifies the process how mountain region accepts the several mountaineering booms, through the analysis of mountain huts in terms of changes in management and function. The case of Northern Japanese Alps is investigated, which contain Mt. Yurigatake (3,180 m), one of the most famous mountain peaks in Japan. Over 360,000 hikers visited in this area in 2014. There are 15 mountain huts, which stand at interval about 5 km along trails. Major mountain huts opened around 1920 and enlarged its management scale around 1960, because the number of hiker rapidly increased. The maximum lodging capacity of some huts reached 650 persons. Since 1980, although the number of hiker gradually decreased to approximately half of the peak, many huts have tried to maintain their profit through the improvement of its services reflected the demands of the old and middle age mountaineers, and through the putting up price per customer. This profit is used for environmental conservation which is needed in massive using. Because mountain huts flexibly corresponded to mountaineers whose preferences are changing both quantitatively and qualitatively, this area seems to be able to develop sustainably. In recent years, some other improvements are required for new comers such as foreign mountaineer or extreme beginner.

The Distance Effect in Spatial Interaction and Spatial Similarity: a Big Data View of Tobler's First Law

Di Zhu, Yu Liu

Institute of Remote Sensing and Geographical Information Systems, Peking University, Beijing, 100871, P. R. China,
zhudi-001@163.com

Abstract

Distance is an essential topic when considering spatial problems, as was stated in Tobler's First Law (TFL) that "everything is related to everything else, but near things are more related than distant things." Spatial heterogeneity and spatial interaction are two typical phenomena in the complicated real world. Classic studies focused on models in spatial interaction and geostatistics based on spatial heterogeneity, while neglected the general nature of distance-decay in the two geographic process. The arriving of big data era brings us plenty of spatio-temporal data that can be used in geography fields, provides us an opportunity to revisit the distance effect in geography. Our research indicates that the power-law distance-decay in spatial interaction implicates a long-range effect, a slower attenuation and higher possibility for distant interaction activities. However, spatial similarity is a localized phenomenon, of which the short-distance effect can be characterized by an exponential-based distance-decay. The main objectives of our study were to emphasize the research area about the different distance effect in spatial similarity and spatial interaction via a big data perspective. A case study of Beijing taxi trajectory data was used to verify our view.

Distance-decay; Spatial interaction; Spatial similarity; Tobler's First Law

The Limit of Wireless City: Spatial Distribution of Public Wi-Fi Access in Shanghai

Mingfeng Wang

Center for Modern Chinese City Studies, East China Normal University, Shanghai 200062, China,

mfwang@re.ecnu.edu.cn

Abstract

Wireless communication technologies is changing the social life of people, and promoting the emergence of the mobile communication society. Especially, wireless technology is making an increasingly marked effect toward urban spaces. Most literature on the development of wireless cities focuses on cities in Western countries, and few have discussed how Chinese cities have adopted wireless technologies in their urban infrastructure development efforts. This article discusses urban internal differences in wireless infrastructure arrangement in the construction of smart cities which bucks the trend of digital divide. Using Shanghai as a case, we adopt Shanghai CMCC's public wireless local area network (WLAN) hotspot data, and analyze the spatial distribution features and dynamics of wireless network access devices. The spatial distribution of WLAN hotspots reflects the network operator's choice of facility location, which provides a new micro view to understanding the new trend in the alteration of urban spatial structure. Based on the results of case analysis, this article also provides some recommendations for the development and planning of wireless and smart cities.

Key words:

wireless city; digital divide; Shanghai

The Potential of “Soundscape” in Terms of Community Development –A Case Study of the Chirping of Bell Cricket in Matsukawa Village, Japan

Sakamoto, Y

University of Tsukuba, Tsukuba, 305-8572, Japan, ysakamoto@geoenv.tsukuba.ac.jp

Abstract

In Matsukawa village, Nagano prefecture, a project named “village of the bell cricket” is being undertaken by a community organization to determine the potential use of bell cricket sounds (chirping etc.) in community development. Conventional community development is biased towards visual resources. However, the elements constituting a local area should not be limited to visual impacts only. This study focuses on the sense of hearing, which humans use as a second sense in interacting with the environment. The study determined Matsukawa village is one of rare natural habitats of bell crickets. Some community organizations worked on the protection of the bell cricket’s natural habitats and they decided to send live bell crickets throughout Japan. Therefore, comprehensive environmental protection has been realized through these activities, for example, the prohibition of crop-dusting and road maintenance. Moreover, the bell cricket sounds delivered to people outside the village reminded them of natural scenery and projected a positive image of the natural environment in Matsukawa village. Therefore, the utilization of auditory resources in community development can facilitate comprehensive understanding of local areas, which cannot be grasped and understood only by visual interaction.

Key words:

community development; soundscape; comprehensive environmental protection; bell cricket; Matsukawa village; Japan

The Relationship between Urban Form and Medical Facilities Visiting:

A Comparative Study of Beijing and Shanghai

Shen Y

The Center for Modern Chinese City Studies, School of Urban and Regional Science, East China Normal University, Shanghai, 200062, China, shenyue0519@163.com

Abstract

People's behavior of visiting medical facilities reflect their demand and utilization of the health care services, which is also highly related to people's health and life quality. However, existing studies on people's behavior of visiting medical facilities in China paid more attention to institutional factors, while the spatial factors are rarely considered sufficiently, which is partly because the complex medical security system.

Based on the "space-institution-behavior" research framework, and the dynamic monitoring data of floating population collected by National Health and Family Planning Commission in 2014, this study analyzed the spatial pattern of people's behavior of visiting medical facilities, and compared the patterns of floating population with registered population, Beijing samples with Shanghai samples. Using ordered logit model, this study focused on the effects of spatial factors such as the accessibility to hospital on people's intention of visiting doctor, after the socio-economic attributes and the institutional factors are controlled for, and compared the results of Beijing samples with Shanghai samples. Trying to reveal the relationship between urban form and people's behavior of visiting medical facilities, and provide related suggestions to optimize the distribution of public health care facilities in mega-cities of China.

Key words:

medical facilities; health; urban form; Beijing; Shanghai

The Strategy and Influence of How the Rural Areas in Japan Attract the Foreign Tourists

Chenghung WU

WASEDA UNIVERSITY Graduate School of Education, Tokyo, Japan, quatrewinner.tw@gmail.com

Abstract

In recent years, Japan is committed to tourism industry development via loose Visa restriction, the depreciation of Japanese yen and other policies; a substantial growth of foreign tourists arrivals. But the surged visitors is still focus on the conventional tourist areas and routes, yet extend to other internal traditional tourism areas in Japan, which leads the shorts of accommodation and transportation in certain areas. Even so, the local governments in Japan still have high expectation in the economic benefit from the foreign tourists. Therefore, how to spread the tourists and benefit all the areas in Japan has become a major issue for the government. Meanwhile, the studies of relative subjects have rapidly increased in Japan. However, the research still focus on the traditional tourist area, which is difficult to be a reference for the area which lack of tourist resource or difficult to access. Although there are some areas has successfully attracted foreign tourists to visit through utilize the local resources and provide variety of “experience”. But this is a new way to attract foreign tourists, so the research and investigation are still in the accumulation. This report will analyse lide (Yamagata), and summarize how the remote town attracts foreign tourists successfully and the influence of the international tourism toward this town.

Key words:

foreign tourists; lide town; snow park; farm-inn

Tourism of Mt. Fuji in the Chinese Group Tours

Hai REN

Nihon University, College of humanities and Sciences, Tokyo, 1568550, Japan, nin.kai@nihon-u.ac.jp

Abstract

In recent years, tourism industry has been attracting attention in Japan. Particularly inbound tourism has been emphasized as a pillar of economic development. In the other hand, China has become the largest outbound tourism market in the world. Against this background, Tourists from China, as a potential source of inbound visitors for Japan, that aims at promote the tourism industry. There are many famous tourist attractions in Japan. Among of that, Mt.Fuji has very good name recognition in China. Most Chinese will go to visit Mt.Fuji, when their first visit to Japan. This study used the data on package tours of Japan from Shanghai, to clarify the characteristics of Chinese group tourist visiting the Mt.Fuji.

The results of analysis show that, the destination in tour schedule of package tours, were concentrating on the north side of the Mt.Fuji, region of Fuji Five Lakes. And group tourist from China, have to follow a planned schedule and spend a certain amount of time at every famous lookout points, only 30~40 minutes average. And although 90% of package tours went to the mountain's fifth station, but the residence time was brief, only 38 minutes average. Another result is that the tour schedule could be changed, with the change of seasons or climate.

Chinese; Group Tours; Stationary time; Shizuoka Prefecture; Mt.Fuji

Based On the Analysis of Community Scale Urban Ecological Vulnerability in Time and Space Differentiation- Was Ganjingzi in Dalian City as an Example

Yingying Guan,

Liaoning Normal University, China, 584943591@qq.com

Abstract

The research based on the principle of urban ecological vulnerability, was seated in dalian city as an example, using a certain evaluation method, to the community as the research scale, was seated in dalian from 1998 to 2013, urban green space changes impact on the urban ecological vulnerability evaluation analysis. The results show that: (1) with the continuous development of urban construction, urban green space area is gradually reduced, the negative effect of urban environment, is the important cause of urban ecological fragile degree aggravating. (2) was seated 15 years the ecological fragility of change quickly before they are slow, clear difference was seated between community ecological vulnerability, the ecological vulnerability of the community in different regions of the evolution also presents different features.

Key words:

urban greening; Urban ecosystem vulnerability; dalian

Based on the Disequilibrium Model of Global Urbanization Paths and the Study of Space Organization Form - In 286 Chinese Cities, for Example

Yanhua Ju

Liaoning Normal University, China, 1846134080@qq.com

Abstract

Research on China's 286 cities as unbalanced global coordination issue in the development of urbanization and global urbanization paths for research first established population, economic, social and ecological index system of the five systems, analysis, besides economic urbanization development level decreased population urbanization development level, social and ecological system has a rising trend, secondly using ARCGIS spatial analysis technology, it is concluded that the cities as population, economy, society and ecology coordination on the space of global urbanization development level is less and less, finally put forward from the population transfer, urban development layout, urban comprehensive carrying capacity, ecological check and measures to deal with the environment, politics and so on five aspects to promote the implementation of global urbanization path.

Key words:

unbalanced development; Global urbanization; Coordination; Prefecture level; Realize the path

Modeling the Species Composition, Age Structure and Biomass of Pine-Fir Plantations in South China under Different Harvesting Intensities

Dai, E. F., Wang X. F., Zheng, D., Wu, Z., Xi, W. M., Dou, Y.

Key Laboratory of Land Surface Pattern and Simulation, Institute of Geographical Sciences and Natural Resources Research, Chinese Academy of Sciences, 100101, Beijing, China, daief@igsnrr.ac.cn

Abstract

In China, plantations have been developed for decades to ensure timber requirement, while leading to poor quality, simple structures and weak ecological functions. Sustainable forest management strategies are indispensable approaches for structure optimization and function improvement. This study aims at determining the optimal harvesting management approach. We used LANDIS-II and PnET-II models to simulate long-term changes in species composition, age structure and aboveground biomass (AGB) of the plantations under a factorial experiment. We simulated structure and function on plantations at landscape scale of Taihe County over 100 years considering major controlling factors. Results show that the harvesting age and cut-block size have little impacts on forest area, while great influence on AGB. The harvesting area ratio and frequency are the most important factors influencing both forest area and biomass. For the most appropriate forest management in our study, following aspects should be adopted, including 20% harvesting area ratio, 5ha cut-block size and 10year harvesting frequency. And on harvesting ages, different species should be harvested at 21-year-old on Chinese fir, 26-year-old on pine and 41-year-old on broad-leaved forest. On practical viewpoint, this study provides a feasible harvesting strategy for plantation management in red soil hilly region of South China.

Key words:

Harvest intensity; aboveground biomass; landscape pattern; plantations; LANDIS-II; red soil hilly region of South China

Quantifying the Influence of Sea Level Rise, Land Subsidence and Estuarine Topography Change on Storm Flooding in a Coastal Mega-City: A Scenario-Based Study in Shanghai, China

Jun WANG^{1,2}, Si YI^{1,2}, Chengcheng SONG^{1,2}, Mengya LI^{1,2}

¹Key Laboratory of Geographic Information Science of Ministry of Education, East China Normal University, Shanghai 200241, China, jwang@geo.ecnu.edu.cn

²School of Geographic Sciences, East China Normal University, Shanghai 200241, China

Abstract

This paper focuses on the evaluation of anthropogenic impacts on storm flooding in Shanghai, a coastal mega-city of China. We used a scenario-based approach to examine how sea level rise (SLR), land subsidence (LS) and estuarine topography change (ETC) would affect the evolution and impacts of a super typhoon storm in three target years (2010, 2030 and 2050). A two-dimensional hydrodynamic model (MIKE 21) was used to simulate the storm flooding associated with each scenario. Considering the extensive damage in history, we selected TC9711, TC8114, TC0012, TC0205 and TC1109 as references to design case typhoon events causing storm surges with three categories of paths (SHLD, ZNLD and GNS). Results demonstrate both the individual and the combined influences of SLR, LS and ETC relevant to anthropogenic impacts on storm flooding possibly striking Shanghai within the next four decades. Apparently, storm flooding formed in the compounded scenarios was much serious than that in each single scenario. In addition, the influence of the three impacting factors is quantified to determine the key factor. During 2010-2030, estuarine topography change (ETC) has major impact on the projected storm flooding, while during 2010-2050, the impacts of sea level rise (SLR) and land subsidence (LS) was larger due to their complex spatial and temporal interaction.

Key words:

Storm Surge Flooding; Scenario Analysis; Influencing Factor; Model Simulation; Shanghai

Research on Grid System of Intelligent Community Public Opinion Agency

Ruimeng Yang

Liaoning Normal University, China, 523494232@qq.com

Abstract

The grid system of intelligent community and public opinion agency based on diary and public opinion management, Used Visual Studio 2010 as system integrated development environment ,combined with WebGIS and realized the 8 types of social conditions and events of acceptance, transfer, processing, verification and completion function, is an auxiliary tool to carry out democratic scientific decision making. In this paper, the overall structure of the social situation and public opinion system, the realization of technology, the main function of the design and implementation are described in detail. This system is mainly based on the modular structure, and it can get the data information produced by the community residents in a timely manner, which is helpful to solve the residents' suggestions and interests of public affairs.

Key words:

Social situation and public opinion system; diary of public; the demands of public opinion; WebGIS

Abstract

Ecological health assessment can provide indispensable information for wetland protection and management. Poyang Lake is the largest fresh-water lake in China. The wetland is recognized as one of the most important wetlands in the world because it provides habitats for many unique species and its great ecological and economic importance to millions of people in the middle and lower Yangtze region. Currently, there is no indicator framework to determine the status and trends of Poyang Lake wetland condition at a basin scale. The index of biotic integrity (IBI) is the most widely-used method for wetland monitoring in North America. Plants are well-suited as indicators of ecological health because they are immobile, relatively easy to sample and identify, and respond to anthropogenic disturbance on an ecological time scale. In the study, we aim to develop a vegetation-based index of biotic integrity (V-IBI) and assess the health condition of Poyang Lake wetland. V-IBI was based on samples at 30 sites that were randomly selected. Least disturbed sites defined the reference conditions. Water and soil chemicals, habitat quality, and land use were used as criteria to identify reference sites. Metrics related to plant richness, composition, life form and disturbance tolerance were screened by sensitivity and redundancy tests. Five metrics (species richness, % cover of annual species, number of non-native species, % number of monocots, % number of sensitive species) were finally used to construct the V-IBI. The V-IBI scores were obtained by combining the rating categories (excellent, good, fair, poor, and very poor). The ecological status was then evaluated based on the V-IBI scores. The results indicated that the general ecological status of Poyang Lake wetland was rated lower than “good”. Sites located in nature reserves were rated as the best, while those close to intensive farming lands and big cities were the worst. The V-IBI scores showed a significant negative response to an increasing gradient of disturbance, indicating that it is a useful tool for ecological monitoring in Poyang Lake wetland.

Poyang Lake-Yangtze River Interaction and Its Influence on Lake Hydrology

Zhang Q

Nanjing Institute of Geography and Limnology, Chinese Academy of Sciences, Nanjing, 210008, P. R. China,
qzhang@niglas.ac.cn

Abstract

Lake hydrology is largely dependent on its connection with surrounding rivers. Poyang Lake, the largest freshwater lake in China, is one of the few lakes that remain naturally connected to middle reach of the Yangtze River. The past decade saw an increasingly frequency of floods and droughts in Poyang Lake, causing great threats for 12.4 million inhabitants and 3.9 million hectares of arable lands in the lake region. In addition to the impacts of climate changes in the lake catchment, the interaction between the Lake and the Yangtze River was found to have played an important role in affecting the Lake water balance. Strong human activities in the upper Yangtze River, e.g. the operation of the Three Gorges Reservoir located some 955 km upstream, were found to alter significantly the hydrological connection of the Lake and the River. This talk presents the latest research work on the Lake-River interaction, and how the modification of the interaction influences Lake hydrological and hydrodynamic processes. Contributions of the Yangtze River on the occurrence and severity of floods and droughts in the Lake are explored and discussed. Research outcomes are expected to provide scientific support for Lake-River integrated management.

Lake-River interaction; Lake hydrological and hydrodynamic processes; Poyang Lake

Remote Sensed Study on Eco-environmental Dynamics in the Poyang Lake, China

Xiaoling Chen, Lian Feng

State Key Laboratory of Information Engineering in Surveying, Mapping and Remote Sensing, Wuhan University, China,
254524243@qq.com

Abstract

Poyang Lake, the largest freshwater lake in China, is one of the most important wetland in the world considering its critical ecological functions. The lake inundation area by remote sensing showed a significant decreasing trend in the time series from 2000 to 2010. Water budget with RS and hydrological measurements demonstrated that the impoundment of the Three Gorges Dam (TGD) in June 2003 has led to a loss of 7864.5 million m³ of water from the lake in a short period. The decrease of inundation area has caused rapid changes on the Poyang landscapes, vegetation area in dry seasons increased by 16.6% of the lake area from 2001 to 2013. The relationships between the water levels and vegetation coverage also showed two regimes in both dry and wet seasons for the pre-TGD period (before 2003) and post-TGD period (after 2003). The water quality of the Poyang Lake also experienced significant spatio-temporal variation over the past decade. TSS was low in wet seasons and much higher in dry seasons, and quantitatively TSS showed generally higher turbidity of the north lake, an evidently increased turbidity was found after 2002. The Chl-a concentrations also showed apparent spatio-temporal gradients, but no significant trend was found in recent years.

Study of Lake Ecosystem Integrity and Its Variation Using the LEI Index in the Middle-To-Lower Reaches of the Yangtze River, China

Gao Junfeng¹, Huang Qi²

¹Key Laboratory of Watershed Geographic Sciences, Nanjing Institute of Geography and Limnology, Chinese Academy of Sciences, Nanjing 210008, P.R.China, gaojunf@niglas.ac.cn

²Key Laboratory of Poyang Lake Wetland and Watershed Research, Ministry of Education, Jiangxi Normal University, Nanchang 330022, P.R.China

Abstract

The evaluation of the lake ecological integrity and its variation provide the basis for environmental management of lake ecosystems and its basin. In this study, we built a multi-scale lake ecological integrity (LEI) index system including natural ecosystems health (NEH) and ecosystem service (ES). Metrics of physical, chemical, and biological integrity were developed and calculated to assess natural ecosystems health, and metrics of water supply, flood control were developed and calculated to assess ecosystem service. The final scores for the LEI index were divided into five categories. We applied the method to evaluate the lake ecological integrity of lakes in the middle-to-lower reaches of the Yangtze River in 2012 and 2014. The result indicated that the LEI scores ranged 0.62 to 0.73 in 2012 and 0.63 to 0.72 in 2014 respectively, rated as good. Moreover, the NEH scores ranged 0.57 to 0.71 in 2012 and 0.58 to 0.69 in 2014 respectively, rated as fair to good, and ES ranged 0.67 to 0.75 in 2012 and 0.69 to 0.75 in 2014 respectively, rated as good. The comprehensive scores show a descending tendency in Poyang Lake and a rising tendency in Taihu Lake and Chaohu Lake, these differences demonstrated how the effects of global environmental change and human activities on the lake ecological integrity of different aspect in the three large lakes during the 3 years. Consequently, the LEI index system can provide a scientific basis for Lake Ecosystem restoration and protection not only in natural ecosystems health but also ecosystem services.

Virtual Geographic Environments Based Integrated Simulation Service System for Water Pollution Management

DING Yulin, LIN Hui, Chen Min

Institute of Space and Earth Information Science, the Chinese University of Hong Kong, Hong Kong, China,
rainforests@126.com

Abstract

With the rapid economic development and the enhancement of human activities, water pollution has been one of the most serious environmental problems. However, as exist environmental management systems operate in a typical passive data-centric mode, the accumulated resources cannot be fully utilized. Data-centric environmental management systems were designed and implemented by a software house for their specific purposes, and these systems often will not fit the needs of the actual environmental management tasks of other user communities. This impediment is being partially addressed by the increasingly complex application requirements from multiple-levels of users, as well as by the growing availability of diverse resources, including data, models, geo-tools, software packages, monitoring sensors, mobile terminals, and highly efficient hardware resources. In practice, trivial and time-consuming operations to integrate various resources have cost most the manual resources rather than improving the decision-making. This is why most existing environmental management systems have been of limited use until now. To overcome the shortcomings of a centralized, isolated, passive data-centric environmental system, we propose a novel Virtual Geographic Environments (VGE)-based integrated simulation service system, which is capable of scheduling and allocating multiple resources to dynamically generate collaborative and on-demand information services in a holistic way. We focus specifically on how to convert the existing heterogeneous and distributed related resources into services. Through the seamless integration, collaboration and reuse of existing environmental resources, the system could provide on-demand services for stakeholders from multiple levels to perform their water quality management tasks in a holistic and efficient mode.

Key words:

virtual geographic environment (VGE); Resource integration and collaboration; Water pollution simulation

Evaluating Runoff Variability Using SWAT Model in the Ganjiang River Watershed of Jiangxi Province and a Comparison with IHACRES Model

Liu G H^{1, 2, *}, Qi S H^{1, 2}, Xu N Q²

¹ Key Laboratory of Poyang Lake Wetland and Watershed Research, Ministry of Education, Jiangxi Normal University, Nanchang, 330022, P.R.China; ² School of Geography and Environment, Jiangxi Normal University, Nanchang, 330022, P.R.China, yafeng9918@163.com

Abstract

Water supply availability has significant impacts on the Poyang Lake watershed. As the largest river of Poyang Lake basin, the hydrological regime changes of Ganjiang River had an effect on water ecosystem health of Poyang Lake Basin. The SWAT (Soil and Water Assessment Tool) model and IHACRES (Identification of unit Hydrographs and Component flows from Rainfall, Evapotranspiration and Stream flow data) model were used for modelling runoff variability in Ganjiang River watershed to determine the applicability of hydrological models to the Poyang Lake basin. Both SWAT and IHACRES models represented observed runoff well that R² (coefficient of determination) and NS (Nash-Sutcliffe) were both greater than 0.7 and PBIAS (percent bias) was smaller than 25. IHACRES model was easy to be used for less data-preparation in primeval times of 1955-1979 while performed unfavourable during 1980-2010. This would attribute to climate change and human activities experienced in the watershed recent decades which had significantly impacts on hydrological cycle. By contrast, the complex, processes-based SWAT was a better choice to simultaneously simulate runoff variability and evaluate the effects of land use change and human activities in the basin where agricultural activities are intensive. It was possibly suitable for water resource planning and management.

Key words:

Hydrological modeling; Ganjiang River watershed; runoff variability; SWAT model; IHACRES model

Preliminary Study on Benthic Macroinvertebrate Index of Biotic Integrity (B-IBI) for the Health Assessment in the Poyang Lake, China

Huang Qi^{1,2}, Liu Lizhen³, Gao Junfeng⁴, Cai Yongjiu⁴, Chen Yuwei⁴

¹Key Laboratory of Poyang Lake Wetland and Watershed Research, Ministry of Education, Jiangxi Normal University, Nanchang 330022, P.R.China, huangq@jxnu.edu.cn

³Poyang Lake Research Center, Jiangxi Academy of Sciences, Nanchang 330096, P.R.China

⁴Nanjing Institute of Geography & Limnology, Chinese Academy of Sciences, Nanjing 210008, P.R.China

Abstract

The water and habitat quality in Poyang Lake are being degraded by the global environmental change and anthropogenic impact. Thus, the need for standards, especially those examining the biological attributes of lake systems, are urgently required. A preliminary benthic macroinvertebrate index of biotic integrity (B-IBI) was developed to evaluate the ecosystem health of Poyang Lake in winter by means of the data that were collected from 15 sites in October and January in 2012 to 2014 in the central of Poyang Lake. The method of the least disturbed condition was used to find the reference sites. Four metrics were selected from five categories (50 metrics). We then calculated the total MMI scores by summing metrics for each site after transformation by 0-1 scaling system. The final B-IBI include the total taxa number, (Crustacea+Mollusca) taxa, the Berger-parker's index and biotic index. Then the ecological conditions of the sampling sites were evaluated based on the B-IBI scores, which were transformed into a uniform score by ratio score method and summing up. Overall, the ecological conditions of references sites were "Good", B-IBI scores were significantly reduced at impaired sites, where affected by anthropogenic impact. Health condition of center region in the Poyang Lake was found to decline gradually from 2012 to 2014. Sand mining and water pollution were suggested as the major factors affected B-IBI. Our results suggest that long-term data would benefit the development of a robust B-IBI and its use in practice of Poyang Lake health assessment.

Separating Different Fractions of Soil Organic Carbon in a Poyang Lake Wetland

HU Qiwu^{1,2}, JIN Qi¹, CHEN Mingyue¹, KUANG Wei¹, WU Qin¹

¹School of Geography and Environment, Jiangxi Normal University, Nanchang, 330022, P.R.China

²Key Laboratory of Poyang Lake Wetland and Watershed Research Ministry of Education, Jiangxi Normal University, Nanchang, 330022, P.R.China, huqiwu1979@gmail.com

Abstract

Separating different fractions from total organic carbon pools could help to improve modeling variations in soil organic carbon stock and its feedback to global climate change. Poyang Lake is the largest freshwater lake in China. In this study, soils at a depth of 0-15 cm and 15-30 cm were sampled along water table gradient in a typical wetland of Poyang Lake. Subsequently, total soil organic carbon (SOC), heavy fraction organic carbon (HFOC), light fraction organic carbon (LFOC), microbial biomass carbon (MBC) and dissolved organic carbon (DOC) were measured, respectively. The objectives of this study were to quantify the contribution of various organic carbon fractions to the total organic carbon, and explore the response of different organic carbon components to water table and vegetation variation. Our results showed that the ranges of SOC, HFOC, LFOC, MBC and DOC were 4.92~48.14 mg·g⁻¹, 4.66~41.42 mg·g⁻¹, 0.46~6.52 mg·g⁻¹, 124.22~419.23 mg·kg⁻¹ and 33.17~153.63 mg·kg⁻¹, respectively. The organic carbon fractions varied significantly with plant communities and among soil layers. Each of the soil organic carbon fractions under various plant communities decreased from the top soil to the deeper soil profile. The contribution of HFOC and LFOC to total soil organic carbon varied from 86.46% to 96.39% and 3.61% to 13.54%, respectively. The MBC/SOC and DOC/SOC ratios ranged from 0.28% to 3.44%, 0.16% to 2.16%, respectively. The distribution patterns of LFOC, MBC and DOC were not spatially consistent, suggesting that these active organic carbon fractions were not controlled by the same environmental factors.

Abstract

Using next-generation DNA sequencing techniques to exploring the genetic information of microorganisms, the paper studies the diversity and abundance of river-lake ecotone of Poyang lake basin, and the difference of the microbial population distribution, and studies the interaction between the river and lake water of river-lake ecotone from bacterium view. In addition, in combination with the hydrological geology and chemical ion methods, Research on the key environmental factors that affecting ecosystem of river-lake ecotone, the paper further expounds the mechanism of the difference of the microbial population distribution in river-lake ecotone, attempts to reveal the differentiation characteristics of bacteria response to environmental variation at different underlying surface, and studies the ecological change of river-lake ecotone, which can be wide used in disease control and city water resources plan.

Wetland Vegetation Feature Extraction in Poyang Lake from Multi-Sensor and Multi-Temporal Images

Zhang Li ^{1,2}, Fang Chaoyang ^{1,2}, Qi Shuhua ^{1,2}, Xuhan zheyu^{1,2}

¹Key lab of Poyang Lake wetland and watershed Research (Ministry of Education), Jiangxi Normal university, Nanchang, Jiangxi, 33022, P. R. China

²School of Geography and Environment, Jiangxi Normal University, Nanchang, 330022, P.R. China, zhanglinu@126.com

Abstract

Feature description of Poyang lake herbaceous wetlands vegetation is not easy to be described by one source or one time phase image. Time-series Sentinel 1A (C-band) for Radar images and for multi-spectral optical satellite data Sentinel2 and Spot 5- take5, are combined to investigate the spatial-temporal variation of wetlands object in autumn and spring growing season. Normalized different vegetation index (NDVI), soil-adjusted vegetation index (OSVAI), Simple Ratio (SR) and Modified Normalized different water index (MNDWI) will be extracted from optical images to study the vegetation variation trends during the two periods for different vegetation types. Backscattering coefficients, Shannon Entropy (SE) and H/Alpha wishart classification value will be selected from the Sentinel 1A to study the scattering scheme and structure information of the wetland vegetation. The results showed that NDVI will be saturated or not sensitive to each other when the value get to 0.7. Variables discriminating reed marshes from other land covers were the NIR band between March and June, the OSAVI of January, and the MNDWI of September. Submerged macrophytes beds were discriminated with the shortwave-infrared band of January, the NDVI & NDWI of September, the red band of September and the SR index of April and August. For Sentinel 1A data, VH polarization is better to investigate the wetland vegetation data than VV polarization. Spatial-temporal Shannon Entropy and H/Alpha classification values could be a good way for the dual-polarization Radar to describe the different scatter scheme of the wetland vegetation during different growing statues of vegetation communities.

A Study on the Correlation between Local Studies and Local Development

- Focusing on the Case of Korea "Gangneung Study"

LEE KYUTAE

Catholic Kwandong University, South Korea, kdsino@hanmail.net

Abstract

As local studies grow in Korea, a variety of discourses on objectives, scopes, and research methods of local studies have been presented, and ways of their theorization also have been explored. In general, local studies focus on history and culture, but it is also true that local studies should contribute to the local development. For instance, local governments of Korea support local studies at present with the aim to explore the local identity through local studies and to seek local characterization based on the local identity. In other words, local governments support and organize local studies because they expect that studies on the local history and culture would contribute significantly to the local development. Still, how local studies focusing on history and culture can affect the local development is quite controversial. Specifically, the issue of the academic nature and policies of local studies is open to dispute. This study aims to analyze discourses on the correlation between local studies and local development based on the case study of 'Gangneung Study(江陵学)', a local study of Gangneung that is a local city in Korea. The major contents are as follows: 1) Theoretical discussion of the correlation between local studies and local development; 2) Korean local governments' policies of supporting local studies; 3) Gangneung Study and Gangneung City's supporting policies; and 4) discourses on the correlation between Gangneung Study and the development of Gangneung City.

Key words:

An Analysis on the Discipline Attributes of Local Studies

ZHU Yongjie

Institute of Beijing Studies of Beijing Union University, Beijing 100101, China, ldyongjie@buu.edu.cn

Abstract

This paper not only points out the research area coverage of Local Studies and its relationship with Capital Studies, but also mainly discusses the discipline attributes on Local Studies. Local Studies is a subject studying the formation and evolution law of the regional complex which is composed of the natural and human environment of a region. Capital Studies is a type of many local studies, and there is a certain relationship between Capital Studies and Local Studies. If Local Studies is an independent subject, according to study objects, it is an integrative discipline linking physical science and social science. According to the analytical methods of discipline attribute in Sociology, Local Studies is a “soft” discipline with extensive “application” and a discipline with higher “divergence” but lower “urbanization”. Therefore, it is significant to strengthen relation between local Studies and other disciplines, to broaden research area coverage, to take many study modes, to enhance applied theory research, to increase the chances of critical communication.

Key words:

Local Studies; research area coverage; discipline attributes

An Experience of Yamaguchi-Gaku Project of Yamaguchi University

Araki H

Yamaguchi University, Yamaguchi, Japan, arakih@yamaguchi-u.ac.jp

Abstract

Yamaguchi University is located in Yamaguchi City, Yamaguchi Prefecture, Japan and I would like to introduce Yamaguchi-Gaku (山口学) project in Yamaguchi University as a case of local studies in Japan. It was set up in 2002 as an interdisciplinary research team by 11 initial members including 3 geographers in the faculty of Education in our university. Since then Yamaguchi-Gaku members had conducted monthly meeting and annual symposium/forum. For example, the theme of symposium in 2002 was *Sagiryu Kyogen*, a traditional drama like *No* carried on in Yamaguchi and the theme in 2003 was *Sumie* (ink painting) and Sessyu who was a famous artist living in Yamaguchi. That in 2007 was Japanese Sake and that in 2008 was Japanese sword, the both were major products of traditional industry of Yamaguchi. Since 2009, Yamaguchi-Gaku reorganized as a collaborative project with Tamkang University, near Taipei. Tamkang University also had a local study project named Tamsui Xue(淡水学) and Tamsui is a place-name of the university. We are continuing mutual visit by project members of the both universities every year and have launched a new journal named "Journal of East Asian Identities" in this year.

Fujiology; The Worship of Holy Mt. Fuji and Mt. Fuji Sightseeing

SANO Mitsuru

Nihon University · The Association of Japanese Geographers, Tokyo, 156—8550, Japan, sano.mitsuru@nihon-u.ac.jp

Abstract

Fujiology (FUJI-GAKU) is the synthetic and interdisciplinary study which makes a research area Mt. Fuji and the foot of Mt. Fuji (related area in Mt. Fuji in a broad sense). It is a comprehensive field of knowledge, including natural science, humanities and social science. 40 million people who are 1/3 of population of Japan can see Mt. Fuji as a landmark. It was listed in UNESCO's World Culture Heritage catalogue in 2013. The holy Mt. Fuji is a graceful mountain, a symbol of Japan. And there is also an object of mountains worship. As a form of nature-worship, Mountain climbing began from the 14th century, and in the 17th century (Edo period), the Mt. Fuji climbing boom of the public for the purpose of sightseeing started. This boom became the origin of the present-day Mt. Fuji sightseeing mountain climbing.

For the past few year, tourism business is more and more being paid attention to in Japan. And for this reason, there are many foreign tourists Visit Japan, and go to visit Mt. Fuji. As a result, there were 200,000-300,000 sightseeing mountaineers climbed the Mt. Fuji, in the summer of 2015 (July to August). At the same time, mountaintop and the trail to the mountaintop become crowded. This presentation will introduce the cultures, such as nature-worship, of Mt. Fuji in general, and attempts to carry out a preliminary discussion of the tourist behaviour in Mountain climbing.

Key words:

Fujiology; nature-worship; sightseeing mountain climbing; World Cultural Heritage; holy Mt. Fuji; visit-to-Japan foreign tourists

Place, Placeness, Place Identity: Concepts Inspiration for Local Studies

Zhifen Cheng, Baoxiu Zhang

Beijing Union University, Beijing, 100101, P. R. China, zhifencheng2004@163.com

Abstract

In recent years, the researches for local studies in China are ascendant and show vigorous development trend. However, these researches are still too heavily weighted in local culture's practices. And theories researches are still sorely lacking. Place, placeness, place identity are the core concepts and the theoretical perspectives for cultural geography, and they can provide academic nutritions for local studies. This paper adopts literature analysis and comparative analysis methods, and it combs the concerned research fruits about place, placeness and place identity at home and abroad, then it presents the suggestions. First, local studies' research should be guided by the cultural geography's core concepts: place, placeness and place identity, excavate deeply each place's placeness. Second, local studies' research should analyze the changes of place identity from the local residents. Third, they should explore ways to strengthen the identity of local residents to the place.

Key words:

place; placeness; place identity; local studies

Role of Geography in the Theory and Practice of Local Studies

Baoxiu ZHANG

Beijing Union University, Beijing, 100101, P. R. China, baoxiu@buu.edu.cn

Abstract

Geography is a field of science devoted to the study of the Earth's surface (space), as well as the regional system of man-land relationship. The science of local studies, with local name knowledge, is an interdisciplinary and comprehensive research area relating to the place, which studies the local characteristics, evolution, and their relationship of the various local elements of a regional complex, and predicts the development law and future trend. "Localology" maybe used as the academic term in English to refer to the modern local studies. Its mission is to study the local place, mine its culture, inherit its cultural context, and serve the local development. Geography and local studies have both similarities and differences. The role of Geography in the theory and practice of local studies is the first important, which, especially Historical Geography and Cultural Geography, can give the local studies some knowledge of theories and research methods. In China, the early local studies refer to such three major studies as the Dunhuang Studies, the Hui Studies, and the Tibet Studies. After the reform and opening up to the outside world since 1978, especially in recent years, the local studies in China have been flourishing rapidly and many institutes of local studies have appeared. The Institute of Beijing Studies is one of them, which is the present executive chairman of the Association of Chinese Local Studies now. We need more theory knowledge and research methods from Geography.

Key words:

Geography; theory and practice; local studies; Localology; Beijing studies

The Land Use Change by Urban Design and the Conservation of Urban Agriculture

Ena KONNO

Japan Livestock Industry Association, Tokyo, Japan, ena0225@yahoo.co.jp

Abstract

Urban design is effect to change the land use and industry, especially agriculture. 37 kinds of vegetables and spice were planted in 23 wards that is the capital sphere. But, in 1968, new urban design was enforced, and farmers who live in, and produce in the urbanization promoting area are difficult to continue the agriculture. Because, some area in the urbanization promoting area is set down as the production green land area, and the other area set down as housing land. Around 1990s, most local people rethink to prevent the production green land area with the objects of food safety, food and agriculture education and relaxation. 4% of Tokyo is the agriculture field, and most farmers produce vegetables, fruits and flowers. If the farmers have animals that are cows, pigs and so on, they have to deal with the disposal of excreta and bad smells. So that, they should pay huge cost for these facilities, therefore they are difficult to maintain the management. When we keep urban agriculture in and around Tokyo, we should think about the methods how to ride on the strength of urbanize feature. For example, the land use which utilize the rooftop terrace and narrowing area, high technology which is like the plant factory, the relationship between producers and consumers, and recreation farm which is picking vegetable and fruit.

Key words:

Urban Agriculture; Urban design; land use; the production green land area; Tokyo

The Transforming Processes of Kyoto, the Millennium Capital of Japan

Aki Yamamura

Kyoto University, Kyoto, Japan, yamamura.aki.8m@kyoto-u.ac.jp

Abstract

From 794 to 1869 Kyoto remained the capital of Japan. This presentation outlines the geographical change of Kyoto as the capital, from the end of the 8th century to the beginning of the 17th century. The capital started as a preplanned city. It modeled Changan, the capital of Tang, which was the Chinese dynasty at that time. Like Changan, the city streets had a grid pattern, which we can still find in the central part of Kyoto. However, unlike Changan, it did not have city walls. Even before a century had passed since its construction, the density of buildings within each grid got uneven. And as it was not surrounded by city walls, the city easily extended its areas into the suburbs. These new urban areas developed like clusters around temples and shrines. The resulting medieval Kyoto consisted of the remaining ancient city and these clusters. In the war-torn eras from the 15th to the 16th century, each cluster was surrounded by city walls, and became more cohesive within itself. From the late 16th to the early 17th century, gradually a unified power emerged and the battle of warlords ceased. In that process, Kyoto was surrounded by big city moats called “Odoi.” A castle was built within the moats, and Kyoto thus became a large castle town.

Abstract

Predictive mapping (such as digital soil mapping, landslide susceptibility mapping and habitat suitability mapping) involves complicated inference models and tedious data preparation processes. Recent demands and trends calls for an ease-of-use and high-performance software platform for predictive mapping. This paper presents a novel predictive mapping platform, CyberSoLIM, which provides a heuristically driven, visually assisted, high performance computing enabled cyber environment for digital soil mapping. CyberSoLIM consists of one knowledgebase, two databases and five modules. The knowledgebase contains the knowledge on DSM modeling processes and knowledge on data processing. The two databases, one contains the web services which wrap parallel computing enabled programs of inference model and data preparation algorithms, and the other contains field samples and the spatial data describing the environmental covariates. The five modules include visualization of model building, heuristic model building, workflow execution, information publish and display, and data management. CyberSoLIM was applied to infer the silt content in top soil (0-20 cm) in Anhui Province of China as a form of evaluating its ease-of-use and high-performance capability. This case study shows that CyberSoLIM is easy in user experience and efficient in mapping productivity. Of course, the accuracy of the product depends on the inference method used.

Abstract

It is an emerging interest to use crowdsourcing sample data in geospatial modeling. Since sample data from various sources were collected in different levels of quality, and legacy data may become outdated, it is necessary to dynamically evaluate sample reliability. The study developed a method to evaluate and update the reliability of crowdsourcing sample points in digital soil mapping (DSM). Based on the assumption that similar environmental conditions correspond with similar soil, the reliability of a soil sample point is defined as the repeatability of the Soil-Environment relations at the sample location. The reliability of a sample point was first initiated with a middle value (i.e. 0.5); if the value of targeted soil property of the sample point can be replicated at other environmentally similar sample locations (i.e. supportive points can be found), its reliability was increased; otherwise, the reliabilities of both the point and the conflicting point were reduced. The method was tested in Anhui Province, China. 570 soil sample points from four sources were collected since 1970s. The reliabilities of sample points were evaluated and updated in a temporal order. A reliability threshold was set to select the sample points used in DSM methods. At any point in time, the predicted soil property maps were more accurate if only using reliable sample points; the prediction uncertainty was also more indicative to prediction accuracy. It is concluded that the method is effective in evaluating the reliability of crowdsourcing sample data and can be used in other geospatial modeling applications.

A GIScience Hybrid Cloud Service to Advance Geographical Studies

Chaowei Yang

NSF Spatiotemporal Innovation Center, George Mason University, Fairfax, VA, 22030-4444, cyang3@gmu.edu

Abstract

Cloud Computing becomes a paradigm shift for providing computing support to scientific research and engineering developments. Geographical study started to benefit from this innovation and join in the advancement of cloud computing in the past few years. To best leverage cloud computing for geographical studies, we built a hybrid cloud computing facility at the Spatiotemporal Innovation Centre, the first NSF innovation center chartered to the GIS domain with base at George Mason, Harvard, and UC-Santa Barbara. The facility includes over 500 computing nodes, over 6000 CPU cores, ~2 PB storage, and networking of two 20Gbps internal and one 10Gbps connection to the Internet 2 backbone. It has enabled many research including the big data container and planetary defense studies for NASA, EarthCube Integration and Testbed Environment for NSF, Semantic Testbed for ESIP, deep learning and user profile mining for ocean and land sciences, and many others. As the largest of its kind dedicated to GIScience and Geography studies, we expect the hybrid cloud service to provide leading service to our domain in the next 5 to 10 years. We are opening its usage for the general geographical domain. Application to use the hybrid cloud service can be submitted at <http://cloud.gmu.edu/>.

Abstract

Modular hydrological modelling has become an important trend in recent years, and numerous modular modelling frameworks such as OMS and OpenMI have been developed. However, existing hydrological modelling frameworks seldom consider the use of parallel computing techniques. This has hindered their application in high-resolution hydrological modelling over large watersheds. In this paper, a modular and high-performance framework for one common type of distributed hydrological models was proposed. In this type of model, routing is performed sequentially from upstream simulation units to downstream simulation units. Firstly, the modular architecture was designed. A set of standard interfaces for each module was proposed and the data structure used to store the information of spatial simulation units and the interactions among them was defined. Then, a two-level parallel computing framework oriented to this type of hydrological models was constructed, in which parallelizability at both the sub-basin level and the basic simulation-unit level (e.g., the grid-cell level) can be utilized simultaneously. Finally, this framework was tested in two real-world applications using different types of spatial simulation units (i.e. grid-cells and irregular polygons) and model structures (i.e. one for long term daily simulation and the other for high temporal-resolution storm simulation). The framework proposed in this paper illustrated how to achieve high-performance parallel computation in a modular modelling framework, and can provide a methodological reference for analogous studies.

Accelerating Spatial Aggregation Query for Large-scale Moving Objects

Songbing Wu, Luo Chen

College of Electronic Science and Engineering, National University of Defense Technology, Changsha, Hunan Province, China, wusongbing14@gmail.com

Abstract

Spatial temporal aggregation (STA) query is a common but very important functionality in many emerging geo-spatial applications. Given a spatial temporal data set R and a user-defined spatial temporal query window (q, t) in certain scale s , STA aims to retrieve the statistical information of all records overlapping with (q, t) at s . A typical STA operation is “present the distribution of the number of taxis with speed less than 5 kilometers per hour in Changsha City during a given day at current viewport and with 5 minute intervals”.

The fast progress of location acquisition technologies have led to an explosion of spatial temporal datasets, which brings new challenges in efficiently answering exploratory STA queries in large spatial temporal databases. Exploratory STA may emit the query at multiple spatio-temporal scale to investigate the general or detailed knowledge of the observed dataset; this leads to heavy computational and space cost and requires expensive aggregate operations.

The works studied so far can roughly be classified in two categories: one is to improve the query performance with hierarchical disk-based data structures, such as aR tree, MR-tree, MRA-tree, aP-tree, aRB-tree and nano-cube index. These methods use a top-down manner to answer the aggregation query with high level index nodes and avoid accessing the raw spatial temporal data as far as possible. The other approach is to take the advantage of modern parallel computing infrastructure, such as multi-core CPU and many core GPU, MapReduce. All the above works aim to produce the exact answer to the STA query, which takes very high computational cost. We observe that in many cases, the approximate query is more useful to the application, especially in exploratory query scenario with time-critical response requirements, which provides approximate but meaningful answers.

In this abstract, we make the investigation to the problem of accelerating exploratory STA query with approximate answer for massive moving object data streams. Our works are summarized as follows: 1. We introduce a hybrid quad-tree/B-tree based cube pyramid structure to set up the multi-scale indexing of spatial temporal domain for massive moving objects, and to facilitate the updating of the spatial temporal locations. 2. We develop a scale-adaptive algorithm to quickly answer the STA query at any exploratory scale with bounded error estimation. 3. To further improve system performance, we propose a parallel strategy for multi-core CPU clusters to process large scale STA queries.

Advancing Dust Storm Simulation and Analytics by Leveraging Advanced Computing Resources

Taylor George, Manzhou Yu

George Mason University, Fairfax, VA 22031, USA, getaylornc@gmail.com

Abstract

Dust storm represents a serious hazard to health, personal property and the environment. To mitigate the hazard, dust models simulate and predict upcoming dust storm events and assess the uncertainty. The simulation of dust storms is intrinsically computing intensive because it utilizes massive data inputs from ground and atmospheric conditions and conducts numerous iterations of the same set of numerical calculations. If higher spatial and temporal resolution is needed, the execution time to generate a simulation result is unacceptably long. To provide real time simulation results for decision-making purposes, advanced computing resources (e.g., High Performance Computing, Cloud Computing) are utilized accelerate the computing process. A framework of Big Data management, processing and visualization is developed based on advanced computing resources. This proposed framework benefits dust storm simulation and analytics in three ways: (i) integration of real-time observations as initial conditions on the fly, resulting in more accurate and complete simulations; (ii) effective management of large input and output datasets, with high-performance selective queries *via* progressive streaming techniques on distributed data storage; and (iii) advancement of three-dimensional visualization and analytical capabilities of simulation outputs. The leveraging of advanced computing resources in dust storm studies fosters interdisciplinary collaborations involving expertise in atmospheric sciences, public health and public policy.

⁵Jiangsu Center for Collaborative Innovation in Geographical Information Resource Development and Application, Nanjing, Jiangsu 210023, China

Abstract

Fuzzy characterization of slope positions (e.g., ridge, backslope, and footslope) can provide important terrain information for geographic modeling. Among existing methods to deriving fuzzy slope positions, the prototype-based inference method is more reasonable because of not only its inference in both spatial and attribute domain, but also its use of the typical locations as prototypes, which inherently contain the characteristics of the slope position distribution in a study area. However, the practicability of the prototype-based method is currently limited due to the manual operations and parameter-settings, such as preparing topographic attributes as input, finding prototypes of slope positions, and setting parameters for fuzzy inference. This study proposes an approach to automate the whole workflow of the prototype-based method. Instead of being determined totally by user in the original method, in the proposed approach the typical locations and the fuzzy inference parameters for each slope position type can be automatically determined based on the frequency distribution of topographic attributes and a rule set of prior expert knowledge. Furthermore, the preparation of necessary topographic attributes is automated, which means that the proposed automatic approach needs only one necessary input, i.e. the digital elevation model (DEM) of the study area. The proposed approach is implemented as a configurable Python script to organize the workflow, when all of the compute-intensive procedures are speeded up by parallel computing based on message passing interface (MPI). A case study shows that this approach can derive fuzzy slope positions reasonably and efficiently.

Computation of Massive Spatial ABM Driven by Dynamic Data: Challenges and Solutions

Huayi Wu, Xuefeng Guan, Zhenqiang Li

The State Key Laboratory of Information Engineering in Surveying, Mapping and Remote Sensing, Wuhan University, 129 Luoyu Road, Wuhan, 430079, P. R. China, wuhuayi@whu.edu.cn

Abstract

Significant computation challenges occur when agent-based models (ABMs) become extensively complicated and dynamic observation data are as part of the input of the model. For example, best route is subject to change on the run while dynamic traffic information of the road network is considered. More accurate simulation results with less computing time are desirable. Here are two fundamental problems for this computation: 1) How to integrate near real-time observation data into spatial-explicit ABMs effectively? 2) How to address the problem of massive data storage and intensive computing demand?

A distributed dynamic-data driven simulation and analysis system (4D-SAS) was proposed for massive spatial agent-based modeling to support real-time representation and analysis of geospatial phenomena. 4D-SAS consists of three components: distributed spatiotemporal database (DiSTDB), distributed ABM simulation engine (DiSIME), and visualization & online analysis UI (VAUI). The DiSTDB adopts an object-oriented spatiotemporal data model to support real-time observations data warehousing through powerful streaming channels, which is the foundation for DiSIME to query up-to-date information to update agent context. The DiSIME employs high performance computing to improve simulation performance. It can automatically decompose simulation tasks and distributes them among computing nodes following two common schemes: order division or spatial decomposition. The VAUI was developed to help clients understand model execution and model outputs efficiently, including animated display, spatial-temporal statistics tools.

Two ABM examples, an en-route choice model and a forest fire propagation model, were created on 4D-SAS to evaluate the system's efficiency and scalability. Simulation results illustrate that 4D-SAS provides an efficient platform for dynamic data-driven geospatial modeling, e.g. both discrete multi-agent simulation and grid-based cellular automata, demonstrating efficient support for massive parallel simulation.

Improving Computation Efficiency of Geospatial Modeling Forest Landscape Change at Regional Scales

Hong S. He

School of Natural Resources, University of Missouri, Columbia, MO 65211, U.S.A., heh@missouri.edu

Abstract

Geospatial modeling has benefited greatly from ongoing advances of computer technology and software engineering. However, computer memory overhead and run time efficiency are primary limiting factors when applying spatially explicit forest landscape models (FLMs) to simulate large region with fine spatial resolutions. We introduce LANDIS PRO, a landscape model that simulates forest succession and disturbances on a wide range of spatial and temporal scales. LANDIS PRO improves on existing FLMs with new data structures and algorithms (hash table and run-length compression). The innovative computer design enables LANDIS PRO to simulate very large (>200 million ha) landscapes with a 100-m spatial resolution, which to our knowledge no other raster forest landscape models can do. We demonstrate model behavior and performance through applications in the U.S. Central Hardwoods. The simulation results showed significant and variable effects of changing spatial extent on simulated forest succession patterns. Results highlighted the utility of a model like LANDIS PRO that is capable of efficiently simulating large landscapes and scaling up forest landscape processes to a common regional scale of analysis. The programming methodology presented here may significantly advance the development of next generation of forest landscape models.

Landscape Builder: Software for the Creation of Initial Landscapes for LANDIS

William D. Dijak¹, Stephen Shifley¹, Hong S. He², Wenjuan Wang², Frank R. Thompson III¹

¹ USDA Forest Service, Northern Research Station, Columbia, MO, 65211, USA, wdijak@fs.fed.us

² School of Natural Resources, University of Missouri, Columbia, MO, 65211, USA

Abstract

Landscape Builder is used to create spatially explicit landscapes as starting conditions for LANDIS Pro 7.0 and LANDIS II landscape forest simulation models from classified satellite imagery and Forest Inventory and Analysis (FIA) data collected over multiple years. LANDIS Pro and LANDIS II models project future forest landscapes by simulating tree growth, tree species succession, disease, insects, fire, wind, and management disturbance. Landscape Builder uses inventory plot attributes from the FIA inventory database, FIA unit map, National Forest type map, National Forest size class map, land cover map, and landform map to assign FIA plot attributes to raster pixels representing a real forest landscape. In addition to creating a detailed map of current (initial) forest landscape conditions, the software produces specific files required for use in LANDIS Pro 7.0 or LANDIS II format. By restructuring forest inventory plot data sets, the software can be used to create initial forest maps and associated files for other countries. Other tools include the ability to create a dominant species and age-class map from previously created LANDIS maps, a tool to create a dominant species and age-class map from a stand map and field plot data, and a tool to convert between Esri ascii rasters and Erdas file format types. The program is stand-alone software with a user friendly interface written in Visual Basic and Ansi C and is available as a free download.

Real-time Parallelization of Spatial Interaction ABMs with High Velocity of Spatial Big Data

Zhaoya Gong¹, Jean-Claude Thill²

¹University of Birmingham, United Kingdom

²University of North Carolina at Charlotte, United States, Jean-Claude.Thill@uncc.edu

Abstract

Spatial interactions are omnipresent in a wide range of geographic phenomena from individual communication and information exchange to transportation flows and human migration at a more aggregated level, and from trading between regions and countries on the earth to the gravitational interaction between celestial bodies at the largest scale. Agent-based models (ABMs) are well suited to capture the complexity of spatial interaction systems, because they characterize the spatiotemporal dynamics of global patterns emerged from local processes involving spatially distributed entities and the feedbacks of global emergent to the development of local interactions. Previous research has been dedicated to improving the scalability of spatial ABMs fed with big spatial data by taking advantage of various parallel computing resources in the emerging cyberinfrastructure (Gong et al., 2013; Gong et al., 2015). Specifically, the special parallel paradigm of Non-Uniform Memory Access (NUMA) has been proposed to tackle the uneven distribution of computing overhead due to the heterogeneous patterns of spatial interactions. The known structure and its constancy of interaction patterns is presumed, so that the optimized decomposition and allocation of spatial domains across computing resources can be performed to minimize the data access cost and enhance scalability. However, big spatial data feature not only large data volumes but also high velocity, such as real-time traffic information, meaning that data streams come in so fast with ever-changing patterns that are almost impossible to be predicted. This new challenge points out the deficiency of existing parallelization paradigms or approaches whose performance gain stems from determining the optimal parallelization strategy given an interaction pattern; yet, it cannot keep up with the pace of pattern change of incoming data. In this study, we propose to employ a new many-core co-processing platform, Many Integrated Core (MIC) coprocessors, to resolve the real-time parallelization of spatial interaction ABMs with high velocity of spatial big data. The MIC platform provides dedicated enhancement for non-homogenous data access patterns without the interference of external optimization strategies for data access cost. This allows the external parallelization strategy to focus on domain decomposition and load balance. By comparing the proposed paradigm applied to an ABM of spatial interactions with the previous NUMA paradigm, we demonstrate the superiority of the MIC platform over others with respect to the scalability of parallel processing of real-time spatial interaction data.

Toward Easier Geographic Computing using the Parallel Cartographic Modeling

Language

Eric Shook

Department of Geography, Environment, and Society, University of Minnesota, eshook@umn.edu

Abstract

Leveraging cloud and high-performance computing (HPC) environments for geospatial information processing is challenging. Geographers and geographic information scientists (GIScientists) must gain deep understanding of both parallel computation and geospatial analytics to develop effective parallel methods that balance computational workloads amongst multiple processing cores and handle big spatial data. Eliminating the need for deep understanding of parallel computation will make it easier for GIScientists to exploit these computational environments leading to advances in geocomputation and new scientific discoveries. To achieve this goal, a new domain-specific language is established called the Parallel Cartographic Modeling Language (PCML), which is designed to be easy to use, easy to develop, and scalable for handling big spatial data. PCML extends the well-known Cartographic Modeling Framework to make it easy for GIScientists to use. PCML is developed in the Python programming language to make it easy to develop new methods. PCML supports automatic parallelization to enable scalable geographic information processing without requiring deep understanding of parallel computation. This paper will discuss how PCML achieves automatic parallelization through the use of a novel methodology for parallelizing spatial data processing called parallel cartographic modeling. Using several examples ranging from processing spatially-explicit social media data to digital elevation models, the paper highlights current challenges and potential opportunities in leveraging HPC from both parallel computing and geospatial analytics perspectives with specific focus on usability and automatic parallelization for geographic information processing.

A Method of High Resolution Urban Region Remote Sensing Image Segmentation

Zhu S, Li SD, Yang RH

College of Earth Sciences, Chengdu University of Technology, Chengdu, 610059, P.R. China,
563745108@qq.com

Abstract

Sustainable urban development is the fundamental guarantee for the sustainable development of human society. With the popularization and cutting-edge researches of high resolution (HR) remote sensing image and its application, HR image is gradually and widely employed in urban planning and construction which contribute to sustainable urban development. Taking diversity and complexity of HR image, especially urban region into consideration, as well as advance in image resolution resulting in more abundant surface feature details and diverse scale processing requirements, a new method was design to split HR urban region remote sensing image. The new method integrated region growing algorithm with Gray-Level Co-occurrence Matrix (GLCM) from the perspective of multiscale. To improve original growing principle, it calculated GLCM and corresponding texture statistical features of R, G and B bands respectively then adopted their average values. To acquire global and local information of the image, it employed multiscale segmentation idea that assigned a proper scale parameter described by pixel and texture feature values to various ground objects like buildings and green areas to achieve a better division. The experimental result manifested the usage of RGB image GLCM and its statistical features rather than homogeneous gray level information as growing criterion raised splitting accuracy and precision in region growing process. Moreover, scale parameter was propitious to abstract diverse urban features with distinct spatial and spectral dimensions.

Key words:

Analyzing Sustainable Cities by Comparing Two Chinese Experiences: Beijing versus Changsha

Qiu Li, Ma Xiao.

Hunan University, Changsha, 410082, P.R.China, 1522083733@qq.com

Abstract

Generally speaking, a sustainable city is an eco-friendly, balanced and intensive human settlement. Nowadays, many cities have taken initiatives to achieve more sustainable development or to become sustainable cities. However, no standard definition of sustainable city is widely accepted and few efforts have been made to actually measure achievements in these so-called sustainable cities. This paper adopts seven sustainable cities' dimensions to definite what sustainable cities are. The methodology is based on an over view of these dimensions though reviewing different reference of sustainable city index and analysis the data via OURSUS project which is a data base has collected possible open access knowledge of the two cities by volunteers' devotion. And then describe the degree of Beijing and Changsha's sustainable development, using these dimensions and analysis. The study concludes that Beijing and Changsha are making great changes towards sustainable development but they often focus on only a few dimensions of the development. Based on data and text collected from the two cities, we can analyze and learn from these experiences for developing the sustainable cities of the future. Meanwhile, both of them face some unsettled problems and should be constructed on the basis of its weak points to achieve healthier and optimum development.

Evolution of Spatio-temporal Association Structure of Urban Coordination Degree in Shaanxi Province

Jinhui JIA

College of Tourism and Environmental, Shaanxi Normal University, Xi'an 710062, P. R. China, 568866379@qq.com

Abstract

This paper selects Shaanxi Province as empirical area, uses each county of Shaanxi Province statistical data, based on a comprehensive coordination index system of town development which has four parameters of population, economy land, society, through entropy method, integrated comprehensive evaluating, spatio-temporal autocorrelation techniques and Arcgis spatial analysis methods, uses four time sections (from 2000, 2005, 2010, 2015), study the spatio-temporal association structure and evolution of county coordination degree. There are some conclusions about this paper: ①The coordinate index in cities and towns of Shaanxi Province is on the rise and coordination of regional difference is larger. Its space distribution is related to the Shaanxi three geographic area; ②The distribution difference and its change of local spatio-temporal association types of county potential are obvious. The spatio-temporal HH type units are larger and begin to appear new Spatio-temporal LL type units. The spatio-temporal heterogeneity area changes significantly. ③Economic development level, people's income level and urbanization level are the important reasons for the coordinated development of Shaanxi towns. And the low utility efficiency of urban land resources and unreasonable industrial structure are the key factors restricting the coordination development of Shaanxi towns.

coordination degree; spatio-temporal autocorrelation ; spatio-temporal association structure; Shaanxi Province

From Fragmental Knowledge to Integrated Issues in Sustainable Development Communication

--Rethinking the Popularization of Science for Geographers

Qiu Li¹, Ton Dietz.²

¹Hunan University, P.R.China, 78486190@qq.com

²Leiden University, the Netherlands

Abstract

Sustainable development (SD) communication is one of the most important elements in general education, which helps to construct sustainability cognition and ecological behavior in being a sustainable society. With the rapid development of internet communication technology, such as we-media, blog, internet publication, more and more SD knowledge are produced by different individuals or agencies. It is possible for the public to accept massive knowledge in understanding the reality, changing cognitions and devoting actions for free or low cost. While in the fact, most of the open SD knowledge is fragmented into different pieces because of its diversification and flooded under the internet by other more attractive information such as entertainment or shock news. The public are limited to benefit from the open access and be cultivated into public awareness of SD. To solve this problem, some nonprofit organizations are attempting to build up platforms to attract experts and volunteers to share SD knowledge and do the popularization of science; some pioneer governments from the top to bottom way to collect SD knowledge and build up experts' network or sustainable cities network. All the attempts are helpful for the public to get the holistic view of SD and construct understanding by themselves.

The geography discipline covers or contains most sustainability issues, and geographer is the natural General Educator to sustainable development. International Geography Union (IGU) as the biggest organization of geographers has its mission to fulfill the responsibility in improving the depth and breadth of the popularization of science in sustainable development. Since 2012, during the 32th international congress in Cologne, IGU committee reached a consensus to try a platform named OURSUS in the brief meaning of Our Sustainable Society, with two websites named OURSUS.org in English and oursus.org.cn in Chinese, purposing on mobilization of knowledge-sharing from geographers and help them to integrate knowledge into different issues to assist general education or popularization. To obtain the purpose, we have continued experiencing on system design, open data collecting and testing based on volunteers' devotion. Until now, we have built up a functional system and collected thousands of articles from open access and produced 120 'special issues' of SD. We invited 20 undergraduate volunteers who are very interested in sustainable development to evaluate the issues. The research results showed that the platform is very strong with helping users (might be geographers) to collecting interesting SD knowledge by individual tags and producing structure knowledge blocks by making 'special issues'. We believe that if geographers would use this platform to learn by themselves, prepare lessons or popular science, it will exert a great effect in SD communication and education.

Wageningen University, Land Use Planning, Wageningen, PB 9101, 6700 HB Wageningen, lianne.hulsebosch@wur.nl
University Of Amsterdam, Centre for Urban Studies, Amsterdam, PO Box 15629, 1001 NC Amsterdam

Abstract

The strive for higher levels of urban sustainability constitutes one of the most important priorities for city administrations, politicians and citizens all over the world. At the local level of individual cities multiple initiatives are taken place. The chosen approaches vary considerably between cities, due to, among others, geographical and cultural settings, governance issues, funding and network possibilities. As such, developers of sustainable city initiatives can learn much from other experiences elsewhere or within the same context. This makes the exchange of information about achievements, challenges, and failures highly desirable.

This paper focuses on Amsterdam, the Netherlands. In Amsterdam there are many actors involved in developing sustainable initiatives, such as the Amsterdam Investment Fund (municipality), the Urban Cycling Institute (University of Amsterdam) and the Dakdokters (Private sector). Initiatives such as these require time, funds and energy for developing, exploring, learning, implementation and improvement. In this paper, we search how developers can learn from other experiences elsewhere or within the same context. Collecting and sharing information on successful or less successful cases and understanding of communication within and across disciplines is therefore crucial. In addition the paper aims to search for strengthening the links between various Amsterdam-based actors in the field of urban sustainability, including the municipality, private commercial sector, informal non-profit initiatives and academia.

Abstract

As Mobile Internet, cloud computing and virtual social network are becoming more and more popular in the cities at all levels and even in rural areas, the sharing economy has gained widespread attention around the world. Also, it was included in the 13th Five Year Plan put forward by the Chinese Government. Sharing Economy is based on the idea of using rather than possession. It takes full advantage of the market platform established by the third-party to integrate idle resources. And then it provides customers in need with these resources at a cost, by which it allocates resources evenly and improves the use efficiency of assets, skills, time, etc. The process of China's urbanization has seen the allocation of resources excessive concentration, environmental resources bearing capacity, unbalanced regional development and other issues. Thus, Chinese new-type urbanization was put forward as a mode of urbanization to solve these problems. The sharing economy has exerted significant enlightenment on Chinese new-type urbanization in all aspects. By improving the resource sharing and collaborative efficiency in the process of China's urbanization through sharing economy, traditional thinking and mode of economic growth can be changed, stimulating domestic demand. Moreover, it can promote business innovation and tertiary industry development, improve the urban and rural residents' quality of life, promote the coordinated development of regional economy, save resources and reduce energy consumption and optimize the structure of labour force. Besides, the extension of sharing economy can provide fresh ideas for urban planning and management.

Key words:

sharing economy; Chinese new-type urbanization; sustainable development;

Solar Is the Way –Directions for Future Ready India

Arya, J. M., JagMohan, A.M.

Dyal Singh College, University of Delhi, New Delhi. INDIA.110003, dr.anjanageog@gmail.com

Abstract

According to the International Energy Agency India will add between 600 GW to 1,200 GW of additional new power generation capacity before 2050. The technologies and fuel sources India adopts, as it adds this electricity generation capacity, may make significant impact to global resource usage and environmental issues. Traditionally electricity in India has been produced using coal. Smoke from thermal power plants and from burning of fuelwood, agricultural waste and biomass cakes for cooking and general heating needs by the poor households releases high levels of smoke, PM10 particulate matter, NOX, SOX, PAHs, polyaromatics, formaldehyde, carbon monoxide and other air pollutants into the atmosphere. Solar electricity sector may help find a sustainable alternative to traditional fuel burning, requiring zero input and one time investment in equipment. According to WHO, 300,000 to 400,000 people in India die of indoor air pollution and carbon monoxide poisoning every year. Fuel burning releases pollutants 5 to 15 times higher than industrial combustion of coal, thereby affecting outdoor air quality, haze and smog, chronic health problems, damage to forests, ecosystems and global climate. Burning of biomass and firewood will not stop, unless electricity or clean burning fuel and combustion technologies become reliably available and widely adopted in rural and urban India. A Solar City aims at minimum 10% reduction in projected demand of conventional energy at the end of five years, through a combination of enhancing supply from renewable energy sources in the city and energy efficiency measures. The basic aim is to make residents adopt renewable energy technologies and energy efficiency measures in their daily lives- for cooking, water heating, running electrical gadgets etc. In a Solar City all types of renewable energy based projects using solar, wind, biomass, small hydro, waste to energy are installed and supplied to the local population. 48 Cities are being presently developed into solar cities. Zero production of thermal power is sure to lower the air pollution levels. Solar cities are the cheapest and smartest solution for sustainable green energy development of urban areas in developing countries in the energy deficient future.

A survey of the households using solar power to light their homes bring forth interesting facts: the people using solar power naturally become more sensitive towards environment, the carbon footprint of such cities decreases naturally; people become more inclined towards adoption of eco-friendly technology like LED etc.

Key words:

energy efficiency; solar city; green energy

Strategies to Improve the Urban Sustainability: Case Studies from Germany

Soyez, D.

University of Cologne/Germany, Institute of Geography, Albertus-Magnus-Platz, D-50923 Köln, Germany, d.soyez@uni-koeln.de

Abstract

'Sustainable City' has become a buzzword in Germany as in many other countries, thus possibly serving more to hide what the strategies and the objectives are actually about than providing valuable explanations. A closer look into what is going on in different fields, however, is intended to be enlightening for observers from abroad.

The aim of the paper is to present paradigmatic achievements and issues at three levels in Germany: (1) Department level geographical research at the cutting edge of sustainability with examples from urban and periurban agriculture in Germany and Africa; (2) City level themes and issues from one of Germany's 'green model cities', where urban sustainability projects have become touristic 'sustainability destinations' for researchers, bureaucrats and practitioners from all over the world, and, finally, (3) National association level joint endeavours to create forms of interaction and experience exchange between hundreds of German cities and towns.

Urban sustainability strategies; German case studies

Sustainable City Initiatives in Africa: An Exploration and Comparison with the OURSUS Approach

Ton Dietz

Chair of the IGU Special Project Team for Our Sustainable Cities (OURSUS), director of the African Studies Centre Leiden, The Netherlands, dietzaj@asc.leidenuniv.nl

Abstract

Africa's cities have grown very fast. In 1960, during a period when most African countries became Independent, Africa's urban population was just 20%: 65 million out of the Continent's 325 million inhabitants. Currently the urban population has grown to almost 500 million out of 1.2 billion, and soon more than half of Africa's population will be living in cities, and many among them in metropolises of more than one million inhabitants. Demographic predictions show a rapid further growth and it is not unlikely that Africa in 2050 will have 1.2 billion urban people, out of its expected 2 to 2.4 billion. Many African cities can be found along its coasts, and in other vulnerable places. Africa's cities cope with huge demands and challenges, with many unplanned residential areas, and many dangerous working and living conditions. Coping with climate change is only one of their problems. However, also African cities try to be or become 'green cities', and promote changes in urban design and lifestyles that try to become more sustainable. In this paper the results of an exploration will be presented, based on information on websites and digitally available scientific and other types of publications. Special attention will be given to the African Green City Index (by the Economist Intelligence Unit, sponsored by Siemens), and its approach will be compared with the OURSUS approach, developed under the umbrella of IGU.

Key words:

sustainable cities; oursus; Africa

Sustainable Development Projects in the City of Riyadh, Saudi Arabia

Makki, M S,

The Saudi Geographical Society, P.O. Box 2456, Riyadh 11452, Saudi Arabia, sgs@ksu.edu.sa

Abstract

The paper attempts to consolidate the architectural heritage in the Kingdom of Saudi Arabia by giving examples of the components of urban civilization dating back to ancient times, then move to the gaps and discontinuity between the authenticity of this heritage and urban updated strange combinations on the local environment and that created some disharmony in cities components. There is an attempt to identify the causes of this disharmony.

This paper also exposed to modern efforts formal and informal to create a kind of harmony in the cities combinations by undertaking several policies to maintain the architectural heritage. In spite of these efforts, it seems that there is a lot of work required to achieve balance in the urban growth that combines conservative and modernity for the benefit of human and place.

Saudi Arabia; heritage; development; tourism

Evaluation on Construction Land Intensive Use in Guangzhou City

Dafang WU, Jialiang ZHONG

School of Geographical Sciences, Guangzhou University, Guangzhou 510006

Abstract

China is one of the countries which of land resources is shortly and urban construction land are used extensively and inefficiently in the preliminary stages of the urbanization process. Taking the central urban area of Guangzhou City as an example, this text use an evaluation index system of land intensive use, which is reasonable, and can be easily manipulated, to evaluate the level of land for urban construction use. Meanwhile, evaluate the construction land in city quantitatively, and communicate its intensity and potential by the software such as ERDAS2010, SPSS and so on. Finally, combined with the actual situation in Guangzhou city , put forward that the ways to promote land intensive use.

Key words:

construction land; evaluation of land intensive use; Guangzhou city

The Political Geography of Urban Sustainability

Mamadouh, V.¹, Yamazaki, T.²

¹University of Amsterdam, The Netherlands, v.d.mamadouh@uva.nl

²Osaka City University, Japan

Abstract

Political geography can shed lights on the politics of urban sustainability. We'll discuss three domains. First political geography can help analyse the dynamics of local government. It should be stressed that this is not limited to the study of how a local government 'governs' a locality but that it also included research into the ways cities are involved in (multiscalar) networks of governance in many guises: cooperation between local governments in an agglomeration, policy networks between local and supralocal governments, regional and national governments and beyond with the European Union and international organisations such as the UN, as well as urban networks (i.e. networks of cities) over great distance and across state borders. Second political geography can help analyse grassroots actions engaged with sustainability issues. Finally in the subfield of critical geopolitics, it can help analyse and question the geographical imaginations and geopolitical representations of sustainability, including main threats and opportunities, key actors (state and non-state), and preferred strategies. A better understanding of the different facets of the politics of urban sustainability is necessary to enhance the circulation of (new) knowledge and (innovative) practices to create, maintain and improve sustainable cities.

Key words:

urban sustainability; political geography; critical geography

Agricultural Development Pattern and Research Cooperation Mode along ‘The Belt, the Road’ Region

Fujia Li

The Institute of Geographic Sciences and Natural Resources Research, China, lifujia2003@163.com

Abstract

‘The Belt, the Road’ region, is connecting Europe, Asia and Africa, the route area of it with vast area and complicated ecological environment, which have rich agricultural resources and agricultural countries. Strengthening the agricultural cooperation of countries in ‘the Belt, the Road’ region can promote trade and the optimal allocation of production factors, which is great significance to the world food security, to social stability and economic development. But in recent, the studies are less on the time-space distribution of agricultural resources of the Belt, the Road Initiative, on international agricultural products trade, on the difficult situation of agricultural development in countries, on exploring the main demand of international agricultural cooperation, which is enough far from to provide support of science and technology, with strategic consulting for countries developing the future large-scale agricultural cooperation in the Belt, the Road Initiative.

Therefore, this study promote innovation mode and related policy for green agricultural cooperation in the Belt, the Road Initiative, with approach of advanced applicable technology, equipment and exports as the way, with gripper ‘high-tech’ green agriculture parks, with organizational mechanism of ‘international cooperation and development of national alliance for a green agriculture in the Belt, the Road Initiative’, which is based on the spatial pattern of national agricultural resources, advantages and difficulties of agricultural development, agricultural bilateral trade situation of cooperation for Chinese and major agricultural countries. The suggestion have strong theory value and realistic significance to promote optimal allocation of agricultural resources, to the discussing, sharing and building cooperation, to promote sustainable of economic and social development in the Belt, the Road region.

Key words:

‘The Belt, the Road’; agriculture; cooperation

Data Sharing and Collaborative Innovation Information Network Platform in OBOR Area

WANG Juanle, SUN Jiulin

Institute of Geographic Sciences and Nature Resources Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, wangjl@igsnr.ac.cn

Abstract

One Belt and One Road (OBOR) area is involved in many countries, with large amount of population, unbalanced economy development level, fragile ecological environment, and diverse cultures. Under the dual stresses of environmental change and human activities, OBOR faces a series of challenges, like global change, ecological deterioration, energy crisis, poverty, etc. Thus, it does need the decision support for the regional sustainable development. Data is the blood of research. Geo-science data sharing will contribute to the research and collaborative innovation in resource and environment field. The international scientist alliance of OBOR is ready for initiating to providing a platform for geo-data sharing and innovation generation. Universal standard system and data sharing mechanism was designed firstly. Second, huge geo-science data were accumulated in the alliance. These background data indicators included geographic location, administration division, landforms, soil, climate, lake and river, water resource, land resource, biology resource, mineral resource, tourist resource, nationality and religions, economy and social development, etc. Lots of science expedition data in the area were integrated in the platform as well, including Mongolia plateau land cover change and aridification monitoring, water resources and environment situation in Selenga river basin, etc. Third, a prototype of collaborative innovation information network platform is developed. One of the main purposes of this platform is to push the think tank development and support the decision of stakeholders along OBOR.

Key words:

One Belt & One Road; data sharing; scientist alliance; collaborative innovation platform

Development Patterns and Countermeasures of the Construction of the Silk Road International Ecotourism Zone

Dong SC¹, Zhao MY^{1,2,3,*}, Guo P⁴, Li Y¹, Li ZH¹

¹Institute of Geographic and Natural Resources Research, Beijing, 100101, P. R. China,

³University of Chinese Academy of Sciences, Beijing, 100101, P. R. China

⁴National Tourism Administration, Beijing 100740, P. R. China

Abstract

The international tourism cooperation of Silk Road began in the 90's of the last century, and strengthening tourism cooperation and expanding the scale of tourism has become the highlights of the cooperation of the "One Belt One Road " strategy. The Silk Road international ecotourism zone based on natural and cultural ecotourism resources, even point into line strung along the Silk Road International Eco tourism area network, and develops green industries which forest ecotourism as the leading factor. These will not only to promote the overall development of tourism resources, but also can solve the dilemma of ecological fragmentation and economic backwardness. Implementation of ecological civilization tourism model and comprehensive tourism model will realize the overall goal which constructs of two point four belts seven areas, and will become a new growth of strategic leading industry, will promote China's forest ecological economy and tourism industry transformation and upgrading strategy.

Silk Road; international ecotourism zone; green industry

Ecological-economical Estimation of Ecosystem Services Demand in Baikal Region

A. Mikheeva

Baikal Institute of Nature Management, Siberian Branch, Russian Academy of Sciences, Russia,
asmiheeva@binm.bscnet.ru

Abstract

For the Baikal region an integrated assessment of ecosystem services is due to the need to substantiate recommendations on improving environmental management, to put in place infrastructure facilities, construction of industrial complexes and tourist and recreational zones.

Currently, in the Baikal Lake region, important ecosystem services, for which markets are created, are the services to ensure high quality water, timber and non-timber forest products, biodiversity conservation and the services associated with the aesthetic properties of landscapes.

The main economic instruments are environmental fees for the maintenance of ecosystem services, which are charged with economic entities for the use of natural resources and provision of the negative impact on the environment. However, the collection of payments for ecosystem services is limited and predominantly associated with higher rates of water tax and fees for use of water bodies located in the basin of Lake Baikal.

The assessment of demand for water services has revealed a consistently high level of needs and peculiarities of the market, due to the observance of standards of maximum permissible harmful effects on the ecological system of Lake Baikal, and also showed the structural features of formation of cost and tariff rates for the enterprises of the regions under consideration.

The calculations showed that the highest valuation of ecosystem services is for biological resources, which is due to the implementation of the most important habitat-forming and security functions.

Environmental Vulnerabilities and Their Adaptation Strategies in Mongolia

Qinxue WANG¹, Masataka WATANABE², Ochirbat BATKHISHIG³

¹Center for Regional Environmental Research, National Institute for Environmental Studies, Japan, wangqx@nies.go.jp

³Institute of Geography, Mongolian Academy of Sciences, Mongolia

Abstract

Because a significant part of the country's population depends on climate-dependent sectors for livelihood, especially on pastoral livestock husbandry, Mongolia is one of the countries vulnerable to climate change. The objective of this study is to evaluate the vulnerabilities of ecosystems caused by climate change in Mongolia and put out some proposals on climate change adaptation strategies. The historical records show that the average annual temperature of Mongolia increased by 2.1°C since 1940. However, annual precipitation has decreased. Model results predict that further warming will continue if emissions of greenhouse gases continue. Area averaged mean annual temperature and precipitation of Mongolia predicted by five CMIP5 models (MIROC-ESM of Japan, NCAR-CCSM4 and NOAA-GFDL-CM3 of USA, BCC-CSM1.1 of China and MPI-M-ECHAM6 of Germany) from 2006 to 2100 shows a gradual increasing trend in both temperature and precipitation. Another significant feature is that climate system will become more and more unstable. This might indicate that the inter-annual variability of precipitation might be increasing, and the intensity of extreme event (drought, dzud, flood and heat wave duration) might be strengthened in the future.

Our research shows that Mongolia's fragile steppe ecosystems are being affected not only by rapid warming, but also by increased grazing pressures from livestock husbandry. Meanwhile, various sectors can also contribute to climate change, for example, loss of vegetation cover means a decreased absorption of CO₂. Mining sectors, livestock husbandry and arable farming synergistically affect land use and land cover, and further deteriorating habitat quality, land productivity and ecosystem services. Our research also shows that different geographic regions are burdened with different sets of risks. Usually, this country was divided into five regions: Western, Khangai, Central, Eastern and Ulaanbaatar. Water-related changes associated with climate change will affect people in the arid and semi-arid regions more than Khangai region. Arable farming is limited to north central regions in Mongolia, which will be stressed by water shortage due to the increase of evapotranspiration. Desertification is the most important challenge in southern regions and surrounding areas of Ulaanbaatar City. Northern part of the country is vulnerable to permafrost melt because increased depth of thawing with its seasonal thaw-and-freeze cycle affects structural integrity of infrastructures.

To against these climate-related risks, we put out some strategies for climate change adaptation as follows:

- 1) To improve the monitoring capacity of climate and strengthen the early warning system with regard to extreme climatic events and weather conditions.
- 2) To improve the construction technologies to withstand permafrost melting, because the increased seasonal thawing depth (active layer) of permafrost makes a challenge to build a basic infrastructure in northern areas of Mongolia.
- 3) To train herders to keep suitable livestock number according to local grassland productivity. Alternative means, such as more productive livestock breeds, apiculture or orchard business should be explored.
- 4) To formulate legislative baseline (perhaps using a tax-based approach) to regulate pasture use and arable farming management. Grazing pressure will be disbursed with more water supplies for herders and livestock, thus creating more wells and water points in remote areas may decrease competition over pasture.
- 5) To develop and transfer more renewable energy technologies, such as the Film-solar Power System for Gel, Solar Powered Well Pump System, Permafrost Refrigeration System, may contribute to decreasing GHG, smog, and other pollutants are important for sustainable development and human health concerns.

Features and Prospects of Transborder Tourist Development in the Zone of Influence of the Silk Road and Tea Road

L.B.-ZH. Maksanova

Baikal Institute of Nature Management, Siberian Branch, Russian Academy of Sciences

lmaksanova@yandex.ru

Abstract

In modern conditions among the most important factors of international tourism development there is the implementation of cross-border tourism projects based on common historical, cultural and economic interests, and implemented under a single brand. The most significant international project is the "Silk Road", the implementation of which is being carried out for 20 years as part of the UNWTO Silk Road Programme for the 30 member states in Europe, Asia and the Middle East. In June, 2015 in Ufa at the tripartite meeting of the BRICS summit, the Russian President Vladimir Putin, the Chinese President Xi Jinping and the President of Mongolia Tsakhiagiin Elbegdorj noted the importance of international tourist route "The Great Tea Road" and supported a launch of a tourist train on this route.

The features and tendencies of the development of cross-border tourist routes unambiguously confirm that the tourist exchange between the peoples will never stop, and in matters of development we must take into account the characteristics that determine the current geopolitical and economic situation in the world and events in the international tourism market. In today's economic realities, "The Silk Road" and "The Great Tea Road", which are the longest transcontinental tourist routes, can be an effective tool in the context of co-development of "Belt and Road" new forms of international politics and economics.

In connection with this of high relevance are complex economic-geographical study of the processes of tourist development areas, the integration processes in the field of international tourism, the study of potential prospects and assessment of the impact of cross-border tourism projects and programs in the area of influence of the Great Silk Road and Great Tea Road.

Geographical Factors of Urbanization and Communicative Processes between Russia and China within the Area of Potential Impact of the Great Silk Road

Leonid Bezrukov

Sochava Institute of Geography SB RAS, Russia, bezrukov@irigs.irk.ru

Abstract

We generalized the experience of geographical study of urban settlement and, in particular, of urban agglomerations formation within the Eurasian transboundary area (Russia, China, Kazakhstan, Mongolia), which can become a zone of the Great Silk Road's influence. The comparative analysis of the urban settlements dynamics and of agglomerations of model territories in Asiatic Russia and northern China is performed against the background of urban changes in Russia and China. It is shown how agglomerations use the economy-wide benefits as a result of the general capital, labor, real estate, information and consumer goods markets.

From the transport and logistics point of view we analyzed the competitiveness of the main international rail corridors, designed to provide latitude transit traffic between East Asia and Western Europe. We consider the development of optimal interaction schemes of the Trans-Siberian Railway and the Northern Corridor of the Great Silk Road to be effective in order to maximize the reduction of transport costs and efficient maintenance of cargo flows in the enormous large Eurasian region. Both transport corridors should help to intensify transboundary economic co-operation between the related parts of Russia, China and Kazakhstan, which is a promising direction of weakening unfavorable consequences of their inland location. The paper materials have been obtained during the joint Chinese-Russian expedition, made in August 2015 in northern China and in September 2015 in the Irkutsk agglomeration (Russian Federation), on the subject "*Economic-geographical analysis of urban agglomerations of Russia and China under the formation of New Silk Road*" (Project RFBR 15-56-53037-GFEN_a (Russia) and the Project number in China)

Green Development Modes of “One Belt One Road” Initiative

Abstract

Chinese President Xi Jinping raised the initiative of jointly building the Silk Road Economic Belt and the 21st-Century Maritime Silk Road (hereinafter referred to as one Belt one Road) in 2013, which has been supported by over sixty governments and heads of countries in the world. This paper analyzed the patterns of resources, environment and economy of about one hundred countries along “one Belt one Road” through spatial analysis by GIS and regional horizontal comparison method, and depicted the rule of territorial differentiation of one Belt one Road, as well as the characteristics of resources, environment and economy. As far as resources are concerned, countries along the Silk Road have inherent advantages in resources cooperation and huge development potentialities in resources market, due to their geographical adjacent features, close historical relationship, and the areas of resources consumption are not coupled with that of production. It is showed obviously characteristics that ecological environment of the eastern and western part of one Belt one Road are in relatively higher quality and partial regions are heavily polluted, but the central part is drought and ecologically fragile, there being an remarkable feature of atmospheric pollutants transporting cross-border from Europe in the west to Asia in the east, throughout the whole areas, affected by westerly, as well as human activity and global climate change. Economic pattern can be depicted as "saddle", with high level in Europe and East Asia, but low in middle of one Belt one Road, showing that industries of these countries are highly complementary. Based on empirical analysis of the main scientific problems, the authors put forth green development frame work of one Road one Belt, including the modes of ecological civilization, circular economic development fitting to developing countries with Chinese characteristics and experiences, eco-city construction from six aspects, jointly building the international ecological tourism belt along silk road, and international collaboration in treating cross-border ecological environment problems, to coordinate the relationship between man and nature, enforce the capability of sustainable development and fulfill the green development goal, and provide a green development model for the other regions.

Key words:

Green Development Modes; One Belt One Road; Ecological Civilization and Circular Economy

Is there an Environmental Kuznets Curve for the Silk Road Economic Belt Countries?

Fei Li, Suocheng Dong

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, P. R. China, lf@igsnr.ac.cn

Abstract

The present study concentrates on the Silk Road Economic Belt countries and China context and attempts to explicitly examine the impacts of economic growth and urbanization on energy and CO₂ through investigation of the existence of an Environmental Kuznets Curve. Within the Stochastic Impacts by Regression on Population, Affluence and Technology framework, this is a fresh study to simultaneously explore the income/urbanization and energy/CO₂ nexus, using heterogeneous panel cointegration methods in this significant area. We find evidence in support of an inverted U-shaped curve relationship between economic growth and emissions, and examined the income and urbanization elasticity of energy consumption. These findings contribute to advancing the emerging consensus on the income/urbanization- energy/CO₂ nexus.

Environmental Kuznets Curve; Silk Road Economic Belt; China

Structure and Ecological Potential of Baikal part of Siberia's Geosystems

Igor Vladimirov

Sochava Institute of Geography SB RAS, garrison@irigs.irk.ru

Abstract

The Baikal part of Siberia is a complex region as regards its natural environment and landscape characteristics; it is endowed with immense reserves of various natural resources, the industrial development of which is steadily progressing, thus posing challenging ecological problems.

For assessing the ecological potential of geosystems, the landscape-typological map of the Baikal part of Siberia was generated. The classification of geosystems was carried out on the basis of the taxonomic system of hierarchical units of natural environment as developed in the Sochava Institute of Geography SB RAS. Cartographic analysis determined the most informative units of geosystems of regional dimension which made it possible to carry out a classification separation of the landscape structure of the Baikal part of Siberia.

The investigations into the ecological potential, the factors and the conditions having influence upon its formation used: SRTM data, WorldClim global climate data; data on Net Primary Production; Normalized Difference Vegetation Index, Enhanced Vegetation Index.

The main principles of GRID modeling and the Analytic Hierarchy Process technique were used to assess the ecological potential of the Baikal region's geosystems which made it possible to represent the set of natural conditions needed to satisfy the requirements of the population for all the necessary primary means (merely ecological, unassociated with production). The evidence obtained concerning the ecological potential provide a natural scientific basis for a reasonable regional ecological policy, an improvement of the population distribution pattern and the social sphere, a rational organization of labour and recreation, and for the protection of human health.

Key words:

Landscape structure; ecological potential; geosystem; SRTM; NDVI; Baikal; Siberia

The Great Silk Road: History, Problems and Prospects

Arnold Tulohonov

Member of the Federation Council of the Russian Federation, Corresponding Member of RAS, aktulohonov@binm.ru

Abstract

Traditionally, the Silk Road is regarded as a trade route linking commercial markets in Europe and Asia. Meanwhile, in the new conditions of globalization the Silk Road should be considered first of all as the contact zone between the two great civilizations of East and West, the three world religions: Buddhism, Christianity and Islam. At the same time this way is not the direct distance between two points of production and marketing. During the whole period of its existence there were natural and historical processes, which significantly changed the trade routes.

Given that the general population of the Great Steppe were nomadic people, whose economy was largely determined by the productivity of steppe landscapes, we can assume that migration, the emergence of new states have been linked to global climate change, droughts. This factor applies equally to the emergence of the empire of Genghis Khan, the resettlement of the Xiongnu, blossoming and fading of the Central Asian khanates.

In contemporary history a significant impact on the effectiveness of economic relations affect the geopolitical instability in the Middle East, South Asia, which covers practically the possibility of entering transport systems in the Indian Ocean. Moreover, the events in Nagorno-Karabakh, Kurdistan, Turkey can become a real barrier to trade routes through Asia Minor.

The development of the Silk Road infrastructure primarily involves the common interests of all countries located in its area. From this point of view, relatively little attention is paid to environmental problems. This primarily includes water supply areas. Moreover, the majority of these regions relates to the centers of agricultural production.

Meanwhile, there is a sparse river network which also crosses borders of the countries that have their own interests in the use of water resources. The Ural and the Irtysh relate to cross-border category. The Amu-Darya and the Syr-Darya have practically no effect on the level of the disappearing Aral Sea.

Therefore, one of the most important conditions for the effectiveness of the Silk Road is a balanced water policy of all neighboring countries.

Another specificity is the mountainous terrain in many countries of Central Asia, in China it was created by the latest tectonic processes. The disastrous earthquakes at the beginning of the last century in Bishkek (Frunze), Ashgabat in 1948, Tashkent in 1966 are still fresh in the memory of the population. According to the laws of seismicity after a certain seismopauzy these events should happen again. Meanwhile, seismic service in most of these countries is ineffective and requires restoration.

A fundamentally new transport system factor of the development along the Silk Road area is the construction of high-speed railways, the number of which is increasing especially rapidly in China.

Diversification of traffic while crossing many national borders requires the unification and standardization of customs and border regulations, which sometimes significantly hamper the development of transit. There is another problem with the fact that in the absence of state regulation, road, rail, pipeline and water transport even begin to compete with each other. Meanwhile, each of them has its own economic niche.

Global climate change, including the melting of polar ice opens up another opportunity for the cheapest maritime transport along the Northern Sea Route. At the same time the reduction of the ice cover in the ocean can significantly reduce the transportation time due to displacement of trade routes to the pole. According to the laws of spherical geometry, it is not only the shortest distance here, but also, large depths do not require pilot support. In addition, here in the international swimming area there is no need of registration of border documents.

Even this short list shows the complexity of the efficient use of the Silk Road and the need for scientific substantiation of the various options for its development.

The Infrastructure of the Russian-Mongolian Cross-Border Area

Batomunkuev V.S., Rygzynov T.Sh.

Baikal Institute of Nature Management SB RAS, Sakyanovoi st., 8, Ulan-Ude, Russia,
670047, bvalentins@yandex.ru

Abstract

The article deals with the infrastructure sector of the Russian-Mongolian cross-border area. Infrastructure of the two countries are essential to tell the system to the Russian-Mongolian transboundary cooperation. The peculiarities of the conditions of functioning and development of infrastructure facilities of the two countries. The level of infrastructure development of adjacent regions of Russia and Mongolia at the present stage is a reflection of the socio-economic and political processes taking place in the past two decades. Existing infrastructure stable relationship and the urgent need for the development of infrastructure facilities on both sides of the Russian-Mongolian border create the preconditions for a detailed study of the subject.

The findings based on comparable for the two countries quantitative indicators on the infrastructure of the two countries are the basis for zoning in terms of infrastructure development, taking into account environmental factors. Natural and infrastructure zoning of the Russian-Mongolian cross-border area will assess the level of infrastructure development, highlight the core, peripheral areas at the international level to develop effective schemes of spatial distribution of infrastructure, taking into account the physical and geographical conditions on the basis of ecologically and energy efficient technologies. Actualization of the information is aimed at creating a closer forms of cross-border cooperation, functional zones of advanced development or economic favor.

The accumulated material is the basis for the creation of a GIS system "infrastructure of the Russian-Mongolian cross-border area.

Key words:

infrastructure; border areas; the Russian-Mongolian cross-border area

The Prerequisites and Priorities of Increase of Competitiveness of Border Regions of Russia in the Conditions of Globalization and Integration

Khandazhapova L.M.

Baikal Institute of Nature Management SB RAS, Sakyanovoi st., 8, Ulan-Ude, Russia, 670047, kxanl@mail.ru

Abstract

The paper deals with the basic prerequisites and priorities of improving the competitiveness of the border regions of Russia in the conditions of globalization and integration. Particular attention is paid to issues of evaluation of the competitive advantages of the region in the conditions of activation of integration ties. The method of estimating the region's competitiveness is given.

There is the comparative analysis of the competitive advantages of the border regions of the Siberian Federal District on the basis of rating indicators of infrastructure development, the state of the business environment, human capital, the region's attractiveness for investment and living, readiness of the region to compete with other regions. The results showed that at the present time in the border regions the competitive advantages (proximity of the border, cross-border infrastructure, etc.) are not used. The factors of border regions complicate the economic situation in many regions.

The work proved the main directions of improving the competitiveness of the border regions of Russia for a strengthened role of the state in investment in transport logistics and social infrastructure through public-private partnership, the formation of the business environment, the formation of innovative environment. The paper assesses the economic security of border regions in the context of globalization.

The Problems and Prospects of Development of Green Economy in Border Regions of Russia.

Lubsanova N.B.

Baikal Institute of Nature Management SB RAS, Sakyanovoi st., 8, Ulan-Ude, Russia, 670047, natansonn@mail.ru

Abstract

The paper is devoted to the problems of development of the green economy in the border regions of Russia. The author believes that in the current economic conditions, the basic principles of the green economy - green taxation, promotion of ecological production, environmental infrastructure investments,- should be one of the main conditions for sustainable development of all regions of Russia. Particular attention is paid to the analysis of environmental and economic problems of the border regions. Border regions are different in many unresolved environmental and economic problems, including problems of transboundary water pollution, problems of waste production, as well as the low level of production technology.

The paper assesses the environmental safety of Russia's eastern regions. Estimation technique uses the following indicators: emissions from stationary sources, the number of vehicles, discharge of pollutants from sewage into water bodies, waste production and consumption.

The basis for improving environmental security worldwide are green technologies being introduced in the fields of energy, transport, construction, agriculture and waste management of production and consumption. This paper gives the results of calculations of innovative security of regions of Russia. The eco-innovations in Russia were aimed at reducing material costs for the production (53.6%), reduction of energy consumption (58.3%), the reduction of emissions in the atmosphere of carbon dioxide CO₂ (43.6%), the replacement of raw materials to a safe or less dangerous (44.1%), reduced pollution (83.7%), the implementation of recycling waste products (49.8). In the paper there is the critical analysis of the legal framework of stimulating environmental innovation in the regions of Russia, justified suggestions for changing this framework.

The Transformation of Substances in Adaptive Reactions of *Artemisia* Species Plants, Growing in the Countries along the "Belt and Road Initiative"

Radnaeva L.D.^{1,2}, Zhigzhitzhapova S.V.*^{1,2}, Zhang Faqi³, Shilong Chen³

³Northwest Institute of Plateau Biology, Chinese Academy of Sciences (CAS) Northwest Institute of Plateau Biology, Chinese Academy of Sciences, Xining, 810008, P. R. China

Abstract

We have jointly studied 15 species of the *genus Artemisia* plants growing on the territory of Russia and China. *Artemisia* L. (*Compositae*) is one of the largest and widely spread genus with more than 400 species. Species of the genus are herbs or small shrubs, with special organoleptic characteristics. Their species are used in traditional folk medicine, particularly for the treatment of malaria. They are mainly found in Asia, Europe and the North America (Mucciarelli & Maffei, 2002). About 186 species of the genus are widely spread in China, including 82 endemic species. *Artemisia hedinii* Ostenf. et Pauls is an annual herb, which grows in Qinghai-Tibetan Plateau (QTP), on altitude between 1000m to 4000m, extended to Kashmir and Tajikistan (Shi et al., 2011). In current study, for the first time we reported the composition of *A. hedinii* essential oil to provide more information for potential applications of *Artemisia* in QTP (Zhigzhitzhapova et al., 2014). *Artemisia vulgaris* is widely spread species. We analyzed the VOCs extracted from *A. vulgaris* using two different methods (hydrodistillation and headspace extraction) and tested the impact of climate of the regions where the plant grows on the composition of VOCs (Zhigzhitzhapova et al., 2016).

Key words:

Artemisia hedinii; *Artemisia vulgaris*, essential oil; chemical composition; chemotypes

The Transformation of the Natural Environment in the Tea Road Corridor

Garmaev Endon Zh.

Baikal Institute of Nature Management SB RAS, Sakyanovoi st., 8, Ulan-Ude, Russia, 670047, garend1@yandex.ru

Abstract

An analysis of the meteorological series of air temperature and precipitation in the whole Lake Baikal basin carried out that based on the initial data of meteorological stations and global geospatial meteorological database of Climate Research Unit – CRU (spatial resolution of 0.5×0.5 angle degree). A statistically significant trend of increasing temperature and decreasing rainfall was installed. Two humidification periods were allocated: the period 1980-1998 years – wet; 1999-2015 years – dry. The wet period is characterized by positive trends of precipitation totals for almost the whole lake Baikal basin, with the highest growth rate observed for ridge Khamar-Daban – 14 mm/yr, and the area of Middle Baikal – 10 mm/yr. There is a negative trend in the number of precipitation for Lake Baikal basin during the dry season 1998-2015 years. Extreme reduction in moisture is marked for ridge Khamar-Daban and makes -30 mm/yr. The rate of decline in basins of the Upper Angara and the Barguzin rivers reaches -18 mm/yr. At the long-term fluctuations of river flow rather the effects of precipitation than other elements of the water balance affect.

Thus, the average annual precipitation decreased by 41.4 mm, and the mean annual air temperature in the Selenga river basin increased by 2.29 °C (let us note that simultaneously the annual average temperature throughout the world increased by 1.2 °C) over the past 75 years. The increase in temperature is observed for the whole pool area of Lake Baikal, while areas with low growth of surface temperature rates are interspersed with areas with high growth rates, both in latitudinal and longitudinal directions.

According to gauging stations and dendroclimatic stations, a spatio-temporal reconstruction of river flow parameters in the Selenga river basin has spent. As a result, water flow model reconstruction of Selenga river and its tributaries – rivers Uda, Khilok, Chikoy, Dzida, Orkhon and Kharaa – was obtained. For individual watercourses the time-series until 1666 has been restored. This allowed to reveal regularities of moisture fluctuations in Baikal Asia in retrospect. The obtained statistical model reconstruction of runoff of Selenga river basin represents to 55% of the average annual flow variations.

The history and problems of regulating of the level of Lake Baikal were considered. The analysis of changes of water level, fluctuation range and useful inflow over the observation period (1898-2015) were carried out. In this study the main causes and effects of extreme water shortage in the basin of the lake in the 2014-2015

biennium are discussed.

The analysis of the inflow of water into the Baikal is made. The minimum and maximum water flows, the volume flow of major rivers of Lake Baikal basin were considered. The formation of water resources in the catchment area of Mongolia which accounts for 67 % of the watershed district Selenga was considered.

Land degradation and desertification processes are widespread in natural and economic territories of Russia and Mongolia. Over 85% of the Mongolian territory is located in dry climate zones: dry sub-humid, semiarid, arid, and extra-arid. The vegetation is the first experience the impact of desertification, and that's why investigation of its changes have a particular importance. Our research deals with vegetation dynamics of dry climatic zones of Russia and Mongolia from Landsat NDVI time series analysis (1989-2015) and field investigations. A number of model monitoring polygons has been established in different latitudinal zones of the Mongolian territory according to the longitudinal transect (105°-107° E, 51°-44° N). These polygons include a wide range of territories with dry climate conditions. This work revealed the main factors, agents, and trends of development for desertification processes in different climate zones. Almost the entire territory of the emphasized polygons of vegetation digression during this period is traced. At the present time in different climatic zones of Central Asia there are different trends of desertification processes are associated with both climatic fluctuations (mainly aridization) and anthropogenic impact.

The work is supported by the Russian Geographical Society, grant "The transformation of the natural environment of Transbaikalia and adjacent territories: a retrospective analysis and modern condition".

Comparative Analysis of Traffic CO₂ Emissions on Different Grades Urban Road at Different Time Scales

Ji Zheng^{1,2}, Yu Li^{1,2,*}, Suocheng Dong^{1,2}, Xueting Jin^{1,2}, Ding Li^{1,2}

¹Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing 100101

²University of Chinese Academy of Sciences, Beijing 100101

*liy@igsnrr.ac.cn

Abstract

Metropolises are the main area of global CO₂ emissions. Transportation is one of the most important metropolitan terminal CO₂ emission sources, and traffic CO₂ emissions will increase rapidly along with the dramatic economy development. Chinese government promised that by 2030 CO₂ emissions will reach peak and will reach peak as early as possible in the Paris Conference. In the face of the heavy CO₂ emission reducing pressure, urban road transportation has become an important aspect to achieve the low-carbon target. This paper takes two urban road sections of different degree, beltway-the 5th Ring Road and arterial roads intersection – Datun-Beichen intersection, in the Olympic Central Area, Beijing, China. Based on the KM model, define the estimate area of the two road sections. On the basis of the bottom-up method, use the localized MOVES model, the traffic volume video data collected in the field work and the visual interpretation statistical data of different vehicle types to estimate the traffic CO₂ emissions of the two case area for every 30 minutes in 2014. Meanwhile, this paper compares the change characteristics of the traffic CO₂ emissions of the two case area in at different time scales, and analyzes the traffic CO₂ emissions of the two case area in the condition of traffic volume control especially. The results show that the traffic CO₂ emissions of the 5th Ring Road case area and Datun-Beichen intersection area is 44391.51t and 4045.36t, respectively. The annual traffic CO₂ emissions of the 5th Ring Road case area are much higher than Datun-Beichen intersection area. At day and night scale, the traffic CO₂ emissions change trend of the two different grades urban road sections are both “trough-peak-trough-peak-trough” from 6:00am to 1:00am of the next day. There are differences on the start time and duration of the two peaks. The traffic CO₂ emissions change trend and the peak time of workday and weekends are significantly different. At month scale, the traffic CO₂ emissions of the two case areas both exhibit fluctuating uprising tendency from January to December in 2014. And the traffic CO₂ emission of February is the highest, while October is the lowest.

Current Situation and Suggestions to Promote Further Cooperation of Sino Russian Oil and Gas Cooperation

Yang Yang

Institute of Geographic Sciences and Natural Resources Research, CAS, China, feiyang199012@163.com

Abstract

Supply and demand condition of oil and gas resources in China and Russia have fundamentally determined the necessity to develop Sino Russian oil and gas cooperation; Long time bilateral cooperation and communication between China and Russia have laid certain political foundation for Sino Russian oil and gas cooperation, and has paved way for both countries; China and Russia's energy policies are highly complementary, which provides important opportunities for Sino Russian oil and gas cooperation; China and Russia are geographically adjacent, the favorable geographical conditions provides conveniences for carrying out cooperation; increasingly close cooperation of oil and gas between China and Central Asia, and upheavals in Ukraine are catalyst of Sino Russian oil and gas cooperation, which accelerates the cooperation process between the two countries. Developing Sino Russian oil and gas cooperation has great strategic significance to both of the two countries, it will reduce energy's external dependence of the two countries, reduce restraint of other countries to the two countries, improve energy security and furthermore guarantee national security. Up to now, China and Russia have signed a series of oil and gas cooperation agreement, which shows that the Sino Russian oil and gas cooperation has entered the fast lane, but it still faces many uncertain factors. To promote further Sino Russian oil and gas cooperation, following suggestions are given: standing on long-term and overall coordination, highlighting strategic perspective; deepen Sino-Russian Strategic and Cooperative Partnership, enhance political mutual trust; improve China and Russia's energy cooperation mechanism, establish energy security mechanism, reduce cooperation risk; strengthen policy communication, based on "the Belt and Road Initiative", deepen cooperation; improve China's energy price system, strengthen exploitation and utilization of domestic resources.

Key words:

Sino Russian oil and gas cooperation; strategic significance; mutual benefits; promote further cooperation

Informatization Patterns and Strategy of the Silk Road Economic Belt

Cheng Hao, Dong Suocheng, Guo Peng, Li Fujia, Li Yu, Li Zehong

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing

100101, China, chenghao0011@163.com

Abstract

“Silk Road Economic Belt” and “The 21st Century Marine Silk Road” are the major strategic concepts of China to build a new and sustainable international political and economic order, facing the complex and changeable international geopolitical economic patterns and against the global economic crisis. The wide range informatization covering Asia, Europe and Africa is the condition and basis for the strategy of “One Belt One Road”. Through the study of existing literature and data, the author researched the informatization infrastructure and trade development patterns of the countries along the silk road, analyzed the informatization develop patterns, proposed the strategic measures of information industry. It will provide reference for building a new informatization pattern to boost the construction of Silk Road Economic Belt.

Key words:

informatization; development patterns; development strategy and measures; Silk Road Economic Belt

Native Interpretation Attract Tourists Understanding Tibetan Conservation in Potatso National Park, China

Zhao MY, Dong SC, Wang YX, Li Y

Institute of Geographic Sciences and Natural Resources Research, Beijing, 100101, P. R. China,
Southwest Forestry University, Kunming, 650224, P. R. China, my.z@yeah.net

Abstract

Native interpretation connects regional resource, local people and tourist background. Most Tourists thought the native experience as their primary visiting purpose. Based on the investigation of interpretive resource and tourists, the research team proposes “native interpretation” in Potatso National Park which is the first national park in Yunnan’s Shangri-la County, China. It is located in one of the most biodiversity regions of the world. The local Tibetan people preserve natural fauna & flora in their ethnic value and approach. Eight treasures of Tibetan program provide tourists with opportunities to understand local natural conservation, through legends, ceremony, construction and ethic logo. The satisfaction of native interpretation was practical and dire able.

Key words:

Interpretation; Tourists Understanding; Tibetan Conservation; Potatso National Park

Study on China's Geopolitical Strategy Based on the Theory of Externality

Huilu YU, Suocheng DONG, Yu LI, Zehong LI, Fei LI, Fujia LI

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China,
yuhl.13b@igsnr.ac.cn

Abstract

Based on the review of present geopolitical theory, this paper analyzes the shortcomings of these theories which include too broad macroscopic perspective, lack of the foundation of international ethics, and considers that these theories cannot adapt the evolution trends and characteristics of international geopolitical pattern under the backdrop of globalization and cannot provide sufficient theoretical guidance for the formulation of China's geopolitical strategy. This paper puts forward the concept of externality geopolitical strategy, and considers that: in the era of globalization, country's geopolitical strategy would produce externality which will increase with increase of this country's scale and international influence. The minimization of minus externality, which should become the goal of optimization of geopolitical strategy, can help to realize the maximization of state's interests. Based on the guiding principle of minimization of minus externality, this paper analyzes the geopolitical strategies of hegemonic country and China, and summarizes some key issues to which China's geopolitical strategy should pay attention: firstly, strengthen systematic study of the geopolitical patterns of the world and China's surrounding areas in order to achieve the minimization of minus externality and maximization of state's interests. Secondly, respect America's interests and international status, strive to establish a new type of win-win relationship between two countries in which they can live in friendship and develop in parallel, strengthen official and folk communication in order to decrease the probability of conflict because of strategic miscalculation. Thirdly, enhance the right to speak in the field of working out international regulations, improve China's cultural soft power, and increase the number of levels of geopolitical system which is established in the leading role of China and the number of peripheral countries, but never pursue positive externality. Fourthly, learn from China's successful experiences of "crossing a river by feeling the way over the stones" of reform and opening up and construction of economic zones, increase the reserve of geopolitical policies, prepare sufficient emergency plan for future possible geopolitical crisis.

Key words:

geopolitical strategy; externality; minimization of minus externality; hegemonic country; emerging powers

The Infrastructure Resources of Development of Border Areas

Dagdanova S.Zh.

Baikal Institute of Nature Management SB RAS, Sakyanovoi st., 8, Ulan-Ude, Russia, 670047, selmegal@mail.ru

Abstract

The work deals with the basic problems of infrastructure development of border regions of Russia. Particular attention is paid to the study definition of infrastructure limitations and risks of economic development in the region. The international and interregional competition of markets for goods and services grows in modern conditions of the activation of integration processes in the society and in all sectors of the economy. A method for evaluating the effectiveness of the region's infrastructure is given. The method is based on the definition of the integral infrastructure indicators, including indicators of group transportation, communications, electricity, finance and credit, education, health, housing and communal services. It discovers that the most significant constraint on the economic development of the region is the lack of development of transport system, which has close links with all sectors of the economy and social sphere.

In the paper the conclusions need the improving regulatory mechanisms for financing, selection of infrastructure projects, monitoring of infrastructural constraints.

The Social Resources and Social Risks of Border Territories of Russia in New Economic Conditions

Dagbayeva S. D.-N.

Baikal Institute of Nature Management SB RAS, Sakyanovoi st., 8, Ulan-Ude, Russia, 670047, sambrika@mail.ru

Abstract

The paper deals with the main trends and patterns of development of the social resources of the border regions of eastern Russia. Particular attention is paid to the analysis of changes in the structure, the level and quality of life in recent years.

The analysis of the main state social and economic programs that affect the formation of the social potential of Russian regions is given. The results of evaluation of health system development, education, culture, housing and utilities of the border regions are given.

The modern problems of formation of social resources of the border areas of Russia are obtained on the basis of a sociological survey of the population. The technique involves the analysis of the survey population of subjective indicators of social well-being of the population, the definition of social risks. The following conclusions are drawn: solutions of problems of social development of the border regions of Russia need social initiatives to attract Russian and foreign investors in the sphere of trade, provision of household and other services to the population of cross-border territories of Russia.

Abstract

Based on the monthly precipitation data of 30 meteorological stations in and surrounding the Lancang River basin, we analyzed the temporal and spatial characteristics of precipitation from 1960 to 2014 using the climate tendency rate and Mann Kendall trend test, Morlet wavelet analysis, interpolation co-Kriging, and the gravity center model methods. The results showed that (1) in the analysis period, the precipitation in region, northern and central showed rising trend, but decreasing trend in southern precipitation occurred. The region, northern, central and southern precipitation showed an increasing trend in spring, while in summer showed a decreasing trend. In autumn, there was a decreasing trend of precipitation in the region and in the south. The northern and central parts of the region were increasing. The precipitation in the region, the middle and the southern showed a downward trend in the winter except the northern. (2) There were 29 years, 22 years and 5~10 years cycles in the region including northern, central and southern precipitation in the past 55 years. The three cycles in the analyzed period performance was very stable, with a domain-wide. There were still significant period of about 13 years in the region, north and south. Before the middle of 1975, and after 1995 there was also a period of about 13 years in the central area. In the north area before 1975 and 1995 years later, there was a 7~10 year cycle. The first main period of precipitation was 29 years, and the second main cycle was 22 years. (3) The average annual precipitation decreased in the Lancang River basin from the south to the north. The precipitation in the southern basin was most, with average precipitation in more than 1200mm. The average annual precipitation in the middle was 800~1100mm, while the average annual precipitation in northern part was usually less than 800mm, mostly in 400~800mm; the annual and monthly precipitation gravity center of the Lancang River Basin were concentrated in the central region. The precipitation gravity center of November had the largest migration distance, which migrated to southeast with 131.82km. From the seasonal point of view, spring, summer and autumn precipitation gravity center migrated to the southeast, while, migrated to the northwest in winter. The precipitation gravity center in rainy season relatively concentrated, the situation in dry season was relatively dispersed.

Application of SSIM and PNSR in Comparison of precipitation spatial distribution from the different databases

Hao Xiuping, Zhonggen Wang, Changming Liu, Yanfang Sang

Institute of Geographic Sciences and Natural Resources Research, CAS, China, haoxiuping@126.com

Abstract

The collection of Precipitation database is a basic work for hydro meteorological research and water resources management, whose quality has important implications for watershed hydrological simulation and water resources evolution analysis. The density and location of precipitation monitoring stations largely determines the quality of database. To assess the impacts of the rain gauges amounts and distribution, taken Jinghe basin as the study area, this paper analyzed three different sets of precipitation database including the observed data from 8 national basic and benchmark ground meteorological observatory (WS) (total 756 sites), the grid-processed data from high-density national meteorological station (GS) with 28 grids (total 2472 sites) and the observed data from rain gauges of hydrology stations (RS) with the 180 sites in and around the basin.

Spatial described ability were also comparatively evaluated. With the 180 sites, the precipitation data from RS can describe the spatial distribution in detail, while with fewer meteorological stations, the data from WS and GS has a lower representation of the rainfall distribution, especial for some abundant-rainfall area; such as, GS data were generally lower than WS and RS in the center of basin. With the index of PSNR and SSIM, the ability and discrepancies of three sets of database to measure the spatial distribution were calculated, the results showed that PSNR and SSIM of WS-RS is higher than others, which means the data from WS has much more similarity with the RS than GS data. The differences and similarities analysis can provide effective information to achieve the long-time and high-accuracy precipitation data with the reasonable fusion technology, thus reduce rainfall input to the model brings uncertainty.

Groundwater Numerical Simulation in Un-Gauged Areas in China

LIANG K, LIU C M

Key Laboratory of Water Cycle and Related Land Surface Processes, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, liangk@igsnr.ac.cn

Abstract

Protection of groundwater resources and environment is very important for safeguarding China's water security and construction of ecological civilization. A large number of industrial construction projects in China, especially the energy and chemical projects, generally located in the regions with lack of hydrogeology data (called as un-gauged areas), may have a remarkable impact on groundwater environment. It is necessary to study that how to accurately evaluate the impact on groundwater environmental problems caused by the construction projects lied in un-gauged areas. Groundwater numerical simulation is the most commonly used tool for quantitatively evaluating the impact of climate change and human activities on groundwater resources and environment. But there is a big contradiction between the fact that most of construction projects were built in un-gauged areas and the other fact that numerical simulation has a high demand for hydrogeological data. This paper systematically summarizes the process to construct stratigraphic model, groundwater flow model and pollutant migration model, simultaneously analyzes the main data required and how to obtain the data, and at last does a detailed explanation taking the two typical un-gauged areas as examples. This paper draws a conclusion that collecting the previous research works can make up the problem of scarcity of regional-scale data, and as far as the local scale data of the specific study area, we can obtain the first-hand data and hydrogeological information in order to construct a well conceptual model and use a reasonable model parameters on the basis of detailed fundamental hydrogeological field work.

un-gauged areas; water security; groundwater environment; groundwater numerical simulation

Hydrologic Alterations in the Crisscross River Network in the Pearl River Delta, South China

Yongqin David Chen

Department of Geography and Resource Management, The Chinese University of Hong Kong, Shatin, Hong Kong, China, ydavidchen@cuhk.edu.hk

Abstract

Hydrologic regimes fluctuate in response to climatic variations and human influences. Over the past three decades, the Pearl River Delta (PRD) has been the fastest developing region in China. Human activities mainly associated with urbanization and industrialization in the region have been rapidly changing the environment, making the PRD crisscross river network an ideal area for studying human-induced hydrologic alterations. In this study, we first used linear regression method to systematically evaluate the long-term variations of extreme water levels defined as exceeding/falling below certain thresholds ($\text{mean} \pm \text{std}$) across the delta. It was found that the low water level has been significantly dropping in the upper PRD while the opposite situation has occurred in the lower PRD. Secondly, we used Mann-Kendall trend test and Kriging interpolation method to detect the spatial and temporal patterns of the trends of the extreme high and low water levels related to different magnitudes of streamflow. The results indicate that the high (low) water level along the Pearl River estuary has been increasing and the inner delta region is characterized by decreasing high (low) water level in high and normal streamflow periods, but by increasing high (low) water level in the low stream periods. This phenomenon can be attributed to more significant impact of tidal process on water level in dry season than in flood season. Finally, we applied Beyes model and Lepage test to detect change point(s) of water level time series and analyzed the associated statistical properties of high/low water levels in summer (Jun, Jul, Aug) and winter (Dec, Jan, Feb). With respect to winter mean low water level, 14 out of 19 stations had two change points. The first abrupt change occurred around 1980 and the second abrupt change in the early 1990s. As for summer mean high water level, 12 out of 19 stations have only one change point. The timing of change points of summer mean high water level is similar to that of winter mean low water level. Identification and analysis of the causes for the hydrologic alterations in terms of water level will help us understand the impacts of human activities and thus provide important scientific evidence for managing the water environment in the PRD region.

Hydrological Nonlinear System and Water System Approach

Jun Xia

Research Institute for Water Security(RIWS) , Wuhan University, China, xiajun666@whu.edu.cn

Abstract

This paper introduced a hydrological nonlinear approach based on Volterra Functional Series theory, namely Time Variant Gain Model (TVGM), proposed during early Galway International Workshop of River Flow Forecasting organized by Prof. J.E.Nash in 1989, and new development on PUBs issue and distributed TVGM and applications on climate change and water resources management in China. This paper also addresses relative a new advantage on catchment water system approach based on integrated hydrological process, biochemical & biological processes and human component, and its application in integrated water quality and water quantity management in Hui River Basin. Results show that hydrological system approach still plays a key role on solution of water problem, particular in developing countries in the world.

Impacts from Human activities on Sediments Budget in Poyang Lake during 1955-2010

Shuhua Qi, Mengya Xiong, Fuqiang Liao

1. Key Laboratory of Poyang Lake Wetland and Watershed Research, Ministry of Education, Jiangxi Normal University, Nanchang 330022, P. R. China

2. School of Geography and Environment, Jiangxi Normal University, Nanchang 330022, P. R. China

3. Jiangxi Provincial Key Laboratory of Poyang Lake Comprehensive Management and Resources Exploitation, Jiangxi Normal University, Nanchang 330022, P. R. China

Abstract

Poyang Lake is the largest fresh water lake in China. The sediments disposition is important in providing medium for wetland grassland and benthic animals. In this paper, the water discharge and sediment content gauged by the hydrostations in the main five tributaries (named as Gan River, Fu River, Xin River, Rao River and Xiu River) in Poyang Lake watershed were used to investigate the sediment budget in Poyang Lake. The following results were shown: (1) The total sediments loaded into Poyang Lake from the main five tributaries was about 811.687Mt during 1955-2010, in which Gan River accounted for 59.7%, Xin River accounted for 13.7%, Xiu River accounted for 10.2%, Fu River accounted for 9.7% and Rao River accounted for 6.7%; (2) The annual input to Poyang Lake was mainly decided by water discharged into Poyang Lake. And the inputted sediments were synchronized to the water discharge seasonally. (3) The input sediments decreased sharply caused by reservoir interception, though forest coverage changes also contribute to the decrease of sediments; (4) The total output sediments from Poyang Lake to Yangtze River was about 560.103Mt during 1955-2010. And it showed a decreasing trend during 1955-2000, but the trend was interrupted by the practice of sand dredging in the new century; (5) The sediments budget in Poyang Lake was changed by sand mining. Sediment deposit was estimated about 1.408mm/a during 1955-2000, but outputted sediments showed greater than the inputted sediments during 2001 to 2010 because of the practice of sand dredging.

Abstract

Water supply problems are rampant in NCT Delhi. Water supply data exhibits inequalities in different parts of Delhi. In this paper, the average water supply timings per day, number of tube wells and wells installed by Delhi Jal Board, ground water depletion records throughout Delhi and waterworks which are supplying water to Delhi have been considered. From these data sources water supply problems have been analysed and inequalities measured with the help of Coefficient of Variation. The ground water depletion during 2002-2014 has been shown, in terms of five major regions in the National Capital Territory. There are a total 7 waterworks which are supplying water in Delhi, though; there are total 17 waterworks near Delhi but out of them only 7 are catering to the water supply in Delhi. From the calculation of CV inequalities of water supply in different areas of Delhi NCT has been shown. Total number of tube wells and wells in Delhi, installed by Delhi Jal Board and District Advisory Committee shows that the north eastern part of Delhi has the least number of tube wells and wells. Chatterpur area has been found as the most problematic area in terms of water supply as complaints related to water supply, registered from Chatterpur has increased considerably from 2012 to 2013. Southern Delhi has the worse ground water scenario than northern Delhi.

Parallel Calculation in Simulating Water Movement of Bioretention System

Wang Kaiwen, Yang Xiaohua, Liu Changming

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, wkw123920909@126.com

Abstract

With the quickening of the urbanization process, the original natural surface of city is replaced by buildings and impermeable pavements, which increase the risk of urban water logging. Chinese government put forward the ideas of “sponge city”, an important content of which is increasing the area of bioretention system. In order to estimate the influence of this policy on urban water cycle, it is necessary to use Richards equation to simulate the water movement in bioretention system. Because of the large area of a city and the accuracy requirement of calculation, it's essential to improve the computational efficiency. In this paper, we design a parallel algorithm to solve the semi-analytical solution of Richards given by Parlange. The result shows that parallel algorithm can significantly improve the calculative efficiency. And the operation efficiency will improve with the increasing number of calculation.

Abstract

This study investigated the spatiotemporal variation of precipitation over the last four decades in the Yarlung Tsangpo River basin, China, and the impact thereon of the changing Indian monsoon. Results reflect the spatial variability in the seasonal distribution of precipitation. From downstream to upstream, the rainy season is delayed and becomes shorter, and the ratio of rainy season precipitation to annual precipitation increases but the absolute amounts of rainy season and annual precipitation decrease. All the precipitation series have similar scaling characteristics, reflecting similar climatic condition in the basin. The effect of the Indian monsoon strengthens from downstream to upstream, and on this basis the basin is roughly divided into three regions: east, mid and west. Annual precipitation has been exhibiting a downward trend since 1998, which is mainly caused by the decrease in the rainy season precipitation. The dipole mode index, which describes the pattern of Indian Ocean dipole (IOD), has positive values in all months in positive IOD years, and causes a decrease in the rainy season precipitation compared with that in negative IOD years, during which time the dipole mode index has negative values in all months. The dipole mode index shows a negative relationship with rainy season precipitation at the inter-annual scales. Especially, the continuously positive phase of IOD has caused an obvious decrease in rainy season precipitation after 1998. Effective adaptation strategies should therefore be implemented to cope with the unfavourable water situation likely to be in the future.

Abstract

Shallow groundwater is an important source of water for the maintenance and restoration of ecosystems in arid environments, which necessitates a deeper understanding of its complex spatial and temporal dynamics driven by hydrological processes. This study explores the dominant hydrological processes that control the shallow groundwater dynamics in the Gobi Desert-riparian-oasis system of the lower Heihe River, a typical arid inland river basin located in northwestern China. The dynamic behaviour patterns of the groundwater level at most sites are characterized by a declining trend during the period from spring to autumn and a slightly increasing trend in the winter months. The seasonal variations of the water table are determined by the rate of evaporation and lateral groundwater recharge via riverbank filtration. Further, a water table fluctuation (WTF) method was used to investigate groundwater evapotranspiration (ET_g) processes at two sites dominated by phreatophytes (*Tamarix ramosissima* and *Populus euphratica*). The average ET_g rate during the summer months (June–August) of 2010-2012 was estimated to be 0.63-0.73 mm/d at the site dominated by *Tamarix ramosissima* and 1.89-2.33 mm/d at the site dominated by *Populus euphratica*, depending on climatic conditions, vegetation status, and depth to water table. Additionally, a coupled river-aquifer numerical model was used to calculate the river leakage in the main stream of natural rivers from April 20, 2010 to April 21, 2012. The results showed that the amount of river water leakage was about 2.51×10^8 m³, which accounted for approximately 32% of the amount of river flow. The river filtration rate is mainly determined by the streambed vertical hydraulic conductivity, which is highly dependent on the river water temperature that varies from 0 to 20 °C.

Response of Vegetation to Climate Change in the Qinghai-Tibet Plateau over the Past Three Decades

Liu X.L., Zhao C.S., Yang S.T., Zhang C.B.

State Key Laboratory of Remote Sensing Science, School of Geography, Beijing Normal University, Beijing Key Laboratory for Remote Sensing of Environment and Digital Cities, Beijing, 100875, P.R. China, liuxiaolin25@163.com

Abstract

Global climate change has significantly affected vegetation variation in the third-polar region of the world – the Qinghai-Tibet Plateau. As one of the most important indicators of vegetation variation (growth, coverage and tempo-spatial change), the Normalized Difference Vegetation Index (NDVI) is widely used to study the response of vegetation to climate change. So the spatio-temporal variation characteristics of vegetation and the response patterns of vegetation to climate change were analyzed in the Qinghai-Tibet Plateau from 1981 to 2014 by NDVI acquired from GIMMS. It is found that the spatially averaged NDVI slightly increased over the past 34 years with a rate of 0.001/10a, however in a short time scale the value increased by 0.006/10a from 1981 to 1999 and decreased by -0.004/10a from 1999 to 2014. So the 1999 year seemed like a turning point when the vegetation influenced by climate. While linear trends of NDVI showed a high degree of spatial heterogeneity based on per-pixel analysis. The pixels showing increasing trends were mainly in southwest or southeast with 59% of total area and decreasing trends were mainly in north or middle with 41% of the total area. In the different altitude the value and trend of NDVI also showed different characteristics. The NDVI values were mainly about 0.75 below altitude of 2000m while the values became smaller as the altitude became heighten above altitude of 5000m. The increasing trend of NDVI mainly distributed between the altitude of 3000m and 5000m. These indicated the vegetation distribution and variation in the Qinghai-Tibet Plateau.

Similar Weather Conditions (SWC) Analysis in Distinguish the contribution of Impact of Human Activities and Climate Variability to Runoff and Sediment Load of River

Fei Wang^{1, 2}, Xingmin Mu^{1, 2}, Guangju Zhao^{1, 2}, Peng Gao^{1, 2}

¹Institute of Soil and Water Conservation, Northwest A&F University, Yangling, China, wafe@ms.iswc.ac.cn

²Institute of Soil and Water Conservation, Chinese Academy of Sciences and Ministry of Water Resources, Yangling 712100, China

Abstract

Distinguishing the impacts of climate variability and human activities would improve our knowledge of water resources, climate change and variability and its adaptation, and watershed or river basin management. The mainstream methods are discussed from different criteria of principle and process to compare their functions and shortcomings, especially focusing on how to treat the interplay function of climate variability and human activities. A new simple and robust method to determine the impact of human activities within paired datasets under the same or similar weather conditions (SWC) is put forward to improve the precision of assessment when setting of same climatic backgrounds of 2 stages (single-year pairs or several-continue-year pairs) to avoid the impact of climate variability. These weather conditions cover the main meteorological elements of precipitation and ETO (the reference crop evaporation transpiration), and ETO relating to all other weather factors. If there are two or more periods with similar weather conditions but different runoff, the relative runoff and sediment load changes can be deduced the result of human impacts. The method could describe the net impacts of human activities as a whole, and it could be extended when more detailed data are available.

Assessment of environment impact; human activity; climate variability; similar weather condition (SWC)

Spatiotemporal Variability of Precipitation Extremes and Dryness/ Wetness Patterns in Southeast Coast Region of China, 1960-2014

Ren Wang, Jianyao Chen, Tao Jiang, Kun Li

School of Geography and Planning, Sun Yat-Sen University, Guangzhou 510275, China

Abstract

Changes in precipitation extremes potentially have severe influence on hydrological regimes, human society and natural ecosystem. Based on daily precipitation records at 73 meteorological stations in southeastern coast region of China during 1960-2014, the spatial and temporal changes in 9 extreme precipitation indices and its regional differences were analyzed in 4 climate zones. Furthermore, this study employed standardized precipitation index (SPI), rotated empirical orthogonal function (REOF) and wavelet analysis methods, to assess the characteristics of dryness/wetness patterns as well as its correlations with El Niño/Southern Oscillation (ENSO). For precipitation extremes, most of the indices exhibited an increase trend in regional scale, especially the PRCPTOT, R95p and R99p experienced a upward slope of 2.26 mm/decade, 2.15 mm/decade and 0.78 mm/decade over the past 55 years. On the contrary, a decreasing trend in CWD was detected approximately in over 50% of the stations except in north subtropical zone. As for regional differences, the increase trends in PRCPTOT, R95p, R99p, CWD, RX1day, RX5day, R10mm and R20mm all showed a concentration in north and coastal area, which generally are north subtropical zone, mid-subtropical zone and the coastal area of south subtropical zone, while the stations with increasing trend in the CDD mainly located in south subtropical zone and tropical edge zone. Additionally, three dominant dryness/wetness spatial modes were identified in southeastern coast region of China, namely northeast of Guangdong Province (EOF1), north of Zhejiang Province (EOF2) and northwest of Fujian Province (EOF3), respectively belongs to south subtropical zone, north subtropical zone and mid-subtropical zone. As temporal variation in each spatial model (EOFs), there is no trend in EOF1, while an increasing trend in EOF2 and an decreasing trend in EOF3 was detected over the past 55 years. Furthermore, the variation in dryness/wetness existed a 4 to 12 years period in these three spatial models, and their time coefficients (PCs) exhibited a significant correlation with ENSO especially when the lag time are 6 to 12 months. The results of this study suggest that the frequency of heavy precipitation and the risk of flood is increasing in north subtropical zone (i.e. Zhejiang Province), while reduced water resources amount and increasing drought risk maybe exist in south subtropical zone (i.e. Guangdong Province), so adaptive water resource management and flood/drought mitigation measures should be considered separately for different regions in southeastern coast of China.

Spring Peak Flow Variation under Climate Warming in the Kaidu River Watershed

Zhang FY^{1,2}, Li LH¹

¹State Key Laboratory of Desert and Oasis Ecology, Xinjiang Institute of Ecology and Geography, Chinese Academy of Sciences, Urumqi 830011, China, lil@ms.xjb.ac.cn

²Graduate School, University of Chinese Academy of Sciences, Beijing 100049, China

Abstract

Climate change has great influence on spring peak flow which may cause serious damages in arid and semi-arid areas. Spring peak flow is mainly contributed by snowmelt water and rainfall in alpine regions. In order to analyze the change of spring peak flow under climate warming, the temperature and precipitation outputs based on the scenarios of RCP2.6, RCP4.5 and RCP8.5 from CNRM-CM5 were used as the inputs of modified SDHydro model to simulate the streamflow and peak flow in the Kaidu River watershed. The results indicated that the spring peak flow increased while the summer peak flow decreased under climate warming condition in which the summer peak flow is predominance than the spring peak flow. The beginning time and the occurring time of the spring peak flow occurred earlier under climate warming scenarios. However, the beginning time of spring peak flow is more sensitive to climate warming than the occurrence time of spring peak flow. The reaction of spring peak flow to climate warming is not as sensitive as that of the beginning time of spring peak flow also. Because the beginning time of spring peak flow is controlled by $>0^{\circ}\text{C}$ temperature while the occurrence time and magnitude of spring peak flow is influenced by the increasing rate of temperature and rainfall in spring. The results of the study may provide useful information for water resource managers to manage and allocate the limited water resources, and provide more useful suggestions to prevent damages of spring flood.

Key words:

Spring peak flow; Climate warming; Kaidu River watershed

Summer Runoff Generation Investigation Based On Tracer Technology

(A Case of Mountain Catchments, Monsoon Zone of Pacific Russia)

Shamov V.V., Gartsman B.I., Gubareva T.S., Boldeskul A.G., Lutsenko T.N., Kozhevnikova N.K., Lupakov S.Yu., Chelnokov G.A., Burdukovskiy M.L., Tarbeeva A.M., Shekman E.A., Mikhailik A.A., Tokarev I.V., Kozachek A.V.

Pacific Institute of Geography FEB RAS, Vladivostok, 690041, Russian Federation, shamov@tig.dvo.ru

Abstract

Extremely high variation in rainfall rates (up to 200–300 mm per day as typical for monsoon zone in Asian Russia) brings as usual 10-20 times range of discharge values in river flow, with flood specific discharges sometimes higher than 200 l/s·km². How and how fast does atmospheric water reach the streams? The authors discuss their recent (2011–2015) experience in the present-day chemical tracing techniques application to summer runoff generation research, and offer a sort of methodology named as Mobile Research Watershed (MRW). It is illustrated by case short-term studies from some small research catchments in Sikhote-Alin Mountains, the Ussuri/Wusuli River headwaters. The properties and limitations of use of concentrations as natural tracers in water are discussed, and the available methods of intensive monitoring of precipitation and flow, and chemical features of atmospheric, soil (subsurface), low stream and flood stream water and, also, laboratory analysis of water samples to reveal tracers of stream flow sources, are presented. Combined hydrological and hydrochemical monitoring results in discrete concentration–time series and continuous discharge series, which allow to obtain some detailed information about stream flow generation and flow paths mostly based on the EMMA modelling. The use of tracers provides indications in estimating the volume of contributions of the slope conduits, shallow groundwater and event water to the stream flow. Believable, the proposed MRW–approach seems to have significant implications for short-term hydrological and environmental research in vast scarcely studied areas of North and Central Asia.

Abstract

East Juyan Lake is the terminal lake of Heihe River and is significant in preventing desertification. An official project was launched to convey water from the upper and middle reaches to the lake in 2001 as severe eco-environmental problem occurred due to reduced inflow in the 1990s. Quantifying actual lake evaporation and performing future prediction will provide reference for better regional water resources management. Synoptic factors are crucial in lake evaporation: air temperature reflects the actual thermal conditions and, along with wind speed, drives evaporated vapor diffusion. Relative humidity reflects the available capacity of evaporated vapor and restrains the evaporation process when vapor is accumulated in the air. Wind speed helps to intensify horizontal turbulent diffusion and the transportation of evaporated vapor to nearby atmosphere. Because of extreme weather conditions and high costs in in-situ experiment, reliable data is lacking. In this research, we placed a floating E601 pan to measure daily lake evaporation and conducted simultaneous bankside synoptic observation in 5-min intervals from 2013 to 2015. Single factor correlation analysis indicated the synoptic factors governing lake evaporation are air temperature, wind speed and relative humidity. A semi-empirical daily lake evaporation model was established and validated with moderate accuracy (RMSE and MRE of 0.63 mm, 8.6% (calibration); 0.73 mm, 9.8% (validation)), and we analyzed each factors' sensitivity using this model. Obtaining daily evaporation time series and its relationship with governing factors enable us to better understand regional hydrological cycle and comprehend how climate change affects hydrological processes.

Abstract

Legacy phosphorus in soil is being paid more and more attentions world widely, because it is a grand potential of phosphorus resource as well as a key factor for eutrophication prevention. However, there are three difficulties in recent soil legacy phosphorus research that include its spatial distribution, accurate quantitative calculation and the variation in the long term. These three questions can't be resolved by the conventional soil chemistry methods. In this study, a remote sensing driven model EcoHAT (Ecohydrological Assessment Tool) is applied to obtain the spatial distribution, accurate quantitative calculation at the regional scale and the variation in 15 years (2000-2014) of the soil legacy phosphorus. Remote sensing is used due to it can obtains multi spatio-temporal scales continuous earth information, and the results from the remote sensing driven models can better describe the soil P concentration and the cycle and transportation of soil phosphorus. Our results show that the soil legacy phosphorus have different contents in spatial, the old cultivated land has more legacy phosphorus than new arable land; the total soil phosphorus content in the cultivated land has an increasing trend in the 15 years; the wetland in this area has more legacy phosphorus than before. Our research supplies a useful approach to calculate and detect the spatial distribution of soil legacy phosphorus accurately at regional scale. In future, this approach can gives a good help to explore the potential phosphorus resource in agricultural areas world widely, and gives implications to the phosphorus limitation countries.

Abstract

Topography is an important influence on water and energy of ecosystem in mountains. Vegetation water use and productions are important ecosystem indicators. In this study, we tried to evaluate the topography control on vegetation water use and productions in a mountain area of North China (the Taihang Mountains) by using ecosystem model. The model we used is BIOME-BGC. The model was verified by field data in two experimental sites. Three basins in the Taihang Mountains were chosen for the evaluation. We divide the three basins into 4247 calculate units. The division is based on contours in sub-basins to present topographic and hydrological variability. The results illustrate that in the study area, topography has a significant influence on spatial patterns of transpiration and net primary productivity (NPP) for trees, shrubs and grass. The diversity of transpiration and NPP are larger in high elevation area than those in low elevation. NPP in low elevation is larger than that in high elevation. We believe our results can provide scientific basis for ecosystem recover in the Taihang Mountains.

Abstract

Accurate estimation of hyporheic water exchange is of critical importance in integrated management of groundwater and surface water bodies and in maintenance of ecosystem health of a river catchment. As a case study of the Weihe River in Shannxi Province, China, stream water and groundwater are inherently connected and water quality is strongly interacted. Therefore, the patterns and magnitudes of hyporheic water exchange and their variabilities of the Weihe River along five sites during different seasons are investigated. Using a self-made tube stick containing inside several temperature sensors with slotted holes, the sediment temperatures of different depths are measured synchronously. Then, the temperature profiles with depths are illustrated and the patterns of stream water and groundwater exchange are determined by a simple thermal mapping method. Furthermore, the volume of the hyporheic water flux is estimated by one-dimensional steady state heat-diffusion-advection equation. And the changes of magnitudes of hyporheic water exchange either along test sites or during different seasons are analyzed. The results indicate that the patterns and magnitudes of water exchange in hyporheic zone vary among different seasons in one year even in the same season of different years, and have large differences among test sites from upstream to downstream as well. Distinctive spatial and temporal variabilities of hyporheic water exchange occur in the Weihe River.

Abstract

To reveal how water and vapor transfer in vadose zone affect evapotranspiration in Gobi desert and riparian in hyper arid region is important for understanding ecohydrological process. Field studies and numerical simulations were imported to evaluate the water and vapor movement processes under non isothermal and lower water content conditions. The soil profiles (12 layers) in Gobi desert and riparian sites of Ejina were installed with sensors to monitor soil moisture and temperature for 1 year. The meteorological conditions and water table were measured by micro weather stations and miniDivers respectively in the two sites. Soil properties, including particles composition, moisture, bulk density, water retention curve, and saturated hydraulic conductivity of two site soil profiles, was measured. The observations showed that soil temperatures for the two sites displayed large diurnal and seasonal fluctuations. Temperature gradients with depth resulted in a downward in summer and upward in winter and became driving force for thermal vapor movement. Soil moistures in Gobi desert site were very low and varied slowly with time. While the soil moistures in riparian site were complicated due to root distribution but water potentials remained uniform with time. The hydrus-1D was employed to simulate evapotranspiration processes. The simulation results showed the significant difference of evaporation rate in the Gobi desert and riparian sites.

A New Method on Evapotranspiration Data Assimilation Based on Hydrological Models

ZHAN Chesheng¹, DONG Qingqing², WANG Huixiao², HAN Jian¹

¹Key Laboratory of Water Cycle and Related Land Surface Processes, Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing 100101, China, zhancs@igsnrr.ac.cn

Abstract

A comprehensive review of evapotranspiration data assimilation based on hydrological model is provided. The difficulty and bottleneck for ET is elaborated to construct data assimilation relationship as a non-state variable, with a discussion and analysis about the feasibility of various hydrological models to assimilate ET. Based on this, a new evapotranspiration assimilation scheme is proposed. The scheme presented is an improved data assimilation system that uses distributed time-variant gain model (DTVGM) which contains evapotranspiration-soil humidity nonlinear time response relationship. Moreover, the evapotranspiration mechanism in DTVGM is adjusted to perfect the ET data assimilation system. The new method on evapotranspiration data assimilation based on DTVGM has been applied in lots of river basins successfully in China.

A Study on Characteristics of Drought-Flood Based on Precipitation Data in Yunnan Province over the Past 61 Years

Liu Jiaxu^{1,2}, Li Lijuan^{1*}

¹Key Laboratory of Water Cycle and Related Land Surface Process, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China, 983052779@qq.com

²University of Chinese Academy of Sciences, Beijing 100049, China

Abstract

Analyzing the characteristics of spatio-temporal variability of droughts and floods are very important to reduce losses and costs. Based on monthly rainfall data from 1954 to 2014 collected from 32 meteorological sites in Yunnan province, the spatio-temporal variability and periodicity of drought-flood were analyzed using SPI, EOF, RBF spatial interpolation, wavelet analysis. The results show that there is a tendency of drying in Yunnan province during the last 61 years (the slope of SPI is $-0.0091/\text{year}$), and the SPI series indicate a great fluctuation and a high frequency after 2000. General flood year, normal year and general drought year account for 88.52% in the 61 years, and great drought year, extreme drought year and great flood year account for 4.92%, 3.28%, and 3.28%, respectively. Since 2003, what's more, the occurrence of drought event is more often and the impact is more remarkable with the aggravating drought degree. There are two regions that droughts come more often than other regions in Yunnan province, and they are Jinghong-Simao-Yuanjiang and the northeast of Zhanyi site. In addition, there are three regions where floods come frequently, and they are the west of Lincang-Dali-Huaping line, northern Zhaotong site, and the southeast of Yunnan province. The probability of drought and flood events have a good correspondence, but the probability of drought is slightly higher than flood. The first modal of EOF analysis reveals that Yunnan province presents the consistency of flood or drought, moreover, this modal may be affected by the large-scale climate characteristics. The second modal may be controlled by topographical factor, and the third modal may result from comprehensive function of multiple factors, such as longitude, monsoon. Furthermore, the time coefficient of first three modals also confirms the trend of drought in Yunnan province. Finally, the periodic oscillation of SPI series is concentrated in expectant 2 years, 6 years, 8 years, 18 years and 28 years, and especially in expectant 28 years which has the strongest energy.

³China Renewable Energy Engineering Institute, Beijing, 100120, P. R. China.

Abstract

Ecological water shortages in karst regions are mostly due to significant losses of hard-to-use leaked blue water, and thus transforming leaked blue water into green water is the key to solving the problem of ecological water shortage. We used the RS-SVAT model and remote sensing data to simulate the spatial distribution of blue and green water in the Guiyang City suburban area and found that: (1) In 2013, the green water in the area accounted for less than 50% of rainfall, which is well below the world average of 65%, while leaked blue water accounted for 15.16% of blue water and 7.62% of rainfall, suggesting a large volume that could be adjusted; (2) Once vegetation coverage increased by more than a percentage, the contribution of vegetation to reducing infiltration decreased sharply; (3) Increasing the soil thickness by 20 cm greatly decreased infiltration by converting blue water into green water, suggesting that increasing soil thickness is the most effective way to convert blue water to green water; (4) In dry years when the soil thickness increased to 20 cm, the infiltration decreased more than in normal and rainy years so that the order of infiltration reduction from lowest to highest was: dry year scenario > normal year scenario > wet year scenario, effectively alleviating the ecological water shortage for vegetation. Therefore, this study suggests that the ecological water shortage in karst regions would be best alleviated by increasing soil thickness.

Abstract

Vegetation coverage is an important input parameters of hydrological models. It impacts on the runoff of hydrology confluence process. Usually, the vegetation coverage values is acquired by the different band of remote sensing satellite image. This article is related to the vegetation typical single class (farmland, forest and grassland) and synthetically, to compute vegetation coverage under the different height of Google's RGB image. In the meantime, we verify the accuracy of vegetation coverage by UAV images. By spatial analysis of vegetation coverage value, the result shows: First, within the scope of a certain height, the vegetation coverage remain unchanged basically to single class. Second, it remain the same rule between comprehensive classes with a single class. Third, with the increase of altitude of UAV images, the vegetation coverage showed a trend of decline. Within the scope of a certain height of Google images, the resolution of images remain unchanged. It show that vegetation coverage based on Google cannot serve as input parameters of hydrological model.

Abstract

Sediment yield is one of the most important factors in environmental degradation assessment and the main carrier for nutrients' transportation. The modified universal soil loss equation (MUSLE) is often used to estimate the sediment yield for watershed. However, it is difficult to obtain the daily runoff data which is one of the key factors in the MUSLE model in ungauged regions. In this paper, we combined MS-DTVGM (Multi-Spatial data-based Distributed Time-Variant Gain Model) with MUSLE to simulate the Sediment yield in Sanjiang Plain in China from 2000 to 2010. MS-DTVGM was used to calculate surface runoff volume for the region and the results were calibrated by three years' daily discharge data from two gauges, the daily R^2 is 0.69 and 0.54, and the daily NSE is 0.49 and 0.28. Then runoff data were applied to simulate the sediment yield in Sanjiang Plain. The results revealed that: (1) the model has simulated the runoff volume within a range of acceptable accuracy; (2) the soil erosion modulus in Sanjiang Plain mainly belongs to micro soil erosion, namely less than 200 t/km²*a, and the erosion intensity change slightly during 2000-2010; (3) the sediment loads experienced temporal and spatial variations, with strong correlations existing between the land use and the precipitation; (4) the coupled model is driven purely by data from common platforms, thus it can be used in other ungauged area.

Abstract

Ecological water demand is a hot field of the ecology, hydrology and science of water resource, scholars from different points of view put forward a variety of methods to calculate ecological water demand, and based on these methods study on ecological water requirement calculations for different scale area. However, in the conventional calculation methods how the flow rate of the demand for multiple species coupling together is an unresolved issue, which affects the reliability of calculation results, and thus affect the regulation of water resources. In this paper, we introduced dominance index as weight to coupling each species' eco-velocity, improved the method of Adapted Ecological Hydraulic Radius Approach (AEHRA), established a multi-species eco-velocity coupling model. This provide a new general solution--which is more in line with the objective, less hydrological data needs and high feasibility--for multi-species ecological water demand computing. Through the application in Xiaoqing River Basin we found that, this method is effective for multi-species eco-velocity coupling calculation, the monthly calculation result of ecological water demand show difference between seasons in water demand--the spawning season of fish needs more water compared with non-spawning period less. The result describes the objective situation more accurately, reveals ecological water requirement of seasonal differences in Xiaoqing River Basin and provides reference for the watershed regulation of water resources.

Abstract

The effective management of water requires an integrated approach with a balance between socio-economic development and protection of natural ecosystems. It is therefore essential to know the real availability of water in order to develop management measures that, from a holistic perspective, help to strengthen natural and anthropic systems. From this perspective, the aim of the authors is to stimulate a discussion in the scientific community that serves as a preamble to lay the foundations for a further hydrological study of a region of the NW of the Iberian Peninsula (Galicia, Spain).

Galicia has an area of ~30,000 km², containing a drainage system with more than 100 rivers of a length greater than 20 km (scale 1/25,000). In total, they amount to ~4,800 km of river, of which currently more than 560 km are dammed (~11.7% of the total). Hydrologically, Galicia is organized into four hydrographical confederations that operate independently. However, there is a large network of gauging stations and weather stations that provide abundant data.

It is urgent to establish a line of research that characterizes the hydrological variability and addresses the issues raised by a spatiotemporal analysis approach. In addition, hydrological mapping provides the population with easy and concise access to information. This also represents significant added value in decision making about water use and conservation, allowing us to confidently face the social, economic and environmental challenges of the coming years.

Joint Simulation of Evapotranspiration from Non Uniform Underlying Surface in Semi-Arid Environment Based On the Combination of Remote Sensing Model and Hydrological Model

Yin J^{1, 2}, Zhan C¹, Zhao Y²

¹Key Laboratory of Water Cycle & Related Land Surface Processes, Institute of Geographical Sciences and Natural Research, CAS, Beijing, 100101, P. R. China, igc2016@igsnr.ac.cn

²School of Resources and Environment, Anqing Normal University, Anqing 246011, China

Abstract

The evapotranspiration from non-uniform land surface reflects the water consumption of vegetation in the basin, and quantitative estimation of evapotranspiration has been an international frontier in water sciences for a long time. Hydrologic models are usually capable of simulating time-continuous evapotranspiration processes at daily time steps, but the accuracy of such models is poor when compared with remote sensing evapotranspiration models. Meanwhile, the applicability of remote sensing evapotranspiration models based on the surface energy balance is restricted by the lack of high-frequency and high-resolution thermal data. We build a remote sensing evapotranspiration model including three parts: inversion of the evaporation ration using double layers model, calculation of total daily net radiation, and estimation of daily evapotranspiration. Compared with the data of flux measurement equipment, remotely evapotranspiration shows a high accuracy in the case study area in semi-arid environment. The remotely data used as a observation to optimize a hydrological model based on data assimilation structure. The results shows that the integrated method is proved better, and improves the hydrological modeling accuracy by nearly 10%. After the assimilation, the evapotranspiration process achieves a better probability. Data assimilation improves the shortcomings of the hydrological simulating the impact of human activities to the water cycle process. The study develops a new evapotranspiration modle which can simulate regional evapotranspiration with high accuracy and continuous time series. The new land surface evapotranspiration model not only follows the surface energy balance, but also meets the regional water balance, and has more perfect water thermal coupling mechanism.

Abstract

According to the runoff characteristics in Beijing mountain area, the distributed hydrological LCM model, combining with multi-source remote sensing data, we simulated the runoff process of design rainstorm for the return period of 1 year, 3years and 10 years under present conditions of the Huaijiu River Basin and validated with site data. The result shows that, (1) if antecedent soil water content increases from 10mm to 20 mm, the peak flow of three types of design rainstorm each increased by 6.5%, 26.0% and 12.2%. When the antecedent soil water content increases from 20mm to 30 mm, the peak flow of three types of design rainstorm increased by 6.1%, 32.8% and 11.0%.(2) In drought conditions (antecedent soil water content is designed 10mm), the peak flow for the return period of 1 year is 39.0797m³/s, at the same time peak flow for the return period of 3 years is 169.597 m³/s while for the return period of 10 years is 694.992m³/s. The results provides a theoretical reference for small watershed comprehensive management.

²School of Geographic and Environmental Sciences, Guizhou Normal University, Guiyang, 550001, P. R. China

Abstract

A significant change in vegetation cover has occurred in the ten tributaries of Yellow River in recent decades, the authors adopted dimidiate pixel model based on NDVI to calculate the vegetation coverage in 1980, 1998, 2010 and 2014 by using multi-source remote sensing data, and analyzed the spatial and temporal variation of vegetation coverage in the ten tributaries. Some conclusions can be drawn as follows: (1) During 1980-2014, the vegetation coverage in the ten tributaries showed a consistent growth trend, from 18.66% in 1980 to 52.17% in 2014. The increasing rate of vegetation coverage was significantly faster in the whole basin after 1998, the area ratio of medium vegetation coverage increased was the main feature of the vegetation restoration. (2) In the past 35 years, complete recovery type and recovery type were the main vegetation change types in this basin. Complete recovery, recovery and slight recovery types have accounted for 90.26% in the whole basin; the total areas of serious degradation, degradation and slight degradation types accounted for 7.36%. (3) The increasing rate of vegetation coverage was significantly faster except downstream after 1998. In 1980, the order of vegetation coverage in different typical geographical units of the ten tributaries was the Western upstream > Eastern upstream > Downstream > Eastern midstream > Western midstream. During 1998-2014, the order changed to be the Eastern midstream > Eastern upstream > Western upstream > Western midstream > Downstream. The implementation of returning farmland to forest and grass project was the main reason for vegetation restoration.

vegetation coverage; dimidiate pixel model; dynamic change; the ten tributaries basin

Water Environment Change in Extreme Arid Region Indicted By Vegetation Dynamics

Yichi Zhang, Jingjie Yu, Ping Wang, Chaoyang Du

Key Laboratory of Water Cycle & Related Land Surface Processes, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, 11A, Datun Road, Chaoyang District, Beijing, 100101, P. R. China

Abstract

With increasingly intensified water resource exploitation along with climate change, the arid inland areas of northwestern China have experienced serious environmental deterioration and ecosystem degradation since the 1950s, which was especially remarkable in the lower basins. As this situation had severely threatened local and regional human society, exploratory measures were successively undertaken to increase water supply in order to restore the ecosystems in several basins after 2000. How the hydrological regime change has abstracted much attention, while extensive observation is unpractical due to complex natural environment and human activity. Due to the limited precipitation, vegetation growth is primarily dependent on the combined effect of surface water flow and shallow groundwater in arid inland areas. It is possible to study region hydrological regime change by vegetation dynamics. In this study, we firstly investigated the relationships between vegetation condition and the surface /groundwater dynamics (river flow, depth to groundwater table) in the Ejina Oasis, a typical hyper-arid region of northwestern China, by combing remote sensing with surface/groundwater observation data. The results showed that the natural vegetation was distributed where the depth of groundwater ranges from 1 to 4 m, and the change in NDVI was highly related to the groundwater depth, such that the vegetation NDVI increases with the depth to water table, reaching its maximum at the depth to water table of approximately 3 m; then the vegetation NDVI starts decreasing with depth to water table. And then, combining this result and gridded NDVI, hydrological regime in the Ejina Oasis was investigated. The results suggested that past water resource management improved the groundwater level in most areas, while resulted in remarkable decline in some regions at the same time.

Abstract

NCT Delhi is not only the largest urban agglomeration in India, but is also the fastest among others in terms of population growth. The region receives considerable migrants some of whom settle down in informal settlements. Also, spurt in industrialization in the region has lead to massive demand for water in a water scarce region. Another imminent problem is heavy industrialization and this can be viewed in the light of release of harmful substances vis-à-vis the existing very poor sewage system. Water distribution pattern in Delhi is also quite fluctuating and irregular.

In the light of these facts, the present paper is focused on analyzing the existing water related problems in NCT, Delhi. An attempt has also been made to critically review the policy issues of the water supplying agencies, viz the Delhi Government and Delhi Jal Board. Delhi Jal Board has started comprehensive distribution of water throughout Delhi through outsourcing of water supply in two operational zones. Pilot projects were planned to improve water supply services to poor people. This project was called as Phase-I. Delhi Government and Delhi Jal Board kept some approaches in a workshop in 2011. Recently, Dwarka Water treatment plant has been commissioned to improve water supply at Dwarka sub city. Delhi Jal Board is taking measures to improve all the working waterworks. To stop water contamination, old pipeline systems in Delhi are being totally altered by new. During last year, throughout Delhi, total 4400 major pipeline faults have been repaired.

The 6th Global Environment Outlook Report (GEO-6)

Jinhua Zhang

SciencePolicy Officer, United Nations Environment Programme (UNEP)

Abstract

Unprecedented economic growth has lifted millions out of poverty in Asia and the Pacific but is putting heavy pressure on ecosystems and the climate. The GEO-6 report looks at the state of play in key areas, highlights drivers of environmental impacts and looks at ways to address them.

Increasing unsustainable consumption patterns have led to worsening air pollution, water scarcity and waste generation and threaten human and environmental health. Increased demand for fossil fuels and natural resources - extensive agriculture, palm oil and rubber plantations, aquaculture and the illegal trade in wildlife – are causing environmental degradation and biodiversity loss. The situation is exacerbated by adverse climate change effects and an increasing number of natural disasters, which are causing devastating human and financial losses in the region. Extreme climate events are projected to become the new normal.

Meanwhile, countries are taking action towards a green growth path, with regulations, policies and programs. They make increased investments for example in renewable energy, along with enhanced environmental awareness of emerging middle class. A few national examples to mention include China's Circular Economy Promotion Law, Republic of Korea's Framework Act on Low Carbon Green Growth and India's Jawaharlal Nehru National Solar Mission program. Important policy pathways for countries' considerations to charter socio-economic development that is environmentally sound include:

- Greater emphasis is required for developing *regional* and *local* level climate change adaptation policies for increased resilience to climate change impacts.
- More sustainable production and consumption patterns, increased resource efficiency and a decoupling of economic growth from resource consumption are needed.
- Low-emission development pathways delivers significant national co-benefits, such as improved energy security and resilience to energy price shocks, improved health due to lower local pollutant emissions, and increased agricultural and land-use productivity.
- The region's shift towards green energy is currently held back. Countries in the region are encouraged to work more closely to enhance financing and energy market regulatory reforms, and to reduce fossil fuel subsidies.

- Building stronger institutions, governance and stricter monitoring are especially important, including mainstreaming the environment in other policy areas, to close the widening gap between policy formulation and its implementation.
- Strengthening international cooperation underpinned by national commitments provides another way forward, for example The ASEAN Agreement on Transboundary Haze Pollution, signed by all ASEAN countries, strengthens cooperative action to control smoke haze caused by wildfires.

The Power of Indicators to Track Environmental Performance and the SDGs

Robert Chen, Robert S. Chen, Alex de Sherbinin, Marc Levy

Director, Center of International Earth Science Information Network (CIESIN), Columbia University, USA

Abstract

In the year 2000, CIESIN, a center at the Earth Institute of Columbia University, and the Yale Center for Environmental Law and Policy launched the Environmental Sustainability Index (ESI), a pioneering effort to develop the best available indicators to measure the relative environmental sustainability of each country. Recognizing that policy makers needed more tailored information on environmental performance in order to ground decisions, CIESIN and Yale launched the Environmental Performance Index (EPI) in 2006, and have published the EPI biennially since then. In the 16 years since the launch of the ESI, much has changed. The Millennium Development Goals (MDGs) demonstrated the power of monitoring systems and indicators to drive policy changes and improvements in human wellbeing, but included few environmental indicators. The Sustainable Development Goals (SDGs) are much more comprehensive, including 17 goals with 169 targets covering human and environmental aspects of sustainable development. This paper reviews the CIESIN and Yale experience in developing the ESI and EPI, providing valuable lessons for implementation of the SDGs.

Abstract

Recently the global ecological environmental problem is becoming increasingly acute because of the consumption of Earth resources and damage to the environment by humankind, the ecological environmental problems such as global climate change, water shortages, pollution, decreasing biodiversity, desertification etc have effected the global economy and the society sustainable development. Retrieving the ecological environmental parameters at global scale through available technology is very important to the research on global changes and to the international collaborations on responding to the environment problems.

Earth observation technology has grown rapidly in recent years in China, and an integrated Earth observation satellite system has been created to include satellites of land and resources, meteorological, marine, high-resolution and commercial ones. There are over 30 Earth observation satellites are in orbits. Great progress has also been made in remote-sensing technology research with active international co-operation. Through an inter-governmental collaboration mechanism of China GEO, an effort has been made to work on an annual report on global ecosystem and environment was produced since 2012. This work is led by the National Remote Sensing Center of China (NRSCC) and jointly carried out by various institutes and universities. The report focuses on the global monitoring of land cover, growth of agriculture, changes of land surface water, vegetation, wetlands distribution by remote-sensing observation. Analysis of global environment is the primary element but a focus was also given each year for a particular region. Regional reports for Africa, Southeast Asia and “the Belt and Road” areas have been produced. The reports are released annually on the World Environment Day by the NRSCC each year. The reports and data sets are available on the web. The work is treated as an important contribution by China to the GEO progress and the work is endorsed by the GEO secretariat. Primary users are domestic governmental agencies, research organizations and international organizations like GEO, FAO, UNESCAP etc.

GlobeLand30 and its Utilization

Jun Chen

Chief Engineer, National Geomatics Center of China (NGCC) and President of International Society of Photogrammetry and Remote Sensing (ISPRS)

Abstract

GlobeLand30 is the world first wall-to-wall 30-m global land cover (GLC) data products (www.globeland30.org) in 2000 and 2010, which were developed by NGCC team with a POK (Pixel-Object-Knowledge)-based operational mapping approach. It consists of ten land cover classes in the two time periods. On Sept. 22, 2014, GlobeLand30 was donated to United Nations by Chinese government and has now more than 6,000 users from 118 countries. This presentation will give a brief introduction of GlobeLand30 and its applications, as well as future developments. The major contents include: the operational production and on-line service of GlobeLand30, the geographical and domain analysis of users, its current and potential applications in supporting sustainable development goals (SDGs), as well as its validation and updating.

GCdataPR: Data Publishing and Sharing for GlobalChange in Local Places

Chuang Liu

Professor, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences and Co-Chair of CODATA PASTD Data Publishing Subgroup

Abstract

Millions of scientists, professors, policy makers, private sectors and even citizens are involved in the global change observations and studies. Most of them are focusing their efforts on the local places instead of global scale. How to make these local experiences and products worldwidesharable is challenging to all of us. The solution of the Global Change Research Data Publishing and Repository (GCdataPR) is to recognize and creditthe data authors' contribution to the global change studies by peer review data publishing and worldwide openly available, free access these products. More than 300 data authors from 10 countries published 150 datasets, more than 15,000 IP end users from 53 countriesdownloaded the data since June 2014. The GCdataPR solution makes so diverse data both in spatial and temporal, scale and author, content and format on global change in local places into easily accessible platform.The reliable,repeatable, re-useful data as resources may make more opportunities for both end uses (such as more than 15,000 end users) and value added services (such as GEOSS Portal, DCI) in the big data age.

Historical GIS Approach for Mapping the Open Space Transformation of Nanjing

Xu Zhen¹, Han Lingyun²

¹Nanjing Forestry University, Nanjing, 210037, P.R. China, xuzhen@njfu.edu.cn

²Jiangsu Second Normal University, Nanjing, 210013, P.R. China

Abstract

Since the beginning of the industrial era the relationship between human beings and nature has changed greatly. This is reflected in the morphology of urban open space. This has not been paid enough attention in either planning practice or academic research.

Through the analysis of historical maps and other archives, the present authors investigate the transformation of open space in Nanjing in the Twentieth Century. With the GIS platform, four main elements, i.e. streets, parks, waters and historical relics, are analyzed for they constitute the framework and utilization of open space. Streets system is analyzed in their impacts on the urban morphology and parks' accessibility. Parks and plazas are analyzed at city scale to find the networks change, and key types and processes. The waters are found decreased extremely, and the consequential change of naturalness and connectivity are illustrated. The historical relics, especially the city walls, are analyzed in its relation to open space and townscape change in the fringe belt.

Understanding these problems is pertinent to appreciation of the city's present ecological health and citizens' access to nature. The authors also found it's important to establish a Historical GIS which integrate the spatial and temporal data such as the maps, old photos, social value, historical events and collective memory. The Historical-GIS framework for open space will have potential in social and historical and ecological study, as well as in planning evaluations, which will offer valuable knowledge for more sustainable landscape management.

Investigating Chinese “Shanzhai” (copycat) Fever: Towards a Perspective of Cultural Economy

Guo Junwanguo, Qian Junxi, Zhu Hong

School of Geography, South China Normal University, Guangzhou, 510631, P. R. China, junwanguoguo@foxmail.com

Abstract

This paper argues that Shanzhai (copycat) in contemporary China is not merely the embodiment of China's fake industries, but the burgeoning economy of grassroots culture in China, and a form of indigenous innovation, which plays a great role in low-end globalization. To substantiate this claim, I probe into why shanzhai appeared and widely spread around the world; how the manufacturers of shanzhai manipulate cultural discourse (advertisements and so on) to influence the consuming conception of customers, especially those with low social status and incomes. While studies on shanzhai have examined intensively in the dynamics of appearance, its influences in innovation, and the disputes of intellectual property, less attention has been paid to interpreting shanzhai as a localizing cultural phenomenon responding to the dramatic globalization; what is the cultural meaning underlying emerging shanzhai economy and how it participates into the globalization process, especially the low-end globalization are still under explore. This study is based on detailed analyses of exhibitions of advertisements, and in-depth interviews with both producers and consumers regarding the meaning of shanzhai. Overall, this paper argues that the understanding of shanzhai should not embed in the binary opposition (negative or positive): it is not just a phenomenon economic production, but represents a complicated process of the localization of global culture and construction of meanings of culture. Because of the shanzhai, China enables at least some of the fruits of science and technology goodness, even if copied, to be spread all over the world.

Key words:

Shanzhai; low-end globalization; culture locating; indigenous innovation

Online Social Networks as Sources to Discover Cyberspace Geographies: The Examples of a Hungarian Social Media Site

Ákos JAKOBI

Eötvös Loránd University, Budapest, Hungary, jakobi@caesar.elte.hu

Abstract

Online social networks (OSNs) are basically virtual creations, which stand for expressing real life friendships in forms of virtual space acquaintance. They serve also as major platforms of ICT-enabled communication, supporting place-independent social life, however, recent findings suggest that geographical location of users strongly affect network topology. As a matter of fact, OSNs may be related to locations, since the users themselves could be at large geographically located as well. By retrieving geolocated data from the network-database of an OSN it becomes possible both to visualise and to analyse geographical relations of users.

This study attempts to introduce how online social network connections are following geographical rules by the assistance of geovisualisation and analytical techniques. Examples of iWiW, the once largest Hungarian social media site, are applied to show that such networks are evolving and are structured not independently of spatial constraints. Different maps and analytical outcomes of network topology lead us to a conclusion that proximity-driven processes have been predominant in the network formation. Also maps of settlement level aggregated data have been applied to reflect user rates, connectivity and space-time diffusion patterns of the Hungarian OSN in order to understand how cyberspace relations are attached to geographical conventions.

Abstract

This contribution explores the potentialities of a method (i.e. PAK MAP: Photo Apperception Knowledge Map - <http://pakmap.net>) that proposes the combination of different visual and participatory techniques to collect qualitative data on the social perception of Mega Events and on the material and immaterial transformations they produce. Such a method - first experimented for the Expo Milano 2015 - adopts a programmatically open and interdisciplinary approach that sees the dialogue between researchers, visual artists and a variegated constellation of social actors (inhabitants, tourists, etc.) as a crucial component of the whole research process. More specifically it avails itself of the construction of "mind maps" within the setting made available by "photo-elicitation interviews" (i.e. in particular a photographic composition on the past-present cityscape of Milan) and of a peculiar declination of what radical interactionism calls "soliloquy". Moreover, in PAK MAP also the temporal dimension assumes a decisive consistency in methodological and content terms, both for the techniques employed and for the different timing considered of the phenomenon observed, i.e. 1) the "before" tied to the expectations about the event; 2) the "here and now", represented by the opening of the Universal Exposition (1st May - 31st October 2015); 3) the "post" event, and the effects perceived in the following months. In this way the research process is articulated, as a whole, through the different visual, multisensory and narrative itineraries that the actors develop of the social world and places that, from various angles, intercept the "fleeting" cosmos represented by a Mega Event.

Key words:

perception; participatory techniques; visual techniques

Fair Cities: Can World's Fairs Build a Better City?

Wilson, M. and Shim, K. I.

School of Planning, Design and Construction, Michigan State University, East Lansing MI 48824, USA.

wilsonmm@msu.edu

Abstract

Mega-events—the Olympics, World's Fairs, and World Cup--offer opportunities for the remaking of their host cities and regions. The excitement, prestige, and glamour of the event brings together many interests that wish to use the event to achieve goals of profit, social change, urban development and city branding. Mega-events are often seen as ephemeral, yet the change to the built environment associated with them must be recognized and understood if the legacy is to be useful to the city. Usually, hundreds of hectares are redeveloped for the site of the events, accompanied by large scale infrastructure projects to serve the needs of participants and visitors. While often popular, these events do not always receive the critical evaluation such major projects deserve. With hundreds of cities planning bids to host large scale events, it is essential that planners and policy makers develop a clear understanding about what mega-events can do to improve cities, and how they can avoid making poor investments for their residents. This study examines the experience of sixteen world's fairs held between 1980 and 2020 as a way to identify the factors associated with successful regeneration, as well as the causes of poor investment decisions by host cities.

Key words:

Mega-events; world's fairs; urban regeneration; tourism

Making the Event-City: Urban Image Construction From Beijing to Rio

Broudehoux, A.-M.

School of design, University of Quebec at Montreal, Canada, broudehoux@mac.com

Abstract

This paper analyses the mechanisms of urban image construction deployed at the occasion of mega-events such as the Olympic Games. It draws upon over twenty years of empirical research in both Beijing and Rio de Janeiro, which each embraced a particular image construction paradigm, defined as the city as spectacle, which rests upon a Deborian vision, and the city of exception, inspired by Agamben's thought. The paper contrasts the strategies used by both cities to conceive and project a particular place image, dividing these approaches into their mediated, physical and social dimensions. The paper discusses the highly selective and political nature of this process, that draws upon seduction to build a consensual, if illusionary image, while also resting upon strategies of exclusion, to limit what is to be shown to the world. The paper concludes with discussions of the concrete impacts of such practices and the diverse resistance strategies used by groups excluded from these representations.

Key words:

Mega-events; Beijing; Rio de Janeiro; Olympic Games; urban image construction; city branding; city marketing; spectacle.

Perception Dimensions of Local Mega-events from the Perspective of Urban Memory: A Case of Qinhuai River Lantern Festival in Nanjing

ZHOU Wei^{1, 2}

¹School of Economics and Management, Nanjing Institute of Industry Technology, Nanjing 210023, China;

²School of Geographical & Marine Science, Nanjing University, Nanjing 210023, China

Abstract

Owing to the social functions of distinctive local characteristics, historical- cultural connotation and urban excellent cultural image of local Mega-events, the paper selects Qinhuai River Lantern Festival in Nanjing as a typical case to construct a theoretical model of the perception dimensions of local Mega-events from the perspective of urban memory, with a qualitative research method of the grounded theory. The research suggests that Bi-directional Dimensions of the visitors and tourists' perception constitute the statically real memory and dynamically activating memory elements, open coding and axial coding reveals the main category of a specific place of historical architectural landscapes, former residence sites and old leisure places, wherein the main category of celebrity masterpieces constitutes historical celebrities and literary works, the main category of experiencing the taste Chinese New Year constitutes Lantern Festival amusements, local delicacies and folk handicrafts, which categories of rich historical-cultural connotation and distinctive local characteristics prove to be the spotlight of perception and memory of the visitors and tourists. The cultivation and development of local Mega-events, as an important component of the urban cultures, should be paid more attention and support from the academic communities and social circles.

Key words:

urban memory; local Mega-events; perception dimensions ; Qinhuai River Lantern Festival in Nanjing

Race and Urban Policy in Rio De Janeiro's Olympic Games Process

Santos, Renato Emerson

State University of Rio de Janeiro, Rio de Janeiro, Brazil, renatoemerson@hotmail.com

Abstract

In the last decades, the Olympic Games have been meant as opportunities for positive urban changes. Beyond political marketing, these meanings often are basis for politic and economic coalitions which defines new material and immaterial contents for the cities. In Rio de Janeiro's case, project of Olympic Games (2016 edition) as a possibility for achieve a global city status has been purposed and accorded since 1992. Several changes on urban structure are happening, and one of the most important projects, going on the central area, is called Porto Maravilha Project, a public-private partnership that seeks a urban renovation of the old port zone. Covering a five million square meters of a centrally located waterfront area, it seeks to stimulate new buildings and renovations, increasing the occupation from 28 to 100 thousands habitants. One highlight is the creation of a "Historical and Archaeological Circuit of Celebration of the African Heritage". For the first time in the history of urban change operations in Rio, a project brings any positive value about the afro-Brazilian presence, culture and heritage as contents of urban space. By other side, the changes involves removal of poor and predominant black population, and undercounting of important cultural goods (the circuit is only six points, while the protected goods are almost forty, and more than sixty sites related to samba's schools - a restrictive concept of this culture and heritage, as archaeological, touristic and elitized). This paper seeks to discuss the ambiguous roles of race issues on this urban project.

Key words:

Racism and urban planning; City project and Racism; Olimpic Games and urban project; Rio de Janeiro.

Abstract

The issue of tourism development, related with sport events, is an aspect of growing relevance for its impact in terms of economic regeneration, but also for its impact on the quality of life. Extraordinary and global mega-events, such as the Olympic Games, or local events such as city marathons are achieving a growing importance in positioning the localities in the touristic market, improving their image, endowments and territorial infrastructures in general. In particular, considering sports mega-events, cities like Barcelona grew their touristic attractiveness thanks to the Summer Olympics in 1992; also the case of Turin 2006 seems interesting from this point of view, even if the actual time span is too little to understand whether there could be a stable growth in the tourism sector (Dansero, Puttilli, 2009).

The mega events can also be of a cultural nature and food and wine performance as the Expo 2015 held in Milan. However it is interesting to consider the relationship between cultural heritage and popular events in Italy not versus mega events but in a symbiotic harmonious and productive relationship.

Key words:

mega events; sport; territorial infrastructures; economic regeneration cultural heritage; food and wine

Beyond Nature: Patagonia as Utopian Expression of Ecological Well-Being.

Aliste E, Núñez A.

Department of Geography University of Chile, Santiago de Chile, Chile, ealiste@uchilefau.cl

Abstract

The production of images representing the ecological ideal in the world, has taken several scenarios to create an important part of this kind of representation. In this context, Patagonia has occupied an important place as full of a sense of pristine nature associated with the place, inhospitable and untouched geography.

These ideas, largely have been strengthened from the notion of margins, borders or distance, all these topics around the idea of disadvantage that led to these spaces as a neglected territory, but today become a site of interest whose value is it has positioned precisely from its status as distance.

In this communication, we seek to reflect on the condition that has been mobilized by an imaginary ecological ideal, which has relied on the photographic, cinematographic, literary and geopolitical production, which together defined a geography marked by the idea of boundary, inmensity and pristine, thus appearing as a possible utopia for ecological dream of the planet.

The consequences of this production of space, show a process of social, economic and political reorganization of the social and cultural geography, where new interests and strategies start to look around this new source of value and in this sense, created a new sociological morphology around this territory. (Abstract presented with the support of Chilean fund for scientific research, project FONDECYT 1141169).

Key words:

Patagonia; ecology; conservation; imaginary; geopolitics; Chile; nature; sustainable development; cultural approach in geography

Community- Based Tourism: Between A Colonial Experience and A Territorial Resistance.

Fernández SANDRA

Department of Geography, University of Concepción, Chile, sandrafernandez@udec.cl

Abstract

The debate on the role of tourism as a development tool plays an important role in the investigation. In this context, we examine the growing emphasis on promoting public policies in order to present tourism as a major engine for development. The different types of tourism, also triggered different responses from local communities who experience the effects of this socio-cultural practice; thus, we can see how the arrival of travelers may lead to consolidation of stereotypes; promote cultural dialogues; or to a re-appropriation of local heritage. Conceptually, this paper addresses the "social construction" of touristic spaces; both culture and the place it manifests, become a commodity where the emphasis fall to on the production of tourist goods that would satisfy the demand of visitor. Furthermore, we found a strong contradiction in the social construction of "beauty" associated with wilderness, the exotic and untouched – both places and people. We illustrate the ambiguity of these processes with experiences of community- based tourism carried out by small producers in an area inhabited by indigenous people in south-central Chile; these experiences may be considered as a result of a colonial perspective, but also as a tool of resistance that encounter all discourses of development arisen along with the "invention of the third world".

Key words:

Community- based tourism; commodification; exoticism; territorial resistance; Chile

"Continental Rift": Geographical Confine and Shelter of the Indigenous from Huasco Alto, Chile

Molina Otárola, Raúl

Geographer, Phd. Anthropology, Fondecyt Project N°1150876. Santiago de Chile, Chile, raul17molina@gmail.com

Abstract

In 1840, the naturalist Ignacio Domeyko in his trip to northern Chile, commented: "... *in a continental rift remains from pre-Columbian times the Indian redoubt Guasco Alto, whose inhabitants preserve the color and the features of the early Americans*". The Huasco Alto was a confine, something beyond what the eye can see, and an earthly plus ultra, one land beyond the known. This land located between mountains, in the 19th Century geographical maps the routes and places were drawn by the "Río de los Naturales" (River from the Natives); It was inaccessible to foreigners and visitors who traveled from the central valley or from the littoral paths. This continental rift is only accessed by narrow traces that snaking the route through the mountains. Was a mythical place where indigenous subsisted, meanwhile the Republic believed extinct since they were literally wiped off the map in the years 1826 and 1830 when the State orders to suppress the Indian villages which remains from the Colonial period. However, the Huasco Alto was a place that Domeyko enhanced with surprise, by asserting that it was a place of refuge, where ideas and customs from the past are preserved.

This paper discusses the geographical categories of confine, earthly plus ultra and geo-cultural and social invisibility, from the study of cartography and historical documents, making a counterpoint with current processes of the Huascoaltinos indigenous ethno genesis, which become visible by their pre-Hispanic attributes from an unknown geographical territory. Follow a discussion related with theories of "imaginary spaces" (Rojas Mix 2006, Manguel & Guadalupi 2014), "legendary lands" (Eco 2013) and geographical imaginary (Hiernaux & Lindón 2012), and the emergence of spaces of ethno genesis, considered indigenous shelters. (Abstract presented with the support of Chilean fund for scientific research, FONDECYT Project N°1150876).

Key words:

geographical confine; indigenous; ethno genesis.

Disciplining the Borderlands. Representations of Iberian Border Areas in Boundary Delimitation Processes Between Spain, Portugal And France (1750-1900)

García-Álvarez, J. & Puyo, J.-Y.

Carlos III University of Madrid, Spain, jacobo.garcia@uc3m.es

University of Pau, France

Abstract

The period roughly between 1750 and 1900 was crucial for the modern delimitation of boundaries between Spain, Portugal and France. During this period, the governments of these States set up several bilateral agreements in order to define and fix as accurately as possible their respective demarcation lines, both in the colonial and metropolitan domains. In the case of the Iberian Peninsula, the Boundary Treaties will mainly seek to strengthen state control over the borderlands and their local communities and mitigate problems related to smuggling, as well as to end the territorial conflicts existing at a local level among the populations of both sides of the borders. The major tasks involving the preparation and the execution of those Treaties were carried out by International Joint Boundary Commissions, made up by diplomats and military officers trained to complete the necessary technical tasks, which included geographical description and cartographic survey of the border areas, as well as the demarcation of the boundary line. The field reports provided by boundary commissioners and other central government actors on certain border areas convey an image of disorder, social conflict and violence which served to legitimate the intervention of state authorities: the accurate delimitation of boundaries is presented as an essential device for achieving a stable peace and harmony both among local populations and among the central governments themselves. This paper aims to summarize the key features of these images by focusing on some case studies from within the Spanish-Portuguese and French-Spanish borderlands.

Key words:

Iberian Peninsula; border regions; boundary delimitation; boundary commissions; geographical representations

Documentation of Cultural Heritage and Interactive Network Based Information Service

Chen CC, Hua L, Fang H

National Engineering Research Centre of Geospatial Information Technology, Key Laboratory of Spatial Data Mining and Information Sharing of Ministry of Education, Fuzhou University, Fuzhou 350002, P. R. China, chencc@fzu.edu.cn

Abstract

Heritage and culture are two important components in life of societies. Conservation of culture heritage is a major issue for modern societies. In this scenario, documentation of cultural heritage and network information service are increasingly emerging which availably provide interactive user experience and obtain initiative protection for culture. Taking this assumption into account, this paper presents a novel information technique architecture, including documentation of cultural heritage, distributed cloud storage and on-demand service, multidimensional realistic recovery and reconstruction, organization management and real-time rendering of large scale virtual scenes, Network sharing and location based service, 3D geographic information system and linkage of video image, context-aware information push service, creative design and animation production and any other technologies. Then several common key technologies in the field of cultural heritage documentation and information services are condense out, to aim at providing technical support for the development and improvement of China's cultural industry, promoting the integration of technology and culture in depth, and serving the overall target of the national culture and technology innovation project.

Key words:

cultural heritage; network based information service; documenting; geographic information system; distributed cloud storage; virtual scenes

Evolution in The Perception and Treatment of the Border Western Sahara-Ifni-Tarfaya

Rodriguez-Esteban, J.A,
Department of Geography, Madrid, Spain, josea.rodriguez@uam.es

Abstract

The different positions on border limits of Western-Ifni-Tarfaya Sahara (Northwest Africa) and the changing contexts in which agreements are signed and proceeds to final survey and demarcation by Spanish-French and Spanish-Moroccan joint committees, reflect both colonial policies as conflicts created after decolonization.

Key words:

border demarcation; amojonamiento; Sahara; colonization; decolonization

From The “Cursed Land” to The “Reserve of Life”: The Influence of the Myth Over the Evolution of the Territorial Imaginary of AysÉN (Chilean Patagonia)

Pérez, S.

Ecole des Hautes Etudes en Sciences Sociales (EHESS), Paris, France, sofia.perez@ehess.fr

Abstract

The stories that travellers transmitted about Patagonia during the early days fed the myth about a legendary land; of a paradise on earth at the very end of the world, and built an imaginary about Patagonia with exoticism of the unknown. But since Charles Darwin made a detailed description of Patagonia in his book “The voyage of the Beagle” (1839), this imaginary vision changed, marked by the idea of a sterile and cursed land. This most recent vision would prevail for years as the perception of Patagonia, and profoundly blind the Chilean government about the geostrategic importance of its natural richness. Even if Patagonia itself has become a geo-mark as much in Chile as in Argentina, exporting the image of unique landscapes as the perfect destination for nature lovers, the life of its inhabitants is far from idyllic. On the contrary, the weight of “the cursed land” is carried by them still today. After analysing the interviews conducted on field, two main question arises: Are the ayseninos really living in reserve of life as the political discourse proclaim? Is it Patagonia lived as the exported touristic image claims to be?

Geographical Imaginations and Scientific Practices of Argentina and Brazil Through the Resolution of Misiones/Las Palmas Boundary Conflict (1881-1889)

ZUSMAN, P.

University of Buenos Aires, CONICET, Buenos Aires, Argentina, perlazusman@yahoo.es

Abstract

During the period of State formation in the Southern Cone of Latin America, the area of Misiones shared by Argentina, Brazil and Paraguay, was subjected to different enterprises of exploration and occupation. The area of Misiones claimed by Argentine, underwent a similar treatment to that of other parts of the country conceived as the “otherness” of the nation. After Brazil organized two military colonies in the border, the Misiones region was recognized by the Argentine State as “national territory” (1881). This recognition meant that the area should be under the direct control of the State in order to prevent it from being occupied by Brazil. Within this framework, the northwestern boundary of Argentina with Brazil was set based on criteria established by treaties and demarcation commissions arranged between Spain and Portugal in the second half of XVIII century. However, the borderland between two rivers (San Antonio and Pepirí Guazú for Argentina, Chapeco and Chopim for Brazil) was not cleared defined in the XIX century, and the new States incorporated in their own political agenda the definition of the boundary in this area. The paper aims to analyze discussions and criteria developed around the Misiones / Las Palmas frontier conflict. We believe that the arguments put forward by diplomats and technicians provide insights not only about the geographical imaginations that guided the incorporation of this area into Argentina’s territory but also about the most appropriate ways to define the boundary between both States as well.

boundary; Brazil; Argentina

German Templers Colony *Sarona* as *finisterrae* in Today's Israel: Preservations for Remembrance and Recreation as Touristic Attraction under Historical Burden

Haim Goren

Tel-Hai College, Upper Galilee, Israel 1220800 gorenh@telhai.ac.il

Abstract

The map of Israel contains many names originating in the period of intensive German settlement between 1840 and WW1. Though there was significant Protestant and Catholic activity, most of the over one thousand structures, many of them monumental, were built by the only European non-Jewish group to establish successful 'colonies' in Palestine, the *Tempelgesellschaft*. The Templers, a sect founded in Württemberg, established four settlements between 1868 and 1875, and three more in the early twentieth century.

During the last two decades, the Israeli government selected these 'German Colonies' and other monuments for conservation and restoration. Considering the highly burdened history beginning in the 1930's, and the fact that a significant number of Templers joined the NSDAP, this might be surprising. However, the structures are of historical importance in the story of modern settlement of the country. This restoration decision impacts upon 'circles of remembrance', both intimate and national.

The best example of this undertaking is the restoration of the Templer 'colony' Sarona, established in 1871 northeast of Jaffa, in present-day Tel-Aviv. When established as an agricultural settlement in Palestine, Sarona was a real *finisterrae*, although not literally 'the end of the world'; and so, too, were its later transformations to early state governmental offices, a military center, and a recreational area attracting thousands of visitors. This site of history and consequence was already part of the country's narrative, but the project has given the historic colony dual meaning, of recreation and remembrance, in the heart of Israel's largest city.

Key Words:

Templers; Palestine; Israel; restoration; remembrance; Sarona history changes; recreation center

Imagining Chile's Northern Frontier: 150 years of Practicing the Border

Freeman, C.

University of Nottingham, Nottingham, United Kingdom, cordelia.freeman@nottingham.ac.uk

Abstract

Chile in the nineteenth century had expansionist aspirations. Hemmed in by the Andes to the East and the Pacific Ocean to the West, expanding North was a logical plan. This aspiration was realised in the War of the Pacific (1879-1883) when Chile took swathes of territory from Peru and Bolivia. What then follows is decades of constructing this territory as Chilean through imaginative geographies, violence, and propaganda.

This paper will focus on the contentious provinces of Tacna and Arica, held 'captive' by Chile from the War of the Pacific until 1929 when Tacna was awarded to Peru and Arica to Chile. This was a long and complex process that began with an attempted plebiscite but ended with international diplomacy. I will map how Chile was able to construct Chilean sovereignty in the Atacama Desert since the nineteenth century in spite of liminality and harsh conditions and how it has continued to do so into the twenty-first century. The process of border-making did not end with the demarcation of Chile's northern border in 1929 but is an ongoing practice made real through cultural performance, economic schemes, and violence.

The paper will question how the narrative of the extreme north helped to make that territory Chilean, why this territory was so valuable culturally and in respect to Chile's nascent neoliberal aspirations, and how in recent years Chile's ownership of Arica has come under threat by certain social movements.

Borders; Chile; Peru; imaginative geographies; violence

Out of Place. Migration as A Process of Disorientation and Reorientation

Marcella Schmidt di Friedberg

University of Milano-Bicocca, Milan, Italy

Abstract

Getting lost invariably represents a radical discontinuity that impacts on how we perceive our overall being in the world and on our habitual system of reference. Border spaces and the need to negotiate for a new belonging are part of the experience of migration: "Migration could be described as a process of disorientation and reorientation: bodies as "move away" as well as "arrive", as they reinhabit spaces" (Ahmed, 2006, p. 9). The disorientation and reorientation process of migrants may be more or less dramatic depending on the historical and political contingencies, social skills, economic or simply from the body of the subject. This experience is now entered in the literature with an incessant decomposition and re-composition of places and languages. In the writings of authors such as Sarah Ahmed, Edward Said, Gloria Anzaldua, Rachid Boudjedra, Zadie Smith, Abigail G.H. Manzella, we will consider experiences of disorientation in different border spaces.

Key words:

Disorientation, reorientation, migration, border spaces

Patagonia-AysÉN as Life Reserve: The Value of the End of the World and The New Capitalist Utopia

Andrés Núñez, Enrique Aliste

Instituto de Geografía, Pontificia Universidad Católica de Chile, Santiago de Chile. aanunezg@uc.cl

Departamento de Geografía, Universidad de Chile, Santiago de Chile. ealiste@uchilefau.cl

Abstract

Geographical imaginaries have a relevant component of both history and memory and, for the same reason, they are also mobile and changeable. Since the 1990s, after being considered throughout the 20th century as a territory colonised by livestock, imagined in a similar fashion to the American “Far West”, Patagonia-Aysén (Chile) began to be interpreted as a zone essential for conservation and environmental protection. In fact, Patagonia-Aysén started to be promoted under the slogan ‘Aysén, Reserve of Life’, indicating a territory not suitable for extraction and exploitation of natural resources, an inescapable and inevitable neoliberalist platform that had been used in Chile for decades. Thus, the ideas of Patagonia-Aysén and capitalism appear to be representing two very different discourses and are, in many ways, opposed. However, as we have demonstrated in our research, capitalism and ‘green’ discourse are more closely related than it would appear from first glance. In other words, ‘green’ arguments have become the utopian discourse underpinned by a technology of power that radically impacts the local spaces in which capitalism operates through land property. To this end, the ‘green’ discourse ends in the capitalist discourse, in parallel with the exploitation of natural resources elsewhere and the new emerging development discourse

Key words:

capitalism, end of the world, utopia, discourses, conservation, Patagonia-Aysén.

Pilgrimage to Finisterrae (Galicia, Spain): New Meanings and Territorial Implications

Lois González, R.C., Lopez, L.; Pérez Guilarte, Y.

University of Santiago de Compostela, Santiago de Compostela, Spain, rubencamilo.lois@usc.es

Abstract

Galicia is located at the Northwest of the Iberian Peninsula, thus being a border region between Europe and the Atlantic Ocean. Its history as an edge of the world has old roots and it is linked to three geographic facts: 1) the region is peripheral; 2) there is a town called Finisterre; 3) Cape Finisterre is the last stage of the Way to St. James for many pilgrims upon arrival at Santiago.

Looking back in time, despite the geographical distance, precisely this condition of Finisterre allowed the consolidation of the Jacobean phenomenon. This situation, together with other geographic environmental conditions, has represented its distinctive value during centuries, thus leading to cultural representation and imagination of a land border thanks to narratives and historical practices, still in force and mainly linked to the Way.

This paper discusses how these territories have taken on new meanings that have helped spreading an image of this mythical peripheral region (named *Coast of Death*). However, the region has survived on the international stage becoming a tourist destination and promoting the village of Finisterre as the goal of the Way to St. James or a mandatory visit for tourists. We analyze the regional changes paying attention to the movements of tourists and pilgrims, who are redefining new territories and geographic imaginaries. We investigate the appeal of heritage (natural, cultural, immaterial, etc.), as a basis for socio-economic development, as well as the implications of regional relationships and alliances between pilgrims, business, public institutions, associations and the population.

Key words:

Finisterrae (Galicia); Way to St. James; Movements; Heritage; Geographic Representations; Socio-economic Development.

“Repoblar El Territorio”: Territorial Imaginaries, Rural Development, And New “Border Spaces” Of Global Capitalism In Castilla Y León, Spain.

Farris, M.

University of Chile – Geography Department, Santiago, Chile, massimilianof@uchilefau.cl

Abstract

Castilla y León is a region located in the center of Spain. However, its spatial location does not imply a centrality in socioeconomic terms. Rather, it is considered a “marginal region”, included in the Objective 1 of the European Union territorial cohesion policy due to demographic (aging and depopulation) and economic (GDP below UE’s 75% average) problems. Consequently, it has been granted several public policies for development, such as the LEADER Initiative (*Liaison Entre Actions de Développement de l’Economie Rural*) for rural development, from 1992 to the present day.

This paper focus on showing how this region was a “boundary” during “*Reconquista*” and how this past is used today to define the contemporary territorial imaginary. This imaginary is built by means of assessing Castilla y León’s geographical “roughness” (castles, ruins, churches, etc.), agricultural peculiarities (local products with DO) and forest resources.

The hypothesis is that, thanks to the European policies for rural and local development—whose goal is to “repopulate the territory”—, a territorial marketing operation is carried out, which may imply a new “colonization”. Marginal rural territories would be a new “boundary” that is necessary to include functionally in global capitalism processes.

Then, it is analyzed whether and how local development, sustainability and tourism discourses contribute to a commoditization of rural territories, specifically highlighting which are the inclusion strategies and power relations between the different local actors.

Key words:

Rural development; LEADER approach; rural tourism; territorial marketing; sustainability; commoditization of territory; European Union; Castilla y León; Spain.

Représenter le *Kansas Lake* au 19^{ème} siècle, vie et mort d'un objet géographique imaginaire dans un *finisterrae* central, l'Ouest américain.

Morcrette Quentin.

ARC 5 – Région Rhône-Alpes, IRG, UMR 5600, Université Lumière - Lyon II, Lyon, France, quentin.morcrette@univ-lyon2.fr.

Résumé

L'histoire de la cartographie est ponctuée d'inventions de lieux imaginaires, dont la présence sur les cartes se fait plus rare à partir du 19^{ème} siècle (Laboulais, 2004). Ces inventions cartographiques sont liées à une connaissance seulement partielle des territoires représentés (Harvey, 1980). En ce sens, on peut dire que la cartographie des *finisterrae* (par définition, mal connus) est particulièrement propice à l'expression de l'imaginaire géographique (Pelletier, *dir.*, 1998).

Cette proposition de communication souhaite revenir sur un exemple tardif de lieu imaginaire, le *Kansas Lake*. Ce lac, dont on trouve des occurrences sur les cartes à partir du 19^{ème} siècle, est localisé au bout de la *Republican River* (affluent de la rivière Kansas), dans l'actuel Colorado. Il représente un cas singulier d'expression de l'imaginaire géographique, dans un territoire qui, bien que central, a longtemps constitué une frontière : l'Ouest des Grandes Plaines américaines

Trente-cinq cartes américaines ont été recensées (entre 1812 et 1870) représentant de manière plus ou moins formelle le *Kansas Lake*. En exploitant les données issues de ces cartes, le propos sera développé vers trois directions principales. D'un côté, on étudiera la sémiologie et les modalités de représentation du lac (expression de la certitude ou du doute cartographique), de l'autre, la dimension culturelle et le rôle particulier de l'eau dans l'imaginaire cartographique (Burnett, 2000), enfin, l'évolution des levés scientifiques et le recul de la *frontier*. Cette communication proposera finalement une tentative d'explication de l'apparition de ce lac sur les cartes américaines, en lien avec des éléments naturels et historiques.

The Treatment of Frontier Closed Area in Hong Kong SAR, China: Towards an Integrated Borderscape?

LEUNG, Chiu-Yin

Department of Geography and Resource Management, The Chinese University of Hong Kong, Hong Kong SAR, P. R. China, chiuyin@link.cuhk.edu.hk

Abstract

This research investigates the changing treatment of border in Hong Kong. In the context of globalization and territorial restructuring, borders not only delimit the power of states but they also ensemble contingent processes, polysemic landscape, and contested imaginations across cities and regions. Due to the unique status of Hong Kong as a Special Administrative Region of China, its border with mainland is still fenced after the 1997 handover. The various bordering practices and policing regimes often lead to uncanny questions of access, citizenship, and identities over the neighboring places. In Hong Kong, the border zone of immediate contact has been imposed with restricted access as the Frontier Closed Area. The remoteness and barrenness in the virgin territory is contrasted across only one river with the compact, skyscraper filled landscape in Shenzhen, which has developed massively and quickly as a pioneer city of reform in China. Since after the relaxation of the Frontier Closed Area and a heightened socio-economic interaction between Hong Kong and mainland China, however, there emerges a tremendous land commodification and place-remaking at the border zone. Ethnographic fieldworks suggest that differential and conflicting perceptions are intensely heated among the local communities but also across other levels. All these socio-political struggles are then further entangled by the politics of scale, which are constitutive of competing discourses and future imaginations about the borderscape that continues to both divides and bridges the self/other in everyday life.

Key words:

border; cultural landscape; politics of scale

The Vicious Circle of Systematic Poaching in the Context of the Information

Phenomenon. Principles, Solutions and Prospects

Svyatoslav Gorbunov

Peoples' Friendship University of Russia, Moscow, Russia. Moscow, svy-gorbunov@yandex.ru

Abstract

This short communication analyses the current picture associated with the direct destruction of wildlife, defined by the term poaching. It presents the idea of a typology of poaching: review this practice as a sporadic or systematic phenomenon, depending on the motivational basis. Based on the example of large African mammals, this article provides statistics on dynamics in the poaching industry over the last decade. The argument about the root cause of poaching practices presented in this paper is based on the balance and interaction of economic indicators of supply and demand. This paper offers a critical look at the proposal for artificially compensating for existing demand for poaching products through the target breeding of rare species of living organisms. We present the idea of the cyclical development of the poaching industry, including addressing the problem of developing such a system in conjunction with the information phenomenon. Based on these assumptions, argument ensues regarding the most effective anti-poaching measures, recognising poaching as a vicious phenomenon currently taking place. As a result of analysis, the author concludes that the most effective would be a complex combination of "soft" and "hard" measures. In this "flexible" measures are in the long term more effective.

To Incorporate Amazonia: Cartographic languages and Geopolitical Projects for Brazilian Territory

Novaes, A. R.

State University of Rio de Janeiro, Rio de Janeiro, Brazil, andrereyesnovaes@gmail.com

Abstract

Amazonia is a constant concern in Brazilian geopolitical narratives. After the resolution of most border conflicts in the *La Plata* basin during the 19th century, the Amazon region was the new *finisterrae* to be protected and occupied. The debate on public policies for the region was one of the main themes in the Brazilian geopolitical thought during the twentieth century. This paper is the result of a broader research project in which I study the cartographic language used by Brazilian geopolitical authors in order to present the history of national borders. My specific aim in this paper is to identify the cartographic practices used in maps made to propose public policies for the Amazon region. The maps studied here were made to convince the government and the society on the urgent actions to be taken to occupy the "vast and empty area". By comparing maps produced in very different periods during the twentieth century, such as those produced by Backheuser (1926) and Mattos (1979), it is possible to identify not only a constancy of the Amazonia as a central issue in the Brazilian geopolitical thought, but also a certain concordance on what kind of public policies should be adopted. Through this specific example, this study aims to contribute to understanding the role of cartography in the construction of imaginative geographies on *finisterrae*. Maps are privileged tools to locate, classify, and act on these regions, and can be studied in their own visual language.

Key words:

Amazonia, Brazilian geopolitics, cartographic language, borders, *finisterrae*

Assessing sustainable neighborhoods: cultural approaches

Doussard C

Université Paris 1 Panthéon-Sorbonne, ENSAPLV, UMR AUSSE 3329, 60 boulevard de la Villette, 75019 Paris, France, claire.doussard@gmail.com

Abstract

The evaluation of green neighborhoods' performance relies mostly on Neighborhood Sustainability Assessment (NSA) tools, which mainly originate from western developed countries. However, these relatively standardized tools not only rate projects in the countries they were designed, but also abroad. This is consequently contradictory to sustainability principles advocating for developments adapted to a specific local context and urban culture. In this paper, we present first how NSA tools, while relying on standards, get adapted to a specific context, and second what constitute their cultural specificities. We analyzed five international NSA tools, the LEED-ND rating system (US), the HQE-A and EcoQuartier labels (France), the AQUA-Bairros e loteamento assessment system (Brazil), and the HKTS green project award (Vietnam), and evaluated how they were used for the projects they assess at the national and/or international scales. The confrontation of those systems shows that a minority of parameters, essentially related to environmental resources and livability, constitutes the common ground on which most of the certification systems are based. More culturally specific parameters contribute however to adapt those tools to particular contexts and projects according to different strategies exposed in this paper.

Key words:

neighborhood sustainability assessment; assessment culture; standards; rating tool.

Folk Festivals to the Reconstruction of Chaoshan Rural Community: A Case Study on God-Welcoming Festival in Chaozhou, China

lingeng00r@163.com

Abstract

As the most solemn and specific festival in Chaoshan areas, God-Welcoming Festival is a folk belief as well as regional culture closely linking to the life of rural community. From the social constructivism perspective, this thesis explores the ritual changes, parade routes, organization, power relations and local people's emotion and identity of God-Welcoming Festival, the folk belief which is different from religious beliefs. By investigating the spatial practice in the sacrifice circle in urban areas of Chaozhou's traditional folk ceremony God-Welcoming Festival, the local knowledge treated as 'the other' under the view of modernity, we intend to deeply analyze the traditional beliefs power and modernity to the rural reconstruction process and its shaping mechanism to Chaozhou community order which play an important role on the sustainable urban development. Results show that God-Welcoming Festival is a kind of cultural practice of self-adjustment for which Chaozhou people living in city are looking in the period of rapid modernization and transformation. The shared community and cultural connotation tied by geographical and the clans relationships shaped by folk beliefs power are not dispelled by modernity. Instead, it proceeds to a long-term resistance and negotiation with the modernity by the ways of inheriting and innovating the ritual, reconstructing the cultural landscape, standardizing organization and the wide variety of informal dialogues from internal and external powers to seek the reconstruction and regression of rurality constantly for the sustainable urban development.

Key words:

folk belief; rural community; reconstruction; modernity; sustainable urban development; Chaoshan areas

Sustainable Neighborhoods' Assessment: From Standards to Cultural Practices

Claire Doussard

Université Paris 1 Panthéon-Sorbonne, ENSAPLB, UMR AUSSER 3329, 60 boulevards de la Villette, 75019 Paris, France,
claire.doussard@gmail.com

Abstract

The technical assessment of sustainable neighborhoods' performance is today mostly based on international standards. This is however contradictory to sustainability principles advocating for developments adapted to a specific local context and urban culture. In this paper, we present first how certification systems, while responding to international standards, get adapted to a specific context, and second what constitute their cultural specificities. We therefore analyzed four international certifications systems, LEED-ND rating system (US), the EcoQuartier Label (France), the AQUA-Bairros e loteamento assessment system (Brazil), and the HKTS green project award (Vietnam). The confrontation of those systems shows that a minority of standardized environmental parameters dealing with resources management and habitat design constitute the common ground on which most of the certification systems are based. On the other hand, social and economical parameters that relate to a country's peculiar context are more culturally specific, while being less utilized by the studied assessments.

Key words:

Sustainable neighborhoods; certification systems; assessment's culture; urban standards; urban planning and design culture.

What is to be Sustained? A Comparative Perspective on Generations, Consumption and Sustainability

Liu C, Diprose K, MacQuaid K, Valentine G, Vanderbeck R

Department of Geography, the University of Sheffield, S10 2TN, UK, chen.liu@sheffield.ac.uk

Abstract

This paper, based on multi-method research ongoing in three mid-sized cities in China, Uganda and the UK, explores the relationship between consumer cultures of different generations, everyday experiences and ordinary people's understanding of urban sustainable development. In particular, it is concerned with thinking comparatively about both environmental and socio-cultural sustainability across the Global North and South and de-centering debates about consumer culture and sustainable development, which has overwhelmingly been researched from the Western, in particular Anglophone, perspective. The paper will consider how changing consumption values and practices relate to and/or impede the production of intergenerational solidarities, and how generational discourses on consumption and sustainability are intersected by race, class, gender and other forms of socio-cultural difference. This research employs cross-disciplinary techniques including intergenerational theatre, discourse analysis and narrative and family interviews, to explore generational views on entitlement to consumption, how people in different socio-cultural contexts understand obligations to contemporary and future generations, how daily consumption is shaped and changed by people's concerns of sustainability, and how generational and lifestyle groupings influence attitudes towards both environmental and socio-cultural sustainability.

Key words:

generation; consumer culture; sustainability; China; Uganda; UK

Diverse Perspectives on Urban Housing: Institutional, Political Economy, Identity, and Feminist Perspectives

Ryu, Yeon-Taek

Chungbuk National University, Cheongju, 28644, South Korea, ytryu@chungbuk.ac.kr

Abstract

In the field of urban housing studies, many Western scholars increasingly devoted their attention to the meanings and roles of housing agents, institutions, capitalist system, identities, and gender in (re)configuring the internal structure of Western housing markets. However, there is no much Korean housing literature that pays attention to these perspectives in the field of urban housing studies. Given this lack of interests in alternative theoretical perspectives on urban housing in Korean housing literature, the purpose of this paper is to draw more attention to and explore discourses on research subjects of urban housing studies such as agent, institution, capital, identity, and gender. Institutional perspectives on urban housing emphasize the roles and effects of institutions and agents involved in the supply and allocation of urban housing and the relationships between conflict, power, and access in the urban housing market. According to political economy perspectives on urban housing, the forms in which urban housing is provided are interlinked with the reproduction of the social relations of capitalism. Identity perspectives on urban housing regard housing as an indicator or symbol of identity, personality, social status, accomplishments, and group values. Feminist perspectives on urban housing are concerned with women's disadvantaged position compared with men's in relation to access into the urban housing market.

Key words:

urban housing; agent; institution; capital; identity; gender

Excited Body and the City: Chinese Dama's Square Dancing

Huang W, Li F, Yang J.B

Tourism Department & Center for Land Resources Environment and Tourism Research, Foshan University, Foshan 528000, China

Abstract

With the speedy expansion of urban population and the aging of Chinese society, square dancing has become prevalent in almost every city in mainland China. The dancers are mainly middle-aged women from the middle class, famously termed as Dama and usually stereotyped as frenetic about dancing in open outdoor spaces of the urban area. This paper attempts to study the phenomenon of Chinese Dama's dancing in urban public spaces through an integrated geographical perspective of body and city, different from what has been usually done in domestic academia focusing on the spatial distribution of the dance floors and its implications over the development of urban public space. Informed by non-representational theories and the geographies of dance, we are particularly interested in the choreography and movement attributes of Dama's dancing practices, the expression of compressed affect through the bodily performance as resistance of the social identity of the elderly female, and the socio-cultural implications of square dancing as part of the nostalgic culture in the mainland. By taking both the insider and outsider perspective, we studied the case of dancing groups in community parks in the Chancheng district of Foshan City and the various recorded cases of square dancing available online by means of movement analysis. The findings suggest that by dancing together, Dama are becoming the new *communitas* of excitements, as if everybody is walking outside herself; the participation into the activity strengthens their sense of belonging.

Key words:

square dancing; Dama; body; performance; affect; identity; city; China

Gendered Spaces and Places in Indian Print Media: an Exploratory Analysis

Das, KRISHNA

Jawaharlal Nehru University, Delhi, 110067, India, krishnadas.jnu@gmail.com

Abstract

Members of a society have a socially constructed view of reality and gender is a salient social categorization that plays a powerful role in our self-expression and interpretation of others' behavior. Such social constructions play critical role in creating/maintaining gender differences and which are fundamentally social and normative in nature. Media is one of the crucial agents of social change and perpetuation of existing dominant ideologies including gender ideologies. Media actively participates in socialization processes and teaches us the ideal gender identities, gender roles and relations. It is the role of media as an active agent of socialization that is the underlining idea behind this work. Even though that women are taking up many jobs and their presence in public places has increased multiple times, women are surprisingly absent from public places in different media forms, especially advertisements. This study attempts to understand the complex interplay of media technologies in general and advertisements in particular, in perpetuating and articulating stereotypical gender roles and images. Media, especially advertisements portray women and men in segregated spaces, performing stereotypical roles and activities. This work attempts to analyze the nature of gendered spatial segregation and gender role portrayals in media images through magazine advertisements. It is based on the content analysis of print advertisements in selected women's magazines and general-interest magazines in India, published in English, Hindi and two regional languages.

gendered spaces and places; gender Roles; gender stereotypes; politics of representation

Planning with Communities in Regeneration Projects: Towards A Gendered Civic Capacity in Bat Yam, Israel

Fenster Tova

Tel Aviv University, Israel, tovifenster12@gmail.com

Abstract

This article explores the central role that gender plays across a variety of scales in the development of civic capacity among residents of Meonot-Yam neighborhood in Bat-Yam, Israel. The article proposes a new, gendered reading of civic capacity which involves transforming women's and men's ways of thinking and acting out of the ordinary in this regeneration project, with the aim of updating and revising the term as related to planning with communities (PwC) approaches. Using a performative understanding of gender based on feminist poststructuralist analysis to identity knowledge/power and place, we combine the analysis of community and personal scales, looking at 'paradoxical moments' to understand how the transformation in power relations has taken place and how civic capacity is developed. We do so by conducting a critical analysis of biweekly meeting minutes and in-depth interviews held over a three-year period (2010-13). This civic capacity development is particularly important for women who manage to enhance and increase their social capital throughout those years.

Key words:

gender; civic capacity; regeneration

Reimagining the City: Feminist Praxis in the Classroom

Ramdass, K

Department of Geography, National University of Singapore, Singapore, geokr@nus.edu.sg

Abstract

Drawing from pedagogical research conducted as part of a class on Gender and the City, I discuss some of the possibilities for transformational politics both in and beyond the classroom. As part of the course students were asked to read literature in feminist political economy and engage with its framing of social reproduction in the context of cities and urban life. They were asked to keep a journal of their observations relating to three themes in Singapore: consumption, social reproduction and redistribution. Through the process of journaling they were also required to reflect on their positionality, privilege and emotions. Finally, they were asked to work in pairs, drawing from individual learning outcomes to produce a poster on Singapore that recognizes the 'uncountable' and unaccounted for emotional and social logics that underpin social reproduction in the city. By analyzing some of the findings and outcomes of classroom-centred research, my aim is to further contribute to literature on feminist praxis in urban research. Specifically, I discuss the benefits of student journaling in settings where conversations about difference can sometimes be problematic. Through this project, I also hope to emphasize the pedagogical value of feminist praxis in education, and argue that it remains an important starting point for reimagining alternative and more egalitarian urban futures.

Key words:

feminist praxis; city; urban geography; social reproduction; redistribution; education.

Re-Inventing the Traditional Buying Roles – Exploring the ‘New Women’ In Delhi

Sengupta Soma, Sen Anjan

Kamala Nehru College, University of Delhi, New Delhi – 110049, India, dr.somasengupta@gmail.com

Abstract

Financial independence, self-identity, job satisfaction and professional achievement, which were previously considered as the sole prerogative of men, are now desired also by the women in urban India. With the emergence of new family categories, like single-women headed households; and notions of feminism and women liberation touching them; it has led to a major shift in the role-structure of women in family, leading to emergence of the ‘new women’. This is reflected in the market place in the form of a change in the purchase behavior pattern associated with a variety of goods and services.

Traditionally, men dominated purchase-decisions for products like, automobiles and electronics; while women were associated with the role of home-maker influencing purchase of groceries and kitchen appliances. But, the emergence of ‘new women’ has seen a change in the buying roles.

The paper analyses the increasing influence of the ‘new women’ in the purchase decision-making process for different category of products in Delhi. It also explores the impact of socio-economic factors on their buying roles. The study revealed that the ‘new women’ has altogether broken the stereotypical roles, with a role interchange. While men also buy groceries; women too, take important decisions regarding buying cars and electronic gadgets; and even do not hesitate in buying embarrassing products, like, sanitary napkins, condoms, birth control pills, and pregnancy-test kits. The women with more education and better jobs have more influence in purchase decision-making. The study has strategic implications for marketers in terms of product-positioning, advertising and promotional strategies.

De la comparabilité des données migratoires au Sénégal

Sakho, P,

Université Cheikh Anta Diop de Dakar, Dakar, Sénégal, papa.sakho@ucad.edu.sn

Abstract

Les données sur les migrations internationales sont devenues l'objet d'une attention particulière de la recherche à la mesure de la place qu'elles occupent dans les agendas internationaux. En Afrique de l'ouest, l'intégration régionale et le débat sur les relations entre les migrations internationales et développement vont entraîner la nécessité de produire des connaissances sur la question à partir des années 1990.

Ainsi des données ont été produites à travers enquêtes nationales et régionales sur les migrations réalisées surtout dans la décennie 1990-2000 par diverses sources. Seulement leur exploitation se heurte à leur dispersion entre plusieurs structures rendant difficile la lisibilité de l'information tant dans sa nature, la méthodologie utilisée que dans la définition des variables.

Cette communication a deux objectifs, le premier est d'identifier les données migratoires dans les enquêtes nationales et régionales les recensements et les enquêtes à vocation démographique, économique et sociale au Sénégal. Le second objectif est d'analyser la comparabilité entre les données sur les migrations du recensement général de la population 2002 et les données de l'enquête MAFE, une enquête exclusive sur les migrations au Sénégal en 2007.

Elle repose sur l'analyse des enquêtes intégrant des variables migratoires et celles spécifiques sur les migrations menées au Sénégal depuis les années 1990.

Development of International Population Mapping Methods and Datasets at the U.S.

Census Bureau

Comenetz J

U.S. Census Bureau, Washington, DC, USA, Joshua.Comenetz@census.gov

Abstract

The U.S. Census Bureau is expanding its efforts to develop global population map layers.

We completed the first version of the Global Population Map (GPM), a spatial data set that provides seamless global coverage of population estimates linked to subnational administrative geography. GPM links recent population estimates to subnational geography down to the third administrative level where available. The data set currently covers approximately 70,000 subnational areas, and will eventually include several hundred thousand. International boundaries are harmonized based on the U.S. Department of State's international boundary layer.

Our current focus is development of methods for adding variables to GPM, including population estimates by age and sex; language, ethnicity, and/or race; literacy; and income or poverty. For some countries or regions, we will enhance the administrative area mapping with 100-meter grid cell maps. The latter represents an extension of our existing Demobase gridded mapping product.

Data sets and maps already released online include subnational administrative geography and population estimates and projections for more than 20 countries; gridded Demobase data sets for Haiti, Pakistan, and Rwanda; and a global population dot map. While these data have a wide range of applications in government, research, education, and the private sector, our primary goal is to provide the data and maps needed to support humanitarian assistance and disaster relief efforts worldwide.

Key words:

population mapping; GIS; demographic change; grid; ethnicity; humanitarian; hazards

Spatial Mechanism Analysis of Inter-provincial Migration Flows in China

PU Yingxia, HAN Xiao

² Jiangsu Provincial Key Laboratory of Geographic Information Science and Technology, Nanjing 210023, China;

³ Jiangsu Center for Collaborative Innovation in Geographical Information Resource Development and Application, Nanjing 210023, China

Abstract

Since the reform and opening-up policy, migration activities in China have been greatly increased. Simultaneously, researchers at home and abroad have paid much attention on this phenomenon and have gained a lot of theoretical and empirical results. However, most of these studies are based on the traditional gravity model, which emphasizes the characteristics of origin (O), destination (D) and distance factors. It fails to express the feedback and spillover effects on neighboring regions due to not explicitly capture the spatial dependence among regions. This paper investigates the network autocorrelation effects of Chinese inter-provincial migration flows over the 2005-2010 periods. The network weight matrix provides the possibility of investigating the network autocorrelation effects among inter-provincial migration flows. Several spatial OD models are established by introducing different network autocorrelation matrices into the traditional gravity model. Monte Carlo simulation method is then applied to estimate the spillover effects of each independent variable, including total effects, direct and indirect effects. The results are as follows, firstly, the indirect effects of most variables are not zero significantly, which mean the change of any given explanatory variable in a single region will affect the migration flows to and from surrounding regions. Secondly, the direct effects are much stronger than indirect effects, that is, the impacts from a variable change of some region on its own migration flows are larger than those of surrounding areas. This is due to the fact that spillover effects take on a decreasing trend with the increase of the order of network weight matrix. Finally, the spatial OD model without constraint conditions is the best compared with the single and double constraint models. The spatial mechanisms of migration network system can be explained by spatial OD models to some extent.

Construction of Traditional Dwellings Geography

Yongwei Kang, Hongwei Zhou

Hunan Normal University, Changsha, 410081, P. R. China, The Geographical Society of China, kywnch@126.com

Abstract

In the traditional dwellings' protection field, experts from multidisciplinary face to the crisis in common. During the protection course, new discipline of traditional dwellings geography is taking shape. Construction of traditional dwellings geography (THG) should absorb nutrients from related disciplines, but the beginning should be started at geography. On the meaning of the composed phrase (THG), the "traditional" mainly refers to historical evolution and tradition, which focusing on its gradual process and both concern history feature and take care of the current inherited condition, especially those living cultural heritage. "House" is not only the static architectural heritage, but the people's home. It reflects both dwellings of human adaptation to the natural reaction and the extent of the transformation of human nature. "Geography" refers specifically to regional differences, spatial distribution, and the spatial scale; the spatial scale option of traditional dwellings follows the type system of traditional dwellings, building materials, living culture and built environment. Traditional dwellings geography is the study of traditional dwellings traditional dwellings historical heritage, the built environment, residential style type system, living culture, regional differences and spatial distribution of the traditional building materials. Methods of Traditional dwellings geography mainly absorbed architectural historians, environmental studies, folklore, anthropology, cultural geography and other disciplines methods. Practice of geography traditional dwellings should choose the area rich in cultural heritage and in the belt of cultural interchanged district.

Exploring Urban Economic Resilience: The Case of a Leather Industrial Cluster in India

Kamala MARIUS, Venkatasubramanian

University Bordeaux Montaigne, UMR LAM Sciences Po Bordeaux, French
Institute of Pondicherry

Abstract

Unlike some other developing countries of the world, India has shown relative resilience to the global economic crisis (2008-2014) by maintaining one of the highest growth rates in the world. Even if one of the main drivers of India's growth during the global economic crisis has been still the services sector (55%) located in peripheral locations of metros, the manufacturing sector not only in metropolitan areas but also in small and medium towns has contributed to keep its massive informal labour in spite of its low contribution in the GDP (16%). The example of the leather industry is one India's oldest manufacturing industry with a tendency of informalization and feminization of the work of the formal sector. The demand for its products concerns both domestic as well as international market.

In spite of low levels of innovation in Indian clusters, we have to remember the large number of workers employed in the enterprises located in these small and medium towns and its impact on the rural and urban economic growth. The performance of these clusters and their competitiveness in the globalised and liberalized economy become important.

In this context, the main objective of this study is to analyse why some small industrial towns globally positioned are economically resilient while others are not. What distinguishes resilient small towns from those that fail to recover from the economic recession?

A preliminary analytical framework based upon mechanisms, policies, actors can deepen our understanding of the factors of the resilience of industrial towns. This study has engaged with the resilience of small industrial towns well integrated from colonial times into global networks (this study is funded by ANR (French agency) SUBURBIN is a joint project of IFP and CSH, under the responsibility of Eric Denis and Marie-Hélène Zérah)

Key words:

urban economic resilience; industrial cluster; small towns; economic geography

Foreign Immigration and Urban Vulnerability in Spain's Main Cities

Domínguez-Mujica, J., Díaz-Hernández, R., Parreño-Castellano, J.
University of Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, 35003 Spain,
josefina.dominguezmujica@ulpgc.es

Abstract

The Spanish Ministry of Development has published a series of reports on vulnerable city districts in Spain, where vulnerability is defined according to a number of criteria, two of which are closely linked to processes of foreign immigration: the percentage of foreign children under the age of 15 (excluding EU-15 nationals) and the proportion of foreign immigrants in relation to the total population (again excluding EU-15 nationals).

The application of these criteria at a micro scale to Spain's largest cities (Madrid, Barcelona, Valencia, Seville, Zaragoza and Malaga), reveals the persistence of vulnerability associated with foreign immigrants. Consequently, the aim of this paper is to evaluate that vulnerability applying the criteria above to the period 2001-2011, making use of population and housing census data at microscale level.

The analytical procedure developed has consisted in the elaboration of a series of socio-demographic, housing and economic indicators that make it possible to identify vulnerability trends in certain urban areas during this period.

It is necessary, however, to bear in mind the impact the economic crisis has had on Spain since 2008, which has brought about a significant drop in foreign population rates as many immigrants, particularly Latin Americans, have returned to their countries of origin -a phenomenon that should not obscure the issue of ethnic segregation in Spain's main cities.

Key words:

Immigration; urban vulnerability; Spain; residential segregation

Refugees, Violence and Women: A Case Study of Albert Park Area, Durban

Sinenhlanha Memela and Brij Maharaj

Rhodes University, Grahamstown, South Africa. Email: s.memela@ru.ac.za

University of KwaZulu-Natal, Durban, South Africa

ABSTRACT

Women refugees are affected more by violence than any other female group in the world, before, during and after forced migration. Violence against women includes psychological, physical and sexual attacks taking place in the family, community, which is sometimes tacitly condoned by state. This paper examines violence experienced by female refugees in Durban South Africa. Adopting life histories and in-depth interview methods, the specific focus is on domestic violence, the fear of urban public space, and the failure of police protection. As female refugees attempted to settle in a hostile society they encountered various forms of domestic and public violence in Albert Park. Most of the women interviewed did not report domestic violence to the police. They were scared to report it due to stigmatization. Female refugees were afraid of using urban public space because they were subject to physical attacks, verbal abuse and sexual harassment from refugees, local people and taxi drivers and conductors. This was aggravated by the high levels of xenophobic violence in South Africa. Female refugees were not only threatened by the local people but were also harassed by other refugees. The fear of urban violence compounds the trauma that most female refugees experienced in their home countries. Women were also frustrated by the tension between local people and foreigners and the knowledge that police protection was limited. Female refugees are an extremely vulnerable group that needs special attention. South African refugee policies and legal instruments at an international level have failed to protect refugee women.

Smart Cities, Disabled People and Vulnerable Mobilities

Kullman K.

Department of Sociology, Goldsmiths College, University of London, Laurie Grove, New Cross, London, SE14,
k.kullman@gold.ac.uk

Abstract

As notions of smart cities are spreading rapidly around the world, this paper offers critical insight into the largely unexplored question of how these impact the everyday mobilities of disabled people, a particularly vulnerable urban population. Drawing on a European Research Council funded study, the paper examines how contemporary cities are increasingly seeking to respond to the needs of disabled persons through a wide range of smart city solutions, such as digitally enhanced, interactive street furniture, lighting and signage, in order to facilitate their ease of movement. The paper follows smart city practices at different scales and in diverse domains, from urban governance through design work to daily encounters between technologies and users. In doing so, the paper demonstrates how disabled people are chronically absent from smart city discourses, which are mainly concentrated on younger and able-bodied populations to evoke dynamic and future-oriented scenarios for cities, thereby effectively immobilising the former. Apart from critiquing such a limited approach to urban transformation, the paper develops more affirmative alternatives by discussing design projects have started to question prevailing smart city discourses and are currently experimenting with more inclusive forms of technological development by collaborating with disabled people and by thinking closely about how their products impact the urban mobilities and immobilities of vulnerable social groups.

Key words:

Smart cities; urban mobility; vulnerability; disability; design.

Socio-Economic Development of Tribals: A Micro Level Case Study in West Bengal, India

Baskey SUMANTA KUMAR, Jana NARAYAN CHANDRA

Department of Geography, The University of Burdwan, Golapbag, Burdwan, Pin: 713104, West Bengal, India, sumatabaskey@gmail.com

Abstract

Tribal development has been an emerging issue in India since 1950. Tribes have almost always been considered as a peripheral phenomenon even amidst huge diversities of mainstream Indian life and culture. They remained socio-economically backward due to socio-political reasons. The economic reforms in India since 1990s due to globalisation although put an emphasis on the eradication of poverty, but do not consider the problems of tribals on priority basis. Despite the initiation of several developmental programmes at the government level for their welfare, no significant economic growth has taken place among the tribals. Only a small section has been benefited from the programmes. Their economic conditions had gradually deteriorated with more and more tribals becoming landless labourers. Keeping the above situation in backdrop, Manbazar-II Block of Purulia District in West Bengal, India has been taken as a case study for assessing the level of socio-economic development of tribals. In the present study, composite index with the help of principal component analysis and some statistical methods has been used. Result reflects that socio-economic development of tribals is not uniform and wide ranging disparity has been observed within the study area. Overall development can be possible only through improvement of common minimum needs and their awareness and it should focus on the human capabilities. Finally tribal development in real sense requires guaranteed Government action especially for women, elderly and children.

Key words:

Socio-economic development; tribals; principal component analysis; common minimum needs; awareness

"Don't Worry, We Will Tell a Great Story." Narrative and Politics of Migrants

Marianne Blidon

Paris 1-Panthéon Sorbonne University, France. marianne.blidon@univ-paris1.fr

Abstract

Since the 1980s, the French immigration policy was increasingly restrictive. The images of the massive arrival of refugees from the Middle East by sea as well as the attacks in Paris and Brussels have created a tense situation that favors the rise of far-right parties. This situation affects the application of the law by the regional prefects. The regularization of undocumented persons or the granting of asylum depends on the ability of individuals to document their situation and their trajectories. The presentation of evidence and the storytelling as a proof is a key moment in the course of the applicants. Associations help them build their case. From the observation of a permanence in Paris, this paper will examine the expectations of personal narrative which also depends on gender, social class and country of origin. Through this case, the paper tries to think the contemporary geopolitical issues at different levels (European, national, regional, local) and politics of spaces (be in place or out of place).

Key words:

migration; gender; political geography

Migration and Citizenship in Post-Apartheid South Africa: Perspectives On Social Cohesion

Nshimbi Chris

GovInn, University of Pretoria, South Africa. chris.nshimbi@governanceinnovation.org

Abstract

Given that the immigration debate in South Africa has often targeted African immigrants in both actual and symbolic ways, which could be interpreted as exclusionary and granted that I conceptualize social cohesion as constituted by "the elements of social progress which include human security and solidarity, and can be both constitutive to development, and instrumental to other elements of development, for example the ability of social groups to sustainably improve living standards, or the ability of representative institutions to facilitate economic reforms" (Norton and De Haan 2013:4), my paper places a "strong emphasis on the importance of inter-group relations—on overcoming perceptions of grievance held by social groups which can become the basis of conflict, and on actions which can help to overcome such perceptions e.g. by building citizen identities which cross-cut social difference or by conflict resolution approaches"(Norton and De Haan 2013:4). In this regard, I propose, to investigate the context of the migration and immigration debate in South Africa in terms of how it reflects on claims to citizenship vis-à-vis the African immigrants and social cohesion. Being infinitely aware that the South Africa population is not cohesive in its own right, my interest is on the added dimension of African immigrants. How does the presence of African immigrants complicate social cohesion? What livelihoods do African immigrants engage in? Are these beneficial to the host communities? Can this be the basis of social cohesion? If some African immigrants play an important role in their host communities, what can be done to reduce the divide between 'us' and 'them'? Considering that we live in an "era of globalisation, mass mobility and super diversity" (Dyers and Wankah 2012:234), in which migration is not only increasing, but will be a permanent feature of all countries, it is urgent that social cohesion is achieved at least between South African citizens and African immigrants, because "social membership—a clear sense of who belongs (community, nation) is necessary to establish clarity around the basic rights and obligations which govern social interaction" (Norton and De Haan 2013:4).

Key words:

Migration; xenophobia; social cohesion; South Africa

Migration, Regional Cohesion and Citizenship: Teasing Out a Borderless Southern Africa

Moyo Inocent

Geography Department, University of South Africa. minnox@yahoo.com

Abstract

This paper considers the possibility of establishing a borderless southern Africa—under the auspices of regional bodies such as the Common Market for Eastern and Southern Africa (COMESA), the Southern African Development Community (SADC), and the Southern African Customs Union (SACU). Special attention is given to migration and informal cross-border interactions, and corresponding legislations and policies of selected member states of the said regional bodies. This is done, against the realities and understandings of migration and contested notions of citizenship and development in southern Africa. A thorough review of legislative and policy frameworks regarding and affecting migration at the regional and national levels was conducted. Personal interviews with key policy makers selected on the basis of their policy portfolio, migrants, and other non-state actors, and participant observations at border posts/crossings, immigration offices and refugee or asylum application centres, etc. were conducted. Southern Africa is characterized by open borders and substantial formal and informal cross-border movements that have political and socioeconomic costs. While the most preferred destinations by migrants in the region have officially and systematically opposed a formal regional free-movement-of-people regime, geographical logics and realities on the ground indicate the necessity of a regional migration governance framework that is devoid of borders. This, however, needs to be carefully crafted and consider the region's history, the challenges associated with migration to sending and receiving countries and the general fear of the unknown that is manifest in state authorities and national and regional legislators.

Key words:

Migration; Xenophobia; Social cohesion; South Africa

Out of Place: Popular Geopolitics and The Representations of The 2015 'Refugee Crisis' In Europe

Mamadouh, V.

University of Amsterdam, v.d.mamadouh@uva.nl

Abstract

Media representations of the 2015 'refugee crisis' in Europe are key to responses by governments and policy makers at the Union, national and local level, by civil servants on the ground, by journalists and by the general public. They are shaped contingently by a variety of actors, ranging from the conventional media to the migrants themselves through their use of the social media, and circulate within and between nationally shaped public arenas. This paper discusses geopolitical discourses representing migration in general and more specifically the 2015 'refugee crisis'. These geopolitical representations consist of many elements. These include first representations of the actors: the migrants themselves (framed in different groups allegedly deserving different entitlements), and the states involved at different level (local, national, regional, EU) and at different stages of the process (states of origin, transit states, states of destination) – and second representations of the places along their journeys: sea and land borders, migration routes and border crossings, camps and reception centres, cities and public space in Western European countries. They also feature storylines about the deep and direct causes of migration flows, their consequences in the short and the longer term, and the desirable and actual management of the flows, and articulate assumptions about the agency of migrants, the nature of the border, and the ethical challenges for the receiving societies and communities. The paper will focus more specifically on the gendered representation of refugees and/or migrants and their presence 'out of place'.

Keywords:

political geography; popular geopolitics; gendering; othering; Europe; migration; refugee crisis; border; place

The REPLACE Approach for achieving Social Norm Transformation: Tackling Female Genital Mutilation (FGM) in the European Union (EU).

Barrett, H, R, Alhassan, Y, Browne, K.

Coventry University, Coventry, UK. h.barrett@coventry.ac.uk

Abstract

This paper will present the innovative REPLACE Approach for achieving social norm transformation that has been produced by researchers at Coventry University. The REPLACE Approach was developed in response to concerns about the continuing increase in FGM in the EU, despite the practice being illegal in all EU Member States (most with an extra territoriality clause) and many decades of campaigning by third sector organisations to end the practice. The REPLACE Approach brings together Community-based Participatory Action Research methods with behaviour change theories and has produced a five stage approach to social norm transformation. Using the results of the implementation and evaluation of the approach in five EU Member States (Italy, Netherlands, Portugal, Spain and UK), working with a variety of FGM affected African diaspora groups in those countries (Eritrean, Ethiopian, Gambian, Guinean Bissau, Senegalese, Somali and Sudanese) this paper will describe the approach, in particular focussing on the innovative REPLACE Community Readiness to End FGM Assessment. The paper will demonstrate that different communities have different belief systems and community enforcement mechanisms concerning FGM and are at different stages of readiness to end FGM. The REPLACE Approach allows these differences to be investigated and inform intervention activities designed to tackle FGM. Evaluation has confirmed that the REPLACE Approach has potential to transform social norms that perpetuate FGM in the EU and beyond and could be used to tackle other harmful social norms. The REPLACE Project was funded by the European Commission's Daphne Programme (JUST/2012/DAP/AG/3273).

Key words:

REPLACE Approach; Female Genital Mutilation; European Union; Social Norm Transformation.

Collective Identity: Chinese Student Experiences of UK Universities

Ning Tang

Sheffield Hallam University, UK. n.tang@shu.ac.uk

Abstract

The number of Chinese first-years coming to the UK has increased by 59% since 2009/10 with 58,810 Chinese undergraduates started their study in the UK last year, comparing with the total number of 57,190 EU students (HESA Feb 2016). A large body of literature discusses the barriers of integrating Chinese students to the UK campus. An understanding of Chinese students in the UK academic context requires further examination of their conceptualization of their own identities. This paper aims to explore how Chinese student experiences construct a collective identity which helps position themselves as being Chinese enjoying British culture on British campus.

The paper will review existing literature about Chinese student identities in an international context. The concept of collective identity will be discussed which has rarely been applied in the study of Chinese students studying abroad. Drawing on data collected from qualitative interviews and focus groups with Chinese students, the paper argues that the construction of collective identity is a fluid and dynamic process as indicated in the Chinese students' interaction among themselves as well as with home and other international students. This process holds for both individuals and collectivities (Snow 2001). Whilst the issue of identity becomes more problematic and unsettled as societies become more structurally differentiated, fragmented, and culturally pluralistic (Castells 1997; Giddens 1991), the understanding of Chinese students' collective identity and its significance in their negotiating process to be accepted by both English and Chinese cultures is critical in improving Chinese students' experiences in UK universities.

Key words:

collective identity; Chinese student experiences; UK universities

Educational Strategies of Internationally Mobile Students Choosing Denmark as Their Study Destination

Lisanne Wilken

Research director at the Department of Global Studies, Aarhus University, Denmark. ceklw@cas.au.dk

Abstract

Over the past ten years the number of students who go abroad to pursue tertiary education has more than doubled, from 1.9 million in 2000 to 4.1 million in 2010 (OECD 2012). More than half of the internationally mobile students go to just five countries: The USA, UK, France, Australia and Germany, and a substantial number of the rest go to Canada, Russia, Spain, Italy, Austria, China and South Africa (UIS 2011).

In recent years' smaller European countries have entered the competition to attract some of the mobile students. Universities in countries such as Denmark, Norway, and Sweden are increasingly offering courses and Masters Programs in English and adapting their educational structures to the Bologna model in order to ease student mobility. While initially primarily targeting European and select non-European students there is an increasing interest in also attracting students from emerging market economies.

So far very little research has been done into how students come to choose a university in a smaller European country, or who these students are.

With reference to a comprehensive survey of students who attend international study programs in Denmark and to 85 narrative interviews with students from such programs this paper aims at pinpointing the educational strategies of students who navigate the global space of tertiary education and end up in Denmark. The analyses in the paper takes inspiration from Bourdieu's concept of strategy and asks who the students are who go to Denmark and how Denmark becomes the destination of 'choice'?

In a Bourdieusian sense "educational strategies" may be understood as ways of "manoeuvring" in a 'space of possibles' (Lamaison 1986). The 'possibles' that individuals perceive as available options for action depend on their habitus (internalized dispositions acquired through socialization) and their capitals (e.g. exams, language abilities, network and money) with reference to their position in social space. A social space, Bourdieu pointed out, is always a signposted space where different routes are open to different people (Bourdieu 2000). Different individuals may thus see different possibilities in the same space depending on position, habitus and capital.

Thus in order to understand the educational strategies of students who go to specific places we thus need to construct an understanding of not just their nationality, age and gender, but also their social class, previous

33rd International Geographical Congress

21-25 August, Beijing, China

mobility experience, inherited and acquired capitals as well as insights into the position of (in casu) Denmark on their “mental worldmaps” or geographical imaginaries (Wilken 2007, Holton & Riley 2013).

International Students and "Two-Step Migration" Policies in Switzerland: To What Extent Are Federal Policies Re-Interpreted at The Cantonal Level?

Yvonne RIAÑO

Institute of Geography, University of Neuchâtel, Switzerland. yvonne.riano@unine.ch

Abstract

Academics have recently recognized the key role of migration policies in regulating the extent and character of international student flows. However, research in this new field remains scant. As we know, several governments around the globe view international students as valuable future skilled migrants. Accordingly, the Swiss parliament passed in 2010 the "Neirynck initiative", which entered into force on 1st of January 2011, allowing international students who were successful in securing employment to remain in the country. Studies on the implementation of "two-step migration" policies are rare. Furthermore, scholars examining policies of student mobility tend to focus on how 'state actors' influence student flows without recognising the role of the different levels of government from the federal to the local. In Switzerland, federal actors play dominant roles in setting the conditions for how international student flows are handled but the process of how these policies are implemented is largely influenced by cantonal authorities. On the assumption that two-step policies may be re-interpreted at the local level, we formulate the following questions: (a) How is the Neyrinck two step-migration policy understood and implemented by key actors, at the federal and cantonal levels of government? (b) To what extent is the Neyrinck policy reinterpreted by cantonal authorities in its practical implementation, and what types of tensions may exist between the two levels of government? These questions are examined by means of expert interviews with key actors at the federal and cantonal levels, as well as by content analysis of policy texts.

Stay, Return or Move On? Mobility Decisions of International Students in Germany

Glorius, B.

Chemnitz University of Technology, Chemnitz, Germany, birgit.glorius@phil.tu-chemnitz.de

Abstract

Facing demographic decline and shortages of qualified labor force, Germany entered into the international “battle for the brains” by introducing policies aiming to favor the immigration of highly qualified foreigners and – more recently – also policies trying to support international students’ long-term stay in the host country after having completed tertiary education. However, state administration had to realize that the mere introduction of supportive measures is not sufficient for retaining considerable numbers of international graduates.

Before this background, we have to ask how international students actually make their decision concerning future mobility steps. The proposed paper tackles this question by analyzing individual migration biographies and considerations on future perspectives whether to stay, return or move on. It draws on a series of biographical interviews with international students at the University of Halle (Germany). The paper assumes that migratory decisions are individually negotiated using elements of rationality, subjectivity and emotionality. The analysis shows that future mobility intentions are densely connected to life-cycle or career considerations on the one hand, and to character and perception of framing elements such as economic and labour market situation, integration policies or societal conditions on the other. The paper discusses how major findings such as the embeddedness of migratory decisions in the individual and family biography, subjectivity in decision making and a high degree of transnationality in daily life can feed into a broader conceptualization of mobility and migration.

What China? Which Chinese? Reshaping Identity through Transnational Student Mobility: A Case Study of Indonesian Mobile Students in China

Rika Theo

Utrecht University, Utrecht, the Netherlands, rika.theo@gmail.com

Abstract

This paper draws attention to the role of transnational mobile students as social and political agents which was less well discussed in the existing research on student mobility. Using the case study of Indonesian students in China, this paper investigates the deconstruction and reconstruction of the politicized identities on China, Chinese, and Chinese-Indonesian by the transnational mobile students. The dominant politicized identities have been produced under a long fragile historical trajectory of Indonesia and China's relation that intersected with their domestic politics. Chinese-Indonesians in particular have been portrayed as the problematic non-native others who could threaten the nation building and dominate the economic sector. Under the burgeoning economic cooperation and closer diplomatic ties of China and Indonesia, the mobile student are the ones to contest and negotiate previous identity discourses, then reconstruct them with the encultured knowledge obtained during their mobility. This paper investigates the process of attaining transnational identity capital including the tension within in challenging the old myth of identities through the experience of being and becoming the transnational mobile students.
