A Critical View of the Subjectivities behind the Cultural Maps of Beijing

LI Xin, ZHOU Shangyi

School of Geography, Beijing Normal University, Beijing, 100875, P. R. China, zichuan1314@163.com

Abstract

The maps do reflect the so-called real world objectively. It is more obvious of the maps which show cultural features of a place. Both cartographers and cultural geographers are interested in the subjectivity of mapping. This research takes cultural relativism as its perspective and look at the maps of Central Beijing with cultural features. We interviewed the makers of the maps what they wanted to show in the maps and by what cartographical methods. Meanwhile we interviewed the users of the maps what they wanted and gained from the maps. Then we categorized the subjectivities of the map makers, and classified the cultural imagination gaps between the map makes and users, who include locals of Beijing and Chinese and foreign tourists. The conclusions are as following. Firstly, the main landmarks of Central Beijing are the common image components of the map makers and users. It is caused by the influence of the typical cultural representations in many kinds of visual sources. Maps plays a role in cultural identity of Beijing as other visual sources. Secondly, the subjectivities varied among map makers, locals and outsiders. It is good that more and more publication opportunities for common people inside Beijing or outside Beijing to show their cultural images of Beijing, rather than the only source of authority. And the cartographical methods are improved to represent cultural feature creatively.

Key words:

subjectivity of mapping; maps of Central Beijing; cultural relativism

A Geo-Ethical Issue of Caste Base Human Discrimination-A Fault Line for

Harmonious World

Chanyal, P.C. (Assistant Professor)

Department of Geography, Kumaun University, Nainital, India, Nainital 263001, Uttarakhand,
prakash_chanyal78@yahoo.com

Abstract

Caste has been one of the oldest and most distinctive feature of human society of the world, which are discriminate in layers basis on various parameters such as, color, occupation, heredity, rituals and religious as well as by birth. Caste Discrimination Effects (CDE) an estimated 360 million peoples on worldwide, the huge population living in South Asia. These are facing massive violation of civil, untouchability, sexual assault, murdered, economic, social, festivals, and political, however their have suffering from fundamental rights and needs. Caste systems is spreading other country such are Jati in Nepal, Pakistan, Sri Lanka, Burkumin in japan, Baekjeon in Korea, Al-Akhdam in Yeman and as well as in African countries similar to India. Caste system divided peoples into unequal and hierarchical social groups. Those at the bottom are considered lesser human being and polluting to other caste group.

It is a geo-ethical issue for as geographers. In this paper, I will compiled and correlated that we cannot reduce and make harmonious world without mitigation of Caste base discrimination of the human societies in the world. We have try to analyze, how can mitigate the impact of man-made & natural disaster, Climate changes, Inequality, Poverty, Chronic Diseases and Terrorism also. We want introduce also, a new discipline in geography education as a “Caste & Casteism Geography–A Geoethics”, because we believe the sustainable social Development is must be our first priority and we cannot go as untoward, than will be influenced on another issues.

Key words:

Caste Geography; Mitigation of Disasters; Caste Discrimination Effects (CDE); Sustainable Society.

A Research on Buddhist Cultural Landscape in the Guanzhong Region Based on the Culture of Birthplace

Xiang Yuanlin ,Cao Mingming.

Northwest University, Xi'an, 710127, P. R. China, 261029270@qq.com.

Abstract

The Guanzhong region is located in the middle of shaanxi province, China. It is one of the important birthplaces of Chinese nation, and it's also one of the birthplaces of many Han cultural landscapes. The old Chang An is one of the earliest regions when Buddhism introduced into China. In the surrounding of it collected six of the eight birthplaces of Han Buddhist sects . And thus the Buddhist culture spread to the whole of China and the whole of east Asia, formed a unique culture we named it "Culture of Birthplace", attracting Buddhist culture lovers from China,Japan, South Korea and other countries in east Asian cultural circle. Through the analysis of the planning layout characteristics of the six major Han Buddhist birthplaces which remained to now, and the spatial distribution patterns and regulations of the Buddhist monasteries in the Guanzhong region,we explore the effects of diffusion and its inherent regulations of "the Culture of Birthplace" to "the Buddhist culture". Meanwhile we put forward the culture landscape patterns of the Guanzhong region,hoping that we can provide some basises and references to the development of religion and tourism ,the protection and construction of the Buddhist cultural landscape.

Key words:

Buddhist Cultural Landscape; Culture of Birthplace; spatial distribution patterns

Aggressive Dragon or Benevolent Panda? The Dilemmas of the Confucius Institute in Global Expansion and Local Thrust

Hong Zhu, Zhenjie Yuan, Junwanguo Guo

Center for Social and Cultural Geography, South China Normal University, China, zhuh@scnu.edu.cn

Abstract

The Confucius Institute (hereafter, CI) has become the signifier of Chinese soft power. Majority of Anglophone literature tends to see the CI as “Trojan Horse” carrying well-disposed motivations to map China’s soft power globally and insert communist dictatorship and legitimacy locally. So far, the threat of the CI, in a large sense, has been stereotyped and “taken for granted”. However, little attention could explore the capability of the CI in serving China’s exportation of soft power in its continuous and inseparable dynamics of globalization and localization. Borrowing the technical toolkits from Geographical Information System and carrying out ethnographies in four CI branches, this paper attempts to response the question that to what extent could the CI serve China’s soft power agenda. The findings are: 1) unlike the mainstream declaration which portrays the CI as aggressive and wishful actor, this paper tease out the economically- and politically-based logics behind its global extension, arguing the CI is the subtle “consequence” of mutual negotiations where fulfill with ongoing persuasion, compromise and even resistance between China and its collaborators; 2) Moreover, this paper evidences the capability of the CI is systematically-limited in its everyday operations, reflecting China’s impotence in managing such a global cultural network; 3) The dilemmas that the CI shows generosity in economic concession but hesitation in political negotiation echo China’s uneven development of economic and political reform. By the international cooperative project like the CI, China may export its domestic uncertainty and dilemmas to the world.

Commodified Language in Foshan after the Urban Renewal: A Case Study of the Linguistic Landscape in the Lin-Nan New World

Huang W, Li F, Yang J.B.

Tourism Department & Center for Land Resources Environment and Tourism Research, Foshan University, Foshan 528000, China. Vivienne_l_hw@126.com

Abstract

In Foshan's newly transformed neighborhoods, recent commercial establishments, primarily Chinese owned chains, use non-Chinese-language signs as design features targeted towards people who neither read nor have ethnic ties to these foreign languages. Using Lin-nan New World, an urban renewal project for the historic neighborhood of Dong Hua-li as a case study, we applied a contextualized approach to linguistic landscape through a qualitative analysis of a total of 500 visual signs along the main pedestrian street of the region. Drawing from cultural geography and sociolinguistic studies, we analyzed how written language interacts with other features of the built environment to construct commodified urban places. By linking micro-level linguistic and para-linguistic analysis of individual signs to the specific local socio-geographic processes of spatial commodification, we try to attain a greater understanding of the larger socio-political meanings of linguistic landscapes. We found that with one third mono-linguistic English signs, internalization and globalization have steadily made their way into Foshan's urban landscape, as a result of which linguistic landscape have become the most representative sites and as English and other non-Chinese languages are not an officially admitted social interactive means, the commodification of these languages in the construction of urban landscape reflects the gentrification of the neighborhood after the urban renewal.

Key words:

linguistic landscape; urban renewal; commodification; neighbourhood; Foshan

Construction of Cultural Landscape by the Spatial Idea in the Jinuo's Village

CHEN Yapin, ZHOU Shangyi

School of Tourism and Geography, Yunnan Normal University, 650504 P. R. China, 1093060303@qq.com

Abstract

Previous studies of Jino's village cultural landscape mainly focused on the study of material culture landscape. In this paper, the spatial environment of cultural landscape is treated as a concept of the symbolic system, through the research of Jino's spatial idea in the Yunnan, the formation of idiosyncrasy of place, and its role in reconstruction of cultural Landscape. Jino's spatial idea in the village can be divided into spatial impressions and spatial perception. The spatial impression is how Jinuo view the space of the village, the spatial perception is the perceptual structure of relative position of Jinuo's themselves and the surroundings. The spatial perception reflects spatial position and value in Jinuo people's thinking, " idiosyncrasy of place" is a stable relationship of human and environment. " idiosyncrasy of place " is stable relationship between man and the environment created by the spatial idea, all of which converge in the methodical spatial pattern, so that people can better understand the world and shape the landscape of self-identity. Certain cultural space is created in accordance with spatial idea by themselves, concise idiosyncrasy of place, construction of cultural Landscape and give meaning to the landscape. The research methods used in this study are community mapping and PGIS.

Key words:

spatial idea; the structure of spatial perception; idiosyncrasy of place; PGIS; Jinuo's village

Cultural Geography in Russia: Historical Origins and Contemporary Research Areas

Streletskiy V.

Institute of Geography, Russian Academy of Sciences, Moscow, 119017, Russian Federation, vstreletski@mail.ru

Abstract

The paper presents an overview of the historical origins, specific features, development trends, key issues and prospects for the further development of cultural geography in Russia. Establishing of cultural geography in Russia took place in the course of close interaction between geography, ethnography, social and cultural anthropology. In pre-revolutionary Russian geography the anthropo-cultural approaches were widely used; however, since the 1920–1930s most of them were buried, and revival of Russian cultural geography began actually only in the late Soviet period (in the 1980s). The orientation of national human geography toward the cultural geographic dimension at the end of the last century is explored in the paper. Key features and development trends that were characteristic of Russian cultural geography over the past quarter-century are discussed. Statistical data on dissertations in the field of cultural geography between 1995 and 2014 in Russia are aggregated and analyzed. The following directions of cultural-geographical researches reached the prior development in Russia at the end of the XX - early XXI centuries: 1) cultural geography of ethnic groups; 2) confessional geography; 3) the studies of the urban-rural cultural-geographical distinctions; 4) cultural-landscape studies; 5) the studies of regional identity; 6) the studies of geographical images (with their modeling, representation and classification) and perception of geographical space by various cultural groups; 7) the integral regional cultural geography (focused on studies of cultural regions and investigation of regionalism as phenomenon of culture).

cultural geography; Russia; cultural space; cultural regionalism; cultural landscape

Cultural Heritage of Ayodhya (India): an identity of National integrity

Mr. KUMAR, Sarvesh and SINGH, Rana P.B.

Department of Geography, Banaras Hindu University, Varanasi, UP 221005, India, sarvesh1k@gmail.com

Abstract

The concept of heritage appeared with respect of cultural tourism, consisting of all kind of things which give knowledge about the past – they are under the heritage. It is always visible and maintains the relationship between the memories of our past for better consequences of present and future. Since the ancient days of the *Vedas* and *Puranas*, cultural-heritage city Ayodhya has been a famous place of pilgrimage, possessing salvific quality and holy tradition of Hindu religion, wherein the river Saryu (Ghaghara) perceived as a goddess just like the Ganga river. Ayodhya, assumed as birthplace of Rama, the seventh incarnation of Vishnu, and also the birthplace of legendary foremother Korean Queen Huh, the wife of great King Suro. Ayodhya is also sacred to other religions of India, like the Jainism, Buddhism, Sikhs, and Islam (Muslims), representing a symbol of national integrity. There were five Jain temples that are related to the birthplace of five Jain Tirthankaras. According to the Buddhist holy book, Ayodhya was the birth place of Buddhist scholar Ashvaghosha, and here the Gautam Buddha had spent many rainy-seasons. Ayodhya records a number of rituals, festivities, pilgrimages journeys and important ancient temples, river *ghats* (stairways and bathing places), holy tanks, holy wells, and holy ponds; those are the representative grandeur of art and tangible and intangible heritage values of place. This paper describes the cultural, religious and heritage values of Ayodhya as identity of national integrity and basic resources for developing pilgrimage-tourism.

Keywords:

cultural heritage; national integrity; pilgrimage journey; tangible and intangible.

Cultural Transformation of “Deori” S: A Social Geography Perspective

Deori SUJATA

Assistant Professor, Department of Geography, North Gauhati College, Guwahati, India, sujatadeori@yahoo.com

Abstract

Culture is the reflection of livelihood including ethics, values, rituals etc. In many cases, the existing culture of any social group is the result of assimilation with other groups to some extent and influence of Geographical condition to another extent. As a whole, culture is the product of Historical, geographical, social, political conditions and also traditional values are attached with it.

As some Geographers consider Human Geography as Human Ecology, so both living and non-living things are included there. We can observe that culture has living characteristics. It can modify, transform or strictly preserve its tradition. Sometimes it might become completely lost in the vast and broader society.

“DEORI”S are inhabitants of North East India specially Assam, India. They belong to Scheduled Tribe population. Available records show that prior to the sixth century AD, *Deoris* had been living in an around Sadiya (north-easternmost part of Assam) in Assam. The term ‘*Deori*’ is attached to the religious or priestly functionaries of various tribal as well as non-tribal communities of Assam.

Since the time of 17th century the Deori habitat areas had been facing problems. The attack of ‘Manns’ and ‘Mishmi’ tribes, epidemic and diseases and influx of hill tribes from some parts of neighbouring states created problems of shelter and settlement. Internal migration too took place from various parts of Arunachal Pradesh and this had a debilitating effect on availability of land for the community as a whole and the people were migrated to the south of their origin settlements through the Brahmaputra valley.

There was another flow of migration of *Deori*’s in the last century, which was caused due to the devastating earth quake in 1950s and Consequent flood and river bank erosion. They migrated to different districts of upper and middle Assam forming some groups. This process continued up to last century and they are now distributed in eight districts of Brahmaputra valley.

As a result of the migration and consequent spatial distribution of *Deoris* the socio-cultural, economic and religious life of the community is affected to a great extent. Their economic activities have been influenced by the ecological conditions prevailing in the newly settled areas and their earlier pattern of livelihood has changed in a considerable way. A new social transformation has taken place with the assimilation of different ethnic groups.

This research aims at identifying the spatial patterns in the process of migration from earlier settlements to the present locations and the degree of cultural transformation of the community. The research also makes a modest attempt at getting an insight into the causes and consequences of migration of *Deoris* from their original settlements.

Key words: Migration; Cultural Transformation

Culture-Led Transformations of Industrial Heritage at Multiple Scales:

a Case of Xinhua Printing Plant in Beijing

Dai Juncheng

Central University of Finance and Economics, Beijing, 100081, P. R. China, na0228@sina.com

Abstract

In the context of efforts to protect industrial heritage, or in scenarios where industrial heritage is a dimension of conflict, most part of the difficulty has been the challenge of appreciating fully the question of different scales. By invoking scale, we refer to the different power that might relate to heritage, in some instances through highly specific contexts and profoundly local scale and in others through links to national or regional scale. These different scales of power and relationships can both frame and complicate efforts to protect or reuse industrial heritage. In this paper we explore the culture-led transformation that have occurred at Xinhua Printing Plant in Beijing, a famous historical industrial heritage where the attraction of cultural industries has been used to revitalize the area. We employ a multiple framework that considers how different scales of powers that including central government, state-owned enterprises, Beijing and Xicheng government engaging on the process of transformation. It finds that different scales of power with diverse commitments to a particular heritage site or expression are often distinct and not always easily compatible. Our analysis suggests effective ways to align different stakeholder interests in industrial heritage at multiple scales of engagement, and as a basis for relationship-building across fraught geopolitical boundaries, should be an important research priority in the culture-led transformation policy sphere.

Key words:

industrial heritage; scale; power; culture-led transformation; Xinhua Printing Plant;

Different Interpretation Patterns of the Ancient Water System in Hongcun and Its Influence on the Optimization of Man-Land Relationship

Xiang KONG

East China Normal University, Shanghai, 200062, P. R. China, xkong@bs.ecnu.edu.cn

Abstract

Cultural heritage often contains wisdom and experience on harmonious man-land relationship at some specific historical period. Different interpretation patterns of the cultural heritages may affect the cognition of modern people on man-land relationship and thus affect the current construction of ecological civilization. As a model of harmonious man-land relationship, the construction history of river system in Hongcun was explained in different ways by the tour guide words and the residents, which delivers different ideas on man-land relationship. Interviews shows that tourists are mainly humbled by the "cow-shape" water system according to the tour guide words, which may strengthen the cultural determinism thought. However, residents are more likely to combine the construction of water system with the development of the village, which mainly reflect the thought of harmonious man-land relationship. For the current construction of ecological civilization, the thought of harmonious man-land relationship may play a positive role. Therefore, cultural heritage tourism should respect history and convey scientific thought of man-land relationship.

Key Words:

water system in Hongcun; interpretation pattern; man-land relationship

Diffusion of the Morin Khuur Music and Registration to the National Representative List of Intangible Cultural Heritage in Qian Gorlos Mongol Autonomous County, Jilin Province, China

Takahashi K

Komazawa University, Tokyo, 154-8525, Japan, takahasi@komazawa-u.ac.jp

Abstract

The government of P.R. China ratified UNESCO treaty of the Convention for the Safeguarding of the Intangible Cultural Heritage in 2004. They started safeguarding intangible cultural heritage and made national representative lists four times from 2006 to 2014. Though the population of the Mongol in Qian Gorlos Mongol Autonomous County is only 41 thousand (6.8% of the total population of the county), 10 elements of intangible cultural heritage of the county were registered to the national list, all of which are associated with Mongolian culture. Based on field research, the author studied how the Morin Khuur (horse-head fiddle) music diffused in the county. Mongolian political leaders and officers play important roles, from 1990s the local government started introducing this instrument into elementary and middle schools. They invited teachers and players of the instrument from Inner Mongolia Autonomous Region, and supported organizing an official Mongolian music band in the county. Nowadays, thousands of residents, both of the Mongol and other ethnic origins from kindergarten pupils to senior citizens, play the Morin Khuur in the county, which forms a striking contrast to the Cultural Revolution period when almost nobody played the instrument. As a result, the Morin Khuur music of the county was registered to the national list in 2008. Since the Mongolian cultural elements gain popularity, it would promote the vitalization of regional tourism. However the Mongolian tradition in the Morin Khuur music would be weakening simultaneously.

Keywords:

the Mongol; the Morin Khuur; intangible cultural heritage; ethnic minorities; acculturation; ethnic autonomous system; China

Exploring Public Sphere Based on Folk Belief: Case of CunXin Charity Hall in

Chaoshan area of China

Lin G, Lv Z

School of Geography and Planning, Sun Yat-sen University, 135 Xingangxi Road, Guangzhou 510275, China, eeslg@mail.sysu.edu.cn

Abstract

As a cultural force of informality, folk belief inter-grows with the social structure and naturally conforms to the social governance. This paper argued that strong private emotions and social relations generated by folk belief continue to play important roles in the operation of modern social organizations. With an empirical study of CunXin Charity Hall, which originated from the worship of a deity called Dafeng Patriarch in Chaoshan area of China, this paper examined the mutual relationship between “public” and “private” in the following aspects: (1) Belief motivations of members (in public, the purposes include feeding back the society or serving the community; in private, the purposes are seeking shelter and bailment, pursuing happiness after-life or revering ancestors). (2) Management mechanisms (in public, the charity hall adopts a bureaucratic model to promote management efficiency; in private, it retains traditional mentorship on a concentric power structure). (3) Practical activities (in public, Buddha activities, ceremonies, alms giving and folklore festivals have provided opportunities for strengthening collective cultural memory and social consciousness; in private, relative practices have improved interpersonal relationship and mutual understanding among believers and helped construct individual identity and realized self-achievement. Public sphere based on the folk belief has showed a multi-dimensional picture of the “public” and “private” that integrates and interweaves with each other under modernity, which may has some inspiration for the innovation of the pluralistic social governance model.

Key words:

folk belief; public sphere; informality; social governance; China

Fiction and Urban Space in Shanghai in Late Qing Dynasty: the case study based on Hai Shang Fan Hua Meng.

Xiaohong Zhang
Fudan University, China

Abstract

After opening in 1843, Shanghai was the important window through that foreigner and Chinese observed each other as while as it became the largest city in the Far East. There were many records about Shanghai City left, include tourist guides, collections, maps, fictions, and etc. The documentation has different purposes in research of the urban space, especially about urban social space in Shanghai that time: non-fiction records could give us the exact geographic location of streets other than the lifestyle of Shanghai, but the fictions could represent the routine life of the citizens vividly. If we combined the two kinds of documents, we could make a significant breakthrough in the study of urban social space in Shanghai. Therefore, the study aims to represent the active space of Shanghai in the late of Qing Dynasty by analyzing the details in the fictions: Hai Shang Fan Hua Meng, that the social characteristics of space in Shanghai were used to recount the story and the portrayal of the characterization.

Key Words:

Fiction; Urban Space; Opening; Shanghai; Hai Shang Fan Hua Meng

Geographic Scenes and Space Construction in *Macbeth*

Yangming BAI

School of Foreign Languages, Hubei University of Technology, Wuhan, Beijing, 430068, P. R. China, zgbybm@icloud.com

Abstract

In *Macbeth*, Shakespeare designs many geographic scenes, constructing mysterious space and power space, in which the fate changes along with different geographic scenes and the tragedy develops with the shifting of spaces. Differences of geographic scenes in the play present the inevitability of Macbeth's miserable fate. The research, carried on space scenes and space construction from the perspective of literary geography, provides a new way and a new point of view to interpret *Macbeth* and a better way to understand how Shakespeare presents space experience and the characters' fate by way of geographic space.

Key words:

Macbeth; geographic scenes; mysterious space; power space

Heritage Value of Religious Sites and Cultural Landscapes: The Scenario of Hinduism from India

Rana P.B. Singh

Vice-President, ACLA: Asian Cultural Landscape Association (SNU Seoul, Korea), and President: IASR, Indian Association for Study of Religion 2014-16, and Professor of Geography (spel. Cultural Geography & Heritage Studies), Institute of Science, Banaras Hindu University, Varanasi, UP 221005, India. ranapbs@gmail.com

Abstract

Hinduism is experienced through its spirituality, sacredness, architecture, and landscape. Hindu temples are Hinduism's coded religious messages, constructed of symbols, designs, iconography, and depictions of historic and literary events. Combining and unifying these elements, Hindu temples communicate the divine. Eight of the 32 UNESCO's World Heritage Sites (WHS) in India fall in the category of the religious heritage of Hinduism, viz. Chola temples, Hampi shrines, Mahabalipuram, Pattadakal, Khajuraho, Sun temple, Elephanta caves, and Ellora caves. To date 51 properties are listed in the WHS's Tentative List from India, and 7 of them are associated with Hinduism, viz. Bishunpur, Ekambra, Hoysala, Srirangapatan, Kakatiya, Sri Ranganathaswamy Temple at Srirangam, and Majuli Island. In Southeast Asia, there are 5 religious WH sites, viz. Prambanan Temple (Indonesia), Angkor Wat (Cambodia), Pashupatinath Temple and other temples (Nepal), Mỹ Sơn Sanctuary (Viet Nam), and Mother Temple of Besakih (Bali, Indonesia). The case of Varanasi's Riverfront is a unique Religious Heritage and cultural landscape, still waiting for inscription in the WHL, however due to internal politics and lack of coordination, the process becomes too complicated and difficult. As recent discourses identify the unique characteristics and heritage value of Hinduism and its temples, it will affirm the value of the divine in the human experience. As a result, pilgrimage-heritage tourism will promote and contribute to global understanding.

Heritage ecology; Hinduism; Krishna; Riverfront heritagescapes; Shiva; Southeast Asia; Varanasi; Vishnu; World Heritage Sites.

Indigenous Diplomacy: Following the script or writing the book?

Lambert, Simon J.

Lincoln University, Christchurch, New Zealand. simon.lambert@lincoln.ac.nz

Abstract

Indigenous Peoples and ethnic minorities have highly-attuned rituals and ceremonies reflecting their ancient concepts of how to engage with other peoples and societies. These practices not only retain their relevance in contemporary diplomacy but have increasing value as future diplomatic efforts will encompass diverse and self-conscious cultural groupings at both sub-national and international scales.

This paper describes how Indigenous Peoples achieve new roles as diplomatic agents at the fluid borders of international exchange. In particular, the experiences of Maori in New Zealand will be presented as they have increased their presence in international trade from a recent history of 'performing' in the arts and culture, sports, tourism and military roles. It is argued that seeking wider relationships while promoting and protecting self-determined cultural logics, Indigenous Peoples have fundamental insights into how ethical exchanges can be articulated and maintained.

Is Education a Right? Production of Bulletin Board Space Based On a Comparison Between British Columbia University and Xianlin University Town of China

Chao Ye

School of Geographic Sciences, East China Normal University, Shanghai, 200241, P. R. China, yeover@163.com

Abstract

As a kind of micro-scalar space, bulletin board in campus is an important symbol and representation of the university culture, and is a window to observe higher education. Based on a comparison of bulletin board culture between Xianlin University town of China and British Columbia University of Canada, this paper attempts to reveal the dialectical relationship between culture and space: the different cultures shape the different campus spaces, and these kind of spaces also shape people's daily life and cultural values. The same points between the two places are reflecting the cultural diversity of university and very close interaction between university, city and society. By contrast, the academic and humanistic space in Chinese university campus has been squeezed because of erosion from utilitarian and commercial culture, and then forming a tense, separated and rootless university culture; although there is a little utilitarian tendency in Canada but more pluralistic and tolerant than China, and more considerable share on academic and humanistic information on the bulletin board which means more academic spaces. There is a dialectical tension between everyday life and production of campus cultural space. This production of university bulletin board, although it is only a micro scale space, indicates the crisis of higher education, especially for the universities of China.

Lingering Resonance— the Soundscape and Poetic Patina in China Classical Garden

Zhiran Fan, Zhen Xu, Shuaiqi Xia

College of Landscape Architecture, Nanjing Forestry University. 274950708@qq.com

Abstract

"The making of the poetic world is the highest pursuit of traditional China gardening. The integral poetic setting consists of visual form, sound, odor and even tactile perception which derive from stone, water, architecture and plant, catalyzes psychological perception as well as mental reflection of visitors. Sound's contribution to garden patina has rarely been researched for a long period because the difficulties of acquiring or reproducing historical soundscape in gardens. Based on the historical literatures, local annals, construction documents and journals, this paper analyzes the significance and configuration of soundscape in the making of poetic patina, and attempt to contextualizes it in the city sound background of that time.

With measuring and analyzing current soundscape of several existent classical gardens and their surroundings, the author also conduct questionnaire survey and relevant user interviews to acquire contemporary visitors' perception and evaluation.

The paper aims to reconstruct the sound environment of several China classical gardens, and to formulate the contribution of the poetic patina, hence to provide insights of creating sonic amenity with vitality for the hurly-burly urban environment."

⁴Prof. Dr. Département de Géographie et du Programme de Post-graduation en Géographie de l'Université de Chile, Chili.

RÉSUMÉ

Ce document traite de la configuration des microterritoires traditionnels d'origine rural dans l'espace urbain de la ville de Ponta Grossa, état du Paraná, au sud du Brésil. On part de la prémisse que la mondialisation capitaliste et la rationalisation du monde de la vie n'ont pas homogénéisé les spatialités urbaines qui se imbriquent et se hybridisent en résultant aux plusieurs expressions d'identité traduits dans la pluralité de façons de vivre et de habiter. Malgré la représentation sociospatiale hegemonique urbaine (soumis à la temporalité moderne) est imposée comme projet dominant sur d'autres identités et sur les géographies vernaculaires quotidiennes, les imaginaires et les pratiques rurales résistent et s'adaptent au mode de vie urbaine. Ils se présentent comme un projet alternatif d'urbainité en proposant autres façons d'habiter (se relationner) sur et avec l'espace (avec les individus et les choses). Dans la multiplicité sociospatiale urbaine de la ville de Ponta Grossa persistent et se réinventent microterritorialités rurales traditionnelles resubjectivées dans quelques pratiques culturelles telles comme l'agriculture biologique, la médecine populaire et des pratiques alimentaires paysannes. En termes paysagistique ces expressions identitaires sont associés à geosymboles de l'architecture vernaculaire, les parcelles de cultures, les jardins potagers, et l'agencement du voisinage qui révèlent rapports sociaux particuliers. La reproduction des savoirs écologiques, médicinaux et alimentaires d'origine rural forment des réseaux d'acteurs, ce qui permet de réaffirmer les identités traditionnelles et alternatives dans le contexte sociospatiale de la culture urbaine.

MOTS-CLÉS:

microterritorialités rurales; espace urbain; modes d'habiter; imaginaires géographiques; pluralité sociospatiale

Multi-Images of an Historical Area in Central Beijing: A Post-Modern Case Study of Dongjiaominxiang

ZHOU Shangyi, LI Xing

School of Geography, Beijing Normal University, Beijing, 100875, P. R. China, shangyizhou@bnu.edu.cn

Abstract

Administrators want to know the impacts of giving a specific title or defining a specific function to an historical area in the city. For answering this question, we conducted a survey in Dong Jiao Min Xiang (DJMX) which is near Tiananmen Square in Beijing and is one of the 25 historical areas in Central Beijing. We sampled and interviewed more than 100 local people and tourists in DJMX. The questionnaires and interviews reveal that they have more than five images of this place - as a residential area, the embassies area in the late Qing Dynasty, a conservation area of western architectures, a place of patriotism education and a state administrative quarter. The quantitative analysis of the data reveals that the historical and political senses of this area are not more obvious than other images. The Pearson correlations relating individual attributes' and their identities of the images show that there is no common identity within most groups. We conclude that tourists and locals have multiple images of DJMX. This conclusion coincides with perspective of administering postmodernism, that is, there is no apparent reason to label DJMX as a specific image. It may allow people to add more significant meanings to it after their deeper thinking in the future. It also allows to add individual locals and tourists memories and emotions to this historical area rather than to erase them by a single image.

Key words:

post-modern; multi-images; Dongjiaominxiang; historical area

Nanjing Historical Landscape and Its Planning from Geographical Perspective

Yao Yifeng

Nanjing Normal University, China, york2020@vip.163.com

Abstract

The paper endeavors to explore a new framework of thoughts on the research into the landscape of the ancient capital based on the geographic sceneries. Historical cityscape has changed because it was the expression of the dynamic interaction between natural and cultural forces in geographical condition. Geography was the most stable, inheritable and lasting force for its founding and development. Therefore, usually the planning for preserving the landscape of the ancient capital in China tends to proceed from architecture only limited in the architectural space, from individual buildings, streets and blocks to whole city, while lacking research into the landscape of the ancient capital from the perspective of the composition of geography. The composition of geography in Nanjing blesses its development as an ancient capital in history with unique and profound traditions of the landscape. Its structure is mainly as follows: three mountains, two rivers and three lakes. The conception and planning of Nanjing have been following this system of natural geography since its birth along with several subsequent major changes. The modern urban development of Nanjing has segmentally resolved the entity of continuous mountain ranges in history while the river network has fallen into a discontinuous state. The thought of research in this paper is marked by investigating and analyzing the relics of the ancient capital based on the system of mountains and rivers as well as exploring changes of time and space and laws of evolution with regard to the composition of cultural landscape of the ancient capital in the course of exploring the present system of mountains and rivers, so as to further confirm and seek for the geographic key of the development of historic cities in the landscape system, and make analysis of and planning for the preservation of Nanjing as an ancient capital in the light of geographic landscape, i.e. taking the system of continuous mountains and hills, rivers and city-moats as backbones, keeping the continuity of mountain outlines, maintaining the integrity of the river network; taking natural mountains and rivers to link with historic ruins which are independent of one another; taking the city-wall of the Ming dynasty and historic streets as a network as well as important buildings scattered in different places for preservation to constitute a complete composition for preserving the landscape of the ancient capital. The concept of sceneries is to be extended to the entire urban area, hence integrating the preservation of natural resources, land utilization and landscape planning into one.

Key words: Geographic composition of Nanjing; landscape changes; heritage-oriented corridor; landscape planning of the ancient capital.

Old Québec City : Religious, Touristic and Harmonious

Marcotte, P. & Bourdeau, L.,

Département de géographie, Université Laval, Québec, Canada, Pascale.marcotte@ggr.ulaval.ca

Abstract

The historic district of Old Québec City (Canada) is known as the crucible of French civilization in America. In 1984, the Old Québec was designated as a World Heritage (UNESCO). The main reasons were his “coherent and well preserved urban ensemble, ... an exceptional example of a fortified colonial town, and by far the most complete north of Mexico” and because “the former capital of New France, illustrates one of the major stages in the European settlement of the colonization of the Americas by European”. Still today, its architecture and streetscapes shows evidence of presence of French, British, and Canadian rule.

The fortified colonial town refers to its old defense system: authentic fortifications and a substantial citadel. But the Old Québec have also an important religious landscape, legacy of the different empires, and their different cultures and religions.

Today, religious heritage sites and landscape are a major and recognized tourist attraction. But for many years, despite a large number of tourists, these religious sites were not seen as touristic, and the tourism was not seen as a mean of religious heritage preservation and conservation. Today, these tourists facilitate improved understanding between different culture and religion. The religious communities also changed their discourse about religion and tourism.

This communication will present the case of Old Québec City, and specially of Le Monastère des Augustines. Le Monastère occupies the historic wings of the Hôtel-Dieu de Québec (1639) and offers a unique wellness experience connected with the Augustinian Sisters' heritage, but in a non-confessional setting. The transformation of the former cloister into experiential accommodation with holistic care offers a peaceful oasis. The Augustinians has also social implications, while they hire people who are vulnerable or disadvantaged to work with the tourists. Is a monastery can become a tourism product without affecting the essence of his heritage?

Key words:

Tourism; religious heritage; landscape; heritage preservation and conservation; Québec city.

On Literary Landscapes

Zeng Daxing

Guanfu Culture Study Center Guangzhou University, Guangzhou, 510006, P. R. China, daxingzeng@163.com

Abstract

Literary landscapes which gain and expand reputation with literature works have closely related with literature. Compared to general landscapes, literary landscapes, natural or cultural, have rich literary implications. This paper launches the initial study on the definition, types, criterion of classification and values of literary landscapes. It is believed the significance of literary landscapes is protean for it can be determined greatly different at different time, from different angel, in different ways and mood, and even by different sightseers. Literary landscape, as a kind of landscape text, can be more profoundly interpreted than paper text. The significant implications for literary landscape cover in many aspects, geographical, historical, architectural, fine arts and tourist economic as well. According to statistics, there are more than 4768 literary landscapes in the long history of China and many of them have been retained today. They deserve further research, protection and developing to yield greatest returns on cultural and literary heritage.

Key words:

literary landscape; definition; type; classification criterion; significance

On Modification of Literary Region to Current History of Literature in Terms of Literary Geo-criticism

Zou Jianjun

Central China Normal University, Wuhan, 430079, P. R. China, zoujianjun001@126.com

Abstract

Although the compilation of the history of foreign literature or the history of world literature has witnessed great progress and quite a few textbooks with high quality have been put into use in recent three decades, the history of literature concept seems rather conventional, conservative and to some extent confusing due to the lack of the awareness of literary region. This article compares three popular textbooks of literature history, points out the serious problems in the current narratives in the history of literature and analyzes the reasons to these problems. And it argues that if the concept of literary region in terms of geo-criticism is put forward to the compilation work, some consequent modifications will contribute to frame a more comprehensive, reasonable, objective and scientific history of literature, even rewrite it. The conventional East and West framework ought to be taken place by an organic one which is based on the objectivity and originality in terms of natural and cultural literary geo-criticism. To relocate literary regions and research their respective features is a must in the future narratives in the history of literature.

Key words:

literary geo-criticism; modification; literary region; history of world literature; history of foreign literature

Public Awareness of Beijing City's Axis

Li Xinya¹, ZHANG Baoxiu²

¹Yunhe Middle School, Beijing, 101100, P. R. China;

²Beijing Union University, Beijing, 100191, P. R. China

Abstract

Beijing city's axis is the significant linear legacy through the old city of Beijing. The paper is mainly concentrate on the public awareness of Beijing city's Axis. Beijing city's axis is divided into fifteen units for questionnaire. And the survey was focus on the person who are living near Beijing city's axis and visiting the unit of Beijing city's axis.

Based on the questionnaire data, public awareness of Beijing city's axis is preliminary presented in three conclusions. First, public cognition of the starting and end positions of Beijing city's axis is ambiguous. Second, the younger the respondents are, the less they know about Beijing city's axis. Third, the public awareness of different units of Beijing city's axis is diversity. The results illustrate that raising public awareness of Beijing city's axis as the linear legacy is necessary.

Beijing city's axis; public awareness

Religious Landscape of Mountain Buddhist Monasteries in Korea

Ril, Hae Un and JUNG, Ju Yun

Dongguk University, Seoul, 04620, Republic of Korea, hurii@dongguk.edu

Abstract

The number of Traditional Buddhist Temples including Monasteries are recorded as much as 944 at the end of 2014. The Traditional Buddhist Monasteries are mainly located in the mountain areas harmonized with the nature, have a long history from the its foundation in the history of the nation and Buddhism in Korea, and are the practical place of Buddhism by Buddhist monks and ordinary peoples. In the Monasteries, Buddhist monks and other persons are living in the monasteries, and monks are only concentrated to study for two times in a year. Many people are also staying for a while or living for considering as a healing places. In fact, Korean Mountain Buddhist monasteries are the living heritage, in the harmonizing with the man and nature. All of them are sacred and religious places. In this paper, we will discuss about the location, history and landscape of the monasteries as a harmonizing place with the nature. We also analyze these monasteries are considered as a healing places and sacred places.

Key words:

Traditional Buddhist Monasteries; living heritage; sacred places; religious landscape

Reproducing Sacred Landscapes: A Case Study of Industrial Uses of Ancestral Temples in Rural Wenzhou, Southeast China

Ningning Chen

Department of Geography, National University of Singapore, Singapore, 117570, ningning@u.nus.edu

Abstract

This paper explores the reproduction of sacred landscapes in contemporary rural China. Drawing on the analysis of the transformation of sacred ancestral temples into private factories in rural Wenzhou, China, it firstly investigates why and how ancestral temples are secularized in the context of rapid rural cultural-economic restructuring. It further explores the discursive strategies developed by lineage groups and private factory to re-interpret the significance of ancestral temples and economic production, thereby promoting the conversion of temple spaces. This paper finally shows how traditional sacred temples are re-produced through lineages' ritual performances and factory owners' worship and daily protection. In so doing, this paper foregrounds the complexity and flexibility of sacred-secular entanglement, and reflects on the changing traditional sacred landscapes in rural China.

Key words:

sacred landscape; secularization; ancestral temple; Wenzhou; rural China

Results of Planning the Historical Landscapes in Georgia

Prof. Dr. NodarElizbarashvili,

The Geographical Society of Georgia, Tbilisi, Georgia, nelizbarashvili@yahoo.com

Abstract

Besides, UNESCO has summoned Georgia, in addition to different data, to identify the clearly non-stable (sensitive) areas of the historical landscape of Mtskheta (Historical Capital of Georgia), develop the general conservation plan considering the specific landscape environment, identify the functional areas related to a historical monument, and alleviate the negative impacts on the historical landscape. Thus, within the limits of the said measures, the process of studying and planning a historical landscape is in fact a pioneering initiation for the country.

The research of the following questions were linked to the major goal and objectives of the study: review of the legislative base of the landscape use and protection and identification of their peculiarities; specification of the essence and borders of historical landscape; classification and description of the traditional typology of the landscape; identification of the factors (natural, anthropogenic) and processes (erosion, denudation, flood, borrow pits, pasturing, exploitation of forest resources, etc.) affecting the study area and analysis of the associations between them; identification of the properties of the landscape important in cultural (material objects, non-material objects) and natural (eco-systems) respect; identification of the material and non-material attributes of the landscape promoting and/or showing the particular universal value of the landscape; functional zoning of the landscape; fixing the visualization points for periodic monitoring of panoramas and views; development of the recommendations and guidelines of management, rehabilitation and sustainable use of the landscape (based on the methods of landscape planning); specification of the world heritage buffer zones.

Key words:

environment; historical and cultural landscapes; UNESCO nomination; landscape planning; Functional zoning; management.

“Revitalizing Soul of the Heritage City”: Exploring the New Agenda for Integrated and Sustainable Development of Heritage Cities in India

Bali, B.

Department of Policy Studies, TERI University, New Delhi-110070, India, bhawna.bali@teriuniversity.ac.in

Abstract

Heritage conservation and management strategies have been adopted across different countries, both within the established international frameworks as well as national policies. In India, heritage has been mostly confined to the fringes of conventional planning and policies for urban development. Aligning heritage management within the city development planning processes offers an opportunity for holistic urban development. This has been aimed at through the recently concluded urban development initiative of Jawaharlal Nehru National Urban Renewal Mission (JNNURM) and is followed by Heritage City Development and Augmentation Yojana (HRIDAY). With Mathura as a case study, this research explores the city development planning process adopted under the recently concluded JNNURM, and the on-going centrally sponsored mission for heritage cities HRIDAY. It further aims to examine the integrated city development approach of socio-economic, urban planning and heritage management planning adopted under the HRIDAY mission for revitalizing the city. The study is based on an analysis of policy documents, heritage toolkit, projects implemented in the city as well as observations drawn from the field and discussions with the officials of implementation agencies. The study has identified four areas for remedying policy gaps of JNNURM, viz. community participation as primary stakeholders of heritage assets, legal and institutional set up for heritage conservation, financial support, and capacity building of implementing agencies. These are expected to be addressed through the HRIDAY mission.

Key words:

Heritage cities; JNNURM; city development plan; heritage toolkit; HRIDAY; heritage management plan

Sacred Water Bodies and Cultural Practices in Varanasi City, India:

An Exploration into Challenges to their Sustainability

Singh, RAVI S. , Singh, PRATIBHA

Professor: Dept of Geography, Institute of Science, Banaras Hindu University, Varanasi 221 005 (UP), India. Email: ravisingh.geog@gmail.com

Abstract

Water bodies are immensely significant for the human settlements, especially the large urban ones, as the source of water (supply) and also for their often overlooked role in the process of ground water recharge. Varanasi, one of the most sacred Hindu pilgrimage centres of the world, is a million-plus city too. Sacrality has an over-arching influence on both the natural and man-made elements of (urban) landscape here. Hence, nothing could be truly envisaged in this city in the absence of the sacred context.

The lakes (variedly termed as *tal*, *jhil*, and *sarovar*) in the city have been under threat since many decades. They were an integral part of the natural urban drainage system and were also important source of water for sacred and profane purposes alike. Urban growth, the ever increasing and pressurising demand for land led to their encroachment from all sides. Mushrooming buildings around made them detached and isolated from the natural drainage system, whose part they were in the past, and thus, threatened their existence. Such encroachments, made by individuals and even by the (local) government, together have sealed the fate of lakes here. The interventions to save the lakes here mostly are from the voluntary organisations which have several limitations and eventually turn out to be non-effective 'face-lifts'.

This paper is a modest attempt to understand the importance of water bodies, especially the lakes, in the city life; challenges to their sustainable existence; and present a critical appraisal of the interventions made since recent past.

Singapore: Heritage Sites & Cultural Landscape in Harmonizing the World

Maria Boey

Institute of Parks and Recreation, Singapore

Abstract

Synopsis: Singapore, as a young country is small in area and has very few heritage sites or cultural landscape. Due to its limited resources, it became more significance to the identity of its country that its few heritage sites and cultural landscape be conserved and enhanced.

Historically, Singapore was known as Temasek, a Malay Fishing village with a Sultanah descended from Johor, Malaya. There is an historical sultanate with its kingdom at Fort Canning which was sacred. Fort Canning has also a cultural landscape of archeological and historical value of the British Empire since the founding of Singapore by Sir Stamford Raffles in 1819.

The British ruled Singapore until 1960 and handed the island to the Singapore Government formed by Late David Marshall. In 1965, late Prime Minister, Lee Kuan Yew formed the Singapore Government to rule Singapore as an Independence country. Without any natural resources, the Singapore Government built up the economy of the country. Most of the heritage sites were conserved and upgraded in its maintenance. Areas of cultural heritage were conserved for its buildings and culture based on the foundation of the British's planned area for the Civic District, Chinatown, Kampong Glam and Little India as Singapore grew from an entreport to a first world City State.

The British also left behind the Botanic Gardens which is now the first UNESCO Botanic Gardens in Asia.

With progressive planning and implementation, most of the Heritage sites and religious buildings are conserved and maintained. Religious buildings provide the strong communities which are well respected in harmonious relationship. Thus, Singapore is known as a mutli-racial and multi-cultural country and a vibrant and melting pot of culture and natural heritage.

Spatial Narratives in the Perspective of Geographical Criticism---A Case Study of Sutpen's Hundred in Faulkner's *Absalom, Absalom!*

Wang Haiyan, Liu Fen, Hu Zhaoxia

South Central University for Nationalities, Wuhan, 430074, P. R. China, cathywhy@mail.scuec.edu.cn

Abstract

Sutpen's Hundred is a geographical space constructed by Faulkner in his *Absalom, Absalom!* Besides serving as the setting for narration and the aid for character portraying, Sutpen's Hundred is utilized to represent time, to arrange the structure of the novel with its spatial logic, and even to push forward the whole narrative process with the spatial changes. Sutpen's Hundred, totally different from the conventionally chronological narrative, achieves spatial narrative touch by breaking through the monotony constraints of linear narrative.

Key words:

Sutpen's Hundred; geographical space; spatial narratives

Spatial Reconstruction of Cultural Heritages: An Example of the Beijing City's

Central Axis

Baoxiu ZHANG

Beijing Union University, Beijing, 100101, P. R. China, baoxiu@buu.edu.cn

Abstract

The purposes of the spatial reconstruction of cultural heritages are to reorganize, rearrange, and reread spatially the existing factors of cultural heritages, systematize the scattered pattern of cultural heritages, strengthen their intrinsic relationship, and form the new, prospective, inheritance-and-developing combined, tangible-and-intangible combined pattern of cultural regions in the background of modern urban and regional cultural development facing the future. On the base of rich research results, it's necessary, significant and feasible to study the preservation and utilization of cultural heritages from the point of cultural spatial reconstruction, which is the efficient path and means to build modern metropolitan cultural space. Here is the example of the Beijing city's central axis. The central axis, starting from the south to the north through the old city of Beijing, is 7.8 kilometres length. During the time of Ming and Qing Dynasties, it reflected the supreme imperial power of the core value and its spatial structure consisted of sixteen units, forming four kinds of cultural regions including imperial power political region, security defense region, sacrificial rites region and commercial folk region. Nowadays, its spatial structure can be divided into fifteen units with four types of cultural regions including political and cultural square, museum and cultural palace, people's park and commercial leisure space, which reflects the complete change from serving the feudal emperors to serving the common people. The continuous changes of its spatial structure, symbol of the nodes, service function and culture connotation is the process of constantly reconstructing its cultural regions.

Key words:

cultural heritage; spatial reorganization; reconstruction; Beijing; Beijing city's central axis; cultural region

Study On Interactive Mechanism Between the Inheritance and Innovation of Regional Culture and The Characteristic Development of Animation Industry in Jiangsu Province

MENG Zhaoyi, QU Aixue

School of Urban & Environmental Sciences, Jiangsu Normal University, Xuzhou 221116, P.R. China. jsmengzhaoyi@163.com, jsquaixue@163.com

Abstract

Formation mechanism of placeness is the scientific basis for the protection of traditional placeness and the development of new placeness. Under the condition of market economy, the development of cultural industry is an important means of cultural and placeness reproduction. Therefore, it is of great theoretical value and contemporary significance to explore the influence of cultural creative industry on placeness. In this paper, based on the case of Jiangsu animation industry, from a view of the synergistic effect of humanism and structuralism, and from the perspective of the interactive mechanism of regional culture inheritance-innovation and animation industry characteristic development, the deconstruction and reconstruction of Jiangsu placeness as well as its dynamic construction during this course of deconstruction and reconstruction are explored. In the study, based on the comparison between regional cultural elements including the historical stories, intangible cultural heritages, dialects, landscape features, value ideas and anime works elements including the contents, stage lines, images, music, scripts, characters and style, the influence of government and the economic mechanism on Jiangsu animation industry are investigated and analyzed by using the method of structuralism, meanwhile, the recognition degree of animation enterprise, local government and consumers on placeness is discussed by using the method of humanism. Results are as follows. (1) Traditional placeness is the source of feature established and core competitiveness for animation industry formed, and at the same time, the characteristic animation industry is a contemporary way to inherit and carry forward the traditional placeness. (2) The selective and innovative use of traditional placeness in the development of animation industry is an important path to form a new placeness. (3) On the one hand animation industry faithfully reproduces the traditional placeness, on the other hand it selective and innovative utilizes the traditional placeness, its development is a course of dynamic construction with the synchronous deconstruction, reconstruction and reformation of placeness. In essence, this process is a circle of cultural capital and economic capital, also the process is an integration of culture and economy. (4) The selective use and innovative utilization of traditional placeness is not only the results of the recognition of animation enterprises, local governments and animation consumers on culture but also the consideration of economic interests, it is the results of synergistic effect of the both. (5) The selective and creative use of the characteristic culture of Jiangsu animation enterprises is narrow and uncertain. Based on above, in this paper, some

suggestions are given. Animation enterprises should be encouraged to expand the field and the scope of cultural capital; popular culture and elite culture, culture placeness and culture diversity should all be paid attention to optimize the structure, improve the quality and enlarge the capacity of cultural capital. On the other hand, policy leverage such as tax action and financial subsidy should be strengthened to promote the virtuous cycle and the dynamic balance of cultural capital and economic capital, characteristic animation should be encouraged to realize the inheritance and innovation of regional culture which can conversely boost the characteristic development of animation industry.

Key words:

regional culture; animation Industry; placeness; formation mechanism

Temporal-spatial Characteristics of World Cultural Landscape Heritage and the conservation of Honghe Hani Rice Terraces

Yuanmei JIAO

School of Tourism and Geography Science, Yunnan Normal University, Kunming 6500500, China

Abstract

Cultural landscapes have been formally acknowledged as world heritage by UNESCO in 1992. Since then to 2013, 85 cultural landscape heritages have been inscribed in world cultural heritage list. In this paper, we collect data of all the cultural landscape heritage sites via UNESCO's official website, analyze the spatial and temporal characteristics, the evaluation criteria and the types. Taking the Honghe Hani Rice Terraces as a case, we discuss the challenges to conserve world cultural landscape heritages. The results indicate: (1) The amount of cultural landscape heritage sites keeps increasing steadily since 1992. (2) The cultural landscape heritage sites are mainly located in developed countries in mid-Northern latitudes. In the global political and economic culture partition, cultural landscape heritage in European and American area is more than 50% of the world. (3) The 85 heritages were conformed to the evaluation standard mostly on iii, iv and v. It shows that evaluation of the cultural landscape heritage is focus on the continuous evolution. (4) The world cultural landscape heritage will increase and relatively keep balance in spatial distribution in future. Re-classification of cultural landscape heritage types will facilitate the submission and protection of them. (5) Honghe Hani Rice Terraces was listed in world cultural heritage in 22 June 2013 which inscribes on the basis of criteria (iii) and (v) with the outstanding universal values. Its conservation should be an integrated serial strategies of agriculture production, natural resources such as water, forests protection, eco-tourism development and poverty elimination.

Cultural landscape heritage; Temporal-spatial characteristics; Evaluation criteria; Heritage types; Cultural Landscape of Honghe Hani Rice Terraces

The Buddhist Temples and the Buddhist Culture in Ancient XIYU in China

Renxiong G

Northwest university for nationalities, Lanzhou, 730030, P. R. China, gaorx@163.com

Abstract

China's western region XIYU lies in the Central Asia which is the nodal region for eastern and western cultural exchanges and commixture. The Silk Road pass through here. It has a long-standing oasis agriculture civilization and grassland nomadic civilization. According to the historical records of Han Dynasity and Wei, Jin, Northern and Southern Dynasties, the ancient XIYU Regions has abundant religious culture and arts of music and dancing. There had a variety of national languages and the corresponding literature activities. To the middle Tang dynasty, with the Huihe westward migration and Tujue southern migration, the Islamism spread to the east and the nationalitise of ancient Western Regions generally accepted Islam in the later of Yuan dynasty. From Han to middle Tang Dynasities, Buddhism prevails in ancient XIYU Regions, especially for the oasis city-states around the Tarim Basin such as Khotan and Qiuci. There had a lot of buddhist temples and grottoes. The buddhist grottoes reflects the high level of culture and art.

The landscapes of buddhist towers, temples and grottoes is the outcome of prevailed Buddhism. When the Buddhist godliness become popularization that the buddhist culture evolves popular culture in XIYU. Meanwhile the diversity architectural art, statuary art and painting art had developed. The literature also be produced by Buddhism, as the poetry, the religious drama, the religious music and dancing be developed. Meanwhile the novel descriptive skill had developed, and translatology had developed too .

In Short, the landscapes of buddhist towers, temples and grottoes reflect the Buddhist popularization and the harmonious ecological environments.

Key words:

Ancient XIYU region; Buddhist Temples; Buddhist Culture

The Real and Imaginary Sacred Landscape of Bodhgayā

Joshi NIKHIL

National University of Singapore, Singapore, 117 566, Singapore, abhivyakti13@hotmail.com

Abstract

The UNESCO's decision to put the Mahābodhi Temple complex in Bodhgayā on its World Heritage List in 2002 was a moment of victory for heritage brokers who had been pushing to attain that status for years. Over the course of time, this so called prestigious designation did far more damage to the local heritage and divided Bodhgayā into boundaries – World Heritage Site core zone and the rest of the village. In addition, the Temple complex and its surrounding landscape is being continuously invented and re-invented for consumption of mainly foreign pilgrims and tourists.

This paper would argue that sacredness goes beyond scriptural texts and archaeological remains per se. Its significance lies mainly in an active interaction between religious architecture within its dynamic ritual settings. The Mahābodhi Temple complex and its immediate surrounding cultural landscape is a 'living' heritage, which has been produced socially and constitutes differential densities of human involvement, attachment, and experience. Hence, it is highly unlikely that everyone would equally share and experience this place in a similar way as advocated in authoritative heritage discourses, which are often written with a little understanding of working of the 'living' places. In the end, a conservation framework will be proposed to address cultural heritage management issues in India and would also highlight the effectiveness of people-centric conservation policies for managing the 'living' cultural landscape.

The Research of Relationship Between Geographical Space and Image of Literature in The Novel the Ordinary World

Cai Lu, Ma Beibei

Shaanxi Normal University, China. 1240270843@qq.com

Abstract

The relationship between people and region has an impact on the creation of literary works, which subtly reflects on the personalities of the characters, story structures, historical backgrounds, natural climate and plot developments in novel. Therefore, in order to study how the natural environment influences on the natural imagery in the novel *The Ordinary World* written by Yao Lu, this paper attempts to analyze the natural environment of farming-pastoral zone where the terrain is the loess plateau landform with the characterization of transition zone in the northern of Shaanxi. In addition, by studying the human geography environment in northern Shaanxi which combines the traditional culture and the multi-culture, the author reveals how the cultural environment can influence on the humanistic implication. On the whole, the regional culture elements in Yulin City of northern Shaanxi has an effect on the cultural implication in Yao Lu's novel, which reveals internal connection between abundant culture implication in novel and diversified artistic style of the author's novel.

Abstract

This article examines the role of government in space construction of the legendary heritage site which is regarded as the ancestral mausoleum for all Chinese. The government helped to make this site a National 5A scenic spot and upgrade its ancestral rites into a national memorial ceremony in the heritage cite. This change brings more visitors, media, enterprises and worshipers from all around the world. To explore the role of government in space construction process, this paper adopts the method of discourse analysis and in-depth interview to analyze the role of government in the field of national memorial ceremony, local memorial ceremony as well as everyday life. Government attempts to use tourism as a political instrument to legitimize its power and highlight Chinese national identity.

Key words:

space construction; legendary heritage site; political legitimacy; national identity

Traditional Knowledge and Geographic Ideas in the Disaster Risk Reduction under the circumstances of Climate Change -- A Comparative Research Between Tibetan in China and Aborigine in Australia

Lun YIN, Melissa NURSEY-BRAY

Yunnan Academy of Social Science, Kunming, 650034, P. R. China, 13888267735@163.com

University of Adelaide, North Terrace, 5005, South Australia

Abstract

Modern Geographic knowledge differs from traditional geographic knowledge in being thoroughly quantitative. We exemplify this difference by comparing modern geography with traditional knowledge about the land. Modern geography understands the land as a system of global, quantified interrelationships, whereas traditional knowledge about the land relates it to a system of local, qualitative interrelationships of humans and spirit powers. Against this background we examine traditional knowledge and geographic ideas in the disaster risk reduction under the circumstances of climate change. We argue that traditional knowledge and geographic Ideas in the disaster and climate change and its impacts are very detailed and can give important insights into local concerns and processes of in the disaster risk reduction. Perceived disaster and climate changes differed significantly even within a small geographic area. Furthermore, disaster and climate changes was seen as a moral and spiritual issue. These interpretations affect how people deal with disaster, climate change and its impacts and which solutions are regarded as relevant. In order to effectively address disaster impacts at the local scale and to enable the process of reduction, it is necessary to address a combination of perceptions, local variations, moral and spiritual interpretations, and locally relevant solutions.

Key words:

traditional geographic knowledge; disaster; risk; climate change

Trans-Regional Culture and Trans-Place Construction: A Case Study of Urban Hui Immigrant Communities in Hohhot Hui District

Shaowei Ai, Hao wang

Center for Yellow River Civilization and Sustainable Development, Collaborative Innovation Center for Yellow River Civilization, Henan University, Kaifeng, Henan, China, 475001

Abstract

Place is the key dimension to understand the structure and change of the urban minority community. In the context of globalization, urbanization and trans-regional migration of the minorities, place will be constructed or reconstructed, and it will obtain a changing meaning over time. Taking Hohhot Hui District as a typical case, the paper focuses on the place construction of the structure of urban Hui immigrant community, especially the integration, assimilation and separation effect which are dependent on the social and economic interaction of Hui population from different places. The urban Hui immigrant community is a social cultural space where the different Hui cultures interact from the different Hui places, and the community structure is determined by the combination of multiple local cultures, forming a kind of trans-cultural place. This Study has shown that the "residential structure", "economic structure", "dietary structure", "relational structure" and "teaching structure" of Hohhot urban Hui communities are dependent on the place construction or trans-place construction of "East Hui" and "West Hui". The integrated place has been embodied in "mosque-centered residence" structure, the "economic structure", "dietary structure" of Hohhot urban Hui communities have shown the significant assimilated place, and the "relational structure" and "teaching structure" perform as a strong characteristics of separated place. At the same time, the emergence of the new phenomena, such as "Collective Grave Digger", "Mosque Restaurant", "Islamic Style Street", "Hui Commercial Street", "New ethnic Teaching" in Hohhot Hui District, result from the place reconstruction based on the collaboration of local government, economic elite, religious elite, ethnic institute, and Hui people. The paper argues that these practices on place construction of trans-regional cultures contribute positively to the formation and evolution of Urban minority community. (Supported by the Project "Spatial Pattern & Development Path of Modern Transformation of Urban Hui Communities: Case Studies of 'Zheng-Bian-Luo-Hu' Urban Ethnic Districts" (Project Number: 41471104) awarded by National Nature Science Foundation of China)

Key words:

Wilderness of Russia Landscapes and Ecoregions

Bocharnikov V. N.

The Pacific Institute of Geography of the Russian Academy of Sciences, 7 Radio st., Vladivostok 690041, Russian Federation, vbocharnikov@mail.ru

Abstract

A reasonable balance in the relations of man and nature is impossible without understanding the ratio in which today really is nature and society as well as the weight of each of these components. Soviet geographical science coined the doctrine of nature, where the most basic fractional unit used nature territorial complex concept, whose dynamics was determined by the production system, and have a rational (sustainable) and unsustainable (unsustainable) nature. Human culture clearly forms the shape of the anthropogenic landscape and cultural heritage is part of the cultural landscape, which are represented by objects, where traditional and cultural activities. There is a special understanding of the radically changed landscapes – anthropogenic, such as rural-, urbolandscape, etc. nd wilderness in its essence it is a missing link in landscape ecology, and physical geography in general. The article presents the preliminary results of the GIS assessment of the degree of anthropogenic transformation of landscapes within territory of Russian Federation. This paper shows and discusses the algorithm of calculation of an index of wilderness, allows to clearly determine the real extent of human impact on the surrounding natural environment. The article presents the results of quantitative assessments of large wilderness areas within its official administrative units (Federal district). The conclusion about the low level of representation of wilderness of Russia within the territory of natural reserves, national parks and wildlife refuges of Russia made, there are prognosis about the possibility of preserving Russian wilderness for future generations shows by the map. The degree of preservation of wilderness in Global200 - ecoregions of global importance situated in Russia as of special map are considering. A statement is substantiated the necessity of further continuing and more details of inventory and monitoring large areas of wildlife remaining on the territory of the Russian Federation.

Key words:

large areas of wilderness; protected areas under federal jurisdiction and international importance; ecoregions; landscape zoning

Woodcarving Allocating Management System of Irrigation Water in Hani Rice

Terraces: A Case Study of Yakou Ditch in Yuanyang County

WANG Mei, JIAO Yuan-mei

School of Tourism and Geography Science, Yunnan Normal University, Kunming 650500, P.R. China

Abstract

Water resource is the key to the stability of the Hani Rice Terraces. To adapt the high slope of mountainous environment, utilize water resource rationally, avoid disputes of water use, the Hani people created and maintained an unique woodcarving allocating management system of irrigating water (WAMSIW) during the rice farming of terraced fields. We take the WAMSIW of Yakou ditch in Yuanyang county as the object, based on field investigation and interviews, sum up the ditch excavation, the electing way of ditch leaders and their responsibilities, and draw the spacial distribution of the water-allocating woods, quantify the number of water-allocating woods and their relationships. The results are as follows: 1) the irrigation water of rice terraces in Yakou area is come from the Yakou River directed by the Yakou ditch which was excavated by human beings. The ditch irrigate rice terraces belonging to eight villages. 2) the ditch leader, who is elected by a certain way of villagers, should to manage the Yakou ditch. He is responsible for the inspection, maintenance, water allocation and water disputes regulation. Certainly, he can get a certain number of ditch grain as labor compensation. 3) There are 16 water-allocating woods on the Yakou ditch, among them 12 woods have 2 carving-gates, 1 wood has 4 carving-gates and the other 3 woods has 3 carving-gates. Impacted by the micro-topography, the water-allocating woods is mainly distributed in lower part of Yakou ditch. 4) About the length of water-allocating woods, the longest is 254cm, the shortest is 86cm and the average is 141cm. The speed of water flow is $39.44 \text{ cm} \cdot \text{s}^{-1}$, the maximum, minimum and average water flow is $387.50 \text{ cm}^3 \cdot \text{s}^{-1}$, $12.50 \text{ cm}^3 \cdot \text{s}^{-1}$ and $168.75 \text{ cm}^3 \cdot \text{s}^{-1}$ respectively. If the terrain is flat, the water-allocating wood's length is longer, and the water speed is slower, which indicate the water flow is impacted by water depth, flow speed and topography. 5) Every year, the ditch leader can get 1326kg to 1770kg wet rice just harvested from rice terraces as the labor compensation to manage the Yakou ditch. It is equivalent to the rice harvest of 3 to 4 *mu* terraced fields which shows a good income of ditch leader.

A Study on Community Planning Framework Based on Resilience Concept

Chong Peng, Zuyuan Guo, Minhang Yuan.

College of Architecture and Urban Planning, HUST, Wuhan, 430000, P. R. China, guozuyuan@hust.edu.cn

Abstract

Resilience, due to its profound influence on urban planning and management in disaster prevention, has attracted global attention of scholars both inside and outside China. Especially, the community resilience which is representative and practical in urban inner space refers to a set of capacities (such as the ability to adapt to changing conditions and to recover rapidly from disruptions) , also a process of capacities improvement and disaster adaptation, and even future objectives of community development. Based on resilience concept, the objective of community resilience planning could be summarized as enhancing the capacity to cope with hazards. Then the study in this paper managed to establish a planning framework of community resilience from three dimensions comprising physical and cultural environment buildings, community organizations, and governance and risk response. (1) On physical environment, based on community inner needs, resilience assessment and gaps between desired and anticipated performance, the study determined priority by assessment outcome; on cultural environment, the study built a culture of hazard prevention, promoting public awareness of disasters and capacity of dealing with disasters and recovery. (2) On community organization and governance, the study set up a scaffold for cooperation among government, public and social groups, raising the level of leadership and building disaster safeguard mechanism. (3) On risk response, the study tried to establish the mechanism for multi-scenario response. Finally, we forecasted the focus of China's resilient community planning in the future based on the sum-up hereof.

³ Cold and Arid Regions Environmental and Engineering Research Institute, Chinese Academy of Sciences, Lanzhou 730000, P.R. China

Abstract

The Yellow River source region has a sensitive response to global change due to its unique cryosphere processes and geographical conditions. Any slight changes in natural elements and human activity can have a magnified effect on grassland ecosystem, animal husbandry, and pastoral livelihoods since its economy is exclusively dominated by grassland animal husbandry. Because snow disaster has been one of the major natural disasters in the source region, it is crucial to explore the economic impact of snow disaster on animal husbandry and identify effective adaptation measures. A nonlinear model of meat production was established in relation to snow disaster, grassland productivity, and disaster prevention by introducing a snow level index, and selecting three key indicators of grassland productivity and disaster prevention, including grass growing season precipitation concentration, sown grassland area, and warm barn area. This is an inverse of negative correlation, less meat when there is more snow. Per unit increase in snow level in the source region led to a decrease of 0.213 units in meat production. However, production losses caused by the snow disaster could be effectively suppressed by the increase in scale and intensity of sown grassland and warm barn construction. Per unit increase in sown grassland and warm barn area led to an increase of 0.240 and 0.610 units in meat production, respectively. The effects of sown grassland and warm barn area in reducing snow damage at different snow levels were analyzed. Finally, authors give some suggestions for raising the adaptation.

Key words:

meat production; snow disaster prevention; adaptation; adaptive performance

Abstract

Previous research on the local air pressure system of central Japan in the fine day has revealed that local high pressure is generated by the earth's surface cooling at night, while local low pressure is generated by the heating of the ground by solar radiation in the daytime. For a more detailed analysis of this local air pressure system, we placed a high-precision barometer in a vehicle, and moved it along the highway for observation during the evening and early morning. The observation of local pressure system was carried out by selecting a day atmospheric changes in the synoptic covered in widely high pressure is low. In the evening, the pressure deviation distribution was classified into four patterns. One type reduced air pressure in the pan bottom shape of the Matsumoto basin from spring to summer. This was the case in which the most local low-pressure system developed. In other types, local low pressure become weaker as it went from one type to another. Furthermore, in some types, pressure increased in specific locations, such as in a basin. The cause of this pressure variation was estimated to be a cold airflow from the basin west of the mountains. In the early morning, the pressure deviation distribution was also classified into four patterns. These indicated the presence of a local high pressure that developed during the night.

An Impact Analysis of Industrial Growth on Water Quality of Ghaggar River: A Case Study of Panchkula District, Haryana

Dr. Rohtas Godara

Government P.G. College, Panchkula, Haryana, India, 134109, rohtasgodara@gmail.com

Abstract

Rapid industrialization and related population growth in the developing world has significant impact on the land, air and water resource of the region. Ever growing industrialization and urbanization has been exerting too much of pressure and deteriorating the limited available resources in these regions. Therefore, it warrants an impact analysis study in order to avoid the overuse and damaging of the natural resources beyond sustainability. Water as a resource has numerous uses viz. transportation, hydroelectric power generation, recreational, domestic, agricultural, industrial and commercial. Moreover, it supports all forms of life and affects human health. The study area is an important industrial centre in Northern Haryana. In the study area the industrial effluents, domestic and municipal wastes pour into Ghaggar river along its course in the upper reaches. The study is based on secondary data collected from the Haryana Pollution Control Board. The monthly averages of various biological, chemical and physical parameters have been computed, analyzed and compared with the national standards to gauge the impact of industrial growth on the water quality of Ghaggar river. The higher values of BOD and COD clearly indicate the extent of pollution in the river. The study provides a valuable insight into the impact of industrial growth on the water quality of Ghaggar river on one hand and the need for effective treatment and management of the industrial effluents and municipal wastes on the other hand.

Assessing Expansion of TshoRolpa Glacial Lake and Induced Risk Potential in Nepal Himalaya using satellite Data

MAL, SURAJ¹, Schickhoff, U.², Singh, R. B³

¹Department of Geography, Shaheed Bhagat Singh College, University of Delhi, India, surajdse@gmail.com

²Institute of Geography, University of Hamburg, Germany

³Department of Geography, Delhi School of Economics, University of Delhi, India

Abstract

Glacial lakes have increased in numbers and size as a response of climate change. The expansion of glacial lakes and increasing water volume in higher Himalayan regions poses significant damage potential to downstream regions. Therefore, the study compared Corona (1962), Landsat-MSS (1972 and 1979), TM (1992), ETM+ (2002) and OLI (2014) images for assessing the changes of TshoRolpa glacial lake in Nepal.

The study reveals that Tsho Rolpa Lake has significantly increased during 1965-2014. The surface area of lake was about 0.26 km² in 1965 which increased to 0.72 km² in 1972, 1.05 km² in 1979, 1.41 km² in 1992, 1.52 km² in 2002 and 1.55 km² in 2014. Lengthwise, it increased nearly four times from about 800 (1965) to >3.5 km (2014). Expansion of lake has also led to unusually higher retreat of the Rolwaling glacier i.e. 40 m⁻¹ (1968-2014). The TshoRolpa Lake has been identified by ICIMOD as one of most critical glacial lakes in Nepal due to failure risk; therefore, an artificial outlet has been constructed to prevent an outburst flood. The study aims to improve understanding of glacier induced risk together with development of metrics and models for community resilience.

glacial lake; risk; potential; Nepal

Assessment and Management of Water Quality in River Yamuna, Delhi

Vishwa Raj Sharma

Shaheed Bhagat Singh College, University of Delhi, rsharma2002@gmail.com

Abstract

The BOD level in the Yamuna River has been in the range of 12 to 51 mg/l. The range of Chemical Oxygen Demand in Delhi varied from 50-155 mg/l. However, during its exit, the water quality becomes unfit for any purpose. Research paper analyse the present status of the river Yamuna. Despite ongoing research efforts on land-cover and land-use patterns, there remains a need for development of basic land-cover datasets providing quantitative, spatial land cover information. With the rapidly growing population in Delhi, pollution levels are at an all-time high and continue to become increasingly dangerous to city residents. Delhi is subject to pollution in all forms and has been categorized among the top ten most polluted cities in the world. The pollution of the river Yamuna has a variety of impacts on Delhi's environment. This paper analyzed land use/cover (LULC) of the past, present and futuristic modeling along river Yamuna, evaluated Land use/cover Change (LULCC) on the basis of socio-economic parameters.

To assess and analyze land use/cover (LULC) of the past, present and futuristic modeling along river Yamuna.

To evaluate Land use/cover Change (LULCC) on the basis of socio-economic parameters

To quantify and analyze the impact of LULCC on the basis of land, water and air along the river.

To establish Sustainable Socio-Economic Framework (SSEF) for better LULC practices in accord with Delhi Vision 2021.

The LULC data collection, classification and analysis has been done for over a decade (2001-2012) on the basis of LISS III, Landsat TM/ETM, STRM-DEM, SOI toposheet, from various government agencies and organizations. The physical data has been collected from organizations like: Survey of India Publications, Topographical Map 1: 50,000, National Remote Sensing Agency (NRSA), Hyderabad, Central Pollution Control Board (CPCB), New Delhi and socio-economic data from Census of India Population Totals for Delhi, 1991 and 2001; District Statistical Handbooks etc. Remote sensing data and techniques and geographic information systems (GIS) provide efficient methods for analysis of land use issues and tools for land use planning and modelling. After completing the analysis to show the maps cartographically correct, various cartographic techniques in ERDAS 9.1, ArcGIS 10 and ArcView 3.2a has been used.

Key words:

Changes in Confluence Characteristics in Downstream Direction of River Bhima in Maharashtra

Unde M G

Associate Professor and Head, Department of Geography, Ahmednagar College, Ahmednagar - 414001. Maharashtra State, India, maya4unde@gmail.com

Abstract

Flow and form variables of the river represent channel morphology of main stream and tributary streams. Channel morphology of river confluences is studied by number researcher but studies on downstream changes in confluence zone are bit less. Confluences of the source zone and confluences of middle and lower reaches are different in morphological characteristics. Present study aims to understand the downstream morphological changes in five major confluences of river Bhima in Maharashtra. In all five confluences are taken for study. In this paper researcher has tried to describe changes in channel geometry occurring at every tributary junction. Bhima basin in Maharashtra is second largest river basin. It has 4 left bank and 9 right bank tributaries in Maharashtra. All 9 confluences have observed for last 7 years and found that the cross sectional characteristics of the upper reaches and lower reaches differs in width, Depth and velocity. The entire hydraulic geometry variable adjusts according to its proportion with discharge they are interrelated and hence it difficult to find out complexity in them.

Junction angle of all the tributaries is wide angle between 50° to 80° . It is found that width - depth ratio of these tributaries is increased. These confluences are dominated by junction scoure. Depth of these scoure is of 2-4 times of confluence channel. After the junctions scoure mid-channel bars are found in 3 tributary confluences.

Morphological characteristics in source region and downstream on smaller or large tributaries are same and proportional.

Abstract

Water crisis is one of three crises that persecute the whole world. China is among the countries which face severe water shortages. Water scarcity and water pollution have seriously affected China's sustainable development in economy and society. Due to the limited water resources, increasing the water use efficiency (WUE) has become a crucial issue for sustainable development in watershed. In Heihe River Basin, the consumption of irrigation water accounted for 90% of the total consumption. Increasing the WUE of agriculture is thus particularly important for alleviating the water scarcity in Heihe River Basin. Unfortunately, due to the limitation of knowledge in irrigation water in spatial and lack of crop type distribution information in spatial, the changes in WUE of agriculture in Heihe River Basin is still not clear, particularly at a large spatial scale. In this paper, we first extracted the crop type distribution in Heihe River Basin at a 30m raster pixel during 2007-2014 using TM images and NDVI time series method. Then, we established an empirical equation to assess the relationship between irrigation water and physical geography conditions. By the empirical equation, we allocated the total irrigation amount in 30m raster pixel. Finally, we calculate the actual evapotranspiration of different crops in spatial. The WUE of agriculture was defined as the ratio of actual evapotranspiration to irrigation water. The changes in WUE of agriculture in Heihe River Basin at 30m pixel were finally assessed.

Key words:

water use efficiency; crop type distribution; irrigation water; Heihe River Basin

Climate Change and Glacial Fluctuation in Pindari Region, Himalaya

Santosh Kumar¹, R.B. Singh¹, Anju Singh²

¹Department of Geography, Delhi School of Economics, University of Delhi, Delhi-110007, INDIA

²Aditi Mahavidyalaya, University of Delhi, Delhi-110007, INDIA, skpkaimur@gmail.com

Abstract

Climate change is considered as a significant man-made global environmental challenge currently faced by the mankind today. The warming has a direct impact on the temperature sensitive snow and ice cover. Recent evidence suggests that most glaciers in the Himalaya have been retreating with greater pace in terms of climate change. The present research paper tries to access the climate change trends and estimation of glacial fluctuation in the Pindari Region, Himalaya. Climate change analysis (1901-2010) results show that annual mean air temperature has increased by 1.6°C during the past 110 years, as against the global average of 0.5°C; the Pindari region trend indicates an increase of 0.0105°C per year. Glacial fluctuation analysis (1976-2013) illustrates that Pindari glacier area has reduced by 0.998 km², with an average loss of 26.97 m² per year. This reduction in glacier area is 14.9 per cent over 1976. With a reduction in the area and length of the Pindari glacier, there has also been a retreat in the snout position. The trend shows that the length of the glacier has reduced by about 0.535 km in 37 years, from 1976-2013, with an average retreat rate of 14.459 m/year. Analysis shows that the glacier is not only receding in length but also in terms of glaciated area from all the sides. The huge amount of moraines and number of debris cones and talus fans along the valley were observed at the front of Pindari glacier, which clearly indicates influence of climate change in Pindari region.

Conservation of Water Resources: A Case Study of Northern Portugal

Lohani Meenakshi

Department of Civil Engineering, University of Minho, Braga, Portugal, meenakshilohani@yahoo.co.in

Department of Geography, Km. Mayawati Government Girls P.G. College, Badalpur, Gautambuddha Nagar, Uttar Pradesh, India- 203207

Abstract

Portugal is a republic comprised of a continental part and two autonomous regions. There are three different administrative jurisdictions governing the Water Framework Directive (WFD) implementation in Portugal: mainland Portugal (PTRH1 to PTRH8) governed by the Portuguese Environmental Agency (APA) and the Azores (PTRH9) and Madeira (PTRH10) governed by the respective autonomous region environment authority. The Azores autonomous region is comprised 9 islands, while the Madeira autonomous region is comprised of 2 islands. Portugal shares four river basin districts with Spain: Minho and Lima, Douro, Tejo and Guadiana. Both countries signed a bilateral agreement on the shared water resources safeguarding quantity and quality of water.

In the present study the status of water resources in the northern part of Portugal will be taken up In terms of conservation and management of surface water, groundwater and coastal waters. The focus will be on the impact of Water Framework Directives implemented in 2000 and also on the new Blueprint for Safeguarding Europe's Waters, which aim to protect the quality and quantity of Europe's waters. In the paper, the past and the present status of Portuguese waters and future sustainable planning will be discussed.

Decentralisation in China's Centralised Water Governance System:

Authoritarianism, Pluralisation and Local Practices

Wang, Y.¹, Liu, T.²

¹Faculty of Social Sciences, The University of Hong Kong, Hong Kong SAR, P. R. China, wangyuray@connect.hku.hk

²School of Sociology and Population Studies, Renmin University of China, Beijing, P. R. China

Abstract

The Chinese state has been commonly viewed as an authoritarian regime which lacks of pluralisation in most realms of politics and policy making. In environmental governance, although democratic political regimes characterized by polycentricism and public participation can be responsive to environmental challenges, authoritarianism is meanwhile favoured by some analysts for effectively enforcing stringent regulations without being hindered by ceaseless lobbying and interminable negotiations. This paper engages in this debate, not by focusing on the comparative performance of polycentricism and authoritarianism, but by exploring the extent, scale and rigorousness of how environmental authoritarianism operates in the context of China. Using empirical evidence collected from irrigation districts in semi-arid Ningxia autonomous region, it challenges the prevailing perception that China signifies environmental authoritarianism. It argues that China's water governance model is a dynamic mixture of both centralised policies and decentralised practices. This model, on one hand, contains a state-centric policy process which has been not only informed by local socio-economic conditions, but also manoeuvred by local jurisdictions to facilitate their pursuit of interests. On the other hand, peasants at the local level still enjoy some flexibility to adapt to local changes, reconcile local conflicts and maximize local benefits, despite the overt top-down imposed policies. The findings of this study have implications for China's future water policy reform. They also highlight an imperative need for examining environmental governance beyond traditional theories. Extra attention should be paid on not just national discourse, but also local practices as well as their complex interconnections.

Key words:

environmental authoritarianism; China; water governance; decentralization; irrigation; collective action

Demarcation of the Groundwater Potential Zones of Kumari Watershed in Drought Prone Purulia, West Bengal: An Integrated Approach for Water Resource management

Ghosh PRASANTA KUMAR, Jana NARAYAN CHANDRA, Bandyopadhyay SUJAY

Department of Geography, The University of Burdwan, Golapbag, Burdwan, Pin: 713 104, West Bengal, India,
gprasanta05@gmail.com

Abstract

Being the world's most precious natural and valuable resource, groundwater is largely unexploited for agricultural development till today in drought prone western part of West Bengal, India. In drought prone areas, micro-watershed based development strategy may be considered as the best practice for integrated development. On this background, the micro-watersheds of Kumari River Basin in West Bengal have been selected for better water resource management. Geologically the area consists of Chotanagpur granite-gneissic complex while physiographically highly dissected in nature with lateritic upland and skeletal soil. Eventually, cultivation of this area is dominated by monocropping and thus per hectare production is also low as compared to other parts. So, the supply of sufficient water resource is more important to offer food security instead of rain-fed subsistence farming. In this context, the present study has been endeavoured to evaluate the potential zones for groundwater in Kumari River Basin with the help of quantitative geomorphological analysis in combination with satellite data, maps and field verification. To fulfill the objectives, the study area has divided into seven watersheds and subsequently the groundwater potential zones were identified based on linear-area-relief parameters, grid-wise theme-weight and class-weights of the watersheds in GIS environment. The analyses of the results reveal that the elongated shape, favourable drainage network, permeable geologic formation and low relief makes the south-eastern and south-western part of Kumari as the promising groundwater potential zones. In addition, efforts have been made to find out the artificial recharge structure and sites for the better usage of groundwater.

China

Abstract

Nine plateau lakes in Yunnan is an important carrier of water resources. With the economic development rapidly in recent decades, the resource utilization intensity of plateau lakes continued to increase and caused eutrophication and other issues, which need to strengthen the dynamic monitoring on water resources status. This study illustrated the user's needs, the system functional structure, system logical architecture and system functional realization respectively, and also implemented the dynamic forecast system of Yunnan plateau lakes water resource that applied the remote sensing image timed harvest, cloud servers, the open source map server and other new technologies into the system development effectively. So, it is this system that provided an important support on optimization management and pollution prevention of Yunnan plateau lakes water resource.

Abstract

As water is closely associated with economic activities, the growing population, agricultural development and reallocation of water resource of Heihe River Basin have highlighted the issues of intensified water consumption and groundwater overexploitation in Zhangye. Here we conducted a quasi-dynamic input-output analysis to investigate the changes of water footprint among different sectors of Zhangye during 2002-2012, and clarified the driving mechanism of these changes. Results showed that the direct agricultural water consumption coefficient calculated by using input-output table and other water-related data, is the largest among coefficients of all sectors, and especially the fishery sector still consumed about 1m³water per unitoutput in 2012. We found water-saving technology made evident contribution to the decrease of total water consumption during 2002-2007 but induced the rebound of total water consumption during 2007-2012. At the same time, other sectors cannot take away the water resources consumption from the primary industry, which caused the expansion of cultivated land and the increase of virtual water by the trade of agricultural product and. This study provides insights into water challenges in Zhangye and sheds lights on the combating strategies in the future. It is also an endeavor to enhance the policy relevance of land use governance and industrial transformation. The comprehensive exploration on the system of water-ecosystem-economy is critical in integrated water management.

Droughts over Marathwada Meteorological Sub-division of India: Climatological and Remote Sensing-based Assessment

Dhorde A G

Department of Geography, Savitribai Phule Pune University, Pune, 411007, Maharashtra, India,
amitdhorde@unipune.ac.in

Abstract

Like many other agricultural regions of India Marathwada is also highly dependent on performance of monsoon. The rainfall from June to September is a primary source of moisture. Good rainfall during these months ensures good agricultural production during Kharif season and also lays the foundation for Rabi season. Marathwada receives moderate to scanty rainfall, and is therefore, always susceptible to drought. It has been realized that this hazard has been visiting this area with increased frequency. The main objectives of the research were: (1) To investigate long-term trends in monsoonal rainfall (June-September) over Marathwada. (2) To assess drought conditions during the months of October and November using indices derived from remote sensing data. The analysis revealed that, over majority of the districts monsoon rains showed decreasing trends, significant over couple of districts. Remote sensing based drought indices such as Temperature Condition Index (TCI), Vegetation Condition Index (VCI) and Vegetation Health Index (VHI) were used for drought assessment. These indices were computed using Moderate-Resolution Imaging Spectroradiometer (MODIS) level-3 datasets. The drought conditions during the low rainfall year of 2002 reflected very well in the output maps. Maps prepared for average conditions during the post-monsoon months of October, November and December revealed greater temporal and spatial details throughout the last one and half decade. According to VCI, during November of 2003, conditions were severe in the districts of Aurangabad, Beed and Osmanabad (Western Marathwada). The research also highlights need of better river basin/watershed management strategies to mitigate droughts.

drought; monsoon; long-term trends; temperature condition index; vegetation condition index; Marathwada

Flood of 2015 That Engulfed *Rarh Plains* in West Bengal, India: A Wake-Up Call for Society

Jana NARAYAN CHANDRA, Bandyopadhyay SUJAY, Ghosh PRASANTA KUMAR

Department of Geography, The University of Burdwan, Golapbag, Burdwan, Pin: 713 104, West Bengal, India,
jana.narayan@gmail.com

Abstract

The South Bengal flood 2015 was one of the important river disasters in recent history, which affected more than 10.6 million people in *Rarh* plains of West Bengal. Although incessant rainfalls during the month of July 2015 and Komen, the cyclone that hit on 30th of July 2015 have been cited as the major causative factor for this disaster, but the human interventions in the river system over the years made this disaster a catastrophe. Geomorphic analysis suggests that the rivers of *Rarh plains* had a very dynamic regime in the past. These rivers are eastward flowing parallel debouching into the Bhagirathi-Hooghly (a distributary of the Ganges) and represented by five major western tributaries: the Mayurakshi, the Ajay, the Damodar, the Silabati-Rupnarayan and the Kangsabati-Haldi. However, the river has now been constrained by embankments on both sides, and several dams have been constructed along the river. As a result, the floodplain undergoes great changes as a result of the aggrading river bed and confinement of flow due to construction of embankment. Confinement increases stream power that facilitates sediment entrainment (erosion from bed and banks) and transport within the system which leads to devastating breaching of embankment. Further, embankment breaching results in large area inundations and subsequent sand incursion in the fertile and densely populated floodplain. It is therefore of utmost importance to identify such areas and suggest mitigation measures to reduce the risks and vulnerability. We emphasize the role of geomorphology in flood analysis and management and urge the river managers to take relevant steps urgently to incorporate the geomorphic understanding of these Cratonic Rivers in river management plans.

Framing the Land Use Dynamic Modeling with Regional Climate Models

Wang P^{1,*}, Deng X²

¹Zhongnan University of Economics and Law, Wuhan, 430073, P. R. China, wangpei@igsnrr.ac.cn

² Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, dengxz@igsnrr.ac.cn

Abstract

A framework of land use change dynamics (LUCD) model compatible with regional climate models (RCMs) is introduced in this study. The LUCD model can be subdivided into three modules, namely, economic module, vegetation change module, and agent based module. The economic module is capable of estimating the demand of land use changes in economic activities maximizing economic utility. A computable general equilibrium (CGE) modeling framework is introduced and an approach to introduce land as a production factor into the economic module is proposed. The vegetation change module provides the probability of vegetation change driven by climate change. The agroecological zone (AEZ) model is supposed to be the optimal option for constructing the vegetation change module. The agent-based module identifies whether the land use change demand and vegetation change can be realized and provides the land use change simulation results which are the underlying surfaces needed by RCM. By importing the RCMs' simulation results of climate change and providing the simulation results of land use change for RCMs, the LUCD model would be compatible with RCMs. The coupled simulation system composed of LUCD and RCMs can be very effective in simulating the land surface processes and their changing patterns.

Key words:

land use change; land use change dynamics model; regional climate model; computable general equilibrium modelling; agroecological zone

Geographical Assessment of Community-based Traditional Water Tank Structures (Maji-Malgujari Talav) in Eastern Vidarbha, INDIA

Magar P. P.

PG Department of Geography, Govt. Vidarbha Institute of Science and Humanities, Amravati (MAH) 444604, India,
prashantpmagar@gmail.com

Abstract

India is blessed with traditional water tanks as rainwater harvesting structures for agriculture, drinking, domestic needs and groundwater recharge. Rural community fulfills their water needs from these traditional tanks. These tanks are easily adaptable to the village administrative system that prevailed during the mediaeval period. One such community based traditional water tank structures of water management exists in the eastern Vidarbha region of Maharashtra locally known as Maji Malgujari Talav (MAMA Talav). Present work attempts to understand the geographical aspects of traditional water tanks structures, that have been used to store rain water for agricultural use in various villages of eastern Vidarbha region of Maharashtra. Many of the tanks have become dry, dis-functional and silted up resulting into the decline in their potentiality. The study recommends repair and restoration of these tanks by creating water users' associations. De-silting, rearing of fish to enhance the aquaculture, community use of water for domestic purpose to avoid the stagnation of water, regular maintenance and cleaning of the tanks are some of the measures suggested to restore and rejuvenate these traditional water tank structures. Scientific and technical study would be the real gateway for further exploration of surface and groundwater harvesting in the watershed areas of traditional water tanks.

Glacial Lake Outburst Floods and Integrated River Basin Management: A case of Lahaul and Spiti district, Himachal Pradesh

Pankaj Kumar and R.B Singh

Department of Geography, University of Delhi, Delhi 110007, pankajdsedu@gmail.com

Abstract

Lahaul and Spiti district forms central part of the Northern Himachal Himalayan region comprise an area of around 13988 sq km. Glacial lake formation is currently being observed in the glaciated regions of the district. Glacial lake outburst floods and associated geohazard like flashflood, landslide and avalanches are common in the district. The paper deals with the inventory and mapping of glacier lakes, and potential danger glacier lakes of Lahaul and Spiti district and its impact on Integrated River Basin Management. Satellite imageries of Landsat TM and Shuttle Radar Topographic Mission (SRTM) Digital Elevation Model (DEM) have been acquired from GLCF and Earth Explorer for the year 2011. Mapping of glacial lakes has been done using Normalized Difference Water Index (NDWI) and Normalized Difference Pond Index (NDPI). In order to identify potential Glacial Lake Outburst Floods (GLOFs), the present paper uses a technique adopted by Clague and Mathews (1973) for estimating maximum instantaneous discharge from a lake at the time of outburst. Potential GLOF can pose danger to Integrated River Basin Management of the downstream in coming decades. The example of Glacial Lake Outburst Flood (26th June, 2005) of Paree Chu lake of Tibet Himalaya has been taken for detailed study of its impact on Integrated River Basin Management of downstream population living in the Spiti river valley of Himachal Pradesh. Preventive techniques have been discussed to mitigate the adverse effect of GLOFs on community residing in the region.

Groundwater Resource Management using Geospatial Techniques: A Case Study of Jaipur District, Rajasthan, India

Ajay Kumar and R.B. Singh

Department of Geography, Shaheed Bhagat Singh College, University of Delhi, Delhi, India, mail_kumarajay@yahoo.com
Department of Geography, Delhi School of Economics, University of Delhi, Delhi, India

Abstract

Effective management of aquifers is becoming an increasingly important aspect of water resource management strategies. Application of geospatial techniques in site selection for artificial recharge and flood spreading management have been the topic of several researches. As the study area has semi-arid climatic conditions and receives normal annual rainfall of 565mm, therefore it becomes important to conserve water resources through recharge of groundwater. The paper attempts to identify direct surface recharge sites by recharge ponds, as the soil of the study area has a good permeability and the area of implementation is wide enough. Intensive data have been collected to carry out the study like satellite images, maps, reports, soil characteristics and hydrological data. All of these data have been stored and manipulated by using ArcGIS 10.2. The results show that the western part of the district has huge potential for ground water recharge sites compared to the central and southern parts of the district. The southern part of the district has the least potential for establishment of groundwater recharge sites due to excessive concentration of salts in the region. After detailed scientific studies, massive programme needs to be taken up for artificial recharge to groundwater using suitable techniques like harvesting roof top rainwater (RTRWH), storm rainwater runoff, dug well recharge in farms, constructing sub surface barriers across streams. Along with the water harvesting and recharge of groundwater, conservation strategies need to be adopted for securing groundwater availability in Jaipur district.

Key words:

Groundwater recharge; aquifer management; water conservation; semi-arid; GIS

Hydrological Study of Watershed programme in Tonk District of Rajasthan

Wadhwa Rakesh

Govt.P.G. College, Mandi Dabawali(Haryana), prof.wadhwa@gmail.com

Abstract

Tonk district covers an area of 7298.29 Sq. Km. which is located in the North eastern part of Rajasthan. Physiographically, the area is characterised by plains with scattered hills in Tonk, Newai, Todaraisingh and Deoli blocks. It is mainly drained by Banas River and its tributaries. The district is comprises of six blocks. The main water bearing formations in the district are Older Alluvium, Mica Schist and Gneisses. The watershed approach has conventionally aimed at treating degraded lands with the help of low cost and locally accessed technologies such as in situ soil and moisture conservation measures, afforesting etc. and through a participatory approach that seeks to secure close involvement of the user communities.

Many projects designed within this approach were at different points of time, taken up by the government of India. The Drought Prone Areas Programme (DPAP) and the Desert Development Programme (DDP) were brought into the watershed mode in 1987. The Integrated wasteland development of the national wasteland development board also aimed at the development of wasteland on watershed basis.

Key Words:

Tributaries; watershed approach; Drought Prone Areas Programme; wasteland development

Identification of Groundwater Scarcity Zones in the Karha River Basin with the Help of Groundwater Fluctuation

Nagarale VIRENDRA, Gaikwad PRAVIN

Department of Geography, S.N.D.T. Women's University, Pune, Maharashtra. INDIA, 11038, drnagarale@gmail.com

Abstract

The Maharashtra State enjoys a tropical monsoon climate. Despite of the incidence of high annual rainfall, hilly tracts and elevated areas in the study region experience drought during summer season. The vast majority of groundwater scarcity problems present today are caused by overexploitation of water resources. Rapid growth of urbanization in the Karha river basin resulted into depletion of groundwater level in pre monsoon season. The groundwater depth in the region decreases season by season because of lack of proper management of water resources. In the Study area groundwater is only source of drinking water, agricultural and industrial use, thus a large population is exposed to risk of groundwater scarcity. The Study Area is located at Purandhar and Baramati Tahasil in Pune District Maharashtra State. Karha River basin covers most of the area of these two tahasils. Karha river is a seventh order stream with a basin area of 1357.4 square kilometre. In present study, total 30 Dug-Wells has been take in to consideration for fluctuation of groundwater and on the basis of that data Various thematic maps has been generated (like pre-monsoon groundwater depth and post-monsoon groundwater depth), from those maps we can understand and can delineate the ground water scarcity zones.

Groundwater Fluctuation; Water Scarcity; Drought

Impacts of Water Allocation on Long Time-Series Variations of NPP and Water Use Efficiency in the Lower Heihe River Basin

Yan H M, Zhan J Y, Yang H C, Zhang F

State Key Laboratory of Water Environment Simulation, School of Environment, Beijing Normal University, Beijing, 100875, P. R. China, zhanjy@bnu.edu.cn

Abstract

The Lower Heihe River Basin (LHRB) as a typical arid region in China suffered from increasing water scarcity due to the imbalanced water allocation. The Ecological Water Diversion Project was implemented in 2000 to restore local ecological conditions, it is of great significance to analyze impacts of water allocation on long time-series variations of essential ecosystem services and water use efficiency (WUE) in this region. With net primary productivity (NPP) as the indicator of essential ecosystem services, this study estimated NPP and WUE in the LHRB during 2001-2010 to reveal their long time-series variations under the influence of human activities and climate change, and scenario analysis was carried out to study the impacts of water allocation and climate change on NPP. Results suggested NPP and WUE ranged between 0-448.70 gC/(m²•a) and 0-2.20 gC kg⁻¹ H₂O, respectively, both showing obvious spatial heterogeneity. Besides, NPP and WUE both showed an overall increasing trend during 2001-2010, but accumulative WUE of the whole study area showed a first sharply decreasing and then gradually increasing trend, indicating there was still some improvement scope of WUE. In addition, the fractional vegetation change resulting from water allocation played a dominant role in influencing NPP, accounting for (69.75%) of the NPP change, while climate change also had an overall positive effect on NPP. These results can provide valuable spatially explicit information for formulating more specific policies to further improve water allocation within the LHRB to guarantee sustainable provision of essential ecosystem services.

Key words:

water allocation; water use efficiency; ecosystem services; NPP; Heihe River Basin

Integrated and Adaptive Water Management in the Heihe River Basin of China

Deng X, Wang P

Institute of Geographic Sciences and Natural Resource Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, dengxz@igsnrr.ac.cn

Abstract

In ecologically fragile areas with arid climate, such as the Heihe River Basin in northwestern China, sustainable social and economic development depends largely on the availability and sustainable uses of water resource. However, there is more and more serious water resource shortage and decrease of water productivity in Heihe River Basin under the influence of climate change and human activities. We attempts to identify the severe water scarcity under climate change and presents possible solutions or sustainable development in Heihe River Basin in this study. Three problems that intervened land use changes, water resource, the relevant policies and institutions in Heihe River basin were identified, including (1) water scarcity along with serious contradiction between water supply and demand, (2) irrational water consumption structure along with low efficiency, and (3) deficient systems and institutions of water resource management along with unreasonable water allocation scheme. In this sense, we focused on reviewing the state of knowledge, institutions, and successful practices to cope with water scarcity at a regional extent. Possible solutions for dealing with water scarcity are explored and presented from three perspectives: (1) scientific researches needed by scientists, (2) management and institution formulation needed by governments, and (3) water resource optimal allocation by the manager at all administrative levels.

Key words:

waterscarcity; water consumption; water demand; water management; Heihe river basin

Integrated River Basin Management in A Federal Country: The Case of Piracicaba, Capivari and Jundiai watersheds, Brazil

Muniz Miranda G, Reynard E.

University of Lausanne, 1015 Lausanne, Switzerland, gmunizmi@unil.ch.

Abstract

Currently, governments and international institutions consider integrated water resources management (IWRM) at the watershed scale as the most sustainable way for water management. In centralized countries, its implementation is done in a relatively homogeneous way with the purpose to decentralize water governance. Differently, in federal countries, authority is already more decentralized due to the local autonomy and the share of administrative and political power. Nevertheless, this situation is different in federal Latin-American countries, as in Brazil, where the implementation of IWRM is linked to a wish for decentralization after a dictatorial and very centralized period. In this context, the present article aims to underline the advances and obstacles for IWRM implementation in Brazil, taking as a study case the Piracicaba, Capivari and Jundiai (PCJ) watersheds. The interviews of stakeholders reveal that the integrated river basin management experience increased the participation and local environmental awareness and the efficiency of some management tools, as the charging of water use. Nevertheless, the main obstacles are linked to the share of water-property between federal and state governments (which makes difficult the operation of committees of different states); mandatory plans at all levels (federal, state, regional and local), and the poor implementation and co-ordination between the plans.

Key words:

Integrated water resources management; watershed; governance

Irregular Water Disputes of Brahmaputra River Between India and China and Its Impact on Sino-Indian Relations

Choudhary Pankaj

Faculty of Law, University of Delhi, Delhi, India, pankajchoudhary9871@gmail.com

Abstract

It is said if there is any possibility of third world war it is bound to happen only for Water. So it is quite evident that water has the all the extrapolated potential to be one of the great challenges of the twenty-first century. We know According to United Nations estimates, more than half the global population will live in water-stressed or water-scarce countries by 2025. The vast majority of this forecast population will be in China and India. Changes result from continued economic growth and modernization in these countries—including an increase in irrigated farming, rising industrial production, expanding mass consumption in a growing middle and lower class, and, particularly in China, raising animals for a more meat-centric diet—will place ever-greater pressure on water supplies. Macro challenges such as climate change and pollution will further strain freshwater resources. The present case study examines some of the international, regional, and local challenges that arise from friction over water resources, using as a case study of the Brahmaputra River. It also highlights the other factors including basic water usage data for China, India, and Bangladesh; an overview of the Brahmaputra River's course and geography; and a history of China's dam building and water diversion projects on the river to date. It also explores the understanding and challenges of the Brahmaputra: international river governance norms, food security issues, water governance as an issue involving both international and domestic politics, and the key role that Tibet plays in Asia's water challenges. Up to some extent the study examines the extent to which a dispute over the river's use represents a threat to India and explores India's options as a downstream state.

Land Use/Land Cover Changes in Coastal Districts of Karnataka

Kumar A, Singh A

University of Delhi, Delhi, India asnaik007@gmail.com

Abstract

Coastal environment has an instrumental bearing over the economy of the nation. By virtue of its diverse and precious resources productive habitats, rich biodiversity and its locational advantage to human activities. It contains diverse and productive habitats for human settlements, resource development and local subsistence; coastal zones among the most heavily utilized area because of their resources. The process of land acquisition for beach resort, hotels and industries has changed entirely the land use pattern of the coastal areas, leading to adverse effects on environment and local people. Increase in population and expansion of tourism activities in coastal Karnataka, are the major factor which leads to land use and land cover changes in the coastal zone. The area under irrigation, forest cover are increased whereas the area under unirrigated and culturable waste land is decreased from 1995-2015. The coastal backwaters, estuaries, river-mouths are well known for their productivity. With passage of time, Land use and Land cover of coastal area undergoes significant change due to varying natural and anthropogenic causes. Therefore, it is essential to monitor the changes in land use and land cover at regular intervals for proper management of natural resources of existing area. In the present study deals with the land use and land cover mapping and monitoring of the area around the river mouth, urban and village settlements and infrastructural activities Karnataka coast. The satellite data were interpreted based on visual interpretation keys to prepare land use and land cover map of year 1995 and 2015.

Rainfall Runoff Modelling using Remote Sensing and GIS: A case Study of Bandal Watershed, Dehradun, India

Jat, Birdhi Chand

Lecturer, Deptt. of Geography, Govt. P.G. College, Neemkathana, Rajasthan, India. bcgeography@gmail.com

Abstract

The SCS method of estimating runoff from rainfall is based on method developed by SCS hydrologist. This method is the most commonly used method all over the world for estimation of runoff resulting from rainfall over small watersheds. The SCS approach involves the use of simple empirical formula and readily available tables and curves. The empirical equation requires the rainfall and a watershed coefficient as inputs. The watershed coefficient is called the curve number (CN), which is an index that represents the combinations of hydrologic soil group and land use classes. This model involves relationships between land cover hydrologic soil group and curve number. As satellite data can be used for estimating the land cover distributions, hence it provides useful input support for SCS model. The study area depicts rugged terrain consisting of structural hills, gently sloping piedmont zone bounded by Lesser Himalayas in the North and Shiwalik in the South. In between these two Northern and Southern hill ranges lies the Dun valley, comprising mostly of piedmont zone and alluvial plains. Spatial data base developed during this study was used to obtain all the input parameters of SCS model; The GIS provides estimation of weighted curve number of the watershed. Any future change in land use which is one of the input parameter for SCS model may also be incorporated in the prepared spatial data base and change in runoff may be monitored. This study recommends empirical model in GIS as a potent tool of resource assessment.

Remote Sensing Dynamic Monitoring of the Nine Plateau Lakes in Yunnan

LI Haojie, CHONG Dan, FAN Shuo, ZHANG Shiqiang, WANG Jie

Northwest University, College of Urban and Environmental Science, Xi'an, 710000, China, ihaojie001@foxmail.com

Abstract

Nine plateau lakes in Yunnan province are very important for the sustainable development of social economy in Yunnan province. In this study, the Landsat series remote sensing satellite data and SPOT6/7 remote sensing data were used to monitor the lakes area of Yunnan province in 1989, 1993, 2000, 2007, 2015 years. The results showed that: The area of Yunnan Plateau Lake in 1989-2015 years is a few atrophic, indicating that the nine plateau lakes area as a whole is stable, however, Qilu Lake and Yilong Lake area continued to shrink, 2015 has shrunk about 40%. The lake area in 2015 were less than in 2007, shows that the continuous drought in recent years has had a marked impact on the lake area. The comparison of the nine Lake area in 2015 Landsat 8 OLI data and the SPOT 6/7 solution showed that the results of different spatial resolution were significantly different (even up to 8%), which indicated that the effect of different spatial resolutions on the spatial resolution of the lake area was considered when using multi-source remote sensing data.

Seasonality of Streamflow, Climate Shock, and its Impact on Sustainable Livelihood in the Kosi Region, Bihar, India

Kumar, Rajan

Department of Geography, Delhi School of Economics, University of Delhi, Delhi, India, rajanxdse@gmail.com

Abstract

Anthropogenic activities forced us to think towards rapidly changing climate and sustainable development. The present studies highlight the distortive effect of climate change on social cohesion. The contribution of this study to existing empirical analyses is fivefold. First, it measures climate shocks through deviations from long-term rainfall patterns in a nonlinear (U-shaped) relation, capturing both drought and excessive rainfall, instead of focusing on droughts only. These calculations are based on deviations from normal which exhibit anomaly for different seasons in Kosi region second, it introduces a new set of variables which could analyse and interpret the relation between concerns about climate shock and livelihood. The major concerns have always been related to mass migration which has resulted in human desertification in the region. The other being agriculture sector which is one of the major contributors towards climate change, as well as largely affected adversely by climate change Agricultural productivity is known to be sensitive to climate change induced effects and it has impact on livelihood of families linked with farming. Thus it is important to understand the avulsive nature of Kosi river and what are the existing coping strategies that farmer deploy in case of climate shocks like flood and drought and who is involved in making decision relating to these coping strategies. This paper has focused the Levels of sustainability which will be determined by using standard carrying capacity techniques, geological structure of the landscapes, nature of vegetations, and size of the livestock.

Abstract

The water resource is the basic proposition of agricultural and industrial development in China because of our big population. It is noteworthy that what climate change will affect on Chinese future water resource. The influence of climate change includes precipitation and evaporation, of which the former is more discussed and the latter is readily ignored. This article is based on the regional climate model (RegCM4) which is developed by NCAR/PSU (National Center of Atmospheric Research/University of Pennsylvania). We made a simulation to estimate the future climate change in China with A1B scenario. And got the spatial distribution characteristics of temperature and precipitation in historical period (1981-2000 average annual value) and future period (2041-2060 average annual value). The P-M evapotranspiration model recommended by the FAO is used to calculate the evaporation. And the moist degree is used as the index of water resources. In general, the results showed that water resources in China present latitude zonal distribution, gradually reduce from south to north. From the trend of the change, the water resources in the south of Yangtze river will decrease in the future, on the other hand, in the north of Yangtze river, especially in the north of the Huai-he river, the water resources condition will get better. The most obvious regions for the growth of water resources include the western of northeast China, Huai-he river basin, Si-chuan province and the south of Tibetan autonomous region.

Abstract

Water is an important restricted factors for development, especially in arid area, water is particularly important. The Heihe River, the second largest inland river of China, is located in arid area of Northwest China. Zhangye city is located in the midstream of the Heihe River, which is main region of economic activities, accounting for more than 80% of GDP and attracts 95% population in Heihe River Basin. Naturally Zhangye city is the major region of consuming water of productive use in Heihe River Basin. Water supply has been changing in Zhangye city, which will affect water productivity remarkably. Nevertheless, current studies about water productivity mainly concentrated on agriculture.

This paper studied the effect of change of water supply on water productivity in 48 production sectors which covers the whole production progress in Zhangye city based on the CGE (Computable General Equilibrium) model embedded with water. Preliminary results show that reducing water supply will improve water productivity, and reducing surface water supply will improve water productivity of industrial sectors and service sectors higher than agricultural sectors, inversely, reducing groundwater supply will improve water productivity of industrial sectors and service sectors lower than agricultural sectors. The interesting results may be useful for water reallocation and integrated management in Zhangye city, even in the Heihe River Basin.

Using High-resolution DEM and SWAT Model for Surface Water Resource Management in Ajay River Basin, India

Bandyopadhyay SUJAY

Department of Geography, The University of Burdwan, Golapbag, Burdwan, Pin: 713 104, West Bengal, India, sujaybandyopadhyayest@gmail.com

Abstract

Over-utilization of the water resources due to ever-increasing population and rapid urbanization is exerting pressure on these commonalities which are on the brink of collapse. Along with the problems of population pressure, the world climate is changing more rapidly in recent years and causes difficulty in appropriate water management including storage plans. The impact of climate change would be quite severe for India including Gangetic West Bengal (GWB) because as per IPCC (2013) report, there is a high confidence in a projected rise in temperature and medium confidence in the increase of summer monsoon precipitation in future over South Asia. So, there is an urgent need for the evaluation of water resources in GWB for sustainability of livelihood and regional economy. However, environmentally and socially sustainable sound management of water resources requires long-term, reliable hydrologic information and high resolution topographic database. The present research attempts to fill the vacuum of high quality database and to appraise future changes in stream flow under projected climate scenarios of Ajay River Basin in GWB using Cartosat-DEM and SWAT (soil and water assessment tool) model. The high resolution topographic data has been produced from the stereo coverages of Cartosat-1 data products through digital photogrammetric techniques, in combination with field surveys through DGPS. In addition, the hydrological data were obtained from the Central Water Commission (CWC), India. The results of the SWAT demonstrate that the model reproduces and generates properly the climatic variables and permits correct water resources assessment in this basin.

Abstract

With the rising pressure and costs of energy and environment, there has been a surge of industrial transfer from the east area to central and western areas in China. However, the industrial development in Western China is seriously constrained by the extremely fragile ecological conditions and severe water shortage. Heihe River Basin is the second largest inland river basin in Northwest China and one of the most undeveloped regions, where there is an extremely fragile ecological environment due to the drought. The industrial structure in Heihe River Basin has changed greatly, which may lead to more water consumption and water quality deterioration. This study explores the relationship between economic development and the water consumption and water quantity in 20 industrial sectors in Heihe River Basin during the industrial transfer process on the basis of statistical data. Besides, this study analyzed the effects of industrial structure upgrading on water consumption and water quality during the two periods of 1997-2002 and 2002-2007. The results illustrate that the industrial structure adjustment has different impacts on the water pollution and water consumption efficiency in different sectors. Although there is serious water pollution and more water consumption, it is relieved by the decreasing emissions in other industries such as real estate, leasing and business services and high-tech industry. Those conclusions can provide very important decision support information on how to allocate the water resource through industrial structure adjustment in Heihe River Basin to reduce the water pollution.

water consumption; water quality

Water Resources and Related Issues in the Ganga Basin: An Overview

Pathak, M.

Associate Professor, Department of Geography, SMRDPG College Bhurkura-Ghazipur 233001 (U.P.), INDIA, mpkes@gmail.com

Abstract

The Ganga basin covers about 26 per cent of India's geographical area, supports more than 40 per cent of the population and supplies 30 per cent of the country's water resources. The average water potential of the Ganga basin at present is 525 billion cubic metres (BCM) but only 250 BCM is utilizable. Water is abundant during the monsoon but scarce during the dry season. In the catchment area the mean maximum flow of rivers is about 50 times greater than the mean minimum flow. Due to spatial and temporal variability the basin faces the problem of floods and droughts syndrome. With rapid growing population, improving agricultural activities, urbanization and industrializations, the pressure on water resources is increasing day by day. Over exploitation of ground water is leading to reduction of low flows in the rivers and declining the ground water levels. The quality of surface and ground water resources is also deteriorating because of increasing pollutant loads from point and non-point sources. The climate change is expected to affect precipitation and water availability. The paper presents availability and utilization pattern of water resources in the basin as well as describes the various issues and strategies for developing a holistic approach for sustainable development and management of water resources in the Ganga basin.

Water Scarcity in the villages on Kas-Patan Laterite plateau in Satara District, India

Pardeshi S S, Pardeshi S D

Department of Geography, Annasaheb Magar Mahavidyalaya, Pune, India, suchitrapardeshi@gmail.com

Department of Geography, Savitribai Phule Pune University, Pune, India, sdpardeshi@gmail.com,

Abstract

Dry spell that is pre monsoon phase in peninsular India is very crucial phase with reference to water resource management. People face serious problems of water scarcity in dry spells. The villages located on the hillslopes, Plateaus and hill tops face acute water shortage during dry spell. These settlements are age old settlements and sustained over several decades on the laterite plateau. Earlier the settlements and the size of population were small so the demand for water was less. As the settlements are grown, demand for water also increased in this area. The plateau topography and lithology in the form of laterite rock does not support water storage as an aquifer. The area receives sufficient amount of rainfall in monsoon period. Since the catchment area is small major streams are not formed on the plateau top. Getting water in such conditions is a major challenge in front of the villagers. The settlements like, Ninaiwadi, Dafalwadi, Sada Waghapur, Dhangarwadi on the plateau top and Kas, Jagmin and Keoli on the plateau margin are suffering from water scarcity. The study highlights water scarcity problem in this area. It is also revealed that the agriculture is depending upon the surface water available from rainfall only for a short period. Present study is an attempt to find out the domestic and agriculture water requirement. It is also found the plateau topography can be used to harvest surface runoff and meet the demands of water in the villages.

Abstract

The idea of water use efficiency (WUE) came from constrain of water resources. As an essential material for human life, water saving entered an orbit of unprecedented rapid development. While for water saving, two directions maybe taken into consideration, reduce water use and increase water use efficiency. While WUE increase achievements would greatly accelerate the promotion of water saving. WUE is closely linked to agriculture production, thus affecting the long-term agricultural development potential. This study surveys the water use efficiency in agriculture by applying meta-regression analysis. Thinking about the databases, a thorough review was made in the following databases: Agricola; Agris International; Ingenta; Science Direct; Social Science Citation Index; and the World Agricultural Economics and Rural Sociology Abstracts. This process yield 107 published papers, which include the whole information of present studies. The main goals are to figure out the WUE difference between countries, production function, input-output variables and estimate methods. The results suggest that stochastic frontier models generate lower WUE than non-parametric deterministic models. The studies from Western Europe and Oceania shows higher WUE among the whole world. Aside from the main results, this paper summaries the threshold of WUE is related to average income. This paper will provide some references for WUE calculation.

Watering the Pop-up Mega City: A Study of Water Supply in KumbhMela of 2013 in Allahabad

Mishra, SATYAM, Sen, ANJAN

Ph.D. Research Scholar, Department of Geography, Delhi School of Economics, University of Delhi, Delhi – 110007, India, satyammishra06@gmail.com

Abstract

Allahabad an important city in the state of Uttar Pradesh in India, is glorified as the “*tirtharaj*”, or the king among all sacred places, in various Hindu scriptures. Also known as Prayag, the city is picturesquely situated at the confluence of the rivers Ganga, Yamuna and invisible Saraswati. Every twelve years, Hindu pilgrims and devotees from around the world, congregate in hundreds of thousands to the World’s greatest religious bathing festival, the ‘KumbhMela’.

Making of this temporary mega city inhabited by pilgrims and tourists requires proper planning and execution, done by Government of Uttar Pradesh in consultation with Government of India, which requires massive investment of capital, and human and technical support. As water is a necessary element for human beings to sustain, it remains equally important for the cities as well as the mass gathering. Hence, it becomes important to study the water supply and its management in the mega events like KumbhMela.

This present research paper critically evaluates the various organizations and institutions involved in providing infrastructure support to KumbhMela, like Town and Country Planning Organization, KumbhMela Authority, Tourism Department (Govt. of Uttar Pradesh), etc. Inductive methodology has been used in this research paper to accomplish the objectives of the study. The present paper studies specifically focusses on water supply, key issues related to it, future challenges and prospects in the KumbhMela in Allahabad.

Abstract

Multiscale assessment of the vulnerability of water resources on the basis of political boundaries and watersheds is necessary to adaptive water resources management. Using RESC model, the vulnerability of water resources in the Huaihe River Basin in four scales, namely, second-class water resource regions (Class II WRRs), third-class water resource regions (Class III WRRs), Province-Class II WRRs, and Municipality-Class III WRRs were assessed. And then with the Theil index and the Shannon-Weaver index, the spatial heterogeneity of vulnerability in the above four scales was evaluated. Results show that vulnerability enhances from the west to east, and shows obvious heterogeneity instead of moving toward convergence in multiscale assessment results. Among the Class II WRRs, the vulnerability of the Upper Huaihe River is lower than that of Midder reaches of the Huaihe River, which in turn is lower than that of Yi-Shu-Si River. And the Lower reaches of the Huaihe River are the most vulnerable. In the scales of Class III WRRs and Municipality-Class III WRRs, the vulnerability shows obvious spatial heterogeneity and diversity. Multiscale vulnerability assessment results innovatively provided in this manuscript are important and useful for uncovering the real spatial pattern of the vulnerability and improving water management.

Abstract

The Koshi river of central Himalaya is the most important cross-border river in south Asia region. This river basin is one of the sensitive areas of global climate change, with its special natural and geographical conditions, huge difference in elevation, diversity of land cover and rich biodiversity. With the increasing intensity of human activities and global climate change, scholars pay more and more attention to the study of land cover change in this basin. Based on the vector data of land cover in 1992 and 2010, this study analyzed the characteristics of land cover pattern and land cover change in the last 20 years. Study shows: (1) Grassland, forest, bare land and cultivated land were the main land cover types, which accounting for 25.84 %, 21.19 %, 18.93 % and 15.12 % respectively of the total area in KRB. (2) Due to climate warming and human disturbance, the middle part of the basin of high altitude glaciers and snow was disappeared, along with the ice lake and river area increased. (3) Alpine Grassland in the northern part of the region Continuous degradation. Human activities are the main influencing factors of alpine grassland shrinkage. And the expansion of alpine grassland due to climate warming will offset the increase of population and livestock density to grassland pressure to a certain extent. (4) In the southern area, due to human activities, a large number of forests have gradually changed to the farmland, especially the evergreen broad leaved forest area.

Abstract

The Koshi River Basin is a major transboundary river basin, running across Nepal from the Tibetan Plateau to the Indo-Gangetic Plain. Various freshwater ecosystems found in the basin provide numerous regulatory and provisioning services for the benefit of both natural environment and the socio-economic development of its inhabitants. However, increasing development activities related to agriculture, hydropower and road networks in the basin is reducing the vitality of the prevalent ecosystems.

In this assessment we aimed to produce a knowledge package on the status and trends of freshwater ecosystems in the basin by identifying key drivers, pressures and resulting impacts along with recommendations for their sustainable use.

Critical freshwater ecosystems of the basin were identified with the help of GIS analysis complemented by field verification. Consultations with local communities, thematic experts, local/national level stakeholders and secondary review of relevant literature were carried out to select six most critical sites across three geographical belts (High Mountains, Middle Mountains, Terai/Churiya). Elaborate assessments on physical and chemical characteristics of water and bio-assessment for examining habitat quality and macro-invertebrate assemblage based on the existing stresses were conducted in the selected sites. Focussed group discussions (FGDs) were conducted to triangulate the findings with existing socio-economic stressors.

The results showed that human interference (development activities, waste dumping and agricultural practices) and very less vegetative cover determined the status of the freshwater ecosystems in the study sites. It was found that water characteristics, field habitat conditions and macro-habitat assemblage were in critical conditions in the study sites from Terai/Churiya than High and Middle mountains.

Abstract

For a sustainable sediment management, it is important to know the spatial distribution of different sediment sources and their temporal variability. In the absence of such knowledge, it is difficult to assess the controlling factors of sediment production and transport, which is crucial not only for managing any upstream storage as well as for irrigation schemes but also for reducing flood risk in the plains. The trans-boundary Koshi river (about 87,000 km²) in the eastern part of the Ganges river basin originates from the mountains of China and Nepal and further flows downstream in the Indo Gangetic Plain of India. The river has been documented as a dynamic river and one of the most distinctive characteristics of the Koshi is its high sediment load varying from 100 million tonnes/yr at Chatara (upstream station) to 43 million tonnes/year at Baltara (the last gauging station before the Koshi river meets the Ganges at Kursela). Such excessive sediment load is responsible for extensive sedimentation and associated fluvial hazards downstream. Due to high sediment load and low gradient in the plains, the river channels have shifted westward by about 115 km across northern Bihar State in India over the past 220 years. Though, it is well known that the tectonically active Himalaya is the main source of riverine sediment loads in the Koshi River basin, the understanding of the contributions from different physiographic regions in the basin and their causal factors is fragmentary. This paper aims to investigate the spatial and temporal sediment dynamics in the Koshi river basin and to understand its relationship with several hazards resulting from river dynamics and floods. We have applied integrated approaches including stream power computation, sediment transport capacity modeling and HEC-RAS modeling to quantify the sediment fluxes from the hinterland. Stream power distribution shows a close proximity with the spatial variability in slope data and provides a good proxy for sediment erosion. Significant spatio-temporal variability in sediment yield at sub-basin scale is documented from stream power based approach. The Koshi has a very high transport capacity and our simulated sediment load is in close agreement with the observed sediment load at the outlet of the basin at Baltara. Our model also suggests high specific sediment load values for the Siwaliks and Lesser Himalayan zones. Results obtained from different approaches are currently being integrated to understand the sediment dynamics and sediment connectivity in different components of the Koshi river system such as upstream-downstream and hillslope-channel connectivity.

sediment dynamics; sediment connectivity; Koshi river basin; river hazards

The Varieties of Mountain Hazards and Human Resilience in the Trans-Boundary Koshi River Basin of the Himalayas

Ningsheng Chen*

The Institute of Mountain Hazards and Environment (IMHE), China, chennsh@imde.ac.cn

Abstract

Koshi trans-boundary basin covers an area of 71500km² and enjoys the largest elevation difference in the world. In this basin, the earthquake is frequent and the precipitation is abundant, leading to high frequency of mountain hazards, including mountain torrent, debris flows, landslides and GLOF. Owing to large disparity on natural conditions and social economy, disaster type and characteristic and the disaster mitigation measures such as structural and non structural measures are quite different among China, Nepal and India, respectively in the upper, middle and lower part of Koshi basin. In this paper, few number of regional disaster cases have been discussed to uncover the existing varieties of mountain hazards and highlighting the mitigation measures. In China, landslides and GLOFs is the prime disasters with large magnitude and low frequency and the transformation disaster chain can significantly influence large domain. The government leads the disaster mitigation efforts through spending money on the high standard mitigation measures such as engineering, monitoring and warning works. In Nepal, debris flows and landslides are the major hazards with medium magnitude and low frequency and the disaster chain can pose bad effect to a certain area. The local residents lead the disaster mitigation efforts under government's suggestions, and community based warning is the primary measure, followed by the flexible engineering works. In India, torrent is the main type, covering a large area with high frequency and large magnitude. The government, non government organization and local residents work together and conduct limited flexible engineering works and partly non-structural warning system. Research suggests in the analogous basin, the scientific disaster mitigations should cover the whole basin falling in different countries to make a scientific plan and the utilization of water resource in disaster mitigation. Besides, the resilient alleviation model among different countries requires corporation from all the countries.

Abstract

Global warming increased the risk of glacial lake outburst floods (GLOFs) in the Himalaya mountain region. In the center Himalayas, Poiqu (upstream) - Bhote Koshi & Sun Koshi (downstream), one of the transboundary catchment between China and Nepal, has been identified as highly prone to GLOFs. Through field survey and remotely sensing interpretation, we explored the distribution of and changes of the glacial lakes, past GLOFs, risk from potential GLOFs, and past risk prevent mechanism within the watershed. Previously established empirical equations between lake area and volume of lake water were used to estimate the volumes and the possible minimum and maximum discharges of 10 critical glacial lakes within the watershed. It showed big variations between of the potential minimum and maximum discharges, but even the minimum discharge may cause certain disaster and great loss. The social survey showed both China and Nepal lack of effective mechanism to prevent and reduce the risk of GLOFs within this catchment. We recommend different strategies to reduce GLOF risk and to establish transboundary cooperation mechanism to decrease the potential GLOFs risk.

Key words:

Glacial Lake Outburst Flood Risk; Poiqu catchment; transboundary cooperation mechanism

Improving Integration of wetland Conservation with Utilization of Wetland

Resources Based on Spatial Scale

ZHANG Chunli

Editorial department of Chinese Geographical Science, Northeast Institute of Geography and Agroecology, CAS,
Changchun 130102, China

Abstract

Scale issues in resource and environmental management have received ample attention. Wetland ecosystem services are supplied on (at) various spatial and temporal scales, which have a strong impact on the values different stakeholders attach to the services. However, to date, there has been relatively little elaboration of the various spatial and temporal scales at which wetland conservation and utilization are integrated. This paper analyzes the wetland ecosystem, wetland services and the relationship between stakeholders and wetlands on three spatial scales which are: macro scale (region), medium scale (local) and micro scale (spot). Furthermore, we put forward a different management focus, including a dividing zone on macro scale, selecting a reasonable development model on a medium scale and controlling the exploration scale on a micro scale, in order to accomplish the objective of the integration of wetland conservation with the utilization of wetland resources. Finally, we propose that compensation payment (conflict resolution) is an effective tool to balance the interests of different stakeholders in a cross-scale interaction.

Key words:

Wetland; compensation payment; Spatial scale

Modes and The Characteristics of Cost-Benefit Apportionment Involved in Hydropower Cooperation Cases on the International Rivers

Feng Yan

Aisan International Rivers Center

Abstract

Water and energy security are key issues in the sustainable development, which are also complex and sensitive issues in international rivers. After 32 hydropower cooperative cases with cost-benefit apportionments on 16 international rivers in 1937-2010 are verified, the modes and the characteristics of cost-benefit apportionments can be discovered based on the detail analysis of the cooperative schemes, the mainly results are: (1) hydropower cases are mainly developed on the reaches of international rivers, without cooperation at the river basin level, 3 types of the cost-benefit apportionment modes are formed as equal ratio cost-benefit apportionment, equal one and unequal one; (2) on the cross-border rivers, the mode of equal ratio cost-benefit apportionment is the major one, upper-stream states can share the benefits from down-stream ones' power generation, down-stream states usually should supply compensation to upper-stream ones in order to get their cooperation; on the frontier rivers/reaches, the mode of equal cost-benefit apportionment is the basic one; (3) the major apportionment modes have obvious differences among different developing phases, the major modes are equal one, and equal ratio one until 1950s, equal apportionment is the basic mode in 1950s-1990s, the major modes can't verified since 1990s because of the limited cases; (4) the mode of equal apportionment is mainly used between the states with similar economic level; the states with a certain and big economic gap mainly use the ones of equal ratio one, and unequal one, and among which implement most of the cases with compensation schemes.

Key words:

international river; hydropower development; cost-benefit apportionment

The Framework of Resolving Water Issue in Spatial Planning in Netherlands

Cao Zhejing

Tsinghua University, Beijing, 100084, P. R. China, caozhejing1120@163.com

Abstract

Netherlands is home to spatial planning and has been integrating water issue with spatial planning in the practice of land reclamation and polders, change from water to metalled road, building water ways as driving force for development, water management, key projects on waterfront, etc. Since a large proportion of inhabitable land is below sea level, the principal dealing with water issue in spatial planning is to combine water planning and design with delta management, regional transportation, flood control, military defense, agriculture irrigation, urban and architectural design under the framework of Deltares, Water board, Ministry of Infrastructure and Environment within "Water Act". Thus this paper firstly retrospects spatial planning policy in terms of water planning and design in Netherlands both in history and at present in the perspective of pivotal years, major policy documents, organizations, policy concepts and icons. Secondly, it probes into three major spatial water planning programmes and explains how they are implemented and embedded with existing spatial planning framework, namely "Delta Program", "National Environmental Spatial Strategy" and "Room for the River". In the national "Delta Program", the water management policies in Netherlands delta is examined in four dimensions: future oriented adaptive strategies, multi-governance, institutional arrangements, risk based approach focusing on flood risk management, spatial adaptation, freshwater supply. Further, in "National Spatial Environment Strategies", a large number of cross-sector implementation programmes are combined in one comprehensive vision within which the "water safety and nature" is underlined on different levels of scale. In addition, "Room for the River" movement is being carried out for resolving flood protection and land reserving both in long term and short term in different ecological delta areas.

Quantitative Evaluation of Agro-Meteorological Disasters in China

Du Huishi, Chen Zhiwen, Qi Ji, Zhang Shuang, Zhang Dongfang

Jilin Normal University, Siping Jilin, 136000, China, Chen Zhiwen, sdcwz4489@126.com

Abstract

Using the statistical analysis method on Chinese agro-meteorological disaster data during 1949 to 2012, the rate of meteorological disasters and their variance values are calculated. Thus, we assigned values to the various classifications of meteorological disasters. The grey relativity analysis method was used to compute the correlation of all types of meteorological disasters with the total amount of disasters and determine their impact on agriculture production weights. The objective of the analysis of the spatial-temporal variables of agro-meteorological disasters in China is to assess the degree of influence of meteorological disasters on agricultural production. Results showed that in the last 64 years, the average disaster impact rate of agro-meteorological disasters in China and the average rate of the various types of disasters indicate an increasing trend, with the average drought disaster rate growing the fastest at 0.98% every 10 years. Drought disasters have the largest effect on production weight and mainly affect the northern parts of China. In general, agro-meteorological disasters are at medium levels. In the last 10 years, the frequency of major disasters has increased. The research results in this paper provide a scientific reference for the analysis of the evolution of agro-meteorological disasters, agricultural disaster prevention and mitigation, food production, and yield stability.

Key Words:

agro-meteorological disaster; quantitative evaluation; China; grey relation analysis

Abstract

The “One Belt And One Road” proposal put forward by Chinese government intends to accelerate the regional economic integration by developing the neighboring countries’ economic partnership actively. Belarus is an important node of the economic zone on the land silk road. The China-Belarus Industrial Park in the territory of Belarus established by China-Belarus governments, is not only the biggest industrial park that China has invested overseas, but also an important platform for China to expand the direct investments in Central and Eastern Europe and to establish trade centers. Based on the predecessors’ researches on the economic and trade ties and investment climate of China and Belarus, this paper focuses the study on the investment climate, its industrial park development patterns, the industrial and spatial structure, and the regional impact in Belarus. This paper has reference value for the establishment of other Chinese overseas economic and trade cooperation zones as well as theoretical researches.

Key words:

One Belt and One Road; Economic Cooperation; China-Belarus Industrial Park; Development Patterns; Regional Impact

Challenges to Development and Regional Economic Integration in Brazil: The Manaus Free Trade Zone

PIRES, H.F.

Institute of Geography - Rio de Janeiro State University, Rio de Janeiro, Brazil, hindenburgo@uerj.br

Abstract

Built on the banks of the Rio Negro in Manaus, Amazonas state capital, the Manaus Free Trade Zone (MFTZ) was created in 1957 as a political component of the Amazon Economic Recovery Plan. During the military regime the MFTZ began to play a strategic role in ensuring the geopolitical control of the northern region of Brazil. In the late 70s and early 90s, with tax incentives and unbundling, the MFTZ began to stimulate national industrial components and raw materials. In 1986, it was created the Superintendency of the Manaus Free Trade Zone (SUFRAMA) to promote free trade areas in the western Amazon region. In the mid-90th and early 2000s, the MFTZ experienced adaptations and austerities undertaken by the Real Plan. In the current period, with expansion of the regional economic integration process, the MFTZ is the most important industrial pole of northern Brazil. Thus, in order to contribute a case study on the MFTZ, this study has four objectives: (a) add considerations on the geo-economic role of the MFTZ, in the regional development of Brazil; (b) reveal what were the main changes in the MFTZ; (c) analyze the recent performance indicators MFTZ; (d) discuss the challenges posed by the emergence of secret pacts US euro for creating trade agreements that exclude the BRICS.

Key words:

Chinese sustainable trade and investment to Saudi Arabia

Ma Ying, Guangwen Meng

College of Urban and Environmental Science, Institute of Free Economic Zone, Tianjin Normal University, Tianjin, 300387, China, 781081632@qq.com

Abstract

In the current context of global economic slow recovery, strengthening regional cooperation is an important driving force to promote world economic development. The introduction of Arab countries "Look East" and the "One Belt And One Road" of China strategies has provided a broad cooperation space for bilateral trade and investment. Based on the current status of Chinese investment in Saudi Arabia to discuss the Saudi trade and investment factors. Firstly, the current status of trade and investment in Saudi Arabia, the results show that the two sides are highly complementary trade; Secondly, favorable and unfavorable factors affect Chinese investment in Saudi Arabia, the results show that political instability and trade protection have a greater adverse impact on trade and investment; Finally, to provide relevant recommendations on sustainable investments in Saudi Arabia for China. The study will be of great significance for Chinese sustainable investment to Saudi Arabia in the future and deepen bilateral economic trade cooperation.

Key words:

Trade and investment; sustainability; China; Saudi Arabia

Evolution of Free Economic Zone in India and Its Implications

WANG Xue, MENG Guangwen, SUI Nana

College of Urban and Environmental Science, Institute of Free Economic Zone, Tianjin Normal University, Tianjin 300387, China

Abstract

As the growth pole of the national economic, Free Economic Zones are not only the product of the economic globalization and the regional economic integration, but also platforms for promoting the development of the urbanization and system innovation. India, as one of the five BRICs, is one of the fastest economic growth in emerging economies in the world. India FEZ not only promotes the development of the Indian economy, increases trade volume and expands employment, but also becomes the important platform of regional economic integration. At present, scholars research both in domestic and overseas mainly lie in the background, industry development, preferential policies and management mode of the Export Processing Zones, Science and Technology Parks, Special Economic Zones and China-India Free Economic Zone.

Part of the study also discuss the evolution of a single Free Economic Zone, but they are still confronted with an absence of systematic research in the overall development evolution process of FEZs, as well as the study of the dynamic and the resistance mechanism in the development of all the Free Economic Zones in India. Therefore, the paper adopts literature induction, case analysis and comparative research methods, summarizing that the Indian Free Economic Zone had gone through four periods included Export Processing Zones, Science and Technology Parks, Special Economic Zones and Sino-indian Free Economic Zone. Based on this, the paper summarizes the international and domestic factors. At last, the paper discusses the influence of the evolution of India Free Economic Zone on Chinese establishment of FEZ (pilot Free Trade Zone). This study will improve the theory exploration in India and make contribution to China.

Key words:

Free Economic Zone(FEZ); Free Trade Zone; dynamic mechanism; resistance mechanism; India

Financial Innovations in the Pilot Free Trade Zone (FTZ)

Hei Zuqing

Institute of Free Economic Zone, Tianjin Normal University, Tianjin, P.R. China, heizuq64@163.com

Abstract

In the face of the US rate hike and Chinese economic growth transition, RMB market had been highly volatile. Subsequently, the economy encountered capital outflows pressure, which posed risks to the financial stability. To defend the risks arising from, the central bank should manage the currency regime properly. As a result, the capital account would be liberalized gradually and restrictions on cross-border capital outflows would be tightened.

However, RMB was officially accepted into the International Monetary Fund's benchmark currency basket and it would be a freely usable currency. In order to promote further internationalization of RMB, China could tap financial reforms and innovations in the Pilot Free Trade Zone(FTZ). By introducing the free trade account, they could transact cross-border RMB business and conduct offshore RMB business. They could make RMB more convertible under the capital account by selling RMB-denominated debt overseas and freeing up overseas investment for corporates and individuals. As such, more financial platforms and RMB products and services will be created. This will facilitate investment and trade as well as corporate cash management and push forward development of the Pilot FTZ.

Key words:

Financial Innovations, Pilot Free Trade Zone (FTZ)

Study on Evolution and Dynamic Mechanism of Tianjin Pilot Free Trade Zone

MENG Guangwen, WANG Hongling, YANG Shuang, WANG Xue, Sui Nana
Urban and Environmental Science, Tianjin Normal University, gwmeng98@hotmail.com

Abstract

In recent years, the Free Economic Zones (FEZs), as a product of economic globalization and regional economic integration, have become the growth poles of economic development in developing countries, the motivations of urbanization and a significant stage for the reforms of related institutions. In China, there is an urgent need to construct free trade zones in order to meet the new challenges of globalization and international trade structure, to strengthen the reform motivation, and to carry out the national strategies of One Belt and One Road and Beijing-Tianjin-Hebei integration. At present, some experts and scholars scrutinize the rules and factors contributing to FEZs' development based on the qualitative analysis. However, they are still confronted with less research on evolution law in FEZs on account of quantitative research methods. Therefore, this paper applies methodologies such as interview, and questionnaire to collect data based on domestic and overseas theories and case studies about FEZs. It also adopts the analysis of hierarchy process and fuzzy evaluation method, selects seven elements: policies, markets, environments, industries, inputs, benefits and innovativeness, and establishes the index system and evaluation model of FEZs' development evolution mechanism. Finally, with the aid of the model and combined with the actual situation of Tianjin Binhai New Area, the paper analyzes the main driving forces of Tianjin Pilot Free Trade Zone's development dynamic mechanism. This study is an asset to the transformation and development of the FEZs in China as well as further theoretical research in the future.

Free Economic Zone; Free Trade Zone; dynamic mechanism; fuzzy comprehensive evaluation; Tianjin Binhai New Area

Study on the Construction and Development of Zambia-China Economic and Trade Cooperation Zone

SUI Nana, MENG Guangwen, WANG Xue

College of Urban and Environmental Science, Institute of Free Economic Zone, Tianjin Normal University, Tianjin 300387, China

Abstract

Since the 1980s, China began a direct investment in African. The economic and trade cooperation has been strengthened under the joint efforts of both sides. China has established six economic and trade cooperation zones in Africa according to the successful experiences of Chinese special economic zones, the establishment and operation of these economic and trade cooperation zones in line with interests of both sides and have huge potential for development. At present, foreign and domestic related research have focused on China-Africa economic and trade cooperation zones establishment background, development process and status, analysis of influencing factors, measures and suggestions of sustainable development, but lacking of in-depth research and analysis of a single economic and trade cooperation zone. Therefore, using Zambia-China Economic and Cooperation Zone in southern Africa as a case, the paper analyzes its establishment background, as well as development process, strengths, difficulties and challenges, discusses the experiences and implications of its construction. The study is expected to have the reference value for China's foreign investment theory and constructions of other oversea economic and trade cooperation zones.

Key words:

Free Economic Zone; Free Trade Zone; Oversea Economic and Trade Cooperation Zone; China-Africa Economic and Trade Cooperation Zones; Zambia-China Economic and Trade Cooperation Zone

The Bibliometric Analysis of Domestic China Free Trade Area over Fifteen years

Hongmei WANG, Guangwen MENG

Tianjin Normal University, Tianjin 300387, Urban and Environmental Sciences

Abstract

In terms of research focus, the number of documents, research institutions, research time, researchers and so on, this paper takes a more comprehensive literature econometric analysis to 6000 study documents related the Free Trade Zones from 2000 to 2015 in China National Knowledge Infrastructure (CNKI) database including: the hotspot issues of Free Trade Zones through cluster analysis, the relationship between the number of published documents in the various stages and the national macro-policy institution. Studies have shown that: ① in nearly fifteen years, the number of free trade zones published documents are on upward trend overall, the number of issued are direct close contacted with the national macro-control policies; ② literatures published are based in trade journals, but the number of dispatch core journals very limited; ③ research institution focused on domestic colleges and universities, the top five are the Chinese special economic zones of Shenzhen University Research Center, Hebei University School of economics, School of economics, Shenzhen University, Fudan University, Shanghai Customs College, Tianjin Normal University, urban and environmental Sciences Institute, CASS Institute of World economy and politics Institute, School of economics and management, Southeast University; ④ the top five authors of FTA-related research are Zhong Jian, Liu, haiping Luo, xingping Wang, guangwenMeng, Wang Wenqing, professional research FTA echelon should be further strengthened; ⑤ domestic hot research topic FTA is bonded port, bonded logistics, export processing zones, control zones, comprehensive Bonded Zone. This article reveals the characteristics and development trends Free Trade Area, as well as domestic research scholars seeking partners, domestic academic exchanges and scientific management to provide a reference.

Key words:

FTA; free economic zone; Zone; SEZ; bonded area; regional economic integration

The Development Process and Inspiration of Shanghai Free Economic Zones

GuangwenMeng, Xue Wang, Nana Sui, Chunzhi Wang, Yuanyuan Zhao, Hongmei Wang, Xianan Lu

College of Urban and Environmental Science, Tianjin Normal University

FEZ Institute, Tianjin Normal University

Abstract

Since 1980s, China has been adopting reform and opening up policy, extending unbonded zones and fields gradually, establishing various types of Free Economic Zones (FEZs), and preliminarily building socialist market economy), which makes China not only become the second largest economy and the first manufacturing power worldwide. During this process, Shanghai has fulfilled the development objectives of different phases, restored and strengthened its economic status by establishing various types of FEZs, striding forward to the goal of becoming the economic, financial, trading, shipping and innovative center of the world. Most of the studies on various types of Shanghai FEZs focused on several aspects of establishing background, significance, investment environment, industrial structure and upgrading, developing and management patterns, development and transition, etc. However, there're only a few considering the FEZs of all types in Shanghai as a whole and discussing its development, influences, experience and practical application. Therefore, this paper first analyzes the development of Shanghai FEZs from three aspects, domestic and overseas political and economic environments, the objectives for Shanghai's Development and the establishment and development of FEZs. The paper also explores the reasons behind the successful development of Shanghai FEZs in terms of development objectives, location model, industrial and spatial structure, management and development pattern, preferential policies, etc., as well as the new challenges brought by the new international trade pattern, the economic restructuring in China and the lack of experience in investment and free trade, etc. The last part concludes and discusses not only the experience of Shanghai FEZs in investment environment, preferential policies, types and locations of FEZs, industrial and spatial restructuring, management and development pattern, but also its significance to transition countries.

Key words:

Free Economic Zone; Development Zone; Special Economic Zone; Pudong New Area; Shanghai Pilot Free Trade Zone

The Study of Sustainable Development Strategy on China's investment in Africa trade: In the case of Nigeria

Abstract

The introduction of "One Belt One Road" policy bring new opportunities for Chinese economic "going out" strategy. As an important partner of Chinese foreign investment, Africa shows stronger develop potential under the current background. How to ensure that China's investment in Africa sustainability issues increasingly become the focus of China's foreign investment, but terrorism raging on the African earth has brought great impact on Africa's economic development, made many non-investors to worry about. Most existing research based on the perspective of economic and political, this paper will combine the current situation of China Investment Nigeria analysis, study the advantages and hinder of Chinese investment in Nigeria in the Location Theory Perspective, provide recommendations for the future sustainable development of Chinese investment in Nigeria.

Key words:

One Belt One Road; foreign investment; terrorism; Nigeria; sustainable development

Governing Climate Change: An Analysis of Mitigation Strategies in Brazil and China Over the Past 20 Years

Barbi F., Ferreira L. C.

Center for Environmental Studies and Research, State University of Campinas – NEPAM/UNICAMP, Campinas, Brazil,
fabarbi@gmail.com

Abstract

This paper analyses the internalization process of the climate issue at the government level in Brazil and China. This analysis is based on three main points: i) trajectory of greenhouse gases emissions in Brazil and China, in the period of 1992-2015; ii) political and institutional structures mobilized to the climate issue, focusing on mitigation; iii) political strategies related to climate change mitigation. The results show that regarding political and scientific framework in Brazil, there was a significant increase in the production and systematization of studies and reports, which could assist the design and implementation of policies and reduce some of the uncertainties related to climate change. China has also made some progress in this direction. The internalization process of the climate issue has three phases in Brazil: the first is marked by the establishment of political-institutional and scientific structures engaged with the issue; the second is marked by the development of a political and scientific agenda around the theme and planning actions. Finally, the third phase is marked by the development of climate policies and by the strengthening of the scientific agenda around the theme. In the Chinese case, the internalization process of the climate issue has two phases: the first, has more focus on combating air pollution and energy conservation, whereas climate mitigation stands as a co-benefit and the second phase, more proactive regarding concrete commitments on climate change mitigation, with the establishment of the National Climate Change Program and the National Leadership Panel on Climate Change.

Key words:

climate policy; climate change mitigation; Brazil; China

Quantifying the Co-benefits of CO₂ and Air Pollutants Reductions in China's Actions on Climate Change

Abstract

Co-benefits approach refers to the development and implementation of policies and strategies that simultaneously contribute to tackling climate change and solving local environmental and developmental problems. In the case of air pollution, there are strong linkages between global climate change and local air pollution. As a major force behind anthropogenic carbon emissions, China accounted for almost one third of global carbon dioxide emissions and 80% of the world's increase in CO₂ emissions since 2008. Carbon emissions have been one of the biggest challenges on China's road to long-term sustainability, therefore, we need to have a deeper understanding into China's climate policy at very different levels, particularly from the perspectives of co-benefits in global climate change and local environmental pollution. Thus, our intent is to provide insight about China's policy and actions addressing climate change by applying the co-benefit approach to measure the contribution of GHG emissions as well as air pollutants (SO₂, NO_x, PM₁₀) reductions from 2006 to 2010, mainly based on the *China's Policies and Actions for Addressing Climate Change* reports. Our evaluation shows that the total carbon emission would increase one third more without such mitigation activities, and the activities in mitigation show a significant co-benefits contribution to air pollutants reduction.

Key words:

climate policy; carbon reduction; air pollution; co-benefits approach; China

Sea Level Rise and Lost of Mangrove Forest in the Sundarban Coastal Stretch using Geospatial Technology, West Bengal, India

Ismail Mondal¹, Jatisankar Bandyopadhyay²

¹Research Scholar: Department of Remote Sensing & GIS, Vidyasagar University, Midnapore, 721102. West Bengal, ismailmondal58@gmail.com

²Assistant Professor: Department of Remote Sensing & GIS, Vidyasagar University, Midnapore- 721102. West Bengal, India, jatib@mail.vidyasagar.ac.in

Abstract

Sundarban Coastal zones are highly sensitive where the multivariate geologic/ geomorphic processes viz. tectonic, fluvial, marine and aeolian processes act in varying degrees and exposed to various natural disasters such as coastal erosion, flooding, storm surges, tsunami, etc. The dynamism of these disasters are further incremented by the improper human intervention through the various developmental activities without proper understanding of ongoing coastal processes dynamics. Global warming and its related accelerated sea level rise is one of the major long-term disasters along the low-lying coastal margin of Sundarban. The accelerated sea level rise is likely to become threats and damage to the world heritage Sundarban mangrove forest. Our study observed 1509.9 sq.km forest cover in the year 1990 where as 1582.4 sq.km forest cover in the year 2015. So vegetation loss is very much prominent in the area.

The Sundarban is particularly responsive to changes in Sea Level besides increasing vulnerabilities to storm surges and coastal erosion. It changes tidal forcing and influences estuarine sedimentation. With onset of the Holocene, the sea level rise fast at the beginning, then very slowly from c. 7,000 yr BP to get nearly stabilized at 2,000~3,000 yr BP²(Nandy and Bandyopadhyay). According to the Fourth Assessment Report (AR4) of the Intergovernmental Panel for Climate Change (IPCC), the rise in the sea level picked up again during the 19th century at 1.7 mm yr⁻¹ and escalated to 3mm yr⁻¹ in the final decade of the 20th century (Nandy and Bandyopadhyay). Between 1990 and 2015, thermal expansion of sea water and melting of land ice accounted for about half of the rise. On an average, the rate was estimated by our calculation at about 1.6 mm yr⁻¹ for the last 25 years. The AR4 also unequivocally confirm the human induced global warming responsible for this accelerated increase and suggested a rise of 4 mm yr⁻¹ up to 2090s according to one of its future scenarios.

Key words:

Sea level rise; coastal zone, impacts; adaptation; tide gauge data; Biodiversity

The Impact of Urbanization on Spatial Distribution of Precipitation in Shenzhen

Abstract

Increase of urban rainfall contributed to the city's flood control pressure could cause the urban waterlogging. At the same time it also could cause some secondary disasters. In this paper, in view of the indirect effects of urbanization to precipitation, we use daily meteorological data of 130 observation stations over Shenzhen for the period of 2000 to 2015. After spatial standardization of precipitation data, we analyze the impact of Shenzhen urbanization on the precipitation by employing the trend fitting method and correlation analysis. In our analysis, urbanization factors include topography, land use, urban population, GDP and energy consumption. The results illustrate that in the study area, annual precipitation spatial heterogeneity and the urbanization process is closely linked, and as temperature rises, rainfall increases.

Therefore, urbanization has an impact on urban meteorology and environment. It is obvious that urban rainfall is significantly greater than the surrounding suburban, which makes the formation of urban rain island effect.

Key words:

urbanization; spatial normalization; urban rainfall island; spatial distribution; climatology

Information Engineering University

Abstract

In today's society, terrorist activities has flooded around the world. Obviously, there are certain some objective laws behind these attacks and activities. On the basis of quantitative analysis, this paper analyses the temporal and spatial distribution of global terrorist activities from 1970 to 2014, revealing their patterns systematically from a geographical perspective. Furthermore, characters and primary areas of global terrorist activities are also pointed out in the article. With the analysis of inner mechanism of activities distribution, this paper indicates the coupling relationship between geopolitics and the distribution of terrorist activities.

Key words:

Prediction of Third-party Intervention in the Conflict Based on Artificial Neural Networks

Changqiang Feng, Nan Jiang, Pei Wang

Institute of Geospatial Information, Information Engineer University, Zhengzhou, 450000, P. R. China,
luckystar1682006@126.com

Abstract

Driven by interests, State conflicts often occur. Meanwhile, third-party interventions, especially developed countries, have a greater impact on related countries' conflict resolution and decision-making. Because third-party interventions also involve the interests of themselves, like political, economic and military benefits, intervention forecast is a complex non-linear task, which makes it difficult to be done using traditional mathematical formulas and models. Instead, it mainly relies on qualitative analysis of international political researcher, which has more subjectivity and uncertainty. Given the outstanding performance of artificial neural networks(ANN) in dealing with complex nonlinear problems, this article uses it to predict third-party intervention in the conflict between two countries.

First, from the perspectives of national power, geo-strategic objectives, interdependence and conflict characteristics, the essay resolves the factors affecting third-party intervention, including national strength contrast among conflict sides and intervention one, regional influence of conflict countries, third-party political, economic and military dependence on conflict sides, the influence level and incentives of conflict. Second, analytic hierarchy process is used to quantify the influence level of conflict and third-party political, economic and military dependence on conflict sides. Third, tests are done based on a real case. The initial forecasts of third-party invention are achieved and counted using trained ANN, where the action occurring most frequently is considered as the final prediction of third-party intervention. Experiments show that the method can make an accurate prediction on third-party intervention with a greater probability, and can serve conflict countries' decision-making.

Abstract

Carbon emission is the inevitable result of development. Generally, the developing pattern changes from extensive to intensive with the industrialization. So is there an inherent peak and then obtain reduction naturally? And if the peak does exist, when it would appear? The answers of above questions are directly related to the carbon distribution principle and equity of global carbon quotas. The correlation of different industries, which is the inherent driving force of the upgrade of economic structure, can demonstrate the stage of regional economic development. This paper utilized theoretical and empirical analysis and concluded that the pattern of carbon emission has an Inverted-U shape (Carbon Emission Baseline). This pattern shows that if a region was still in the stage of correlation between low manufacturing and service sector, this region has rights to keep emission increasing to sustain the basic development. Therefore, CEB not only gives a shape of emission, but also provides a standard relationship between the evolution of emission and economic development. On this level, CEB has potential to be a complement principle of global carbon apportion.

A Two-Leaf Model for Improving the Application of PRI to Indicate Vegetation Light Use Efficiency Using Multi-Angle Observations

Abstract

The photochemical reflectance index (PRI) is a promising way to indicate light use efficiency (LUE). However, there are certainly some internal and external factors that affect PRI signals. To consider the spectral difference between sunlit and shaded leaves, a two-leaf approach based on a four-scale optical transfer model is used to process multi-angle canopy reflectance for estimating fractions of sunlit and shaded leaves. Thus, two-leaf canopy PRI (PRI_t) is retrieved using the least square regression with different angles observations, and is compared to simply averaged big-leaf canopy PRI (PRI_b) using observations acquired from April to September 2013 in a sub-tropical coniferous forest in Southern China. Retrieved two-leaf PRI are generally able to capture variations of observed PRI (>70%) at different angles proving that this two-leaf approach is effective for PRI upscaling. The two-leaf approach significantly enhances the sensitivity of PRI to bioclimatic stress and its ability to track LUE variations at either half-hourly or daily time steps. Generally, diurnal correlations between PRI_t and LUE increase with the increases of bioclimatic conditions (e.g. light, temperature and water). PRI_t is very effective in detecting the light stress on LUE. At daily time step, PRI_t is more significantly correlated with LUE than PRI_b does from July to September when weather conditions and background reflectance are steadier than those at the rest time. The correlation is the strongest ($R^2 = 0.785$, $p < 0.001$) in July. Overall, the two-leaf approach overcomes some external effects (e. g. bidirectional reflectance) that interfering PRI signals.

Abstract

MOD17A2 estimates gross primary production (GPP) according to the light use efficiency (LUE) concept relating gross photosynthesis to the amount of photosynthetically active radiation (PAR) absorbed by plants. In this study, we evaluated the performances of MOD17A2 across multiple biomes in China through comparisons with eddy covariance (EC) flux measurements during the period 2003-2005. The results show that MOD17A2 provided better estimates of annual GPP and agreed well with tower-based GPP measurements during the autumn and winter. However, its effectiveness was poor at estimating GPP over 8 days and even worse during the summer. In addition, MOD17A2 was also ineffective when estimating annual GPP for mixed forests (MF), evergreen needleleaf forests (ENF) and cropland (Crop). We further examined the potential error contributions of all input variables used in the MOD17A2 algorithm, including meteorology, leaf area index (LAI)/fractional photosynthetically active radiation (FPAR), land cover and light use efficiency (LUE). It was found that the meteorological reanalysis data failed to properly estimate tower measured vapor pressure deficit (VPD). Moreover, FPAR and maximum LUE (ϵ_{\max}) underestimated the corresponding improved data for most sites. Thus, the qualities of meteorology data and FPAR need to be improved, and ϵ_{\max} in the Biome Properties Look-Up Table (BPLUT) should be adjusted to provide better GPP estimates using MOD17A2 for China's ecosystems.

New Approach of RGB-Composition to The Analysis of Synoptic Situations

Eroshkina N.A., Poliukhov A.A.

Lomonosov Moscow State University, Moscow, Russian Federation, nadezhda_eroshkina@mail.ru,
aeromsu@gmail.com

Abstract

The development of satellite technologies and its application in meteorological researches led to an increasing of the information received from satellites last years. In recent years the RGB-compositions, visualizing data in different wavelengths, are actively being created. These compositions are useful in the manual analysis of synoptic situations, but their large number complicates and slows down the manual processing of the visual information.

To overcome this problem, we made EVSI software. With this software a user can choose a type of satellite information for each color channel. The creation of the efficient software, which would provide more easy and convenient way of the analysis of obtained images, was the purpose of our work. The results of an atmospheric scanning by satellite METEOSAT-10 were the input data for our program.

With EVSI the RGB-composition was created. It is usable for the primary analysis of a synoptic situation over a required region without any other information. This composition is the combination of 10.8 and 6.2 micron channels and the difference of 6.2 and 7.3 micron channels.

The cloud structure looks like white area, so it is easy to differentiate and analyze it. The towering clouds with the precipitation regions and the potential severe weather activity are colored in bright blue on a white background. Additionally, the RGB-composition helps to find information about the properties of air masses. All of it contributes to a fast detection, analyzing and forecasting of the weather in the required region.

Key words:

satellite information; meteorology; RGB-composition; synoptic analysis

YiJie Li (China, Social Resources Institute)

Resilience: New Thought of NGOs to Climate Change?

YiJie Li

Social Resources Institute

Abstract

Due to the uncertainty of climate change, some NGOs have chosen to adapt to climate change through building the resilience of system (individual, family or community) and to regard the management based on resilience as an important way to respond to the impact of climate change. Compared to urban residents, rural ones rely more on agriculture and other climate-sensitive resources to acquire income, and are more climate-sensitive but the fact is the input of domestic NGOs to improving the capacity of farmers in adapting to climate change remains insufficient.

Though quite a few NGOs have worked in rural areas, there are two problems in helping farmers to adapt to climate change. First, there are fewer NGOs directly engaging in the resilience of climate change in rural areas; second, the current resilience relating to climate change focuses on disaster assistance, and most NGOs just don't know what to do with the potential risk of climate change and thus lack planned and proactive actions. The introduction of resilience can establish relationship between the project of NGOs and the adaptation to climate change, more proactive measures can be adopted to improve the resilience of farmers to respond to external risks including climate change.

Thus, through literature research, quantitative research and case studies, this paper studies how NGOs can help to improve farmers' resilience. First, key factors for farmers' resilience are defined; second, it has an analysis of the current actions of domestic NGOs in "improving farmers resilience" from the aspects of types, degrees and recognition on the basis of questionnaire inquiry; third, to detail the practices of NGOs, three cases are introduced to seek experiences to be drawn on and to explore the potential ways of domestic NGOs in participating in the climate change response of rural community.

Quantitative research shows that, most NGOs don't have sufficient understanding of the content of climate change adaptation or clear idea of the relationship between their projects and climate change adaptation. This hinders their introduction of the view of climate change to their projects or a better climate change adaptation. In addition, from the scoring of resilience indexes, NGOs work can effectively improve "farmers' resilience" but there is still a huge potential to rise.

Case studies (the eco-community empowerment of The Daba Mountain Ecology and Poverty Issue Research Institute, underground water protection of SEE Conservation, and community protected area of ShanshuiCenter) show that, NGOs helps to improve community resilience to respond to climate change mainly through improving community ecological environment, farmers' livelihood and community self-development ability but they have different functions and ways. Farmers' effective participation is a premise to improve

resilience, which means whether NGOs' projects meet farmers' needs, and whether they ensure farmers' status as the main body.

At last, the paper gives three suggestions for NGOs, namely taking climate change and resilience into consideration in specific work, climate resilience project should meet farmers' current needs, and the improvement of self-development ability should be taken as the core of improving resilience.

Abstract

Regional warming was identified in the whole Himalayas in the past ~50 years, with larger warming rate in the last decade. During the same period, precipitation decreased in the most areas of Himalayas. Warming-dry regime of climate resulted in widespread retreating of glaciers. Based on in-situ investigations and mapping of satellite images, we studied glacial changes between 1970's to 2008. It shows that in the north slope of Himalayas, retreating glaciers amount to 25.3% of overall glaciers in Ganges basin, 23.3% in Yarlung Zangbo basin, 29.2% in Indus and 25% in other areas. Glacier changes in the southern slope of the Himalayas have larger amplitudes, with averaged retreated distance roughly doubled, than that of the northern slope. Darkening of glacier surface due to black carbon and other light-absorbing aerosols might have contributed to the strong melting, especially in the southern slope.

Using degree-day model (DDM), we estimate glacier mass balance as well as contributions of glacier meltwater to river runoff over different drainage basins in north Himalayas. During 1961-2006, the total mass losses of glaciers amounts to 198 km³, equals to approximately 10 m thinning of glaciers. Among the mass loss, 40 km³ occurred in Ganges basin (10.8m ice thinning) which is 360.4×10⁸ m³ water equivalent, and 168.4 km³ (11.4m ice thinning) occurred in Yarlung Zangbo basin which amounts to 1515.7×10⁸ m³ water equivalent. While glaciers in Indus basin experienced a positive mass balance before 2000 and negative after 2000. The mass balance is averaged -220mm•a⁻¹ during 2000-2006. Glacier melt water increases in the last 5 decades, contributing to an increasing amount to total river runoff in the Indus, Ganges and Yarlung Zangbo Rivers. For instance, melt water averagely contribute about 11.8% to runoff of Yarlung Zangbo during 1961-2008, with the percentage a slightly increasing trend.

Projections of future climate change by Regional Climate Model (ICTP RegCM3) shows continuously warming and drying trends in the most part of Himalayas before 2050, implying continuously retreating of glacier thus depletion of water storage over the Himalayas. Assessment of glacial lake outburst flood (GLOF) disaster risk is completed in the north slope, combined with potential dangerous glacial lakes (PDGL) outburst hazard, regional exposure, vulnerability of exposed elements and adaptation capability (risk management) using the analytic hierarchy process. The zones at highest risk of GLOF disaster are mainly located in Nyalam, Tingri, Dinggyê, Lhozhag, Kangmar and Zhongba, in the mid-eastern Himalayas.

Glacial Lake Outburst Flood (GLOF) Disasters and Integrated Risk Management

Form China

Wang Shijin

State Key Laboratory of Cryospheric Sciences, Cold and Arid Region Environment and Engineering Research Institute, CAS, Lanzhou 730000, China

Abstract

High-risk areas of Chinese GLOF disasters are mainly concentrated on the middle-eastern Himalayas and Nyainqêntanglha, Tibetan Plateau in China. In the past 20 years, glaciers in these regions retreated and thinned rapidly to regional climate warming, leading to the formation of new glacial lakes and the expansion of existing glacial lakes. Meanwhile, these regions are located in the border belt between the Indian and Eurasian plate, in which Neotectonics is strong, and tectonic seismic activity is also frequent and intense. The earthquake often destroyed the stability of mountain body, glacier and moraine dam, resulting in the imbalance of own state of glacial lakes and the increase of loose materials in the channel. It is foreseeable that the possibility of GLOFs and derivative disaster occurrence is great in the background of frequent earthquakes and obvious continued warming. By integrated analysis of temporal and spatial characteristics, incentives and typical cases of GLOF disasters, the objects of the paper is to propose a program of integrated risk management and control of GLOFs disaster with multi-objective and multi-mode features. In addition, the study aims to avoid and mitigate the impact of GLOF disasters on mountain economic and social systems, and enhance the level of the analysis of disaster risk and the capabilities of risk management and disaster prevention and reduction of GLOFs.

Glacier Stagnant in Central Karakorum During 2003 to 2008 Derived from DEOS Mass Transport Model GRACE Data and One Monthly Degree-Day Model

Zhang xiaowen¹, Zhang Shiqiang^{1,2}, Xu Junli²

¹ College of Urban and Environmental Sciences, Northwest University, 1 Xuefu Road, Xi' an, 710027, China, zhangsq@nwu.edu.cn

² State Key Laboratory of Cryospheric Science, Cold & Arid Regions Environmental & Engineering Research Institute, Chinese Academy of Sciences, Lanzhou 730000, China

Abstract

Glacier change in central Karakorum is known as 'anomony' in the late 1990s, where many glaciers expanded and numbers of glacier surged while most of glaciers in the Greater Himalaya rapidly retreated. However, the understanding of glacier change in this region is still poor. Glacier changes for the Hunza river basin (HRB) in central Karakorum during 2003 to 2008 were investigated from different data sources. The mass variation in HRB were estimated from the DEOS Mass Transport Model (DMT-1) GRACE data and the Variable Infiltration Capacity (VIC) model, and compared with the simulated glacier mass balance by one monthly degree-day model. The surface elevation difference of glaciers between ASTER DEM and SRTM were calculated. The mass variations from GRACE data suggest that the glacier mass balance in HRB during 2003-2007 has no clear trend. The cumulative mass balance is positive during 2003-2008. The average glacier surface elevation difference between SRTM DEM and ASTER DEM is 11.8 ± 3.2 m. The average differences of glacier surface elevation of Batura glaciers in accumulation zones is increased with 0.88 m.a^{-1} . These results indicate that there is no significant glacier retreat during 1999 to 2008. The seasonal amplitude of simulated mass variation of the monthly degree-day model agreed well with that estimated from DMT-1 GRACE data, but the simulated glacier accumulation is less than that calculated from GRACE data. The main reason probably lies in that the precipitation of glaciers and unglaciated areas were underestimated, especially in alpine areas.

Glacier change; GRACE; DEMs; degree-day model; Precipitation gradient

Impacts of Surface Air Temperature and Sea Ice Extent Anomalies on Arctic Ocean

Mercury Cycle

Chen L., Zhang W., Tong Y. D., Wang X. J.

Ministry of Education Laboratory of Earth Surface Process, College of Urban and Environmental Sciences, Peking University, Beijing, 100871, P. R. China, chl@pku.edu.cn

Abstract

Mercury (Hg) pollution is of particular concern in the Arctic where populations rely heavily on marine-based diets. Climate changes in the Arctic are more remarkable than low latitudes, which likely affect Hg cycle in the Arctic. We use a global biogeochemical box model coupled to an Arctic mass budget model to investigate the impacts of typical climate changes on Arctic Hg cycle. Difference in present-day anthropogenic enrichment to preindustrial era inferred from lake-sediment records between the Arctic and low latitudinal regions suggests the remarkable impacts of surface air temperature (SAT) and sea ice extent (SIE) anomalies on Arctic Hg cycle. The increase of SAT and decrease of SIE have resulted in the loss of Hg in Arctic surface and subsurface ocean during the last several decades. A decline of -12% (11 Mg) and -9% (39 Mg) is for surface and subsurface ocean, respectively, relative to the absence of climate changes in 2008. Future SAT and SIE projections will mitigate the increase of Hg content in the Arctic Ocean or generate a synergistic effect with mercury control policies. Sufficient efforts should be made to better coordinate the policymaking of Hg controls and climate changes in the future, and then effects of Hg pollution mitigation could be improved.

Light-Absorbing Impurities in Surface Snow/Ice from Glaciers on the Southeastern Tibetan Plateau: Concentrations and Radiative Forcing

Yulan ZHANG, Shichang KANG, Zhiyuan CONG

State Key Laboratory of Cryospheric Sciences, Cold and Arid Regions Environmental and Engineering Research Institute, Chinese Academy of Sciences, Lanzhou 73000, P.R. China, Yulan.zhang@lzb.ac.cn

Abstract

Light absorbing impurities (LAIs) deposited on snow and glaciers darken the surface and reduce the surface albedo. Assessing LAIs in snow and ice on the southeastern Tibetan Plateau is of interest because this region borders the south Asia atmospheric brown clouds, and is an important headwaters of large rivers. Surface snow/ice and snowpit samples were collected from Yarlang, Dongga, Renlongba and Demula glacier in the southeastern Tibetan Plateau in June 2015, providing the comprehensive observation data of LAIs. The results show that LAIs concentrations are higher in surface ice due to the post-depositional processes including melting or sublimation. "Altitude effect" is observed except from Yarlang glacier, indicating more intense melt exposed more LAIs to the surface at lower elevation. Impurity concentrations were highly variable across snowpits with maximum dust, BC and OC concentrations frequently occurring at the lower port of snowpit, except Dongga glacier with maximum at the snowpit top, suggesting that impurities scavenged from upper snowpit layers can flush downward and accumulate at the snowpit bottom layer. The averaged simulated albedo caused by BC and dust account for about 22.1% of the albedo reduction relative to clean snow using SNICAR model. Radiative forcing caused by BC and dust deposition on the Yarlang glacier vary between 6.77-11.21 W m⁻² and 0.70-6.21 W m⁻², respectively. The result indicates that LAIs have potential to accelerate glacial melt during summer and this process enriches BC and other LAIs, which could impact the water resources.

Light-absorbing impurities (LAIs); Glacier; Black carbon; Dust; Tibetan Plateau

Runoff Variation and Its Reason Analysis in Typical River of the Cold Region in China

Jia Qin

Division of Hydrology Water-Land Resources in Cold and Arid Regions, Chinese Academy of Sciences, Lanzhou, 730000, P.R.China, Qinjia418@lzb.ac.cn

Abstract

The Burqin River originated from the Altai Mountain was selected as a typical river to analyze runoff change in cold region and its reasons in the research. Based on the data of precipitation, temperature, runoff, glacier and underlying surface in the past 50 year, it found the fluctuation of annual runoff was significant and runoff turned to increase since the late 1980s in the typical river, which is very similar to runoff change in other rivers of northwest China, While the maximum monthly runoff in the Burqin River (in June) arrived earlier than most other rivers. Except precipitation change in the Burqin River, land utilization and glacier melt also has significant impact on runoff change in the typical river. The effect of climate change and different land cover scenarios on runoff change was analyzed. When the temperature raises 2 °C, river runoff would decreases 12.9%. Glacier melt water would increase significant (28.5%) and total runoff would change little (1.3%) in the next 20 years in the Rcp4.5 scenario. About 65% and 20% runoff was generated in the forest and grassland correspondingly in the typical river. Deforestation and over grazing could significant increase peak discharge, and water resource in the Burqin River basin would decrease as change of the microclimate and hydrological effect.

Runoff change; melt water; underlying surface; climate change; Burqin River

Snow Cover in China and Its Rapid Changes with Regional Differences

Ma L.J., Zhang R.N., Li D.

National Climate Center, China Meteorological Administration, Beijing, 100081, P. R. China, malj@cma.gov.cn

Abstract

With the rapid climate warming, snow cover in Northern Hemisphere suffers obvious decreasing, especially in spring. However, changes in regional snow cover exhibit great differences. What happens in China and what makes those discrepancies? This study, by using observed snow cover data, investigated the changing characteristics of snow depth (SD), snowwater equivalent (SWE), and snow density in China in the past 60 years, and then, revealed the regional differences in snow depth changes and explored the possible reasons in view of atmospheric circulation transition.

Research indicated that, on average, SD, SWE, and snow density were all the smallest in the Qinghai-Tibetan Plateau (QTP), and were greater in northwestern China (NW). Although the trend in China as a whole was not significant, the amplitude of variation became increasingly greater in the second half of the 20th century. EOF disclosed the anti-phase characteristics for snow cover in northern China and the QTP. Significant increasing trends were found in both NW and northeastern China (NE), while SD over the QTP declined into its negative phase, especially since the later period of last century. Analysis investigated that the increases of snow cover in northern China possible link to remarkable warming in Arctic and continuous record-breaking decreasing of Arctic sea ice.

Spatiotemporal Variations of Snow Cover in China based on the Passive Microwave Remote Sensing and in Situ Data

CheT, DaiL, ZhouS, Li X

Cold and Arid Regions Environmental and Engineering Research Institute, Chinese Academy of Sciences, Lanzhou, 730000, P. R. China, chetao@lzb.ac.cn

Abstract

We reported the spatiotemporal variations of snow depth in China in the past four decades. The snow depth data include the observations of meteorological stations of Chinese Meteorological Administrator (CMA) and the retrievals from the passive microwave remote sensing data. First of all, we compared the observations of stations with the retrievals of remote sensing data to see the consistency between them. The spatial representativeness of each station was evaluated based on the topographical factors and land cover types. The observations with the higher spatial representativeness were considered as the higher confidential level and entrusted to validate the snow depth derived from remote sensing data. Secondly, the snow depth data derived from remote sensing data with larger errors were corrected based on the ground observations with the high confidential level. Finally, the snow depth from remote sensing data was used to analyse the spatiotemporal variations in the past four decades, as well as the relationships with air temperature and precipitation. The results showed that (1) snow depth in China has a very large fluctuation on the both of spatial and temporal scales; (2) average snow depth showed no clear positive or negative tendency in the whole of China in the past four decades due to the large annual fluctuation; (3) the snow depth in spring were decreasing significantly in the whole of China due to the increases of temperature; (4) the snow depth in winter in some regions were increasing due to the increases of precipitation.

Spatiotemporal variation; snow depth; passive microwave; remote sensing

The Cryosphere Science: Research Framework and Discipline System

Ding Yongjian, Qin Dahe, Xiao Cunde, Kang Shichang, Zhang Shiqiang, Ren Jiawen, Yang Jianping

State Key Laboratory of Cryospheric Science, Cold & Arid Regions Environmental & Engineering Research Institute, Chinese Academy of Sciences, Lanzhou 730000, China

Abstract

The growing concern of the society on Cryosphere change and its impact has promoted the research on cryosphere, the impact and social adaptation of interaction between different spheres, and cryosphere science rapidly grew. However, the systematic study on the cryosphere science is still very weak, and the scientific connotation and denotation of cryosphere science is still very vague. Based on the international study trends on cryosphere, the scientific definition of cryosphere and cryosphere science, the studies on interaction between cryosphere with other spheres, the scientific framework of cryosphere science, and disciplines of cryosphere sciences were analyzed around the cryosphere science discipline system problems. We pointed out that "Cryosphere Science" as a system of disciplines is the inevitable outcome under the background of international global environmental change and sustainable human development. It should not only enhance the closely connection between cryosphere and other spheres in traditional research, but also pay more attention to the key roles of cryosphere in the interaction between cryosphere and other spheres, and strengthen the relationship between the impact of cryospheric changes on climate, ecology, hydrology and surface environmental change and social sustainable development. The framework of cryosphere science was constructed around the research mainline of changes - impact - adaptation of cryosphere in this paper, and the composition of "cryosphere science" disciplines was combined aim at the characteristic of each element of traditional cryosphere study and new branches of cross study between cryosphere and other sphere, which will provide reference to the systematic and the mature development of cryosphere science.

The Temporal and Spatial Changes in Snow Cover and the Corresponding Radiative Forcing in Siberia from the 1970s to the 2010s

Yu LX, Zhang SW, Liu TX

Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Changchun, 130102, P. R. China, yulingxue@iga.ac.cn

Abstract

The temperature record during the 20th and 21st centuries showed that the temperature increased obviously especially from 1970s. As an indicator of climate change, the snow cover in northern hemisphere has decreased with high confidence according to the satellite records. The warming and the snow cover changes in the Northern Hemisphere's high latitude terrestrial areas represent the important energy feedbacks to climate systems. In this paper, the temporal and spatial changes in snow cover were firstly estimated based on a long time series of remote sensing snow cover data, which showed that the average snow coverage and snow days during 1970s to 2010s decreased at a trend of $-0.8551 \times 10^4 \text{ km}^2/\text{a}$ and -0.2479 d/a , respectively. Based on this, we estimated the radiative forcing caused by the snow cover changes from the 1970s to the 2010s and compared it with the radiative forcing caused by the land cover changes over the same time period in Siberia. The shortwave and longwave radiative forcings caused by the snow cover changes were 2.59 W/m^2 and 0.007 W/m^2 , respectively, while the shortwave and longwave radiative forcings caused by the land cover changes were -0.0178 W/m^2 and -0.000074 W/m^2 , respectively, indicating that the snow cover changes in Siberia can accelerate climate warming while the land cover changes here have the opposite effect, and more than that the snow cover changes may play a more important role than the land cover changes in regulating the surface radiation balance in Siberia on the regional scale.

Snow Cover in the Tarimriver Basinmonitoring by Remote Sensing

Li Jing, Liu Shiyin, Shangguan Donghui

State Key Laboratory of CryosphericSciences, Cold and Arid Regions Environmental and Engineering Research Institute, Chinese Academy of Sciences, Lanzhou, 730000, China, jingli@lzb.ac.cn

Abstract

In this paper, we combined GIS system with MODIS and SSMI/SMMR snow data to monitor the temporal-spatial distribution of snow cover in theTarimRiver basin. The results show snow cover mainly appears at mountainous areas around the TarimRiver basin. The southern slope of TuomuerPeak and the mountainous areas in the southwest of the basin connecting the Pamirs and KarakorumMountains are main areas with snow cover.The snow cover in the basin has significant temporal-spatial variation. Regarding the temporal variation, it has clear accumulation-ablation cycle. The accumulation period is from September to next February, and the ablation period is from March to August. As for spatial variation, both snow cover and snow depth increase with the elevation. Under a global warming climate with more precipitation, the snow cover increase during the past 30 years. But there are distinct seasonal differences for the variation. Snow cover generally increases in the spring, autumn and winter, but decreases in the summer. This is probably due to the increase of the temperature which expedites the melting of the snow.

Abstract

Beijing and Zhangjiakou will hold the 2022 Winter Olympics. For organizing a successful Winter Olympics, it is important to investigate the temporal and spatial variations of snow cover in the past decades, especial the most recent decade, using winter and spring snow-cover data from MODIS 2002 to 2014, DEM and meteorological data 1966 to 2013. It is found that snow cover frequency is low and its maximum is 0.23, appeared at the beginning of January averaged for 2002-2013. The accumulation of snow was slow, but melting was rapid and the distribution of snow cover was patchy. The fluctuation of snow days in winter is larger than that in spring, and in February the number of snow days in Yanqing (4.6d) and Chongli (13.9d), where the main resorts located, was declining. Meanwhile the beginning and ending dates of snow cover are earlier than before while the duration of snow cover was shorter. There were two periods of relatively high snow depth, 1966-1980 and 2000-2012, but with big annual fluctuations. The period between the above two was characterized with low snow depth. It is found that the correlation between snow cover and air temperature (precipitation) is higher in the interseasonal (interannual) variations. Because of unsuitable temperature, less precipitation and inadequate snow days in the Winter Olympics venues, there will probably be insufficient snow for the sports. And with rising in temperature and declining in precipitation, snow depth and snow days, 60%-95% of snow may have to depend on artificial snow, to meet the requirement of Winter Olympics standards.

Enzyme Activities As Affected By Pedogenesis and Permafrost in a Boundary Area of Continuous Permafrost in the Qinghai-Tibetan Plateau

Xiaodong Wu

Cryosphere Research Station on the Qinghai-Tibetan Plateau, State Key Laboratory of Cryospheric Sciences, Cold and Arid Regions Environmental and Engineering Research Institute, Chinese Academy of Sciences, Lanzhou, 730000, China, Wxd565@163.com

Abstract

To investigate the effects of pedogenesis and permafrost on soil enzyme activities in the Qinghai-Tibetan Plateau, this study examined the soil enzyme activities of invertase, amylase, catalase, polyphenol oxidase, urease, and alkaline phosphatase in the north boundary of the permafrost region of the Qinghai-Tibetan Plateau. The results showed that soil properties could be categorized using soil organic carbon (SOC) and total phosphorus, as well as factors that were favorable for their accumulation, such as active layer thickness, moisture, pH, and bulk density. The above factors were closely associated with one another. Invertase, urease, and alkaline phosphatase activities were significantly positively correlated to SOC, total nitrogen, and total phosphorus, while amylase, catalase, polyphenol oxidase showed different patterns. Soil enzyme activities in various soil horizons could reflect the effects of permafrost and vegetation type. Soil enzyme activities in different horizons demonstrate that permafrost, vegetation type and depth has important effects on soil characteristics and biogeochemical cycles.

Abstract

Black carbon (BC) and mineral dust (MD), the most important compositions of light absorbing impurities (LAIs), significantly absorb the solar radiation in the atmosphere, and reduce albedo after being deposited on the cryosphere, thus promoting snow/ice melting and causing positive climate warming feedback. BC and organic carbon over the Third Pole (TP) regions were simulated using a regional climate model (RegCM4.3) coupled with a chemistry-aerosol module. Results showed that mixed carbonaceous aerosols produced positive shortwave radiative forcing in the atmosphere and negative forcing at the surface. Aerosols increased surface air temperatures by 0.1-0.5 °C over the Tibetan Plateau and decreased temperatures in South Asia during the monsoon season. Further, to estimate the impacts of LAIs on glacier and snow cover melt, surface snow/ice samples have been in-situ collected from five benchmark glaciers and snow cove in the TP during 2013-2015, using SNICAR model and a distributed energy-mass balance model. The sensitivity analysis shows that contributions of BC and MD were less than 37 % and 32 %, respectively, of summer melting on Laohugou Glacier No. 12 in the northeast of the TP. While MD (38%) contributed more glacier melt than BC (11%) to Zhadang Glacier, Mt. Nyainqentanglhi in the southern TP. This study provided the baseline information on LAIs' climatic effects and their contributions in cryosphere change over the TP.

Abstract

Similar to most mountain glaciers in the world, Urumqi Glacier No. 1 (UG1), the best observed glacier in China with continued glaciological and climatological monitoring records of longer than 50 years has experienced an accelerated recession during the past several decades. The purpose of this study is to investigate the acceleration of recession. By taking UG1 as an example, we analyze the generic mechanisms of acceleration of shrinkage of continental mountain glaciers. The results indicate that the acceleration of mass loss of UG1 commenced first in 1985 and second in 1996 and that the latter was more vigorous. The air temperature rises during melting season, the ice temperature augment of the glacier and the albedo reduction on the glacier surface are considered responsible for the accelerated recession. In addition, the simulations of the accelerated shrinkage of UG1 are introduced in this study.

Relationship between Climate and Permafrost across the Mid-Latitude Alpine Regions during the Period 2008-2013

Wu Tonghua, Zhao Lin, Li Ren, XieChangwei

Cryosphere Research Station on the Qinghai-Xizang Plateau, State Key Laboratory of Cryospheric Sciences, Cold and Arid Regions Environmental and Engineering Research Institute, Chinese Academy of Sciences, Lanzhou, 730000, P. R. China, thuawu@lzb.ac.cn

Abstract

The links between climate and permafrost were well documented in lots of previous literature. However, the responding mechanism of permafrost to climate change and the feedback of permafrost changes on the climate system were still kept poorly understood until now, especially in the mid-latitude alpine regions such as the Qinghai-Tibet Plateau, the Loess Plateau in China, and the Mongolian Plateau. Three typical permafrost sites in above-mentioned three plateaus were selected to perform the comparison analysis. The related meteorological elements and ground temperatures at different levels were continuously measured over the period 2008-2013. The difference of the impacts of climate on the permafrost was demonstrated in details in this study. The surface offset, the thermal offset, and the air and ground surface freezing/thawing indices were calculated according to the observation data. The possible impacting mechanism of climate conditions on the ground thermal regimes were quantified and compared. This study will enhance our understanding on the response of permafrost to recent climate changes across the mid-latitude alpine regions. The strengthened observations at those sites were suggested in the following work.

Simulation and Prediction of Equilibrium Line Altitude of Glaciers in the Eastern Tibetan Plateau

KeqinDuan

College of Tourism and Environment, Shanxi Normal University, Xi'an 710119, China

Abstract

As the third polar on the Earth, the Tibetan plateau holds more than 40,000 glaciers which have experienced a rapid retreat in recent decades. Glacier loss has increased concern for water resources around the Tibetan plateau. The variability of equilibrium line altitude (ELA) indicates expansion and wastage of glacier directly. Here we simulated the ELA variability in the eastern Tibetan Plateau based on a full surface energy and mass balance model. The simulation results are agreement with the observations. The ELAs have risen at a rate of 2-8m/a since 1970 throughout the plateau, especially in the Qilian Mountain and the southeastern Plateau where the ELAs have risen to or over the top altitude of glacier, indicating the glaciers are accelerating to melting over there. Two typical glacier, Xiaodongkemadi glacier in the center of the Plateau and Qiyi glacier in the Qilian Mountain, are chosen to simulate its future ELA variability in the scenarios of RCP2.6, RCP4.5 and RCP 8.5 given by IPCC. The results show the ELAs will arrive to its maximum in around 2040 in the scenario of RCP2.6, while the ELAs will be over the top altitude of glaciers in 2035-2045 in the scenarios of RCP4.5 and RCP8.5, suggesting the glaciers in the eastern plateau will be melting until the disappear of the glaciers.

The Dangerous Lakes of Kyrgyzstan: Development Caused by Climate Change

BOHUMIR JANSKY

Charles University in Prague, Faculty of Science, Czech Republic, jansky.b@seznam.cz

Abstract

Global warming causes an intensive melting and retreat of glaciers in the majority of high mountains all over the world. This process is also evident in the mountain regions of central Tien Shan. Melting glacier water affects changes in the hydrological regime of water streams and causes overfilling of high mountain lake basins. The dams of many lakes are very unstable and often burst open. To determine the degree of this risk, it is necessary to analyse the genesis of the lakes, to characterize the morphology of the lake basins and to know the particularities of their hydrological regime.

More than 2000 of alpine lakes covering more than 0,1 hectare each have been identified within the territory of Kyrgyzstan. Nearly 20% of these are supposed to be potentially dangerous because of instability of moraine or landslide dams, frequent overflowing, rapid development of lake basins and melting of buried ice inside the moraine. According to the latest inventory, in total 328 lakes have been identified as potentially dangerous, 12 lakes are considered as actually dangerous, other 25 feature high potential hazard. Since 1952 more than 70 disastrous cases of lake outburst have been registered. The hazardous alpine lakes are studied in Kyrgyzstan systematically since 1966. In the last ten years the monitoring work has been carried out within the programme of Czech-Kyrgyz cooperation.

The Last Decade Changes in Glaciers Area in the Caucasus and Altai Mountains

Khromova T, A, Nosenko G, Nikitin S.

Institute of Geography Russian Academy of Sciences, Moscow, 119017, Russia, tkhromova@gmail.com

Abstract

The last decade is of special interest as this comparatively short period of time was marked by a rapid melt of glaciers and increase in the number of natural disasters in the high-mountain area of the Caucasus and Altai - increase in number and capacity of snow avalanches and occurrence of glacial mudflows. Repeated satellite imagery has provided a uniformity of imaging conditions and compatibility of glacier data of different time, and the availability of meteorological stations operating in high-mountain area has allowed to perform comparative analysis of variability of the main meteorological parameters within the period of assessment.

The results of studies have shown that glaciers retreat in both regions was taking place during the second part of 20th century and at the beginning of this century. Considerable variability in glacier retreat (up to complete disappearance) depending upon morphological types, sizes and local conditions of alimentation of glaciers has been identified for the assessed territories. The rate of glaciers retreat during the last decade has increased 1.5–2 times compared with the end of 20th century.

Abstract

To optimize the description of land surface processes and improve climate simulations over the Tibetan Plateau (TP), a revised soil water–heat parameterization scheme (SWHPS) is implemented into the Community Land Model 3.5 (CLM3.5), which is coupled to the Regional Climate Model 4 (RegCM4). This scheme includes Johansen’s soil thermal conductivity scheme together with Niu’s groundwater module. Two groups of climate simulations are then performed using the original RegCM4 and revised RegCM4 to analyze the effects of the revised SWHPS on regional climate simulations. The effect of the revised RegCM4 on simulated air temperature is relatively small (with mean biases changing by less than 0.1 °C over the TP). There are overall improvements in the simulation of winter and summer air temperature, but increased errors in the eastern TP. It has a significant effect on simulated precipitation. There is also a clear improvement in simulated annual and winter precipitation, particularly over the northern TP, including the Qilian Mountains and the source region of the Yellow River. There are, however, increased errors in precipitation simulation in parts of the southern TP. The precipitation difference between the two models is caused mainly by their convective precipitation difference, particularly in summer. Overall, the implementation of the new SWHPS into the RegCM4 has a significant effect not only on land surface variables, but also on the overlying atmosphere through various physical interactions.

Glacier Area Changes in the Tien Shan over the Past 40 Years

CHEN Huijiao, WANG Xianwei

School of Geography and Planning, Sun Yat-Sen University, Guangzhou 510275, China

Abstract

Living water and irrigation in Central Asia heavily depend on snow and glaciers melt. Changes to the glaciers area in the main mountain range in this region, the Tien Shan, have been reported over by CGI1, CGI2, GCL2000, WGI, ESA inventory. However, because those have lower spatial resolution and susceptible to cloud and snow. It is acquired to snowless and cloud-free high resolution satellite imagery to reconstructions over longer time series in perennial snow Tien Shan mountain region. An object-oriented image segmentation method is proposed to map an intact glacier boundary and their changes with multitemporal Landsat imagery. We estimate the overall decrease to total area loss of 1359 km² in 2013, with total glacier area of 29% since 1977. And an average glacier area-change rate of -8.0 %/(10) yr.

Key words:

Glacier area change; remote sensing; Tien Shan; object-oriented image segmentation

Quantification of Recent Dynamics in Glacial and Paraglacial Environment: Application of UAV, Digital Photogrammetry, Terrestrial Laser Scanning and DEMs of Difference (DODs)

Ewertowski MW, Tomczyk AM

Adam Mickiewicz University, Faculty of Geographical and Geological Sciences, Poznan, Poland,
marek.ewertowski@gmail.com

Abstract

Dynamics of glacial and paraglacial environment of several Svalbard glaciers was quantified in different spatio-temporal scales. Time-series orthophotos and digital elevation models from 1961, 1990 and 2009 (with ground resolution varying from 0.4 m to 0.7 m) were used for quantification of decadal changes for the whole catchments. Photographs captured by UAV (Unmanned Aerial Vehicle) and repetitive geomorphological and geodetic field surveys were applied to estimate seasonal (2011-2016) and intra-seasonal transformations of various landforms assemblages and individual landforms.

Research was carried out for several glacial forelands in the central part of the Spitsbergen Island, including: Nordenskiöldbreen, Ebbabreen, Raganbreen, Hørbyebreen, Cambridgebreen, Balliolbreen, Svenbreen and Ferdinandbreen. In the period LIA-2015, glaciers' margins retreated seriously, moreover ice volume and glaciers' surface profiles changed enormously emphasizing the relative importance of glaciers' thinning over area loss. In terms of landscape alteration most important transformation included: (1) developing of a terminoglacial and/or supraglacial lakes, which acted as a sedimentary trap and at the same time probably accelerated glacier recession, (2) developing of the lateral moraines with various magnitudes of debris flow and backwasting activity that changed over time (3) developing of end moraine complexes, which are now the most stable components, alternated mainly by dead-ice downwasting and to a lesser extent by sporadic debris flows. Short-time dynamics of different components showed very high variability in transformation and illustrate relative importance of ice backwasting over downwasting for studied forelands. The research was funded by Polish National Science Centre (project granted by decision number DEC-2011/01/D/ST10/06494).

Abstract

Snow density is a key parameter for snow physical process studies, snow water equivalent assessment, and land surface model validation. Many field methods have been developed for measuring snow density, however, few studies have focused on evaluating the sensitivity and accuracy of snow density measurements. The objective of this study is to evaluate the sensitivity and accuracy of snow density results obtained by using different field methods. We conducted a series of field experiments in the Altai Mountains in February 2015 using three instruments: the snow fork, the 1000 cm³ stainless-steel wedge cutter, and the weighting snow-gauge. The primary results show that snow density measured by snow fork method was lower than the results measured by other methods in the whole snow profile, although snow fork method can provide samples with higher resolution. The average snow density measured by using the wedge cutter method is about 8% higher than that by the weighting snow-gauge method with the correlation coefficient of 0.846 ($p < 0.05$); Snow densities measured by the snow fork is, on average, about 16% smaller than that by the weighing snow-gauge method and about 20% by the wedge cutter method, with the absolute value of relative error up to 40%. For different snow layers, snow density measured by using the snow fork method is, on average, about 22% smaller than that by the wedge cutter method in the depth hoar, and about 18% in the upper layers. In terms of the accuracy of snow fork method, the measurement stability of snow fork method in the depth hoar, which the root mean square error (RMSE) was within 2.3%, was lower than the upper layers with the RMSE was within 1.6%.

Abstract

Snow plays an important role in climate system through strong feedbacks related to surface albedo. Both mean snowfall and the intensity of snowfall are important, with extreme snowfall events having particularly large economic and human impacts. Based on ground-based measurements from 1863 stations across Eurasian continent, we investigated the changes in light snow ($0.1\text{mm} \leq \text{dsf} < 2.5\text{mm}$), moderate snow ($2.5\text{mm} \leq \text{dsf} < 5\text{mm}$), heavy snow ($5\text{mm} \leq \text{dsf} < 10\text{mm}$) and snowstorm ($\text{dsf} \geq 10\text{mm}$) over the period 1966-2012. The results indicated that annual total snowfall did not have a significant trend during the study period over the study area, while the annual snowfall days decreased with a rate of -0.14d yr^{-1} . The light snowfall was decreased at a rate of -0.1mm yr^{-1} ; the heavy snow was increased at a rate of 0.06mm yr^{-1} . The snowstorm decreased with a rate of -0.15mm yr^{-1} before the 1990s, while it increased with a rate of 0.29mm yr^{-1} from the 1990s through the end of the study period; the moderate snowfall had opposite trend with the snowstorm, the annual moderate raised slowly before 2000, and then declined rapidly with a rate of -0.24mm yr^{-1} .

Regionally, northern Xinjiang, the eastern Tibetan Plateau, northeastern China and most of Russia are the key regions of snowfall with more frequency and strong variability. The significant increased areas were located in European Russia, the upper reaches of Yenisei River, Sakhalin and northern Xinjiang, northeastern China and eastern Tibetan Plateau. The significant decreased areas were mainly located in south of China, Central Siberia and on the coast of Arctic Russia. The change of light snow is decreased all over Eurasia, while most of the stations of the heavy snow have positive trends in the north of 40°N . There was a high correlation of snowfall with latitude, which increases with latitude as moving northward with approximately 4mm per latitude. Overall, heavy snowfall increased, while light snowfall decreased, especially in high latitude and high elevation regions.

Snow cover phenology critically effects on surface energy fluxes, surface albedo and hydrological processes. In this study, climatology and spatiotemporal variation of snow cover phenology were investigated using the long-term (1966-2012) ground-based measurements of daily snow depth from 1103 stations over Eurasian Continent. The results showed that distributions of the first date, last date, snow cover duration and number of snow cover days generally represented the latitudinal zonality over Eurasian Continent, and there were significant elevation gradient patterns on the Tibetan Plateau. The first date of snow cover delayed by about 1.2 day decade⁻¹, the last date of snow cover advanced with the rate of -1.2 day decade⁻¹, snow cover duration and number of snow cover days shortened by about 2.7 and 0.6 day decade⁻¹, respectively, from 1966 through 2012. Compared with precipitation, correlation between snow cover phenology and air temperature was more significant. Changes in snow cover duration were mainly controlled by the changes of air temperature in autumn and spring. The decreased number of snow cover days was affected by rising temperature during the cold season except for the air temperature in autumn and spring.

Characteristics of Unfrozen Water Content in Frozen Soils, Qilian Mountain

Hong GUO, Tingjun ZHANG, Bin CAO, Wanwan SHAO, Xiankai ZHANG,

Key Laboratory of Western China's Environment Systems (Ministry of Education), College of Earth and Environmental Sciences, Lanzhou University, Lanzhou, 730000, China, guoh_10@lzu.cn

Abstract

Climate change will result in permafrost temperature increase as having been observed worldwide. Permafrost temperature increase, especially for relatively high temperature permafrost, would result in the increase of unfrozen water which would dramatically impact thermal, electric and mechanical properties of frozen soils. The primary objective of this study is to investigate changes in unfrozen water content with temperature and soil properties using data and information from field measurements and laboratory experiments. We explore the relationship between the unfrozen water and the soil temperature, grain size, and salinity of five different soils in the source area of Heihe River, northeast Tibetan Plateau. Soil temperature and soil moisture were measured by using thermistor string and time domain reflectometry, respectively. Soil basic physical and chemical properties were measured at different depths. We derived five soil types by analysing soil particle size and classifying soil texture according to the United States Department of Agriculture standard. Each soil type has an empirical equation to describe unfrozen water content as a function of soil temperatures and the effect of grain size and salt content. The study confirmed that the factors influencing unfrozen water content in frozen soils are soil temperature, grain size, and salinity.

Key Laboratory of Western China's Environmental Systems (Ministry of Education), College of Earth and Environmental Sciences, Lanzhou University, Lanzhou, 730000, China, shaoww09@lzu.edu.cn

Abstract

Frozen soil regions occupy about 35% of the land surface of the earth. Changes of the near-surface soil freeze-thaw cycle can affect surface energy and water balance, vegetation dynamics, carbon dioxide exchange between atmosphere and soil, and the ecosystems as a whole. The objective of this study is to investigate spatial and temporal changes in the near-surface soil freeze-thaw status in the northern hemisphere using passive microwave remote sensing data. We used the SMMR, SSM/I and AMSR-E EASE-Grid daily brightness temperature products with a spatial resolution of 25km that is publicly available from the National Snow and Ice Data Center. Daily mean soil temperatures at 5cm depth were obtained from China Meteorological Administration to calibrate and validate the frozen soil algorithm (FSA). FSA requires two parameters: a negative spectral gradient between T_{B19V} and T_{B37V} and a threshold of T_{B37V} . Using the validated FSA, daily near-surface frozen soil extent was detected over a period from 1979 through 2014 in the northern hemisphere. Based on the output from the validated FSA, we found that: (i) the average duration of the near-surface soil freeze is about 217 days and the actual number of the near-surface soil freeze days is about 161 days. (ii) Over the period of 1987-2014, with the increasing of the near-surface soil temperature, the freeze/thaw status obtained from SSM/I reveal that the onset date of the near-surface soil freeze in autumn was delayed at a rate of 1.3 ± 1.0 day yr^{-1} , and the last date of surface freeze in spring was advanced at a rate of 1.2 ± 0.6 day yr^{-1} . The duration of the near-surface soil freeze decreased at a rate of 2.5 ± 1.1 day yr^{-1} , while the actual number of the near-surface soil freeze days decreased at a rate of 1.6 ± 0.8 day yr^{-1} . Annual maximum frozen area extent also showed a decreasing trend, with a trend of $(-55.60 \pm 7.20) \times 10^3 km^2 yr^{-1}$. (iii) The rates of changes in the near-surface soil freeze/thaw status increased dramatically at the lower and higher latitude and presented distinct latitudinal zonation and vertical zonation. From 2002 to 2010, compared to the classification results of SSM/I, AMSR-E underestimated the near-surface soil freeze.

The Effect of Wildfire on Permafrost on the Northern Da Xing'anling Mountains, Northeastern China

Xiaoying Li, Huijun Jin*, Ruixia He, Dongliang Luo, Yadong Huang

State Key Laboratory of Frozen Soil Engineering, Cold and Arid Regions Environmental and Engineering Research Institute, Chinese Academy of Sciences, Lanzhou 730000, China, hjjin@lzb.ac.cn

Abstract

The wildfire is one of the main factors influencing the boreal forest ecosystem in many aspects; not only the nutrient cycles and surface energy balance, the changes of soil physical and chemical properties, but also the changes of active layer thickness and soil temperature. Under the context of global warming and increase of the anthropogenic activities, the occurrences of the wildfire have been frequently increased in boreal forest. Previous studies indicated that the wildfire had significant impacts on the hydrothermal of active layer and permafrost, which tends to induce the degradation of permafrost and release of organic carbon. Da Xing'anling Mountain, the ecological barrier of the Northeastern China, is the primary boreal forest in permafrost region of China, as well as the only primeval boreal forest in north of China suffering from the highly frequent wildfire. The wildfire, taken place on 6 May 1987 in the Da Xing'anling Mountain, was the most serious catastrophic one since the founding of the new China. It led to irreversible degradation of permafrost, converse succession of forest and wetland, the loss of carbon storage, thermal subsidence and slumping in Northeast China. Besides, it threatened the buildings on permafrost. However, there were few related studies except the 3 years' research on the impacts of wildfire on the hydrothermal of permafrost in the Da Xing'anling Mountains (e.g., Zhou et al., 1994). Still, long-term and systematic observations and numerical simulations are scarce as well as the applications on the research of frontier discipline basic theory and practical engineering. By means of field investigation, interpretation of remote-sensing images, we found out the fire point in 1987-2015, and determined the different fire intensity. It aims to study the change of permafrost in different years and different fire intensity, and the research of model simulation. This study could provide important scientific basis for reasonable assessment of the impacts of wildfire on boreal forest and wetland in permafrost region, the environmental restoration and management, and the research of shallow carbon pool in mid- and high latitude in China.

An Improved Method for Npp Estimation in Wuhan, China from 2001 to 2010Lunche Wang¹, Chunju Huang¹, Lan Feng², Dongmei Li¹¹Department of Geography, School of Earth Sciences, China University of Geosciences, Wuhan 430074, China²School of Environmental studies, China University of Geosciences, Wuhan 430074, China**Abstract**

Dynamic monitoring of vegetation net primary productivity (NPP) is of great importance for better understanding the carbon cycle of terrestrial ecosystems [1, 3]. By analyzing the dependence of photosynthetically active radiation (PAR) on cosine of solar zenith angle and clearness index (Kt), an efficient all-sky model was introduced for estimating PAR under various sky conditions. As a key variable in NPP estimation, light use efficiencies were also improved by considering the stress factors of temperature/humidity for different types of vegetation [4, 12]. Seasonal and interannual variations of NPP in Wuhan, China from 2001 to 2010 were then investigated using MODIS products and ground meteorological data. The results showed that NPP increased slightly from 2001 to 2005 and decreased from 2005 to 2010; annual mean NPP was about $502 \text{ gCm}^{-2}\text{a}^{-1}$. Significant differences in NPP values for different vegetation types were also found: evergreen broadleaf vegetation produced the highest annual NPP value of $1016.7 \text{ gCm}^{-2}\text{a}^{-1}$, and annual grass vegetation had the lowest mean value of $448 \text{ gCm}^{-2}\text{a}^{-1}$. This study will improve our basic understanding of carbon cycling process in the study area and the proposed model will be useful for other regional NPP estimations in the world.

Assessing Remote Sensing Phenology and its Spatiotemporal Variation Based on Plant Senescence Reflectance Index in the Inner Mongolian Grassland

Shilong Ren, Xiaoqiu Chen*, Shuai An

College of Urban and Environmental Sciences, Laboratory for Earth Surface Processes of the Ministry of Education, Peking University, Beijing 100871, P.R. China, cxq@pku.edu.cn

Abstract

Extracting remote sensing phenology based on the Plant Senescence Reflectance Index (PSRI) may enrich phenological research methods. Here, we used Moderate Resolution Imaging Spectroradiometer data from 2000 to 2011 to calculate PSRI and determine start (SOS) and end (EOS) dates of the vegetation growing season in the Inner Mongolian Grassland, and validated their reliability within situ phenological data and MODIS phenology product at 5 phenological stations. We also conducted partial correlation analysis between SOS/EOS and climatic factors at 56 meteorological stations in order to look for what determines the occurrence of SOS/EOS in temporally and spatially. Results show that (1) PSRI-derived SOS/EOS presents better accuracy and ability in reflecting ground vegetation phenology than MODIS phenology product; (2) precipitation is a more important factor than air temperature in determining the SOS/EOS at most stations; (3) precipitation also influences the spatial distribution of SOS more greatly than air temperature in most years, while precipitation and air temperature both control the spatial distribution of EOS. The significant temporal and spatial correlations between SOS/EOS and thermal-moisture factors provide an indirect evidence that remote sensed vegetation phenology can capture ground-based plant community phenology in the Inner Mongolian Grassland. Moreover, the significant linear trends of SOS and EOS were detected only at small portions of pixels.

Assessment of the Carbon Footprint of Four Commercial Dairy Production Systems in Australia through Integrated Farm System Model

Sejian V, Prasad RS, Lees AM, Lees JC, Sullivan ML, Antis A, Rotz CA, Gaughan JB

School of Agriculture and Food Sciences, The University of Queensland, Gatton 4343 QLD, Australia, drsejian@gmail.com

Abstract

A dairy farm is a complex system with several interacting subsystems. The integrated farm system model (IFSM) is a cost effective and efficient method of estimating greenhouse gas (GHG) emissions from dairy farms and analyzing how management strategies affect these emissions. An IFSM (DairyGHG model) was employed in this study to predict the GHG emission and assess the carbon footprints of four different dairy farms at Southeast Queensland, Australia. Four representative farms were selected: Farm 1 (220 cows; Jersey), Farm 2 (460 cows; Holstein Friesian), Farm 3 (850 cows; Holstein Friesian) and Farm 4 (434 cows; Holstein Friesian). Across the four farms the cows were fed corn silage, grain and had access to grazing. The animal emission contribution to carbon footprints in Farm 1, Farm 2, Farm 3 and Farm 4 were 54.2%, 60.0%, 59.6% and 38.6% respectively for total output. Likewise the manure emission contribution to carbon footprints in Farm 1, Farm 2, Farm 3 and Farm 4 were 30.6%, 29.0%, 29.0% and 58.3% respectively. On the basis of per kg of energy corrected milk the amount of GHG produced in Farm 1, Farm 2, Farm 3 and Farm 4 are 0.39 kg CO₂e, 0.64 kg CO₂e, 0.54 kg CO₂e and 1.35 kg CO₂e respectively. The method and database developed for this assessment effectively supported the calculation of GHG emissions related to dairy production and may be considered an important step towards a harmonized methodology for the quantification of emissions in dairy farms.

Autumn Phenology Shifts and its Response to Climate Changes on the Tibetan Plateau in the Past Three Decades

Jiang N, Zhu W, Zheng Z, Zhang D, Jiang T

State Key Laboratory of Earth Surface Processes and Resource Ecology, Beijing Normal University, Beijing, 100875, P. R. China, jiangnan@mail.bnu.edu.cn

Abstract

Vegetation phenology has been proved as a significant indicator of the climate change. Autumn phenology is as important as spring/summer phenology since it controlled the carbon by determining the length of the growing season. However, the progress of autumn phenology remains unclear and relatively less work has been carried out on autumn phenology, which makes the analysis on autumn phenological events more important and difficult. With the most completed in-situ observation of autumn phenological events for Tibetan Plateau, we revealed the autumn phenology shifts in the past three decades and its response to climate changes. The results showed a postponed trend for all the records of phenological events, however, there remained large differences among different species and phenological events: The woody plants had earlier fruit phenology and little changes on leaf phenology, while the herbaceous plants experienced later leaf phenology and little changes on fruit phenology; the leaf phenology of xerophilous herbaceous plants had advanced trends while those of hygrophilous herbaceous showed significantly postponed trend. Those differences were caused by their diverse responses to climate factors, for example, the xerophilous herbaceous showed negative response to temperature and positive response to precipitation; while the opposite results were observed for the hygrophilous plants. Therefore, we argued that, though the Tibetan Plateau suffered the same background of climate change with higher temperature and fewer precipitation, the autumn phenology should not be easily summed up in delayed/advanced trends. These discrepancies caused by species or events should be fully considered when building phenological models.

Changes in Flowering Phenology of Woody Plants in North China

Wang H, Dai J

Institute of Geographical Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, wanghj@igsnr.ac.cn

Abstract

Over the past several decades, abundant evidences proved that the first flowering date of plants in northern hemisphere became earlier in response to climate warming. However, the existing results about impact of climate change on flowering duration are controversial. In this study, we studied temporal trends in first flowering date (FFD), end of flowering date (EFD) and flowering duration (FD) of 94 woody plants from 1963 to 2014 at three stations (Harbin, Beijing and Xi'an) in North China. Meanwhile, we analyzed the relationship between length of flowering periods and temperature using two phenological models (including regression model and growing degree day model). At all stations, more than 90% of observed species showed earlier flowering over time from 1963 to 2014. The average trends in FFD were 1.33, 1.77 and 3.01 days decade⁻¹ at Harbin, Beijing and Xi'an, respectively. During the same period, EFD also became earlier by a mean rate of 2.19, 1.39 and 2.00 days decade⁻¹, respectively. Regarding FD, a significant shortening of FD was observed at Harbin (-0.86 days decade⁻¹), but FD extended by 0.37 and 1.01 days decade⁻¹ at Beijing and Xi'an, respectively. Through regression analyses, we found more than 85% of time series revealed a significant negative relationship between FFD (or EFD) and pre-season temperature. The regression and growing degree day model could simulate the interannual changes in FFD and EFD, but failed to simulate the FD accurately. Therefore, we concluded that the FFD and EFD advanced notably in recent six decades as a result of climate warming, but the direction of FD changes depended on locations and the species involved. In addition, the conventional phenological models could not explain most parts of interannual variance in FD, partly due to superposition of errors caused by simultaneously simulating FFD and EFD. Therefore, the mechanism of FD changes and more drivers of FD such as soil moisture and light need to be further studied.

Abstract

Palm oil production has increased in recent decades and is estimated to increase further. The optimal role of palm oil production, however, is controversial because of resource conflicts with alternative land uses. Local conditions and climate change affect resource competition and the desirability of palm oil production. Based on this, crop yield simulations using different climate model outputs under different climate scenarios could be an important tool in addressing the problem of uncertainty quantification of those model outputs. Previous studies on this region have focused mostly on single experimental fields, not considering variations in agro-ecological zones, climatic conditions, varieties, and management practices. In addition, most of the earlier studies did not consider various IPCC climate scenarios and were based on single climate model output. Furthermore, the uncertainty quantification of the climate-impact model has rarely been investigated in this region. To this end we use the biophysical simulation model APSIM (Agricultural Production Systems Simulator) to simulate the regional climate impact on oil palm yield over the Nigerian Niger Delta. We also examine whether the use of crop yield model output ensemble reduces the uncertainty rather than the use of climate model output ensemble. The results could serve as a baseline for policy makers in this region in understanding the interaction between potentials of energy crop production of the region as well as its food security and other negative feedbacks that could be associated with bioenergy from oil palm.

Abstract

Extreme climate conditions are deviation from the norms and are capable of causing upsets in many important environmental parameter including disruption of water balance and air temperature balance. Studies have shown that extreme climate conditions can foretell disaster in regions with inadequate early warning systems. In this paper, we combined geographical information systems, statistics and social surveys to evaluate the physiologic indices [(Dewpoint Temperature (Td), Effective Temperature Index (ETI) and Relative Strain Index (RSI)] and extreme climate conditions in different parts of southwest Nigeria. This was with the view to assessing the nature and the impact of the conditions on the people and their coping strategies. The results indicate that minimum, mean and maximum temperatures were higher in 1960-1990 than 1991-2013 periods at most areas, and more than 80% of the people adapt to thermal stress by changing wear type or cloth, installing air conditioner and fan at home and/or work place and sleeping outside at certain period of the night and day. With respect to livelihoods, about 52% of the interviewed farmers indicated that too early rainfall, late rainfall, prolonged dryness after an initial rainfall, excessive rainfall and windstorms caused low crop yields. Main (76%) coping strategies were changing of planting dates, diversification of crops, and practices of mulching and intercropping. Government or institutional support was less than 20%.

Department of Geography and Planning, GEOBIOMET Research Group, University of Cantabria, Santander, 39005, Spain,
pablo.fdezarroyabe@unican.es

Abstract

Influenza epidemics have become of global concern in the last decades. Some influenza viruses related to avian flu such as A (H5N1) and A (H7N9) have caused serious infections in human being recently. A global alert and response to avian influenza and to other minor impacting influenza viruses must be given. According to the Global Health understanding, new approaches to the study of influenza outbreaks should complement the traditional epidemiological ones. In this sense, this research proposed a biometeorological approach to this problem based on the study of the potential relationship between meteorological distressconditions and influenza viruses spreading at a particular geographic region. The Meteorological Contrast Index (MCI) based on the daily changes of Lamb-Jenkinson circulation types in different regions of China is calculated in order to analyse how the physical properties of the atmospheric changes are connected to influenza spreading period in different Chinese regions.

⁴University of Chinese Academy of Sciences, Beijing 10049, China

Abstract

The rising atmospheric CO₂ concentration is expected to increase tree growth worldwide. However, few studies have focused on whether such CO₂ fertilization effect exists for trees at the temperature-limited alpine timberline from a physiological point of view. Herein, we use dendrochronological methods and tree-ring carbon isotope to investigate variations in basal area increment (BAI) and iWUE of Smith fir (*Abies georgei* var. *smithii*) during the past century at the timberline in the Sygera Mountains, southeastern Tibetan Plateau. The random forest model revealed that warming and rising atmospheric CO₂ together contributed to the increasing iWUE. The commonality analysis showed (1) for raw data (mainly including low frequency information), unique iWUE played a more significant role on BAI than unique temperature, common effects among iWUE and temperature usually were stronger than their unique effect; (2) for the linearly detrending data (high frequency data), unique iWUE, common effects among iWUE and temperature had scarcely effect on BAI, while temperature was the still the crucial factor on tree growth. We conclude that (1) increasing iWUE could stimulate tree growth at our site at the low frequency, while increasing iWUE could not stimulate tree growth at the high frequency data.

Estimating the Potential of Energy Saving and Carbon Emission Mitigation of Cassava-Based Fuel Ethanol Using Life-Cycle Analysis Coupled With a Biogeochemical Process Model

Dong Jiang¹, Mengmeng Hao^{1,2}, Jingying Fu^{1,*}

¹Institute of Geographical Sciences and Natural Resources Research, Chinese Academy of Sciences, 11A Datun Road, Beijing 100101, China, fujy@igsnr.ac.cn

²University of Chinese Academy of Sciences, Beijing 100049, China

Abstract

Global warming and increasing concentration of atmospheric greenhouse gases (GHG) and fossil fuel consumption have prompted considerable interest in the potential role of energy plant biomass. While energy efficiency and GHG emission saving vary from one energy plant to another which need to be estimated scientifically. Cassava is an important biomass feedstock of fuel ethanol and has attracted much attention. This article provides an approach for estimating the energy saving and carbon emission mitigation potentials of cassava-based fuel ethanol using life-cycle analysis (LCA) coupled with biogeochemical process model. First, potential of cassava production on suitable marginal land in China was calculated using an optimized biogeochemical process model (GEPIC model); then, this was used to find the spatial distribution of ethanol production through a conversion coefficient between cassava and ethanol. Finally, the net energy potential and carbon emission reduction potential in China were simulated. This study indicates that cassava is one of the most promising feedstock for fuel ethanol production. The use of cassava-based fuel ethanol will mitigate the climate change by producing efficient, clean, and renewable energy. The results of this paper show that the potential of cassava production on marginal land in China is 52.51 million tones, and the net energy surplus of cassava fuel ethanol is about 92.92 billion MJ and the carbon emission mitigation is about 4.59 billion kgC. The mitigation potentials of Guangxi, Guangdong, and Fujian are particularly of note and are identified as target regions for large-scale development of the cassava-based ethanol industry.

³Department of Ecosystem Science and Sustainability, Colorado State University, 213 Natural Resources Building, Fort Collins, CO 80523, USA

Abstract

Flowering duration is a key component of plant physiology that influences plant reproductive fitness in a changing environment. Although, there are evidences indicate that climate change affects plant phenology across different biomes, but little is known about changes in flowering duration under the changing climate scenarios and how the changes in flowering duration was attributed to different flowering phonological components under changing climate. We used data from 7 years' fully-factorial field experimental study to understand how flowering duration of two species (*Potentilla fruticosa* and *Potentilla suandersiana*) were affected by warming (open top chambers), snow addition, and their interaction on an alpine meadow ecosystem in central Tibet. The experiment was started in 2009 and continued up to date. The phenological data were only available in 2010, 2011, 2014 and 2015 due to some logistical reasons. Our results showed that the flowering duration did not significantly differ between treatments in both species, but warming significantly delayed the date of first flowering and warming did not affect the date of last flowering in both species. Snow addition significantly advanced the first and the last date of flowering in *P. suandersiana*, but not for *P. fruticosa*. The flowering duration of both species were negatively and positively related to the date of first and last flowering respectively. These results indicate that flowering duration of alpine plant may be less plastic, even though the date of first and last flowering changed, in order to maximize their reproductive fitness under changing environments.

Hospitals Admissions Related to Influenza Diagnostics and Circulation Weather Patterns in the Iberian Peninsula for the Period 2002-2014

Pablo FDEZ-ARROYABE, Dominic ROYE

Department of Geography and Planning, GEOBIOMET Research Group, University of Cantabria, Santander, 39005, Spain, pablo.fdezarroyabe@unican.es

Abstract

The spreading of infectious diseases is one of biggest concerns nowadays all around the world. In this sense, the study of the relationships between transmission vectors, bacteria, viruses... and meteorological and climatic factors has become a frequent scientific task. In the present study, different biometeorological indexes and statistical models are applied to the analysis of daily circulation weather types in order to assess how relevant weather changes can be in the explanation of the outbreaks of influenza epidemics and in their temporal and spatial spreading in Spain. Firstly, a daily weather classification has been created based on Lamb's approach for the Iberian Peninsula. Moreover, Spanish's hospitals admissions with a primary or secondary diagnose of flu were obtained from the Spanish health system through the hospital database CMBD. This repository of medical data relates to hospitals admissions of citizens and covers the public network of Spanish's hospitals. Codification of diagnoses of influenza patients was done according to the International Classification of Diseases (ICD v.9) (487 and 488). Using both data sources, Meteorological Contrast Index (MCI) has been estimated (Fdez-Arroyabe, 2004) based on weekly circulation weather types and they have been related to influenza spreading in Spain. Generalized Linear Mixed Models (GLMM) were also applied in order to define the relative importance of the sequences of changes in the circulation weather types during the outbreaks and the spreading periods of the infectious disease for the period 2002-2014.

Abstract

The changes in solar radiation components may alter the radiation distribution in plant canopies and influence photosynthesis sequentially. In recent fifty years (1960-2010), solar radiation and direct radiation declined significantly in four sites (Beijing, Tianjing, Jinan and Zhengzhou) in the North China Plain. Diffuse radiation changed diversely in different places. It decreased in Beijing ($\alpha < 0.05$), increased in Jinan and Zhengzhou ($\alpha < 0.01$) and was trendless in Tianjing. Nevertheless, the diffuse radiation fraction (DRF) enhanced markedly in all sites ($\alpha < 0.01$). Though DRF decreased with the increase in clearness index (CI), it was usually regarded as a constant parameter in most crop models. Considering the influence of different sky conditions (Clear, cloudy and overcast), the relationships between hourly DRF and CI were described by Badescu Equation. The equation was parameterized based on field observations and involved in a crop model (ChinaAgrosys). The improved model was used to simulate the impacts of changes in solar radiation components on winter wheat yield and water use in the North China Plain in recent fifty years. The influences of shifts in wheat varieties and field managements were neglected. The effects of precipitation variability were also ignored for sufficient irrigation. The simulation results indicated that the decline in solar radiation may lead to significant reductions in winter wheat yield and water use efficiency (WUE) in the North China Plain from 1960 to 2010. However, the decrease trends were weakened or turned to rise with the increase in DRF and CO₂ fertilization effects.

Infectious Diseases in Different Climate Zone in Western China under the Background of Climate Warming

Ma Y.X, Xiao B.S, Zhao Y.X, Zheng X.D

The Gansu Key Laboratory of Arid Climate Change and Reducing Disaster, College of Atmospheric Sciences, Lanzhou University, Lanzhou, 730000, P.R.China ,mayuxia07@lzu.edu.cn

Abstract

Climate warming has both direct and indirect impacts on public health, including affecting the distribution of infectious diseases and speeding up the diffusion of epidemics. In this study, spatial-temporal distributions of three infectious diseases in Gansu province located in western China are analysed. Results showed that Hepatitis A occurs in all areas of Gansu province, while epidemic encephalitis and epidemic hemorrhagic fever are parochial. The incidences of infections have great differences in different climate areas. The high incidences of Hepatitis A are mainly found in Gannan Tibetan plateau. Epidemic encephalitis mainly occur in south of Gansu, where climate is warm and humid. Epidemic hemorrhagic fever mainly occurs in Gannan Tibetan plateau. The infections also have evident seasonal climax. Epidemic encephalitis mainly occurs from July to September, hepatitis A mainly in August, September and October, and epidemic hemorrhagic fever mainly from October to December and in February. Pearson correlative analysis shows that there are good correlations between the monthly cases of infections and monthly average values of meteorological elements. The above results indicate that climate factors play very important roles in the occurrence of infections.

Key words:

Climate warming; climate types; infectious diseases; spatial-temporal distribution; incidence of a disease

Shift in China's Agro-climatic Resource Inventory under Climate Change

Abstract

China's demand for grains has been growing rapidly and the growth is expected to continue in the coming decades. This leads to a great concern on future supply potentials of Chinese agriculture under climate change and the extent to which China would have to depend on world markets. An array of research results indicate that food crop's yield will reduce by the 2050s. However, these assessments only focus on single crops and neglect the improved multi-cropping opportunities induced by climate change, thus tending to over-estimate the adverse impacts of climate change on crop production. Here we provide an additional dimension of climate change impacts by focusing on the shift in China's agro-climatic resource inventory. Based on an assembling of 30 General Circulation Models under 4 Representative Concentration Pathways scenarios in the CMIP5 (Phase 5 of Coupled Model Inter-comparison Project), the results show that the extents of the multi-cropping classes in current cropland will move northwards and/or northeast-wards. This shift of multi-cropping zones creates significant increases in multi-cropping opportunities. And this significant increase in the production potential of China's agro-climatic resource base calls for technological and policy preparedness so that any newly emerging multi-cropping opportunities can be readily utilized in the decades to come. As more than 70% of China's current food production comes from irrigated fields, securing future irrigation water supplies and improving irrigation water use efficiency will be essential for exploiting future enhanced temperature regimes especially in north and northeast China.

climate change; multi-cropping; China's agro-climate resource

Variations of Leaf Phenology Sensitivity to Temperature in Northeast China and Mechanisms during the Past 40 Years

Junhu Dai¹, Yunjia Xu^{1, 2}, Huanjiong Wang¹ and Zexing Tao^{1, 2}

¹Key Laboratory of Land Surface Pattern and Simulation, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China

²University of Chinese Academy of Sciences, Beijing 100049, China

Abstract

Temperature sensitivity (S_T), a direct indicator of impacts of climatic change on plant phenology, measures to which degree plant phenophases respond to temperature changes. S_T reflects the relationship between climate change and plant phenology, and has been discussed as hotspot topic in recent phenological studies. In this study, we analyzed S_T variations in northeast China by using one of the most systematic phenological data set obtained in Mudanjiang, Heilongjiang Province, from China Phenological Observation Network (CPON). Leaf unfolding date (LUD) of 41 plant species in a mid-temperate mixed coniferous broad leaved forest, together with the corresponding meteorological data from 1978-2014 in Mudanjiang were collected for the analysis. The results show that LUD is sensitive to the average temperature of a certain period before phenophase onset for all the studied plant species, which is called the optimistic period (OP), ranging from 20 to 86 days (with a mean value of 45). The average S_T of LUD for all the plant species is $-3.2 \pm 0.48 \text{ days}^\circ\text{C}^{-1}$, which increased from $-3.14 \pm 1.17 \text{ days}^\circ\text{C}^{-1}$ during 1983-1997 to $-3.36 \pm 0.68 \text{ days}^\circ\text{C}^{-1}$ during 2000-2014. Of all the plant species, 56% show increasing S_T of LUD, and 49% ($P < 0.05$) are significant. S_T for 44% of the species exhibit decreasing trend, and 19.5% ($P < 0.05$) are significant. For different species, there is a significantly negative correlation between S_T and the OP length. Species with longer OP and later phenophase tend to show increasing trend of S_T , while species with shorter OP and earlier phenophase tend to display a declining trend for their S_T . By applying random sampling method, we can detect the relationship between different temperature parameters and S_T . It is shown that the standard deviation of pre-season temperature is the parameter influencing S_T of LUD most significantly.

Phenology; temperature sensitivity; random sampling; standard deviation

Korean Human Thermal Sensation for Beach Tourism

Park S¹, Tuller SE²

¹Jeju National University, Jeju, Republic of Korea, sooland@jejunu.ac.kr

²University of Victoria, Victoria, BC, Canada

Abstract

Climatic index for tourism (CIT) has recently been advanced which includes complete human energy balance models such as physiological equivalent temperature (PET) and universal thermal climate index (UTCI). This study investigated human thermal sensation at Woljung-ri beach, Jeju, Republic of Korea, in spring and summer, 2015. Microclimatic data measurements and human thermal sensation surveys from ISO 10551 were conducted together. 869 adults participated. As a result, perceptual and thermal preference which consider only physiological aspects had a high coefficient of determination (r^2) with PET in linear regression analyses: 92.8 % and 87.6 %, respectively. However, affective evaluation, personal acceptability and personal tolerance which consider both physiological and psychological aspects had low r^2 s: 60.0, 21.1 and 46.4 %, respectively. However, the correlations between them and PET were all significant at the 0.01 level. The neutral PET sensation range in perceptual was 25-27 °C, but PET ranges less or equal to 20 % dissatisfaction which was recommended by ASHRAE Standard 55 could not be achieved in perceptual. Only PET ranges in affective evaluation and personal tolerance affected by both aspects qualified with the recommendation as 21-32 °C and 17-37 °C, respectively. PET heat stress levels ranges on the beach were 2-5 °C higher than those in Republic of Korea inland urban areas. They were similar to high results in Taiwan and Nigeria, and higher than those of western/middle Europe and Tel Aviv, Israel.

human thermal sensation; human thermal comfort; climatic index for tourism; summer; beach; PET

Quantitative Evaluation of Agro-Meteorological Disasters in China

Du Huishi, Chen Zhiwen, Qi Ji, Zhang Shuang, Zhang Dongfang

Jilin Normal University, Siping Jilin, 136000, China, sdcwz4489@126.com

Abstract

Using the statistical analysis method on Chinese agro-meteorological disaster data during 1949 to 2012, the rate of meteorological disasters and their variance values are calculated. Thus, we assigned values to the various classifications of meteorological disasters. The grey relativity analysis method was used to compute the correlation of all types of meteorological disasters with the total amount of disasters and determine their impact on agriculture production weights. The objective of the analysis of the spatial-temporal variables of agro-meteorological disasters in China is to assess the degree of influence of meteorological disasters on agricultural production. Results showed that in the last 64 years, the average disaster impact rate of agro-meteorological disasters in China and the average rate of the various types of disasters indicate an increasing trend, with the average drought disaster rate growing the fastest at 0.98% every 10 years. Drought disasters have the largest effect on production weight and mainly affect the northern parts of China. In general, agro-meteorological disasters are at medium levels. In the last 10 years, the frequency of major disasters has increased. The research results in this paper provide a scientific reference for the analysis of the evolution of agro-meteorological disasters, agricultural disaster prevention and mitigation, food production, and yield stability.

Seasonal Plant Cover Dynamics of Degraded Grasslands in Inner Mongolia Recorded By Continuous Photography Technique

Xu X.^{1,2}, Liu H.^{1*}

¹ College of Urban and Environmental Sciences and MOE Laboratory for Earth Surface Processes, Peking University, Beijing, 100871, China

² Institute of Desertification Studies, Chinese Academy of Forestry, Beijing, 100091, China

Abstract

Recently, the influence of global change on the phenology of grassland has attracted more and more attentions of ecologists. Although dozens of controlled experiment have been conducted, there have been few records of phenology changes of grassland under different human interference. This study used continuous photography to record vegetation cover changes on plots for nitrogen addition and seasonal rainfall control experiments on grasslands along a degradation gradient. After extracting binary data from the photos with mathematic methods, we obtained variation trends of plant cover during the growing seasons for all plots. It is found that, after nitrogen addition, the increase rates of the plant cover in degraded grasslands enlarged obviously, but the increase rates in non-degraded grassland has not been influenced; seasonal rainfall control enlarged the differences between treatments, but the differences tended to disappear after the treatments were removed, while the non-degraded grassland was still not influenced significantly. The analysis of the image data revealed that, nitrogen addition could promote the increase rates of growth and further induced the increase in plant cover. Compared to the total biomass, the seasonal vegetation cover responses of grasslands to different treatments was more obviously. During these responses, the degrade status played a key role.

Abstract

Temperate Eurasian Steppe (TES) is a region with various environmental, social and economic stresses converged. Grazing activity is an important anthropogenic activity and disturbance to the grassland ecosystems in this region. However, because this activity is largely manipulated by human-being, the spatiotemporal trend of grazing consumption is difficult to be monitored and quantified properly. In this study, we try to map the regional grazing impact on carbon cycling by developing a statistics-process based scheme. The distribution of livestock is first determined by the prefecture/province inventory data. At this spatial level, the policy and cultural difference could be largely excluded. Then the regional spatial pattern of grazing consumption could be evaluated by integrating the process-oriental model of herbivore energy circulation model. The result from the year of 2008 indicated that grazing activity consumed about 2 TgC. In Mongol Steppe, the livestock are mainly located in the productive grasslands, but in Kazakh Steppe, the major livestock communities are distributed in the barren areas. The grazing consumption percentages from grassland NPP in Turkmenistan, Uzbekistan and Tajikistan were 15.8%, 9.8% and 3.7%. The corresponding percentages from NEP were up to 34.7%, 18.9% and 12.8% in the three countries. We further propose that this scheme could produce a pixel-based grazing map by incorporating an herbivore adaptive behavioral module. It could contribute to the accurate estimation of regional carbon budget, as well as the sustainable management of grassland resources.

Abstract

With global climate change in the extratropics, the 0°C isotherm will not disappear and associated precipitation events will continue to occur. The near-0°C temperatures should generally move poleward and arrive at many locations earlier in spring or later in autumn. This could potentially affect the seasonal cycle of near-0°C precipitation. The overall warming, together with a larger influx of the water vapor in the winter atmosphere from the oceans (including ice-free portions of the Arctic Ocean) can also affect the amount of near-0°C precipitation. The issue of near 0°C precipitation is linked with several hazardous phenomena including heavy snowfall/rainfall transition around °C; strong blizzards; rain-on-snow events causing floods; freezing rain and freezing drizzle; and ice load on infrastructure. In our presentation using more than 1,500 long-term time series of synoptic observations for the past four decades, we present climatology and the empirical evidence about changes in occurrence, timing, and intensity of freezing rains and freezing drizzles over four countries of Northern Eurasia and two countries of North America. In the former Soviet Union, instrumental monitoring of ice load has been performed by ice accretion indicator that in addition to the type, intensity and duration of ice deposits reports also their weight and size. Estimates of climatology and changes in ice load based on this monitoring at 958 Russian stations will be also presented. The work was supported by the Ministry of Education and Science of the Russian Federation (grant 14.B25.31.0026) and the NASA LCLUC Program.

Nonlinear Response of Streamflow to Climate Change in the Headwater Region of Nenjiang River Basin, Northeast China

Guangxin Zhang

The Northeast Institute of Geography and Agroecology (IGA), Chinese Academy of Sciences (CAS), Changchun, 4888 Shengbei Street, Changchun 130102, P. R. China, zhgx@iga.ac.cn

Abstract

Hydro-meteorological variation in headwater region have received considerable attention due to its significance in regulating water, reserving water and maintaining water balance in the whole river basin. This study investigates the response of streamflow to climate change in headwater region of Nenjiang River Basin (HNRB) using a novel data-driven method named Ensemble Empirical Mode Decomposition (EEMD), which is suitable for nonlinear and nonstationary signals. EEMD is here applied to decompose annual streamflow, temperature, precipitation and potential evapotranspiration record from 1961 to 2010 in HNRB. The reconstructed inter-annual and inter-decadal variability effectively revealed that the streamflow for HNRB changed nonlinearly over the years, namely the states of high and low water period appear alternately. The variation of streamflow showed anti-phase relationship with precipitation in different time scales (inter-annual, inter-decadal and trend variability), while exhibited anti-phase or in-phase relationship with temperature and potential evapotranspiration alternatively. Nonlinear decreasing in streamflow and precipitation and rising in temperature and potential evapotranspiration suggests a strengthening warm-drying trend in HNRB since 1980s, which necessitate more efficient regulation to manage water resources and meet the requirements of agriculture, wetlands and city water consumption in Nenjiang River Basin. Moreover, EEMD is proposed as a powerful method for extracting physically meaningful information from hydro-meteorological data.

Abstract

Global simulations have demonstrated the potential for profound effects of GCM-projected climate change on terrestrial ecosystems at all hierarchical levels. We developed large-scale bioclimatic models to predict progressions of potential vegetation zones (zonobiomes), forest types and major forest-forming conifers in Russia in the warming climate of the 21st century. Three bioclimatic indices (growing degree-days, base 5°C; negative degree-days, below 0°C, and a moisture index) and continuous permafrost (the active layer depth <2 m) were climatic drivers of our models. To provide a range of warming we used 16 AR5 GCMs for the B1, A1B, and A2 scenarios projected the smallest, medium and greatest temperature increases. All bioclimatic simulations were run by pairing our bioclimatic models with the bioclimatic indices and permafrost distributions for the baseline period 1960-1990 and decades of 2011-2020, 2041-2050 and 2091-2100. With these projected climates, the zonobiomes would need to shift far to the north to reach equilibrium with the change in climate. Under the warmer and drier future climate, most of Russia would be suitable for grasslands rather than for forests. Water-stress tolerant light taiga would prevail over water-loving dark taiga in new climates. Permafrost would not retreat fast enough to provide favorable habitats for all conifers except permafrost-tolerant *L. dahurica* that would remain the dominant conifer in the cryolithozone. Increased fuel accumulation and severe fire weather in warmer and drier climates would promote large, high-severity fires, which are expected to facilitate vegetation progression towards equilibrium with the climate.

Abstract

Uncertainties in global change and risks of climate extreme events in combination with the characteristics of complex and varied climate systems pose great challenges to natural resources and socioeconomic behaviour of China. Our research aims to systematically quantify impacts of water resources under different scenarios of policies on socioeconomic behaviour in China and to formulate adaptation to such impacts by integrating a dynamic water- computable general equilibrium (CGE) model.

Water, as a natural resource, is gradually becoming a limiting factor to societal and economic development. Based on the rules of water supply and demand and the law of market economy, this study puts water resources into the CGE model as an endogenous variable and analyzes the change of socioeconomic behaviour such as the gross domestic product and grain output affected by water resources constraint and relevant policies. This is a comprehensive study by taking water resources as an endogenous variable in every stage of production.

The simulation shows that the output and market price change more than expect as to policy only in water industry, for taking water resources as an endogenous variable conforms to the actual situation. In addition, when compared different scenarios of policies, the results show that they all can change water use structure and improve water use efficiency. However, policy has personalized impacts on sectors, especially agriculture and food processing. So government policy makers should be more cautious when make water policies.

Key words:

Water security; computable general equilibrium model; endogenous variable

Simulation Study on Indirect Climate Effects of Black Carbon Aerosol over Asian Monsoon Circulation and Precipitation

Zihao Lu

Nanjing University, Nanjing, 210046, P. R. China, luzihao@smail.nju.edu.cn

Abstract

Black carbon aerosol (BC) is one of the most important aerosol components in atmosphere. It is emitted directly at the source from incomplete combustion processes such as fossil fuel and biomass burning. Former researches find out that the indirect climate effect of BC aerosol is more significant than its direct climate effect, and the second indirect effect is more significant than its first indirect effect. It is meaningful and necessary to investigate the indirect climate effects of BC aerosol over Asian monsoon circulation and precipitation for China emitting high levels of BC and locating at typical Asian monsoon region. Here we first present numerical simulations on accessing the temporal and spatial variations of BC surface concentration, column burden, and optical depth (AOD); then investigated BC induced climate effects (including first indirect and second indirect) using a regional climate model coupled with a troposphere atmospheric chemistry model (RegCCMS). Hydrophilic BC aerosol acting as cloud condensation nuclei (CCN) results in higher cloud droplet number concentration, smaller cloud droplet size under the condition with fixed cloud water and low auto-conversion rate from cloud water to rain water. Due to BC total indirect effects, annual cloud mount and water increase while absorbed solar radiation, surface air temperature and precipitation decrease. Surface cooling and drying leads to less water vapor exchange between land and atmosphere. Additionally, indirect effects lead to summer rainfall drought, downdraft enhanced and atmosphere cooling over China mainland.

Key words:

numerical simulation; black carbon aerosol; Asian monsoon

Water Scarcity under Various Socio-economic Pathways and its Potential Effects on Food Production in the Yellow River Basin

Yin Y.Y., Tang Q., Liu X. C.

Key Laboratory of Water Cycle and Related Land Surface Processes, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, No. 11A, Datun Road, Chaoyang District, Beijing 100101, China, tangqh@igsnrr.ac.cn

Abstract

The Yellow River (YR) plays an important role in the development of the regional economy as the major source of freshwater. Increasing population and socio-economic development have put great pressure on water resources of the basin. The anticipated climate and socio-economic changes may further increase water stress. The water managers of the basin will face great challenges in meeting the human and environmental requirements for water. In this study, we assess water scarcity under climate change and various socio-economic pathways with an emphasis on the impact of water shortages on food production. The water demands in the 21st century are estimated based on the newly developed Shared Socio-economic Pathways (SSPs) and the renewable water supply is obtained from the climate projections under the Representative Concentration Pathways 8.5 scenario. The irrigated agriculture is assumed to have the lowest priority of all water consumers under water stress. The results show that the water demands, especially the demands in domestic and industrial sectors, will grow rapidly and put the middle and lower reaches in conditions of severe water scarcity from the next a few decades. As more water resources would be appropriated by domestic and industrial sectors, a portion of irrigated land would have to be converted to rain-fed agriculture which would lead to more than 13% reduction in food production under various socio-economic pathways. This study highlights the links between water, food and ecosystems in a changing environment and suggests that trade-offs should be considered when developing regional adaptation strategies.

Changes in Glacial Extent in the Tien Shan Mountains of the Kaidu River Basin, Northwestern China – Impacts to Water Resources

Lawson, Tracy, J. Chipman

Dartmouth College, daniel.e.lawson@dartmouth.edu

Abstract

Water resources in the Kaidu Basin are linked directly to runoff from glaciers within three sectors of the Tien Shan Mountains. Glacial runoff provides a seasonally important source of freshwater to the Bayinbuluke Wetland-Grassland conservation region, desert lowlands and Bosten Lake, especially during the dry season. Thus, changes in discharge over annual and decadal timespans affect water availability and management. Quantitative analyses of high resolution satellite imagery from the mid-1960's (Corona) compared to WorldView II imagery from 2012 to 2015 indicate significant reduction in glacial extent across the basin. Similarly, losses are evident on an annual basis in the recent imagery. Thinning and recession of the termini behind end moraines occupied prior to the 1960's has exposed overdeepened basins that are now filled with meltwater. These glacial lakes are increasing in size as the ice margin continues to recede and create a potential hazard if they were to drain catastrophically due to failure of the enclosing moraines or thru other mechanisms. The resulting glacial outburst floods (GLOF's) pose downstream risks to the infrastructure and importantly the local residents.

Key Words:

glaciers; recession; climate change; glacial runoff; glacial lakes; GLOF's; satellite imagery; water resource; glacial hazards

Caspian Sea Water Level Changes: Reasons and Effects

Haijun Deng, Yaning Chen*

State Key Laboratory of Desert and Oasis Ecology, Xinjiang Institute of Ecology and Geography, Chinese Academy of Sciences, Urumqi 830011, CHINA, denghj@ms.xjb.ac.cn

Abstract

The water level changes of inland waterbody are affected by climate change and human activities. In this study, we had analyzed the Caspian Sea water level changes based on the Caspian Sea water level data from 1992 to 2011, furthermore, reasons of the Caspian Sea level changes and its impact on the surrounding environment were also explored. The results are as follows: 1) the level of the Caspian Sea has exhibited a steady downward trend, dropping from -26.05 m in 1995 to -26.96 m in 2011 over the past 20 years; 2) the drop of Caspian Sea water level was mainly attributed to such factors, the decreasing precipitation, increasing temperature and increasing evaporation. 3) meanwhile, the sharp overall drop in terrestrial water storage in the Caspian Sea plains region had a close relationship with the drop in water levels in the Caspian Sea ($R^2_{adj}=0.866$, $p<0.01$) from 2003 to 2011; 4) the drop of Caspian Sea water level caused reduction of ground water and soil moisture in the Caspian Sea plains region, which led to the degradation of vegetation in this region. As a whole, the drop of Caspian Sea water level had negative effects on ecological environment in the Caspian Sea plains region.

Calibration of SCS Model Parameters about Boertala Riverin Xinjiang

WANG Jinjie, Ding Jianli, ZHANG Zhe, ZHANG Cheng

College of Resources and Environment Science, Key Laboratory of Oasis Ecosystem of Education Ministry, Xinjiang University, Urumqi, 830046, China, watarid@xju.edu.cn

Abstract

The water resource is the most important factor for socio-economic development on the background of global warmer, especially in arid regions. The Soil Conservation Service Curve Number (SCS-CN) developed by the U.S. Department of Agriculture National Resources Conversion Service (NRCS) is the most popular and widely applied model for direct runoff estimation. In this paper, using original SCS-CN model and after parameter algorithm improved SCS-CN model respectively to simulation the runoff. Compare the two model simulation accuracy to provide a reference for similar watershed runoff forecast. First time to use the 16m resolution remote sensing image about high-definition earth observation satellite "Gaofen-1" to provide a high degree accuracy data of the land use classification for SCS-CN to determine the curve number. This paper focus on Wen-quan basin and combines 18 rainfall events to simulation the runoff with before and after parameter algorithm improved SCS model. The simulation results show that the improved model is better than original model. Both of them in calibration and validation periods Nash-Sutcliffe efficiency were 0.79, 0.71 and 0.66, 0.38. And relative error were 3%, 12% and 17%, 27%. It shows that the simulation accuracy should be further improved and using remote sensing parameters information technology to improve the basic geographic data for the hydrological model has the following advantages: 1) Remote sensing data having a planar characteristic, comprehensive and representative. 2) To get around the bottleneck about lack of data, provide reference to simulation the runoff in similar basin conditions and data-lacking regions.

Key words:

runoff simulation; SCS model; remote sensing; improved algorithm of parameters

Case Study of Chinese City of Ganzhou on Hydrologic Management in Urban Drainage Basin

LIU C., SHENG K.

China Architecture Design Group, Beijing, 100044, P. R. China, 503958595@qq.com

Abstract

Nowadays, severe shortage of hydrologic resource and deterioration of hydrologic environment have been obstacles in urban sustainable progression. Improper management results in drawbacks of water resource and safety, including structural water shortage. This essay illustrates a case study on city of Ganzhou, one of 291 Chinese prefecture-level cities, which integrates model water treatments on various terrain in its 146 km² existing built up area and becomes a typical case of Lingnan area of China. Based on interviews and investigation with 23 local government departments, the study covers over 150 information of planning, construction schedule, implement evaluation etc., and explores partnership between government departments, enterprises and customers, for instance decision process, object and subject of water management, policy, technical standard, investment and operation. This essay attempts to optimize modes, which firstly classify management object forms, including rainfall, underlying surface, municipal network, water treatment facility, surface and underground water, secondly comb resource administration process of, for example, planning decision making, construction, operation and maintenance, and thirdly make suggestion on technical structural criterion and government ability building in aspect of standard and investment. They are likely to result in urban water resource management with governmental transparency, constructive normalization and cooperative functions, thus fulfill integrated hydrologic goal of quality, quantity and level in urban drainage basin.

Climate Observations Affected by Irrigated Agricultural Development Over Xinjiang, Northwest China

Songjun Han, QiuHong Tang, Di Xu

State Key Laboratory of Simulation and Regulation of Water Cycle in River Basin, China Institute of Water Resources and Hydropower Research, Beijing 100038, China, hansj@ihwr.com

Key Laboratory of Water Cycle and Related Land Surface Processes, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China

Abstract

Meteorological stations in Northwest China are surrounded by large proportions of cultivated land. The relations between observed climate change and the cultivated land fractions (CF) within a 4 km radius at 90 meteorological stations over Northwest China are investigated. Compared with the climate variation in the Tibetan Plateau where agricultural development is negligible, stations with low CF show similar variation, whereas stations with larger CF experience less surface warming, more rapid increase in near-surface atmospheric moisture, and larger declines in surface wind speed than stations with small CFs from 1960 to the end of 1990s, especially during the main growing season. However, the differences were conversed since the end of 1990s. The impacts on observed near-surface temperature, water vapor pressure, and wind speed are attributed to the irrigated agricultural development, which causing local near-surface atmospheric wetting and cooling, as well as increasing surface roughness. The findings suggest that the land use around stations should be considered when analyzing the observed climate changes in Xinjiang, and the local climate effects should be considered to improve regional projections of future agricultural water demand.

Effects of Land Use Pattern on Soil Water in Re-Vegetation Watersheds in the Loess Plateau

Yang Lei, Zhang Qindi, Chen Liding, Wei Wei

State Key Laboratory of Urban and Regional Ecology, Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences, Beijing, 100085, P. R. China, leiyang@rcees.ac.cn

Abstract

Soil water is a critical constrict factor to vegetation restoration in the arid and semi-arid Chinese Loess Plateau because of low rainfall and water scarcity. For decreasing soil erosion and improving environmental conditions, large-scale re-vegetation was initiated in this area in late 1990s. However, these activities may result in excessive water consumption and soil water deficit if no appropriate scientific guidance were offered. This in turn impacts significantly the regional ecological restoration and environmental improvement. In this study, 6 watersheds with different land use pattern were selected. Soil water content and its spatial variability in depth of 0-5 m were analysed based on field observation and geostatistical method. The results showed that: (1) Soil water drastically decreased by introduced vegetation when compared with traditional farmland and native grassland. Introduced vegetation consumed excessive amount of soil water and induced temporally stable soil desiccation. (2) The analysis of differences in soil water for different land use patterns indicated that the land use had significant influence on soil water and its spatial variability. Soil water content at watershed scale increased with the increasing area of farmland, and decreased with increasing area of introduced vegetation. Land use pattern determined the soil water condition and its spatial variation at watershed scale. (3) Large-scale re-vegetation with introduced vegetation diminished the spatial heterogeneity of soil water at different scales. The improvement of land use management was suggested to improve the water management.

Impact of GCM Structure Uncertainty on Future Streamflow Prediction: A Case Study in Tianshan Mountains

Gonghuan Fang^{1, 2, 3}, Jing Yang¹

¹State Key Laboratory of Desert and Oasis Ecology, Xinjiang Institute of Ecology and Geography, Chinese Academy of Sciences, Xinjiang, 830011, China

²Department of Geography, Ghent University, Gent, 9000, Belgium

³University of Chinese Academy of Sciences, Beijing, 100049, China

Abstract

Hydro-climatic effects of future climate change in the Tianshan Mountains (China) are strongly demanded by policy maker. GCM ensemble coupled with hydrological models is often used for this purpose. This paper investigated the impact of GCM structure uncertainty in hydrological impact studies in the Kaidu river basin, a typical watershed in the south slope of the Tianshan Mountains. A 21-member ensemble of General Circulation Models (GCMs) from the Coupled Model Intercomparison Project Phase 5 (CMIP5) under Representative Concentration Pathway scenarios (RCP4.5 and RCP8.5) were used as climatic input to the well calibrated hydrologic model (the Soil and Water Assessment Tool, SWAT). The results show that precipitation predicted by GCM ensemble will increase 3.4% - 13% and 6.8% - 22% and temperature will increase 2.0 °C - 3.3 °C and 4.2 °C - 5.5 °C respectively for the 25% and 75% quantiles under RCP4.5 and RCP8.5. The GCM ensemble projected streamflow will change by -26% - 3.4% under RCP4.5 and by -38% ~ -7% under RCP8.5. However, the simulated discharge forced by different GCMs can diverge widely, with prediction ranges often surpassing current discharge. For hydrological components, the proportion of snowmelt (SM) tends to decrease insignificantly but the timing will be pushed forward about 1-2 months. Evapotranspiration (ET) will increase substantially by 24% ~ 48%. The uncertainty sources of the streamflow projection were quantified using the standard deviation, and results show that uncertainty associated with GCM ensemble contributes the largest part.

Inter-Specific Variation in Nighttime Sap Flux of Three Shrub Species on the Semi-Arid Loess Plateau in China

Weiwei Fang, Nan Lu, Lei Jiao, Yu zhang, Bojie Fu

Research center for Eco-Environmental Sciences, Chinese Academy of Science, Beijing, 100085, China,

nanlv@rcees.ac.cn

Abstract

Nighttime sap flux (E_{night}) may be a significant factor in water budget of ecosystems. In order to identify how plants adapted drought stress according to change nocturnal transpiration, we examined the effects of soil moisture on nocturnal sap flux and the contribution nighttime sap flux to daytime sap flux (E_{daily}) of field-grown three shrub species (*V. negundo*, *H. rhamnoides* and *S. trilobata*) using sap flow gauges during June to September. E_{night} was 5-10% across the growing season in three shrubs, but up to 25.50%, 27.89% and 42.99% on some days after rainfall events for each of them, respectively. There were two main drivers of nighttime sap flow in the shrubs we investigated: nighttime micro-meteorology and soil moisture availability. The results showed that E_{day} and E_{night} was correlated with VPD and RH across growing seasons. E_{night} was more correlated with shallow soil moisture (80cm) than deep soil moisture (200cm) for *H. rhamnoides* and *S. trilobata*. The contribution of E_{night} to E_{daily} was increasing with soil moisture drier to a certain extent for each of them. The diurnal curves of leaf water potential and stomata showed different water relations among three species. Although sap flow methods have uncertainties as to the proportion of refilling and transpiration from the canopy, the difference leaf water potential between 06:00 am and 18:00 pm showed stem refilling existed in three species. Among three species, *H. rhamnoides* has a better adaptability to soil drought with its physiology attributes.

Land Cover Change and Water Management on the Tarim and Konqi River Systems, Xinjiang, China

Chipman JW, Magilligan FJ, Shi X, Chen Y, Li B, Winter J, Sneddon C

Geography Department, Dartmouth College, Hanover NH 03755 USA, jonathan.chipman@dartmouth.edu

Abstract

Water management practices and land cover change have dramatically altered the Tarim and Konqi river systems in western China. Among the most notable changes are a rapid expansion of irrigated agriculture and episodes of intra- and inter-basin water transfers. Using time-series of multispectral satellite images from Landsat TM/ETM+/OLI (1994 to 2015) and MODIS (2000 to 2015), we document the effects of these changes on the riparian zones of the two river systems, and on the broader surrounding landscape. Land cover classification of over 70 Landsat images shows that agricultural lands more than tripled in extent within the study area. Natural riparian vegetation experienced a more complex spatial-temporal pattern of change, with unmanaged riparian vegetation cover decreasing in some areas and increasing elsewhere. Spectral mixture analysis of sub-pixel fractional vegetation cover suggests that interbasin water transfers from the Konqi to the Tarim River resulted in an increase of near-channel riparian vegetation on the Lower Tarim and a loss of vegetation along the Lower Konqi. Finally, the temporally dense record of MODIS images revealed a heterogeneous pattern of increasing and decreasing greenness at the landscape scale, including the loss of vegetation in distal regions that were formerly subject to sporadic seasonal flooding but now may be cut off from their riparian water supply due to intensive water management practices. These results suggest that satellite remote sensing may play a valuable role in monitoring the effects of changing land use and hydrology on riparian systems in Central Asia and other arid regions.

Abstract

Inter-basin water transfer (IBWT) became a major means of Chinese government for dealing with regional water deficiencies. While the debate about the eventual outcome/consequence of IBWT has only gone increasingly intensive and extensive in the past two decades, empirical studies based on existent evidence, especially on the ecological outcome/consequence at a landscape scale, are very limited. The decadal water conveyances over the Tarim River in Xinjiang, China provide a valuable case. We identified four sub-regions that had played beneficiary, loser, contributor, and privilegee roles in the Tarim conveyance project, and studied the outcomes/consequences of the conveyances through examining the land cover change, as we consider the land cover change a sensitive response to and informative representation of the impact of a large-scale water management maneuver on both human and natural systems and their interactions, especially in an arid region that has been experiencing volatile climate change and rapid socioeconomic development. While the conveyances were ostensibly carried on to restore the natural ecological systems (particularly vegetation) along the lower reaches of the river, the intended and unintended, and expected and unexpected, outcomes/consequences of the project form a complex case for researchers and policy makers to examine and untangle.

Potential Impacts of AWarming Climate on Water Tower in Central Asia

Chen Y.N.

State Key Laboratory of Desert and Oasis Ecology, Xinjiang Institute of Ecology and Geography, Chinese Academy of Sciences, Urumqi, 830011, P. R. China, chenyn@ms.xjb.ac.cn

Abstract

The Tianshan Mountains, with its status as “water tower in Central Asia”, is generally a relative abundance of water, stored in the form of glaciers, snow and permafrost. Global warming accelerates the water cycle, which indicates a general prospective benefit for water availability. However, in regions where water resources are dominated by glacier and snow melt from mountains, the availability is more complicated. Over the past half century, temperature rose fastest in Middle and East Tianshan Mountains, while only slightly increasing in West Tianshan Mountains. Precipitation had clear increasing trends in the western and northern parts of the Tianshan Mountains. The rapid warming affected precipitation fraction as well as snowpacks, glaciers, and total water storage. The ratio of snowfall to precipitation (S/P) experienced a downward trend, along with a shift from snow to rain. Spatially, the snow cover area in Middle Tianshan Mountains decreased significantly, while that in West Tianshan Mountains increased slightly. Approximately 97.52% of glaciers in the Tianshan Mountains showed a retreating trend, which was especially obvious in the North and East Tianshan Mountains. However, the retreat rate in 2000-2010s was slower than the rate in 1960s-2000 in the western part of the Tianshan Mountains. The total water storage in the Tianshan Mountains also experienced a significant decreasing trend in Middle and East Tianshan Mountains, but only a slight decreasing trend in West Tianshan Mountains at an average rate of -3.72 mm/a , which indicated the ‘water tower’ had lost about $-2.23 \times 10^8 \text{ m}^3/\text{a}$ in just 10 years.

Raster Cell-Level Wetland Assessment Using Support Vector Machines

Zhaohui Yang, Junwu Bai, Zhihui Chen, Qun Su

Suzhou University of Science and Technology, Suzhou, 215009, China, Zhaohui-Yang@outlook.com

Abstract

We present a raster cell-level wetland assessment approach based on the wetland-environment model, which is built with support vector machines (SVM). Firstly, remote sensing data, GIS data and field data were retrieved and processed. After selected by the local experts, the environmental factors, which include landscape-level factors (i.e., water body density, road density, tourist density, urban area density, vegetation screening index, ground surface temperature index) and field-level factors (i.e., bird observation index and water quality index), were calculated at raster cell level from above data. Secondly, combining the landscape-level factors (as input of feature vectors) and field-level factors (as output of reference results) at corresponding cell location, samples of training set were obtained. Finally, using above samples, the wetland-environment model for wetland assessment was built by using SVM, which could deal with the problems of imprecise, uncertain, and scarce field data, a common difficulty in wetland assessment. After training and testing, the output at any given raster cell, which indicate the wetland condition at that cell location, were predicted rapidly and precisely using the trained wetland-environment model. To illustrate our approach, we implemented an assessment of the wetlands in Suzhou, China as a case study. An overall accuracy of 80% was achieved in identifying output of assessment ranks using the SVM wetland-environment model. The experimental results indicate that our approach can be an efficient and cost-effective way for managers to assess wetlands at raster cell level.

Recent Rises of Global Terrestrial NPP and Evapotranspiration Suggested An Increased Risk of Drought

Li Z.¹, Wang Y.²

¹State Key Laboratory of Desert and Oasis Ecology, Xinjiang Institute of Ecology and Geography, Chinese Academy of Sciences, Urumqi, 830011, P. R. China, liz@ms.xjb.ac.cn

²College of Pratacultural and Environmental Sciences, Xinjiang Agricultural University, Urumqi, 830052, P. R. China, ktwangyang@163.com

Abstract

The past decade has been the warmest in the instrumental record (2000-2014). Overall, the global inter-annual series of net primary production (NPP) slightly increased in 2000-2014 at a rate of 0.06 PgC/yr^2 . More than 64% of vegetated land in the Northern Hemisphere showed increased net primary production, while 60.3% of vegetated land in the Southern Hemisphere showed decreased trend. Vegetation feeds back to the spatio-temporal characteristics of climate through evapotranspiration. NPP correlates positively with land actual evapotranspiration (ET), especially in the Northern Hemisphere, where the increased vegetation productivity (0.13 PgC/yr^2) promotes decadal rises of ET (0.61 mm/yr^2). However, anomalous dry conditions led to reduced vegetation productivity (-0.18 PgC/yr^2) and nearly ceased growth in ET in the Southern Hemisphere (0.41 mm/yr^2). To understand why climates in the northern and southern hemispheres respond differently to NPP, the results showed that temperature is the dominant control on vegetation growth in the high latitude in the Northern Hemisphere, while net radiation is the main effect factors to NPP in the mid latitude, and in arid and semi-arid biomes also mainly driven by precipitation. While in the Southern Hemisphere, NPP decreased because of warming associated drying trends of PDSI. In addition, potential evapotranspiration (PET) as a surrogate measure of atmospheric moisture demand, with an increasing trend overpassed the precipitation in the past 15-year record. It indicates some moisture deficit between available water demand and supply for evapotranspiration. Drought indices and precipitation-minus-evaporation suggested an increased risk of drought in the present century.

climate change; net primary production; evapotranspiration; soil moisture; PDSI

Spatiotemporal Climate Change Features and Trends in Tibet Plateau

Qihu Li

xi'an university technology and science, liqihu1@126.com

Abstract

Temperature and precipitation time series datasets from 1961 to 2013 at 71 meteorological stations were used to reveal the spatial and temporal trends of climate change in Tibet Plateau, China. Annual and seasonal mean air temperature and total precipitation were analyzed using Mann-Kendall (MK) test, inverse distance weighted (IDW) interpolation, and R/S methods. The results indicate that: (1) both temperature and precipitation increased in the past 45 years, but the increase in temperature is more obvious than that of precipitation; (2) for temperature increase, the higher the latitude and the higher the elevation the faster the increase, though the latitude has more influence on the increase. Northern Tibet Plateau shows a faster warming than the southern Tibet Plateau, especially in the summer; (3) Increase of precipitation occurs mainly in the winter in northern Tibet Plateau, although both temperature and precipitation increased in general, the increase is different inside Xinjiang; (4) Hurst index (H) analysis indicates that climate change will continue the current trends.

Climate change

Extraction of Terrace in the Loess Plateau Based on Radial Method

Liu W, Li FY, Li CR

Nanjing Normal University, Nanjing, 210023, China, lifayuan@njnu.edu.cn

Abstract

The terrace of the Loess Plateau is a kind of typical artificial landform and an important measure of soil and water conservation. Former researches of terrace extracting using remote sensing images show both advantages and disadvantages. Fourier transform method can recognize terrace and find accurate position from frequency domain image, but it is more affected by the linear objects in the same direction of terrace. Texture analysis method is simple and has a wide range application of image processing, but this method is unable to recognize terraces' edge. Object-oriented is a new method of image classification, but when introduce it to terrace extracting, fracture polygons will be the most serious problem and it is difficult to explain its geological meaning. In order to positioning the terraces, we use high- resolution remote sensing image to extract and analyzes the gray value of the pixels which the radial went through. During the recognition process, we firstly roughly confirm the position of peak points; secondly, taking each of the peak points as the center to make radials in all directions; finally, extracting the gray values of the pixels which the radials went through, and analyzing its changing characteristics to confirm whether the terrace exists. For the purpose of getting accurate position of terrace, terraces' discontinuity, extension direction, ridge width, image processing algorithm, remote sensing image illumination and other influence factors were fully considered when designing the algorithms.

terrace, extraction; radial method; remote sensing images

The Shrinking Glaciers in the Central Tien Shan Mountains During 1977-2013

Xianwei Wang, Huijiao Chen

School of Geography and Planning, Sun Yat-sen University, Guangzhou, China, xianweiw@vip.qq.com

Abstract

The Tien Shan Mountains are known as the water tower of the arid Central Asia. The mountain glaciers are rapidly retreating under the context of global and regional warming. Many works have been done to analyze the retreating rate of glacier areas and volume against individual glaciers. However, it is challenging to obtain an accurate estimate of the entire glacier extent at the regional scale due to cloud issues and the similar spectral signature of snow and glacier. This study develops an object-oriented classification to map the glacier extent by using landsat images, and then compared the glacier areas with those derived from other research groups and institutes, such as the CGI1, CGI2, GCL2000, WGI, ESA inventory. Our results show that our objected-oriented classification performs better than the regular classification methods, such as the supervised classification with maximum likelihood, band ratio method, snow index method, and so on. Summer snowfall events on the high mountains lead to greatly over map the glacier extent. After carefully selecting the timing of the landsat images and adjusting the glacier extent overestimated due to snow cover, our mapped glacier extent is much smaller and illustrates more reasonable decadal variations than other products. The glacier area shrank by 29% since 1977, with a mean change rate of -7.2% per decade. The shrinking glacier makes this area facing severe challenging for sustainable water supply in the future.

Abstract

Changes in precipitation could have crucial influences on the regional water resources in arid regions such as Xinjiang. It is necessary to understand the intrinsic multi-scale variations of precipitation in different parts of Xinjiang in the context of climate change. In this study, based on precipitation data from 53 meteorological stations in Xinjiang during 1960–2012, we investigated the intrinsic multi-scale characteristics of precipitation variability using an adaptive method named ensemble empirical mode decomposition (EEMD). Obvious non-linear upward trends in precipitation were found in the north, south, east and the entire Xinjiang. Changes in precipitation in Xinjiang exhibited significant inter-annual scale (quasi-2 and quasi-6 years) and inter-decadal scale (quasi-12 and quasi-23 years). Moreover, the 2–3-year quasi-periodic fluctuation was dominant in regional precipitation and the inter-annual variation had a considerable effect on the regional-scale precipitation variation in Xinjiang. We also found that there were distinctive spatial differences in variation trends and turning points of precipitation in Xinjiang. The results of this study indicated that compared to traditional decomposition methods, the EEMD method, without using any a priori determined basis functions, could effectively extract the reliable multi-scale fluctuations and reveal the intrinsic oscillation properties of climate elements.

ensemble empirical mode decomposition; precipitation; nonlinear characteristics

The nonlinear variation of runoff and its response to climate change in Yihe River, East China

Li Baofu, LianLishu

College of Geography and Tourism, Qufu Normal University, Rizhao, 276826, P. R. China, ibf@mail.qfnu.edu.cn

Abstract

The nonlinear variations of runoff in Yihe River during 1951-2013 and its relations to Pacific decadal oscillation (PDO), El Niño-Southern Oscillation (ENSO), temperature and precipitation phase changes from multi-scale were detected by using linear regression, Mann-Kendall test and ensemble empirical mode decomposition (EEMD) and Pearson correlation analysis method. Results show that the runoff shows a significant linear downward trend during 1951-2013, with the rate of $3.33 \times 10^8 \text{ m}^3/10\text{a}$. However, before (after) 1976, the runoff shows a significant downward (upward) trend. Runoff also exhibited a nonlinear variation trend from inter-annual scale (quasi-3 and quasi-6-year), inter-decadal scale (quasi-13-year) and multi-decadal scale (quasi-31-year). The variance contribution rate of components from inter-annual scale was largest, reaching 58%, and that from inter-decadal scale and multi-decadal scale was 6% and 11%, respectively, which indicates that the inter-annual change had a strong influence on the overall runoff change. Results also implied that the effect of climate factors (PDO, ENSO, temperature and precipitation) on runoff in multi-decadal variability scale are more important than that in the other scales, which indicates that the impact mechanism of climate factors on runoff in different scales has obvious differences.

Key words:

runoff; nonlinear variation; different scales; climate change

The Impact of Climate Change and Human Activities on Vegetation NDVI Change in Yulin, China

Tao Wang

Xi'an University of Science and Technology, Xi'an 710054, China

Abstract

NDVI (Normalized Difference Vegetation Index) is an important index of describing and reflecting the condition of vegetation cover in the land surface, and it is also an important reference of regional ecosystem stability. Climate change and human activities are the two important driving forces of ecological environmental change currently, especially of vegetation cover change, which showed the sensitivity of NDVI to climate change and human activities. Yulin area located in the northwest of China, where is the transition zone of monsoon and non-monsoon region, is a typical fragile ecological environment and vegetation cover is strong influenced by climate change and human activities. To evaluation and understanding of the process of the impact of climate change and human activities on vegetation ecosystem scientifically, is helpful to develop and implement policies on ecological environment protection and human activities constraints. In this paper, we analyzed the impact process of climate change (temperature and precipitation change) and human activities on vegetation NDVI change, on the basis of 16d synthetic MODIS NDVI images with 250m resolution from 2000 to 2015, daily temperature and precipitation data from 2000 to 2014 in 10 weather stations of Yulin and its surrounding region, and urban or town distribution, combined with linear trend method, correlation coefficient, partial correlation coefficient and buffer analysis method. The aim of this study is to propose regional ecological environment protection and construction policies scientifically, and to establish the scientific basis of regional social-economy-ecology-environment development, through understanding the relationship between vegetation NDVI, and climate change, human activities.

giorgia.prati@soton.ac.uk

Abstract

The growing interest in the climate change-migration nexus has largely focused on understanding how migration patterns change as a response to climate variability. The feedback process of such response on individuals' capacity to cope with climate stresses is rarely explored and little is known about its interconnections with gender. Yet, migration and adaptation are not gender-neutral processes. This research seeks to investigate how migration shapes gender and power relationships and how this, in turn, affects women's adaptive capacity and wellbeing in the home villages. The study draws on field research conducted in the Mahanadi delta as part of the 'Deltas, Vulnerability and Climate Change: Migration and Adaptation' (DECCMA) project. In contrast to traditional approaches which have focused on the binary analysis of men vs. women, this research is innovative in that it takes an intersectionality approach to contextualise vulnerability in the broader spectrum of social identities and hidden forms of oppression in which it is embedded. Therefore, inequalities are explored as arising from the dynamic intersection of gender, class and caste. Gender identities, relations and power are continuously renegotiated through migration processes with consequences on some of the social and cultural barriers to adaptation. If we are to understand the differentiated impact, as well as potential, of migration on the adaptive capacity of those who remain behind, then we need to investigate how migration interacts with intersectional inequalities. The study has policy implications for local as well as global policymakers and practitioners.

Geographies of Dispossession to Repossession in context of Climate Displacements- Revisiting 'Bhoodan Movement'

Sonali Narang

Panjab University, Chandigarh India, snarang68@gmail.com

Abstract

The impact of Climate migration in South Asia will lead to geographies of dispossession of land and create 'spaces of exception' and 'spaces of exclusion'. Such dispossession will create new 'global souls' [climate Refugees] and new social-cultural geographies of identity determined and organized on the basis of catastrophic climatic events. The momentous rejoinder to climate change will require sacrifices, strong regional Institutions with accurate governance and cooperation across borders. Hitherto, the land management policies of the State in South Asia have failed in supporting the commons and the livelihoods options of the citizens and non-citizens alike. With emerging discourse of climate change new land management policies are indispensable that will further demand committed leadership and powerful regulation. The goal of this paper is to analyse the relevance of Bhoodan movement as an institution to govern the common property management and the use of natural resources in a sustainable way. It is a process of receiving land as a gift, distribution of land to landless and plans for construction and management of land. This paper will further look into how this concept can be used inter-state or intra-state within South Asia as 'geographies of repossession' towards climate displaced community? Can this be applied to Climate refugees and understand that whether it would be able to provide land and dignity to millions who will be crossing edge in search of protected lands and livelihood? Can this have filled hope to those who are dispossessed, disadvantage and homeless in their struggle against Climate geographies?

Livelihood Vulnerability in Coastal India: Applying the Vulnerability Index in Bhitarkaniak Wildlife Scantuary, Odisha, India

Biswal Sonalee

Jawaharlal Nehru University, New Delhi, 110067, India, biswalsonalee@yahoo.co.in

Abstract

Vulnerability can be defined as the degree to which a person or a community is likely to experience harm due to exposure to external stress. Vulnerability assessment describes a diverse set of methods used to systematically integrate and examine interaction between human and their physical social surroundings. A livelihood is environmentally sustainable when it maintains and enhances the local and global assets on which livelihoods depend. The Sustainable Livelihoods Approach, looks at five types of household assets; natural, social, financial, physical and human capital. It is a method to design and develop programme at community level. In this paper livelihood vulnerability index is prepared to estimate differential impact of climate change on two different set of villages whose livelihood depends on natural resource. One set of village is taken from buffer zone of Bhitarkanika Wildlife Sanctuary consisting of four villages and 148 households. The other set of village is from the transactional zone of the study area consisting of four villages and 152 households. Overall 300 households are surveyed for the analysis. The different socio-economic and developmental context of each area allows for spatial comparative analysis. An extensive analysis of all the eight sample villages of Bhitarkanika Wildlife Sanctuary is done. The above test is done to see the Livelihood Vulnerability Index (LVI) for agriculture and natural resources dependent communities in developing countries.

Participatory Approaches for Disaster Risk Reduction: Case Studies

From Uttarakhand and Odisha, India

Fanchiotti, M

University of Southampton, Southampton, UK, m.fanchiotti@soton.ac.uk

UNESCO, Paris, France, m.fanchiotti@unesco.org

Abstract

Community participation has become unanimously recognised as a key factor for successful disaster risk reduction on the grounds that a merely top-down approach to disaster risk management, through which decisions are taken by the government or experts without any involvement of the people who are directly exposed to disaster risk, often fails to capture local needs. Community-based approaches to disaster risk reduction have then emerged as a way to better understand and address local capacities and vulnerabilities and to complement institutional efforts through an inclusive and participatory process. India is one of the most disaster-prone countries in the world and the Indian states of Uttarakhand and Odisha are at particularly high risk due to their high exposure and vulnerability to natural hazards. The magnitude and impact of past hazardous events have often challenged the existing institutional structure to the extent that several spontaneous initiatives have taken place in support or integration of governmental action. This paper presents major findings from two studies from the author, which were conducted in selected communities of Uttarakhand and Odisha respectively. The first study, in collaboration with UNESCO-IHE and UNESCO, aimed to investigate social vulnerability and risk perception in six communities in the Rudrapur district of Uttarakhand following the destructive flash floods and landslides of 2013. The second study is part of the 'Deltas, Vulnerability & Climate Change: Migration & Adaptation' (DECCMA) project and looks at understanding community resilience in selected communities of the Kendrapara district of Odisha in an effort to empirically investigate the attributes of disaster resilience in the study area through active community participation. Common findings from both studies show that, while the legislative and policy frameworks for disaster risk reduction in the country are well-founded, gaps in their enforcement at the operational level and delays in the required decentralisation and deployment pose significant limitations to their effectiveness. In practice, there has been little involvement of communities in risk reduction so far. The level of risk awareness among the general population is high, but major issues in proper risk communication and information dissemination by competent bodies have been reported. The need to put more efforts in the direction of risk prevention and of a systematic approach to community-based disaster risk reduction have emerged from both studies.

⁴Department of Geography, University of Utah, USA

Abstract

The rapid pace of urbanization in India has significantly increased the vulnerability of urban areas to the dangers of climate change as well as and other natural hazards. Characterizing social vulnerability of urban areas should provide a reference for urban risk management. We have developed a Composite Urban Vulnerability Index (CUVI) for India's urban areas by integrating 13 indicators from three aspects (exposure, sensitivity, and adaptive capacity) that shape the vulnerability of a society. The spatial-temporal patterns of social vulnerability of urban areas and its changes over three periods (2004-05, 2009-10, and 2011-12) are identified and mapped. The analysis reveals that social vulnerability has declined considerably over the study periods at national level. There is clearly a heavy concentration of social vulnerability in central and eastern states, such as Madhya Pradesh, Chhattisgarh, Orissa, Jharkhand, and West Bengal, attributable largely to the high levels of poverty, inequality, and problems relating to unemployment, housing, and access to basic civic amenities like safe drinking water and sanitation. Only the urban populations in relatively prosperous Northern and Southern states are relatively less vulnerable to climate change. The results signify that while social communities in urban areas across India are, in general, developing resilience to climate change, large contrasts exist, attributing to the socioeconomic and geographical differentiation among States.

Vulnerable Tribal Spaces: Sites for Development and Destruction of Developmental Ethics- A Study of Sardar Sarovar Dam, Gujrat, India

Arya, J.M., Jagmohan, A.M.

B.R. Ambedkar College, University of Delhi, Delhi.INDIA-110053 jmanjana@yahoo.com

Abstract

Development seems to be the ‘mantra’ in today’s fast moving Indian economy. Sardar Sarovar dam being built over river Narmada, is a classic example of how development for a few in India, is a life threatening and life turning event for the lakhs of people displaced because of it all of them tribals. The Dam & canal network on river Narmada is spread across 4 states and includes 30 large, 135 medium, 3000 small dams. 40,000 hectares of land shall be submerged in the reservoir while 250,000 indigenous people or the ‘adivasis’ or the tribals are being displaced. These are the already disadvantaged sections of the society the Scheduled Tribes. A large number of them do not have any legal title to the land off which they lived. So they cannot even take the legal recourse for compensation of any kind. A majority of people have been left landless and without livelihood and no bargaining power over their fate.

The oustees of the project include: The “Project Affected Persons” - those who are in the submergence zone and also those whose lands have been acquired for construction of canal; Those who do not directly come under the above but whose livelihood directly depends on the environment which shall be submerged/ a canal shall be built on it; Those whose livelihood depends on the downstream fisheries, etc.

These are people who have been forced to become environmental refugees. It seems highly unlikely that these environmentally displaced people, even with the aid of the resettlement scheme, will be fully rehabilitated to the standard of living which they were enjoying prior to the development project. This, of course, has ethical implications for this development. Development is supposed to be beneficial. It is supposed to be the creation of a better life. Within the context of a nation, the state is supposed to be committed to the development of the people as a whole. It has a responsibility to ensure an equitable distribution of the costs and benefits of development projects, especially when they are state projects. Yet the benefits accrue only to those who are better off in the society.

A personal research was conducted in the areas of rehabilitation and resettlement. This included a preprinted questionnaire having questions about the quality of life, fulfillment of promises, involvement in site selection and in decision making, and problems faced by the women etc.

The survey brought out many inferences but also brought into focus many points to ponder over: why zero involvement of locals in decision making; Who owns the natural resources? Is urbanization the only way of development? Why is there so little development using local resources?

Key words:

Development; developmental ethics; vulnerable people

Inequality of Economic Impact from Drought: Modelling Profit Loss Rate in Sugar Industry in Southwest China

Lin L., Wang Y., Chen H.

Academy of Disaster Reduction and Emergency Management, Beijing Normal University, Beijing, 100875, P. R. China,
linle@mail.bnu.edu.cn

Abstract

As a consequence of global climate change, possibility of extreme weather events in southwest China has increased in recent decades. Severe droughts cause great loss to local society and lead to unequal impact on different groups when coupled with their internal socio-economic attributes. This research tries to build an assessing model of drought impact on sugarcane growers and sugar company, which focuses on the generation and transfer mechanism of disaster economic impacts along a simple value chain and the reason why inequality of impact merged under local conditions for coping with droughts. A perspective of profit loss rate is applied to scale economic impact. By using scenario analysis “with and without” disaster, profit loss is defined as the difference in profits. The time series of sugar price “without” disaster is obtained, using an autoregressive error model to separate impact of disasters from the internal trend in sugar price which can be identified by linear regression analysis. Representative sugar prices, which represent value level in disaster-free conditions and disaster-hit conditions, are integrated from a long time series that covers the whole period of drought. As a result, it is found that in a rigid farming contract, sugarcane growers suffer far more than the sugar company when impacted by severe drought and sensitivity analysis of the model reveals that sugarcane purchase price has a significant influence on profit loss rate. This research provides reflections on some economic measure used to tackle with droughts and the unequal nature in it.

A Study of Challenges of Women Empowerment in Haryana, India

Rani S

Post Doctoral Fellow, University of Delhi, ICSSR, and New Delhi, geo.sangeeta@gmail.com

Abstract

Our empirical studies in the context of highly skewed sex ratio in the state of Haryana have made us believe that women from early to middle of their reproductive ages have no sway in the matters of their body, pregnancy, health and fate of foetus in their womb whether it would survive or not. We are convinced that instrumental empowerment initiatives cannot change the situation. Therefore, with view that empowerment is achieved when women have rights to choose from choices in the course of their life course be it education, profession, marriage, health, number and gender of offspring and so on. It has led us to adopt an agent-based phenomenological study of girls and women to understand the issues and challenges from their experience. Out of 70 rural sample subjects, about 47 were found and out of 30 urban samples about 23 have been found useful as the rest were lacking due to adolescent or children recording or detection of recording. On analysing essences of the recorded transcripts, we reached the conclusion that it is patriarchy reinforced by socio-economic conditions that let not break the vicious circle of patriarchy which they hate at the core of their heart and need widespread awareness and mobilisation by feminists NGOs to emancipate themselves from the shekels patriarchy.

Early and Exclusive Breastfeeding Among Women in Bihar and Maharashtra (India)

Ajit Kumar Yadav, Simrit Kahlon,

Dept. of Geography, Panjab University Chandigarh (India), ajitky003@gmail.com

Abstract

This study deal with early and exclusive breastfeeding among women in Bihar and Maharashtra. Exclusive breastfeeding means that the infant receives only breast milk. No other liquids or solids are given – not even water – with the exception of oral rehydration solution, or drops/syrups of vitamins, minerals or medicines (WHO 2013). Breastfeeding is important for young child survival, health & nutrition. Further, breast feeding serves as one of the child spacing methods, which is especially important in developing country like ours where the awareness, acceptability & availability of modern family planning methods are very low (Yadavannavar and Patil, 2011). Early breastfeeding is an important family health intervention, if implemented widely, it can reduce neonatal mortality rate by 20 percent (Mullany et al. 2008). Population Council's study reveals that a little more than a third (36%) of women in rural Bihar initiated breastfeeding within one hour of birth of their child (Aruldas et al. 2012a). The CES-2009 report shows that only 17 percent newborns were breastfed within one hour after birth as compared to the national average of 34 percent (UNICEF 2010). Although Breastfeeding is universal in India, but exclusive breastfeeding practice rates are not satisfactory. In a study in Rajkot, the Prevalence of exclusive breastfeeding at 6 months of age of infants was found to be 62% (Chudasma *et al.* 2014). Furthermore, as per the (NFHS-3) third round, only 69 percent of children fewer than two months of age are exclusively breastfed, which further drops to 51 percent at 2-3 months of age and 28 percent at 4-5 months of age (NFHS-3). There are numerous socio-cultural barriers which potentially may affect the breastfeeding practice. Among all, beliefs like the first milk are not good or there is no secretion of milk in first three days result in practices like discarding colostrums and promoting pre-lactating feeds. Such practices increase the risk of infections and deprive the valuable benefit of colostrums feeding to the vulnerable neonates (Palestinian Family Survey, 2010). This issue becomes an area of concern since large numbers of babies born in India are low birth weight whereas exclusive breastfeeding for the first six months is viewed as the single-most effective intervention among other preventive interventions.

Key words:

Early breastfeeding; Exclusive breastfeeding

Fuelling Urban and Middle Class Kitchen and Gender(ed)dynamics of LPG Subsidy**Shiv Narayan Sidh**

Assistant Professor of Geography, Government College, Gairsain, Chamoli, Uttarakhand & Currently pursuing research at Centre for the Study of Regional Development, Jawaharlal Nehru University, New Delh, shivsidh@gmail.com

Abstract

Access to affordable and clean energy is key to the sustainable energy security of the nation. Local availability makes biomass as preferred fuel for cooking in rural India. In order to reduce the reliance on biomass fuel, government of India has been providing LPG/PNG at subsidised rate to its people. However almost in entirety LPG/PNG subsidies are cornered by the urban areas and rural rich. Analysis of data from Census of India 2011 reconfirms the above stated statement. There are spatial pockets of concentrated usage of LPG/PNG. Developed (relatively) states and urban India have benefited more than the Indo-genetic belt, central tribal and hilly regions of India. Within urban India, million plus cities are biggest beneficiaries. By curtailing subsidy, government of India will be able to reduce the subsidy burden but is risking the marginal people (Women, urban poor, people and just above poverty line). Paper argues that there should be policy support to address the issue of indoor air pollution and transfer of cash should be made in the name of women rather than the head of the household. Alternatively, government should promote and utilise the savings from LPG subsidy for renewable energy such as biogas, and solar energy.

Key words:

LPG subsidies; gender; indoor air pollution

Living Arrangement, Family Support and Social Capital as Determinants of Health and Wellbeing Among Elderly Widows in India

Jain N., Pal K.

International Institute for Population Sciences, Mumbai, India, n4nidhijain@gmail.com

Abstract

In coming decades, population ageing is likely to have serious policy and programmatic implications in developing countries including India. However, there is one section in India that face restrictions and stigma along with other difficulties that comes with ageing – widows. With rapid modernization of Indian society, the scenario of long considered support system of elderly is changing rapidly and elderly widow experience the brunt of this change the most. Thus the aim of study is to assess the effect of living arrangement, family and networking ties on health and wellbeing of elderly widows. Study used data from the large scale project of ageing named “Building Knowledge Base on Aging in India” conducted by ISEC, Bangalore and IEG, Delhi in sponsorship of UNFPA, India. Regression analyses were used to show the effect of social determinants on the health and wellbeing of elderly widows in India. In the sample 60% women aged 60 years and older were widowed. Almost 15% of elderly widows lived alone and out of these 43% stated ‘children away’ as the reason for living alone. The most common social activity among elderly widows was to attend religious programmes. Almost 23% did not have anyone confidante. Living with children, perceived importance from family, satisfactory communication with children were found to be associated with positive health and wellbeing among elderly widows in India. As India continues to experience demographic and health transition, this is a need to critically think about the informal and formal social support system for elderly widows.

Perils of Women Trafficking: A Case Study of Joynagar, Kultali Administrative Blocks, Sundarban, India

Das K

University of Calcutta, Kolkata - 700019, India, karabidas139@yahoo.in

Abstract

The Indian Sundarban, comprising of 19 community development blocks (6 in North 24 Parganas and 13 in South 24 Parganas) is physiographically a deltaic plain, having an intricate network of creeks and is ravaged by natural hazards like Tropical cyclones. The inhabitants of Sundarban are primarily involved in agriculture (monocropping due to increased salinity), aquaculture and collection of non timber forest products and thus do not enjoy adequate income. An ill effect of globalization, trafficking means the trade of humans for the purpose of sexual slavery, forced labor or commercial sexual exploitation of the victim. It is now dominated by organized traffickers who lure young girls by making fake promises of love, marriage and lucrative job offers. Kultali and Joynagar of Indian Sundarban are highly vulnerable to hazards due to their close proximity to river Matla to the east and Bay of Bengal to the south. For this paper, data of women trafficking was collected from police department. Cartograms based on the data have been produced. Analysis of records over the years 2008 – 2015 shows that mostly young girls of age group of 15 – 18 are trafficked in Kultali and girls of age group 15 – 20 are trafficked more in Joynagar. Radhaballavpur, Sankijahan and Beledurganagar show highest number of cases. No definite trend could be seen for Kultali while Joynagar shows increasing trend. Poverty, illiteracy and disasters play pivotal roles in case of trafficking here. Spread of women education and interplay of Government and NGO is necessary to prevent trafficking.

Key words:

Trafficking; Natural Hazards

Socioeconomic Inequality in Utilization of Maternal and Child Health Services in India: A Decomposition Analysis

Pushpendra Kumar, Prof. B. Paswan

Doctoral Candidate, International Institute for Population Sciences (IIPS), Mumbai, India,

Pushpendra.geo@gmail.com

Professor and Head, Department of Population Policy and Programme, IIPS, Mumbai, India, bpaswaniips@gmail.com

Abstract

In India large differentials found in utilization of maternal and child health services despite from several Government programme efforts such as, mother-child health care scheme, National Rural Health Mission (NRHM), Janani Suraksha Yojana (JSY), The Mahatma Gandhi National Rural Employment Guarantee Act (MGNREGA). Additionally, MCH services provide free of cost in public health centre. Still now, the country facing unacceptably high maternal mortality ratio (MMR), accounting for one-fifth (19%) of the global maternal deaths. It is 16 times higher than that of Russia, 10 times that of China and 4 times higher than that of Brazil in 2005. Similarly, country contributes to the highest number of deaths among children under-five in the South Asian region (2.1 million deaths in 2006) and one-fifth of under-five deaths worldwide. However, at the current pace, the country is unlikely to achieve (MDG)-4. These studies using Indian Demographic Health Survey Data through decomposition model, try to explore absolute contribution of selected determinants for inequality in utilization of MCH services. Result showed economic status play the highest role of 42% for inequality in utilization MCH services than other selected covariates such as education 20.2%, social group 14.4%, religion 6.1% and birth order 6.5% respectively.

An Integrated Method for Network-Constrained Point Pattern Analysis Based on Spatial Model

Nie K, Wang Z, Du Q

Shenzhen research center of digital city engineering, Shenzhen 518034, China, nieke@whu.edu.cn

Abstract

With explosive amount of spatial big data, opportunity always walk along with challenge. Previous studies focused on spatial pattern of network-constrained spatial point event have revealed that there were several shortages by applying the traditional analytic paradigm. Therefore, many studies have attempted to develop novel approaches for this point event. In this paper, we aimed at modelling network-constrained point events in geographical space and proposed an integrated method called NKDE-LINCS combining density estimation and spatial autocorrelation. The first step involves in spreading points to a density surface using Network-constrained Kernel Density Estimation (NKDE). The second step is calculating local indicators of spatial association (LISA) taking the smoothed density as input. Furthermore, the availability and practicality has been reviewed through 2*2 groups of experiments each with 10 simulations and a case study by using traffic crash in Wuhan. The simulation has shown network-constrained approaches can avoid error, besides, as for random pattern all the approaches are availability and as for cluster pattern all the approaches work well in detecting clusters, especially, the integrated method can get more clusters which is closer to the real value. The case study has shown traffic crash delineated as a tendency of cluster pattern in the road network, and the cluster pattern was more significant when network-constrained spatial models were used. In the end, the problems were summarized and the further studies were presented. The research is not only an important branch in geographical area, but also a considerable focus in interdisciplinary of traffic safety and geography.

Comparative Space-time Research Questions for Open Source Toolkit Development

Xinyue Ye

Kent State University, xye5@kent.edu

Abstract

Spatial turn in many socioeconomic theories has been noted in a vast field, encompassing both social and physical phenomena. The fast growth in socioeconomic dynamics analysis is increasingly seen as attributable to the availability of panel datasets. By contrast, spatial social scientists have been slower to adopt and implement new spatiotemporally explicit methods of data analysis due to the lack of extensible software packages, which becomes a major impediment to promote spatiotemporal thinking. The current research implements the new methodological advances in an open source environment for exploring space-time socioeconomic data, which lend support to the notion that space and time cannot be meaningfully separated. This research interfaces the open source revolution and socioeconomic analysis, which is among the burgeoning efforts seeking the cross-fertilization between the two fast-growing communities.

Households' Toilet Facility in Rural India: Socio-Spatial Analysis

ARJUN KUMAR

Jawaharlal Nehru University, arjunsingh5184@gmail.com

Abstract

The 2030 agenda on Sustainable Development Goals (SDGs) highlights the importance of sanitation and sets the Goal #6: 'Ensure availability and sustainable management of water and sanitation for all'. While rural households in India have witnessed a marginal improvement in access to toilet facility in proportional terms in recent decades, they continue to face very high levels of deprivation along with spatial and socio-economic disparities and exclusions, which have been highlighted in this paper using data from Census of India, National Sample Surveys and Baseline Survey. Determinants of households having access to latrine facility in the house have been estimated using an econometric exercise and contribution of caste-based factors of the gap in access among various social groups have been estimated using decomposition technique on household level information from National Sample Survey data. Households located in backward regions and belonging to the weaker sections of society, such as Poor, Wage Labourers, Scheduled Tribes and Scheduled Castes, have been found to be the most deprived, neglected and excluded. Thus, there is an urgent need to pace up the developmental efforts for rural sanitation to achieve the SDGs, along with complementary measures to focus on backward regions, weaker sections, and sociospatial situatedness of households in rural India.

Impact Assessment of Dairy Farming on Socio- Economic Transformation of Unorganized Workers in Rural Areas: A Case Study

Md.Akhtar Hasinur Rahaman

Department of Geography, A.M.U, Aligarh, U.P, India, akhtar34@gmail.com

Abstract

Dairy farming, as it is generally understood and practiced the world over, implies breeding, feeding and management of cattle (cows and buffaloes) and production, handling and marketing of their milk and milk products on satisfactory and economic basis. Milk is the second largest agricultural commodity produced in the country next only to paddy. Dairying is not only a source of employment and income for small holders, but also a storehouse of wealth, an asset that often helps tide over unforeseen demands for liquid cash. Income from dairying contributes nearly one third of the rural household's gross income, and in the case of landless wage earning households, it is nearly half. The major objectives of the study are as follows: first, to examine the role of dairy farming in rural economy second, to assess the income and employment generation through dairy farming, third, is to study the impact of sustainable dairy farming on the social development aspects of rural livelihoods, and fourth, to suggest measures to improve the rural livelihoods through dairy farming.

The socio-economic status of dairy farmers has assumed a significant importance in rural social life, as it directly bears their income and occupations. The caste, occupation, education, social participation, landholding, house type, material possession, farm power, family types and family size jointly, health status, per capita income and living standard determines the socio-economic status of an individual farmer. The present study has been made to identify the impact assessment of dairy farmers and to determine the social and rural development of different categories of small and marginal farmers of the study area. Primary and secondary sources of data have been used in the study of livestock potential villages in which data were collected through direct questionnaire; four potential villages are selected on the basis of random sampling method.

Measuring and Analyzing the Spatial Distribution of Mixed Land Use in Shenzhen: 2009-2013

Quan Li¹, Xinyue Ye²

¹School of Resource and Environmental Science, Wuhan University, Wuhan, 430079, P.R. China, leequant@whu.edu.cn

²Geography Department, Kent State University, Kent, Ohio, 44240, U.S.A, xye5@kent.edu

Abstract

Although mixed land use is still controversial, it is clear that it can generate lots of benefits in transportation, public health and urban economy. The current achievements in this research, however, used to focus on macro scale and not consider the effect of neighbour blocks, and almost all measuring are based on a hypothesis that equal proportion of different land use types means the best. What we did was to use a new indicator considering neighbours and ideal proportion of different land use types to measure the land use mix at grid scale. Shenzhen, one of classical rapid urbanization megapolis of China, were chosen to implement a case study. The data processed as follow: 1) to calculate the proportion of land use types for each 250m*250m size grid using convolution method and 11*11 size window; 2) to determine the ideal proportion of different land use type of Shenzhen according 2 national standards of urban land use and planning; 3) to measure the mixed land use of Shenzhen by virtue of a new indicator named MII which actually calculate the sum of squares of difference between real land use type proportion of a grid and ideal proportion; 4) to get the MII difference using MII of 2013 subtract MII of 2009, and MII ratio using MII of sprawled grid from 2009 to 2013 divide the average MII of 2013. The results show the amount of negative value grids, and the amount of grids which MII are larger than 1 were dominant.

Progress of Crime Mapping and Analysis in China

Lin Liu

Sun Yat-sen University, University of Cincinnati, liulin2@mail.sysu.edu.cn, lin.liu@uc.edu

Abstract

Crime mapping and analysis in China is relatively new. Less than 200 research papers have published on this topic in Chinese. A national project on Policing GIS (PGIS) started in 2008 has propelled scholars to pay closer attention to this emerging field. This paper presents major opportunities and challenges of crime research in China, followed by a few case studies on street robberies, burglaries and fraud in selected southern cities of China. GIS based analysis and spatial statistical methods are used to reveal the spatial and temporal crime patterns, and to explore the associations of crime with environmental and socio-economic factors. Comparisons will be made to related research in the United States.

Spatial Mining of Large Administrative Data to Identify and Understand Neighbourhood Problems: The Case in Brisbane, Australia

Yan Liu¹, Lynda Cheshire², Robin Fitzgerald²

¹School of Geography, Planning and Environmental Management, The University of Queensland, Brisbane, 4072, Australia, yan.liu@uq.edu.au

²School of Social Science, The University of Queensland, Brisbane, 4072, Australia

Abstract

The collection of large-scale administrative data from city councils provides new opportunities for researchers and city management to monitor, understand and manage a host of city phenomena. One example is records of complaints made by city residents about their neighbours, including spatial information such as the address of the complainant and the problem neighbour as well as the nature of the problem. While large in size, the data also include records that are not specifically about neighbours, such as reports of problems when passing by an area, or requests for services. This paper presents a GIS based spatial data mining approach to identify and analyse de-identified information about complaints made to the Compliance and Regulatory Services (CARS) division of Brisbane City Council in Queensland, Australia over a seven-year period (2007-2014). By geocoding and integrating the complaint data with other spatial datasets including the Geocoded National Address File (G-NAF) and the Digital Cadastral Database (DCDB), we identified real neighbourhood problems (with both the complainant and offender living within close proximity). The spatial distribution of the problems as well as their change in patterns over time were mapped and analysed. Furthermore, an exploratory factor analysis (EFA) was conducted to identify the underlying factor structure of the problems, and spatial clustering of neighbour problems in different Brisbane suburbs. The spatially integrated data mining and analytical approaches enable us to gain deeper insights to the understanding of the nature of neighbour problems and their spatio-temporal evolution in Australia's dynamically changing urban space.

Key words:

How to Grasp the Distributions of Urban Public Service and Facilities in Big Data Era: Case Study in Guangzhou, China

Zhifeng Wu, Jia Zeng

School of Geographical Sciences, Guangzhou University, Guangzhou, 510006, P. R. China, zuwzf@163.com

Abstract

With the rapid development of the Internet, the era of big data is coming, there are huge amounts of information (include languages, instruction, data, signal, image and sound, etc.) generated and shared every day. People can be very convenient to obtain all kinds of information and to perceive the development and change the world. Urban is the result of the development of human social, economic, political and cultural. How to acquire and sense efficiency characteristic information of a urban is an opportunity and a challenge. Using the Baidu Map API (Application Programming Interface), We developed our own software programme to get quickly to the points of interest (POI). It is convenient to help us grasp distributions of urban public service and facilities. Take the primary schools as example, we accurately get the location information of more than 1000 primary schools in Guangzhou city. We also analyze accessibility, rationality and fairness of the primary school distributions by overlaying resident distribution and transportation Information.

Air Pollution and its Impact on Human Health of Ulaanbaatar city

Dash.M, Erdenetsogt.O

University of the Humanities, Ulaanbaatar city, 14200, Mongolia, dmiigaa@yahoo.com

Abstract

Due to uncontrolled expansion of a city and population growth, air quality issue had been on fire for the last decade in Ulaanbaatar city. The result study aimed to monitor Ulaanbaatar air quality changes and its impacts on human health. Air pollution research study was conducted at the “Environmental monitoring laboratory”, University of the Humanities. The number of sampling of precipitation and soil were prepared. The laboratory experiment result shows that sources of burning organic fuel have been increased heavily in Ulaanbaatar city, which emits NO_2 and SO_2 into the atmosphere, NO_2 and SO_2 react to hydrogen ion in the atmosphere and forms $\text{SO}_4^{2-} - \text{NO}_3$. The amount of the ion has increased in the snow – water. Snow-water is considered as mild type, but its solidity has increased to 2.2-4.6 mg eqv/l for the last year. The soil water sample is 11.46-12.2 mg eqv/l, very hard. The amount of NO_3 in snow - water and soil water is low. The amount of NO_2 in the atmosphere is 2 to 3 times greater than snow-water. According to the average amount of total pollutants, the highest mean was measured in the samples from the air quality measurement points in Bayanzurkh district. As a result of the research, it is shown that the air quality index will be increasing for the last years and it has a clear impact on human health.

Key words:

Urban air pollution; snow-water; soil pollution; human health

Air Quality in Major Spanish Cities: Analysis Based On Modelled Spatial Patterns in Madrid, Barcelona and Seville

Cañada-Torrecilla, M.R., Moreno-Jiménez, A.

Department of Geography, Universidad Autónoma de Madrid, 28049 Madrid, Spain, rosa.canada@uam.es

Abstract

The most highly populated Spanish cities experience difficulties in complying with air quality regulations established by the European Union. Therefore, the Spanish government (Plan AIRE (2013-2016), together with regional and local governments, is driving measures against air pollution and to protect the health of the population.

Our objective was to determine the spatial distribution of the most harmful pollutants, showing intra-urban contrasts. Given that measuring stations are neither abundant nor regularly distributed, extensive areas remained uncovered. Our study, therefore, has made use of spatial interpolation techniques to estimate mean annual levels of pollution. Two techniques were used for modelling nitrogen dioxide, airborne particulate matter smaller than 10 μm and ozone: IDW (Inverse Distance Weighting) and Kriging, using ArcGIS (Geostatistical Analyst).

The results show that in large sectors of Madrid and Barcelona the maximum values of NO_2 are exceeded. In PM_{10} , and applying the criteria of the World Health Organisation, limits are exceeded in the entire urban area of Barcelona, in 98% of Seville and 77% of Madrid. As for O_3 , Seville is the city presenting the worst scenario with 58% of its surface area surpassing an annual mean of 25 days in excess of $120 \mu\text{g}/\text{m}^3$. In Madrid, this threshold is only exceeded at the suburban measuring stations. This legal threshold is not exceeded in Barcelona.

Key words:

Urban pollution; air quality; NO_2 ; PM_{10} ; O_3 ; spatial interpolation; Madrid; Barcelona; Seville

Analysis of Uranium Content of Radionuclide in Surface Water, Paddy Soil and Rice Within the Tailing Dam in East China

Xiang L, Liu P H

East China University of Technology, Nanchang, 330013, P. R. China, 87337377@qq.com

Abstract

To assess contents of radioactive element uranium utilizing X-Series ICP-MS in 3 different ditches nearby tailing dam in east China—totally 12 surface water samples, 9 rice samples, and 9 paddy soil samples were collected, which were based on their relative position to the tailing dam. The radionuclide uranium contamination levels of 3 ditches were measured by using SingleFactor Index Method. The results show that: (1) For the first ditch, the average uranium concentrations in surface water ($27.68\mu\text{g/L}$) and in paddy soil ($69.40\mu\text{g/g}$) were 22.32 and 15.77 times respectively comparing to that of unexploited deposit area and soil uranium element background values of Jiangxi province, indicates severe contamination. The average uranium concentration of rice (3.33ng/g) was 2.85 times of that in unexploited deposit area, indicates moderate contamination. (2) For the second ditch, the average uranium concentrations in surface water ($0.19\mu\text{g/L}$) and in paddy soil ($4.13\mu\text{g/g}$) were lower than that of unexploited deposit area and soil uranium element background values of Jiangxi province. So they were unpolluted. The average uranium concentrations (1.17ng/g) in rice were 1.51 times of that in unexploited deposit area, indicates slight contamination. (3) For the third ditch, the average uranium concentration in surface water ($0.48\mu\text{g/L}$) and in paddy soil ($3.34\mu\text{g/g}$) were also lower than that of unexploited deposit area and soil uranium element background values of Jiangxi province. So they were unpolluted. The average uranium concentrations (2.55ng/g) in rice were 2.17 times of that in unexploited deposit area, indicates slight contamination. In conclusion, the first ditch was directly affected by the tailing dam and the second and third ditches were not. Much work should be done to improve the environment.

Assessment of Groundwater Vulnerability to and Risk of Contamination in Kaduna Metropolis, Northwest Nigeria

Ahmed M.S, Tanko A.I, Badamasi M.M, Abdulhamid A

Kaduna Refining and Petrochemical Company Limited, Kaduna, Nigeria almurtadha2003@yahoo.com

Abstract

DRASTIC index and GOD models were applied in the assessment of groundwater vulnerability to contamination in Kaduna metropolis, Nigeria. DRASTIC index evaluates the contributions of seven environmental parameters (Depth to water level, net Recharge, Aquifer media, Soil media, Topography, Impact of vadose zone, and Hydraulic Conductivity) in the protection of groundwater against contamination. GOD model on the other hand, assesses the significance of groundwater confinement in the aquifer (G), overlying lithology (O) and depth to groundwater level (D) in determining the susceptibility of groundwater to contamination. For the risk assessment, the EU COST Action 620 approach to hazard and risk analysis was applied. Unclassified and classified hazard (contaminants sources) maps of the area were produced. Pollution potentials in the area was found to be generally moderate to low. Using the overlay operation of Arc GIS, the two vulnerability maps generated were each merged with the classified hazard map to produce the groundwater contamination risk maps of the area according to the two models. High contamination risk was found around the Kaduna refinery, the two dumpsites of Mando and Kakau as well as most parts of the residential areas. It is recommended that, strict control measures be put in place when locating land uses with high potential hazards in areas with relatively high vulnerability.

Characterization on $PM_{2.5}/PM_{10}$ During Winter Period in Guangzhou, China

Tian Li xue

School of Geography Sciences, South China Normal University, Guangzhou, China, li-xue.tian@m.scnu.edu.cn

Abstract

With the rapid economic development and urbanization over the past several decades, air pollution and degradation of visibility are common in Guangzhou, especially in winter. Our objective is to generalize the variation characteristic of $PM_{2.5}$ and PM_{10} during winter period in Guangzhou and provide some theoretical evidence for the government and the relevant administration to defend $PM_{2.5}$ and PM_{10} . This article collects the concentration data of $PM_{2.5}$ and PM_{10} in the area of Guangzhou from 2014.11-2015.1 (the winter period), and the concentration of $PM_{2.5}$ and PM_{10} were $(55.01 \pm 78.19) \mu g/m^3$ and $(78.34 \pm 101.76) \mu g/m^3$, respectively. The mean ratio of $PM_{2.5}$ to PM_{10} was 70.59% and the $PM_{2.5}/PM_{10}$ value ranges from 54.61% to 94.37%, indicating that fine particle ($PM_{2.5}$) occupy high proportion in the PM_{10} . In addition, $PM_{2.5}$ has a good linear relationship with PM_{10} . All evidence provides us conclusions that fine particle has a higher proportion in the atmospheric aerosol, and make a major contribution in the air environmental pollution.

Keywords: $PM_{2.5}$; PM_{10} ; $PM_{2.5}/PM_{10}$; Variation Characteristic; Guangzhou

Comparative Assessment of Phytoremedial Potential of Aquatic Macrophytes grown in Industrial Wastewater of Ranchi (India)

Abstract

Contamination of any water body resource is common due to domestic effluents, discharges from industries as well as from agricultural activities. Heavy metals are one of the major contaminant that gets released and causes potential hazard to the soil environment as well as the species of plants that thrive on it. The present study focusses on three plant species namely *Typha latifolia*, *Monochoria hastata* and *Eichornia crassipes* that grow luxuriantly in contaminated water bodies across Ranchi. They were sampled from natural environment, allowed to grow in the mesocosm system, till their acclimatization. After about 20-25 days, industrial wastewater (influent) was given to the plants, and the effluent was collected on Day 1, 3, 5, 7, 9 and 11. Bioconcentration factor (BCF) of both belowground and aboveground biomass was found out. Simultaneously translocation factor was also evaluated. Based on the experimental study it was concluded that root structures are more efficient in taking heavy metals and it translocated less to the aboveground part of the plant. Therefore, TF was less and the values were mostly less than 1. The heavy metal tolerant species which do possess high BCF and low TF can be used for phytostabilization of any contaminated site.

Key words:

Industrial wastewater; phytoremedial potential; bioconcentration and translocation factor; contaminants of concern

Effect of Nitrogen Input on Litter and Soil Properties in a Peatland on Da Xing'an Mountains, Northeast China

Song Y Y, Song C C, Wang X W, Tan W W

Key Laboratory of Wetland Ecology and Environment, Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Changchun, 130102, P. R. China, songcc@iga.ac.cn

Abstract

Nitrogen (N) is a limiting nutrient in many peatland ecosystems. Enhanced N deposition, a major component of global change, affects ecosystem carbon (C) cycle by changing plant and soil properties. However, the effects of enhanced N deposition on peatland ecosystems are poorly understood. We conducted a two-year N input field experiment in a peatland dominated by *Eriophorum vaginatum* on Da Xing'an Mountains, Northeast China. Four levels of N treatments were applied: (1) CK (no N added), (2) N1 ($6\text{ g N m}^{-2}\text{ yr}^{-1}$), (3) N2 ($12\text{ g N m}^{-2}\text{ yr}^{-1}$), and (4) N3 ($24\text{ g N m}^{-2}\text{ yr}^{-1}$). Plant and soil material was harvested at the end of the second growing season. Nitrogen inputs increased litter N and P content, as well as β -glucosidase, invertase, and acid-phosphatase activity, but decreased litter C/N and C/P ratios. Litter carbon content remained unchanged. Nitrogen inputs increased available $\text{NH}_4^+\text{-N}$ and $\text{NO}_3^-\text{-N}$ in the shallow soil (0-15 cm depth), decrease soil labile organic C (MBC and DOC), and appeared to accelerate the decomposition and reduce the stability of the soil C pool. Invertase and urease activity in shallow soils and acid-phosphatase activity in deep soils (15-30 cm depth) was strongly inhibited by N inputs. Our results suggest that an increase in N deposition in peatlands may accelerate litter decomposition and the loss of labile C, as well as alter microbial biomass and function.

Key words:

nitrogen input; peatland; *Eriophorum vaginatum*; soil labile organic carbon; enzyme activity

Evaluation of the Air Pollution Sources in Selected Zone of Textile Industries in Pakistan

Farid M*, Ali S, Rizwan M.

Department of Environmental Sciences and Engineering, Government College University Faisalabad, Pakistan,
mujahid726@yahoo.com

Abstract

The present work reports the gaseous emissions of the following industries, Interloop Textile (IP Tex), Crescent Textile (CT Tex), Kalash Textile (KH Tex), Noor Fatima Textile (NF Tex), Bashir Textile (BP Tex) and Hina Sana Textile (HS Tex) which are located in Faisalabad, Pakistan. Industries were tested for the mixture of gases containing carbon monoxide (CO), nitrogen oxides (NO_x), sulphur oxides (SO_x), carbon dioxide (CO₂) and hydrogen (H₂) emitting from these industries. The maximum amounts of CO, NO_x and SO₂ were found as 4903 mg/Nm³, 437 mg/Nm³ and 3383 mg/Nm³ in boilers and 1927 mg/Nm³, 2297 mg/Nm³ and 0 mg/Nm³ in generators. Similarly concentrations of CO₂ and H₂ were found in the range of 58732-221964 mg/Nm³ and 0-174 mg/Nm³ in boilers and 21714-131429 mg/Nm³ and 0-174 mg/Nm³ in generators. The other factors of pollution in industries are temperature and noise whose values were found to be 521 °C and 97 dB respectively. Smoke opacity of oil generators was found to be exceeding NEQS at 40%. Overall, the combustion efficiency of gas boilers is better than oil boilers and which is found better than generators up to 30%. On the basis of results found it can be concluded that natural gas is better fuel as compared to diesel oil and furnace oil and low state of combustion is unfavourable for use due to low oxidation of fuel.

Identifying the Main Contributors of Air Pollution in Beijing

Li S, Feng K, Li M

Geographical Sciences Department of University of Maryland, College Park, 20742, United,
Stateslisike@terpmail.umd.edu

Abstract

Air pollution has become an emerging environmental issue in developing countries like China in the last two decades. Sulphur dioxide (SO₂) is one of the major air pollutants that poses significant risks in many areas undergoing a process of industrialization such as Beijing. Realizing the main factor causing environmental quality changes is the key to solving this problem. By using an extended version of IPAT model, this paper aims to identify the main contributors of air pollution in Beijing from 1989 to 2012. The result shows that the most influential factors affecting air pollution in Beijing are affluence and emission intensity. From analyzing the historical background, we conclude that the air pollution change in Beijing is heavily policy-driven.

Key words:

IPAT analysis; Beijing, Air pollution; Sulphur dioxide (SO₂); Environment

Mixed Plastic Waste as an Intractable Environmental Problem in Abuja, Nigeria

Dr. A.A Kadafa, Professor H. K. Ayuba and Dr. Idris Nasiru

Department of Geography, Faculty of Social Sciences, Nasarawa State University Keffi, Nasarawa State, Nigeria,
kwaala@yahoo.com

Abstract

Plastic waste is found in all types and forms mostly from packaging material for commercial products, thus resulting in its abundance in municipal solid waste. In the developed and developing countries, high quantities of mixed plastic waste are generated but in the developed countries extensive recycling and reuse strategies have been implemented toward minimizing its quantity in waste flow and that which requires final disposal. However, in the developing countries, the concept of recycling is relatively new, thus recycling is done only informally and carried out by scavengers. In Nigeria the greatest environmental issue in the urban areas is solid waste management and the most difficult aspect is how to handle mixed plastic. Due to its high generation since it is the most common packaging material used by the manufacturing sector within the country. Polypropylene (PP/5) found in confectionery packets and Polyethylene Terephthalate (PETE/1) found in soft drinks bottles are the most commonly generated plastic in Nigeria, which can be found in abundance littering the streets. Its high quantity generated and its non-degradable nature makes it a serious environmental challenge in Nigeria. This paper looks at mixed plastic waste in Abuja, Nigeria and its environmental hazards with the aim of sensitizing solid waste managers and the public to finding sustainable solutions to the problem.

Plastic, Waste; Management; Abuja; Nigeria

PM_{2.5} Pollution characteristics and Its Underlying Risk Factors in Beijing-Tianjin-Hebei and The Surrounding Regions

Lei Zhou, Jianjun Wu, Nian Liang, Yong Ni

China National Environmental Monitoring Center, Beijing 100012, P. R. China, zhoulei8341@163.com

Abstract

The temporal-spatial characteristics of typical PM_{2.5} pollution events in 2013 were investigated in Beijing-Tianjin-Hebei and surrounding areas based on the national urban environmental air quality real time publishing data and geographic national condition monitoring results. The hot spot areas of PM_{2.5} pollution in Beijing-Tianjin-Hebei and surrounding areas were located by the spatial data mining method. Using the geographic detector model, the risk factors of PM_{2.5} pollution and the associated influence degree were quantitatively analyzed. The study found that, there statistically existed the Langfang-Beijing-Baoding-Tianjin-Chengde-Zhangjiakou pollution order in selected cities. Through the spatial hot spot detection, Beijing-Tianjin-Hebei and surrounding areas were divided into five hot spot areas, and the top three of them were distributed in Beijing, Tianjin, and Hebei-central Shandong regions, with areas of 53.1 thousand km², 102.6 thousand km² and 50.4 thousand km², respectively. Among the selected eight PM_{2.5} pollution risk factors, number of industrial enterprises (0.94), precipitation (0.93) and topographic slope (0.89) had significant higher influence on PM_{2.5} pollution than other risk factors. The influence power index order of other risk factors were as follows: population (0.60), number of precipitation days (0.57), land cover (0.52), relative air humidity (0.51) and wind speed (0.33). The study can provide scientific reference and decision support to governments through analyzing the temporal-spatial characteristics of regional air pollution and its regional differentiation, detecting the pollution hot spots, and identifying the underlying PM_{2.5} risk factors.

PM_{2.5}; Beijing-Tianjin-Hebei; temporal-spatial characteristics; spatial hot spot detection; Geographic detector

Pollution Characteristics and Sources of Heavy Metals in Leafy Vegetable-Soil System in Typical Industrial Areas of Suburban Shanghai, China

Bi CJ, Ni WY, Jia JP, Liu C, Zhou XX, Chen ZL

Key Laboratory of Geographical Information Science of the Ministry of Education, College of Geographic Science, East China Normal University, Shanghai 200241, P. R. China, cjbi@geo.ecnu.edu.cn

Abstract

The concentrations of Zn, Cr, Cu, Pb, Cd, Hg, As and lead isotope ratio in soils, road dust and vegetables were measured to analyze the pollution characteristics, risk levels and contamination sources in leafy vegetable-soil system in typical industrial areas of suburban Shanghai, China. A lead isotope simulation experiment was designed to discuss the source contributions of Pb in vegetables from atmospheric deposition and soil. The results showed that the average concentrations of Zn, Cr, Cu, Pb, Cd, Hg and As in soils were 122.51, 79.75, 24.54, 28.14, 0.12, 0.82, 6.49 mg/kg, respectively, which were less than those in dusts. Nemerow and I_{geo} assessment indicated that the contamination of Hg in soils was ubiquitous, and was more serious in the road dust. The average concentrations of Zn, Cr, Cu, Pb, Cd, Hg and As in edible leaves of vegetables were 37.0, 1.94, 4.81, 0.73, 0.44, 0.02, 0.52 mg/kg, respectively. While those in roots were much higher than that, meaning the strong enrichment capacity of roots. Target Hazard Quotient (THQ) of vegetable edible parts were totally less than 1, suggesting no health risk to people. The ratios of $^{207}\text{Pb}/^{206}\text{Pb}$ and $^{208}\text{Pb}/^{206}\text{Pb}$ suggested that Pb in soil was mainly derived from the Yangtze estuarine sediments, while Pb in vegetables and dusts was polluted by human activities, such as industrial emissions, vehicle exhaust, fertilizer, etc. The simulation experiment results suggested that the contributions of Pb from atmospheric dry and wet deposition to both edible leaves and roots of the vegetables were less than 20%.

Key words:

heavy metals; the leafy vegetable-soil system; atmospheric deposition; contamination sources

Reducing Chemical Risks by Amending Soil with Biochar

Wang W, Xia XR, Kong XQ, Shea D

North Carolina State University, Raleigh, NC, USA shea@ncsu.edu

Abstract

The amendment of soil with biochar, produced through the pyrolysis of plant biomass, has been suggested as a means to partially mitigate climate change through carbon sequestration while improving soil fertility. At the same time, biochar has the potential to alter exposure to chemicals in the soil and nearby water and plants. On the one hand, biochar has the potential to increase exposure to PAHs and dioxins that are formed during pyrolysis through desorption of these chemicals to soil and water. On the other hand, biochar has the potential to decrease chemical exposure through adsorption/absorption of other chemicals already in the soil, such as pesticides. We report on the use of passive sampling devices (PSDs) to estimate the bioavailable fraction of chemicals in both the biochar and the soil before and after the biochar amendment of soils. We allowed polyoxymethylene (POM) PSDs to reach equilibrium with biochar-water and soil-water slurries to estimate the amount of chemical dissolved in water. We found that although bioavailable PAHs and dioxins increased following amendment with biochar, the concentrations did not exceed commonly used benchmarks for the protection of human health. We also found a reduction in the bioavailable amount of pyrethroids and DDT in the soil after biochar amendment. Our results indicate that biochar amended soil presents a trade-off in exposure to chemicals, but with a net reduction in risk to human health along with the added benefits of carbon sequestration.

biochar; human health; toxicity; pesticides; dioxins; passive sampling; carbon sequestration; soil fertility

Satellite-based Predicting the Spatiotemporal Distribution of Fine Particulate Matter in China Using Deep Learning

Li TW, Shen HF, Yuan QQ, Zhang XC

School of Resource and Environmental Sciences, Wuhan University, Wuhan, 430079, P. R. China. shenhf@whu.edu.cn

Abstract

Fine particulate matter ($PM_{2.5}$) has an adverse impact on human health, environment and climate change. In this paper, taking advantage of the satellite-based aerosol optical depth (AOD), meteorological data and station-level $PM_{2.5}$ measurements, a deep learning model called deep belief network (DBN) is developed to obtain spatially continuous $PM_{2.5}$ in China. This is the first study to incorporate satellite remotely sensed data into the deep learning model for predicting $PM_{2.5}$ concentrations. Through the layer-by-layer unsupervised pre-training, the DBN model can automatically capture the deep features from multi-source data to improve the accuracy of $PM_{2.5}$ estimation. Moreover, the optimization of model parameters (e.g., the number of layers and neurons) is further discussed. The results indicate that compared with the conventional multiple linear regression and back propagation (BP) neural network models, the DBN model obtains a better performance, suggesting that the proposed DBN model is more effective for the estimation of $PM_{2.5}$. Based on the established model, the spatially continuous $PM_{2.5}$ data can be reconstructed, and the spatiotemporal characteristics of $PM_{2.5}$ concentration in China are investigated at a large scale. The results show the capacity of our study to provide useful information for pollution control and sustainable development.

Satellite-Measured Atmospheric Aerosol Content in Korea: Anthropogenic Signals from Decadal Records

Park S., Choi J.

Pusan National University, Busan, Korea, spark@pusan.ac.kr

Kyung Hee University, Seoul, Korea, cjm89@khu.ac.kr

Abstract

Spatiotemporal characteristics and anthropogenic signals of aerosol optical thickness (AOT) distributions over Korea are investigated in this study using AOT time-series data from the Moderate Resolution Imaging Spectroradiometer (MODIS). AOT observations, a quantitative measure of the atmospheric quality, had significant geographical variations during the study period (2000-2010). Annual means of AOT measurements were higher in western regions than eastern regions, indicating the strong effects of atmospheric effluents from China. Comparing metro cities or counties with similar populations, western regions showed higher AOT values than eastern regions. The transport of particular matters with a diameter $< 10 \mu\text{m}$ (PM_{10}) into the region has shown a strong seasonal pattern with their peaks from March to April and lows from July to September. While the Asian Dust typically blows in March and April in Korea, AOT observations peaked in June nationwide. AOT peaks in summer months and significant correlations between AOT and relative humidity during the AOT-peak month, also indicate that human activities and secondary growth of hygroscopic aerosols are still an important contributor to the urban air quality. With increasing fine-mode aerosols from anthropogenic sources and low ratios of external/internal background PM_{10} sources in summer, urban emission of anthropogenic aerosols becomes a significant, responsible factor for air-quality degradation in the non-dusty season over the Korean Peninsula. Human impacts on the aerosol distributions were also noticeable on different land use types. AOTs in urban areas were significantly higher than those in cultivated land or forests.

Key words:

AOT; MODIS; land use; PM_{10} ; Korean Peninsula; hygroscopic aerosol

Sources and Health Risk Assessment of Polycyclic Aromatic Hydrocarbons in Road Dusts and Vegetable Field Soils from Typical Industry Areas of Shanghai, China

Jia JP, Bi CJ, Guo X, Liu F, Wang XP, Chen ZL

Key Laboratory of Geographical Information Science of the Ministry of Education, College of Geographic Science, East China Normal University, Shanghai 200241, P. R. China, cjbi@geo.ecnu.edu.cn

Abstract

Road dust and vegetable field soil samples were collected from eight sites close to steel mills, chemical plants and municipal solid waste incinerator in suburban Shanghai. Sixteen polycyclic aromatic hydrocarbons (PAHs) were determined by GC/MS. Total PAHs concentrations in road dust samples ranged from 791.61 to 6196.49 ng·g⁻¹ with a mean value of 2378.14 ng·g⁻¹, while they varied from 258.05 to 535.30 ng·g⁻¹ in vegetable field soils with an average of 364.56 ng·g⁻¹. The spatial distribution of PAHs in dusts and soils was consistent. And the wind direction could affect the spatial distribution of PAHs. Organic matter content was found to be significantly positive correlation with PAHs concentration in dusts and soils. PAH isomer ratio method showed that combustion of grass, wood and coal was important source of PAHs in road dusts and vegetable field soils. Toxic equivalent concentrations (TEQ) of PAHs in the road dust ranged from 89.99 to 603.53 μg BaP_{eq}·kg⁻¹, while they varied from 33.04 to 65.92 μg BaP_{eq}·kg⁻¹ in vegetable field soils. Toxic equivalent concentrations indicated 7 kinds of carcinogenic PAHs were major TEQ contributors, accounting for 98% of TEQ, in the road dust and vegetable field soils. Incremental lifetime cancer risk (ILCR) estimation results showed that the PAHs in the dust and soil had potential cancer risk for children and adults by direct ingestion exposure.

Key words:

PAHs; road dusts; vegetable field soils; typical industry areas; Shanghai

Spatial-temporal Characteristics of PM_{2.5} and Correlations of PM_{2.5} and Natural Factors of Cities in China in 2015

HU Zhiqiang^{1,2}, MIAO Changhong^{1,2*}

¹Key Research Institute of Yellow River Civilization and Sustainable Development & Collaborative Innovation Center on Yellow River Civilization of Henan Province, Henan University, Kaifeng 475001, China

²College of Environment and Planning, Henan University, Kaifeng 475004, China

Abstract

Based on the observed PM_{2.5} concentration data of 367 cities in 2015, our research reveals the spatial-temporal variations of PM_{2.5} concentrations and the relationship between PM_{2.5} and natural factors in China with the methods of exploratory spatial data analysis and Spearman correlation analysis. The results show that: (1) In 2015, PM_{2.5} concentration has a periodical double peak, double valley type 24hour variation, huge difference daily variation as well as a U-shaped monthly variation with a higher level in autumn and winter while a lower one in spring and summer. (2) Concentration of PM_{2.5} in urban China shows a significant spatial differentiation and formed two heavy pollution area: North China, central and the area of the south Tianshan Mountains in Xinjiang. From the point of view of the season, PM_{2.5} exceeds the standard serious with a large range of coverage in winter and on the contrary in summer. From the point of view of the month, the standard of exceed rate and cover scope of PM_{2.5} is significant different. The Beijing-Tianjin-Hebei-Henan was the most severely polluted region all the year round. From the point of view of spatial agglomeration, the high value areas are mainly concentrated in the Beijing, Tianjin, Hebei, Shandong and Henan. The low value areas are mainly concentrated in the Guangdong, Fujian, Yunnan, western Sichuan and Southeast of Tibet. (3) PM_{2.5} concentration of the nationwide showed a significant negative correlation with average elevation and relief degree. PM_{2.5} concentration of the nationwide, Beijing-Tianjin-Hebei-Shandong-Henan, Jiangsu-Anhui, Jilin-Liaoning and Chengdu-Chongqing urban agglomerations showed a negative correlation with temperature, humidity and wind power. Of those, correlation of PM_{2.5} and wind power is not significant. The relationship between PM_{2.5} and natural factors in Xinjiang is special. The PM_{2.5} of Xinjiang was significant negative correlation with temperature, positively correlated with humidity, but no significant positive correlation with wind.

Spatio-temporal Visualization and Analysis of Environmental Monitoring Data

Lu Wei, Ai Tinghua

Wuhan University, Wuhan, 430079, P. R. China, whuluwei@163.com

Abstract

The environmental monitor data acts as the integrated information of spatial location, time-series and multi-semantics. To map this kind of data needs multi-dimension visualization tools not only to display the data but also to interactively operate it by a real-time way. Taking the air quality visualization as an example, this study builds a multi-dimension visualization method for environmental monitoring data based on the web 2.0 technology. This research applies Leaflet, an extensible JavaScript mapping library, as the mapping engine to develop the dynamic map layer class for adaptive mutli-scale spatial visualization, and D3, a visualization JavaScript library, as the map symbol engine to create an interactive map symbol class for multi-granularity time-series visualization. Through this kind of software mashup, We use the air quality hourly reported data from 1497 monitor sites of China in 2014 to design a dynamic and interactive online map mashup, which visualizes the multivariate spatial-temporal air quality dataset effectively. By configuring spatial and temporal scale of different pollutant indexes, this mapping application helps to discover some significant spatio-temporal characteristics of air quality in China, and these findings show us clues for further study and analysis on air pollution in China. First, it illustrates a triangular region of bad air quality condition and a coastal line ribbon of fine air condition. Second, different pollutants show different temporal and spatial deterioration patterns which give researchers and administrators clues about forming mechanism of different air pollutants and the controlling strategies for them.

Environmental Monitoring; Multi-scale Mapping; Time-series Visualization; Visual Analysis

A Comparison Research on VOC Components, Resources and Contribution to Ozone Formation in 9 Cities along Yangtze River

Zihao Lu, Lixiang Gu, Yu Huang, Jufen Lai

Nanjing University, Nanjing, 210046, P. R. China, luzihao@smail.nju.edu.cn

Abstract

Yangtze River Area is the third biggest river area around the world, and it contains most economy developed areas of China. As a result, it is important for the future joint governance and sustainable development to research the distribution and connection of VOC(volatile organic compound) pollution in different river reaches. We choose 9 cities along Yangtze River for observation, use Ratio Method to do qualitative analysis on resources of pollutants, and use PCA(principal components analysis) method to do quantitative analysis. Afterwards, we find that pollution resources and contribution rates obviously vary in different river reaches, which may be caused by different structure of production and geographical environment. By correlation analysis and backward trajectory simulation, we find pollutant transportation and shared resources among cities. Besides, ozone pollution become highlighted after strict control of PM_{2.5} in recent years. In our research, we use a zero-dimensional chemical model to make a simple discussion on contribution of VOC to ozone formation.

VOC; Yangtze River Area; ozone formation

Aerosol Remote Sensing Research Based on Surface Partition Reflectivity Model in Pearl River Delta

Wang Dehui, Sun Jie

School of Geography and Planning, Gannan Normal University, Ganzhou, 341000, P. R. China, wdede@163.com

Abstract

This study sets up the AOD (aerosol optical depth) inversion method of 250m resolution in Pearl River Delta (PRD) based on the selection of OPAC aerosol model and the establishment of ground surface reflectance model of ecological geographic partition to cover the shortage and limitation in urban areas and low resolution of traditional dark object method to realize the high-resolution and full coverage aerosol detection in Pearl River Delta by MODIS. Besides, the results has been verified and typically applied in this study. Conclusions are as follows:(1) The OPAC Continental Mean Type Model is better than the Non-absorbent Type Aerosol Model from NASA MODIS in Pearl River Delta;(2) Fine linear relation between MODIS red light and shortwave infrared reflectance (SWIR) exists in all types of ecological areas in Pearl River Delta, and this relation has spatial differentiation and seasonal similarity;(3) The 250m AOD products in this study has better accuracy and fuller spatial coverage than the 10km MODIS AOD products in Pearl River Delta.This study can help to optimize currant distribution of PM2.5 auto-monitoring stations.

Evaluation of Sources and Variation of Nitrate in Surface Water of the Weihe River

Ying Xue¹, Song J.X.^{1,2,*}, Zhang Y.¹, Kong F.H.¹

¹College of Urban and Environmental Sciences, Northwest University, Xi'an 710127, P. R. China

²State Key Laboratory of Soil Erosion and Dryland Farming on the Loess Plateau, Institute of Soil and Water Conservation, Chinese Academy of Sciences, Yangling 712100, P. R. China, nwuxueying@stumail.nwu.edu.cn

Abstract

Nitrate pollution in river water is a major problem in the Earth's surface environments. Concentrations of three forms of nitrogen and isotopic composition of nitrate are measured to analyze and evaluate the sources and variation of nitrate, sampled from Weihe River basin, China during the Oct, 2014. Approximately 32.4% of the water samples exceed the World Health Organization (WHO) drinking water standard for NO_3^- -N. The content of nitrate at the site of Qianhe River is highest in surface water, which might be influenced directly by sewage effluent. And $\delta^{15}\text{N}$ - NO_3^- of water samples ranged from 8.3‰ to 27.0‰ during the test time. Results showed that denitrification had no significant effect on the shift in nitrogen isotopic values in most surface water, except in two samples. In the study, nitrate in surface water was mainly sourced from domestic sewage and agricultural activities. This study provides significant information to estimate the water quality and to develop a more sustainable water management of the Weihe River.

Keywords:

Impacts of Ambient Air Pollution on Roadside Vegetation: A Case study of Faisalabad-Pakistan

Hina. S, Hamd. I, Adrees. M, Saleem. F & Ibrahim. M

Department of Environmental Sciences & Engineering, Government College University, Faisalabad 38000, Pakistan,
saadiahina@yahoo.com

Abstract

Urban air pollution is a serious threat to all kinds of living organisms influenced by four major factors, namely industrialized expansion of the cities, increase in traffic, rapid economic development, and higher level of energy consumption. Motor vehicles emit a cocktail of pollutants that is pervasive phytotoxic dominating the air pollution climate in urban-industrialized areas of the World. Vehicular exhaust emissions being the dominant feature of urban environments, widely believed to have detrimental effects on plants. Roads and exhaust emissions can affect plant communities directly, for example via direct foliar uptake of exhaust products, or indirectly via changes to soil biogeochemistry and hydrology. Like many other mega cities in the world the ambient air quality of Faisalabad, Pakistan is also deteriorating nowadays due to industrialization and transportation. The present work deals with the evaluation of the effects of exposure to a vehicular exhaust emission on physiological and chemical parameters of three different grass varieties grown at three different sites of Faisalabad.

Nutrient Concentrations and Fluxes in The Upper Catchment of the Miyun Reservoir, China and Potential Nutrient Reduction Strategies

Jian Jiao, Ping Zeng, Pengfei Du, Li Zhong, Xin Lu,

China Institute of Water Resources and Hydropower Research, 20 Chegongzhuangxi Road, Beijing 100048, P. R. China. E-mail: 68283847@qq.com. Telephone: 86-10-68786956.

Abstract

The Miyun Reservoir is Beijing's main drinking water source. Increased nutrient levels in the reservoir have resulted in an increased risk of harmful algal blooms. One hundred and ten water samples were collected at a range of spatial scales in the upper catchment of the Miyun Reservoir and were analyzed for total nitrogen (TN), nitrate (NO_3^- -N), ammonium (NH_4^+ -N), total phosphorus (TP) and the potassium permanganate index (COD_{Mn}). Empirical equations were developed from relationships between nutrient concentrations and the main controls on nutrients, and were used to identify parts of the catchment that should be targeted with nutrient-load reduction measures. Cropland was the main source of sediment for the streams, and much of the phosphorus was associated with sediment. The annual mean TP concentrations were closely correlated with both the annual mean suspended sediment concentrations and the ratio of the cropland area to the total basin area. There was a linear relationship between the annual mean TN concentration and the population density in the basins. Soil conservation may play an important role in reducing TP concentrations in the upper reaches of the Chao and Bai Rivers. It may be useful to (1) construct natural riparian buffers and vegetated buffers along croplands close to the watercourses, (2) implement management strategies to reduce nitrogen (N) fertilizer applications, and (3) construct additional wetlands to reduce nutrient loads in the study area.

Key words:

nutrient concentrations; influencing factors; empirical equations; control measures;

Miyun Reservoir

Pollution Characteristics, Source Identification and Lung Cancer Risk of Ambient Atmospheric Polycyclic Aromatic Hydrocarbons in A Coking Industry City in Northern China

Tao Wang, Zhonghuan Xia

School of Environment, Nanjing Normal University, zhhxia@njnu.edu.cn

Abstract

Distinguished by diverse periods (heating period and non-heating period) and diverse districts (urban areas, rural areas and background areas), both gas phase and particle phase samples were collected in 2015 in Linfen, which is a coking industry city in Northern China, and the PAHs were extracted and analyzed by using microwave and gas chromatography-mass spectrometry, respectively, to study the pollution characteristics, sources and lung cancer risk of ambient atmospheric PAHs in Linfen. The results were as follows. (1). The spatial and temporal distribution characteristics of concentrations of PAHs and BaP_{eq} were the same: heating period>non-heating period, urban areas>rural areas>background areas, whereas the phase characteristics of them were contrary as the concentrations of gas phase PAHs were lower than those of particle phase PAHs while the results of BaP_{eq} concentrations were on the opposite. BaP_{eq} concentrations of Linfen were much higher than the level of Chinese National Standard (GB 3095-2012). The PAHs and BaP_{eq} concentrations were 67.06±18.82 and 0.29±0.06, 101.07±40.13 and 11.97±4.73, 168.13±56.62 and 12.27±4.78 in gas phase, particle phase and both phases, respectively. Compared with results from regions at both home and abroad, the pollution of atmospheric PAHs in Linfen were in a relatively high level. Gas phase PAHs were mainly composed of low molecular weight compounds as PHE and FLO were major compounds in urban and rural areas while ACY took a high proportion in background areas. Particle phase PAHs were mainly composed of moderate molecular weight compounds and CHR, BbF and BkF jointly took a higher proportion in diverse areas in diverse periods. Total atmospheric PAHs were mainly composed of lower molecular weight compounds, like ANT, PHE plus FLO and the concentrations of ACE plus ACY were extremely high in background areas in diverse periods. (2). Atmospheric PAHs in Linfen originated primarily from biomass fuel and coal combustion as well as traffic exhaust. In terms of traffic exhaust, gas phase PAHs were influenced mainly by diesel vehicle emissions, whereas particle phase PAHs were influenced primarily by gasoline vehicle emissions. In general, total atmospheric PAHs were primarily influenced by diesel powered vehicles. The sources of PAHs in background areas were complex as several non-traffic exhaust sources were included, such as petroleum and petroleum

combustion. (3). Temporal, spatial and population distribution characteristics of the daily inhalation exposure levels of atmospheric PAHs were obvious in Linfen: heating period>the whole year>non-heating period, urban areas>rural areas, adults>adolescents>seniors>children as well as males>females. Corresponding values were in a relatively high level compared with other results. Temporal, spatial and population distribution characteristics of ILCR values were also obvious: the whole year>heating period>non-heating period, urban areas>rural areas, adults>children>seniors>adolescents, females>males (except adults). All population groups had cancer risk and adults were the predominant. Necessary control measures ought to be taken to prevent the trend. The values of ILCR in Linfen were in a relatively high level among results from other regions.

Key words:

polycyclic aromatic hydrocarbons; pollution characteristics; source identification; lung cancer risk; ambient air

Spatial Multi-Scale Variability of Heavy Metals in Surface Sediments in Radial Sand Ridge Field, Jiangsu Coast

Lv Jianshu

College of Geography and Environment, Shandong Normal University, Jinan, 250014, P. R. China, lvjianshu@126.com

Abstract

Surface sediments from radial sand ridge field, Jiangsu coast were analyzed for Cd, Cr, Cu, Hg, Ni, Pb and Zn. The contents of Cd, Cr, Cu, Hg, Ni, Pb and Zn in surface sediments of radial sand ridge field varied within the natural background, and came from natural sources. Factorial kriging analysis were applied to examine the spatial multi-scale variability of seven heavy metals and to identify environmental factors affecting spatial variability at each spatial scale. Linear model of coregionalization(LMC) fitting indicated that spatial variation of heavy metals in surface sediments of radial sand ridge field was composed of nugget effect, an exponential structure with the range of 7 km (local scale), as well as a spherical structure with the range of 25 km (regional scale). At local scale, the spatial variations of metals were dominated by grain sizes of surface sediments, and the patches with high values were distributed in the northwestern and southeastern parts of radial sand ridge field. At regional scale, the spatial variations of heavy metals were controlled by mineral composition. The sediments of radial sand ridge field showed good environmental quality, and had little environmental risk. The relative high risk was merely located in the region with fine grain size.

Key words:

Heavy metals; Spatial multi-scale variability; radial sand ridge field

The Hyperspectral Response of *Carex cinerascens* to Pb and its combined Pollution Stress

NI C Y, SONG P F, LI H Y, XIONG X Y

Jiangxi Normal University, Nanchang, Jiangxi province, 330022, P. R. China, ncy1919@126.com

Abstract

To build a connection between spectral information from the Environmental Satellite and soil heavy metal stress, the hyper-spectral information captured by portable full spectrum spectrometer (SVC HR-1024) of *Carex cinerascens* (*C.cinerascens*), a dominant plant in Poyang lake wetland, response to the stress of heavy metal pollutant Lead (Pb) and its compound metals (Cu, Zn), was discussed in this study. Results showed that metals' content in plant and soil (bioactivity) raised significantly with the increasing of added Pb, Cu and Zn. The sensitive spectral bands and characteristic parameters of *C.cinerascens* response to single Pb stress were Green Peak Value (550 nm), Depth of Blue Valley (495 nm), Depth of Red Valley (675 nm), Peak Value of Red Edge and Red Edge Slope (725 nm), and Pb content of leaf was positive correlated with Green Peak Value, but were negative correlated with others. When Pb combined Cu, spectral parameters were mainly affected by Cu concentration. While Pb combined Zn, Value of Red Edge and Red Edge Slope were the sensitive spectral parameters. But when Pb combined with Cu and Zn together, no any spectral parameter had significant correlation with the concentrations of added compound metals. So when mention to monitoring heavy metals' pollution in the soil by remote sensing technique, which can catch hyper-spectral information of vegetation quickly in a large scale, the stress of vegetation caused by single metal or compound metals should be treated with caution, most spectral characteristic parameters have better relationship with single metal stress than that of compounds.

Carex cinerascens; Pb stress; spectral parameters; compound pollution

The Impact of Iron Plaque on Rare Earth Elements Uptake and Translocation by Rice

Shulan Jin, Yizong Huang

¹Shangrao Normal University, Shangrao 334000, China, jsl809@163.com

²Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences, Beijing 100085, China

Abstract

We studied the impact of iron plaque on uptake and translocation rare earth elements by rice, using hydroculture method. After soaking 12 pots of rice in Fe_2SO_4 for 36 hours, the root surface appeared reddish brown substance deposition. Using ICP-OES measurements, the results suggest that the root surface of rice formed iron plaque. We added three different concentrations of lanthanum nitrate into 12 pots of rice with iron plaque and 12 pots of rice without iron plaque. 10 Days later, we found that the La content in the root system and stem leaf of the rice with iron plaque is lower than the rice without iron plaque. The results suggest that the iron plaque has inhibition on uptake and translocation rare earth elements by rice.

Iron Plaque; Rare Earth Element; Lanthanum; Rice

The Potential of Seaweeds to Integrate the Remediation of Eutrophic Sea Waters with The Improvement of Inland Iodine Deficiency Environments

Li R¹, Liu J¹, Hong C², Zhou J¹, Hu C¹, Song M³, Dai Z¹, Weng H¹

¹ Institute of Environmental and Biogeochemistry, Zhejiang University, Hangzhou 310027, China, zhedalirui@zju.edu.cn

² Zhejiang Academy of Agricultural Sciences, Hangzhou 310021, China

³ Geological Research Center for Agricultural Applications, China Geological Survey, Hangzhou 310007, China

Abstract

How to effectively remediate the eutrophic sea waters, and to improve inland iodine deficiency, are two critical ecological problems to be solved urgently. The contents of main macroelements and micronutrients of the kelp, a macroalgae growing in Bohai Sea, Yellow Sea, East China Sea, and South China Sea, were measured. Its regional differences in nutrient contents and purification ability for nitrogen and phosphorus in sea waters were analyzed. Meanwhile, the organic iodine fertilizer was made from kelp to cultivate iodine-rich vegetables, and the biogeochemical process of using exogenous iodine to improve soil iodine deficiency was revealed. At last, a kelp-based potential solution to remediate the ecological environment was proposed, which can connect the remediation of eutrophic sea waters and the improvement of inland iodine deficiency in series. This may provide a technical route to foster an environmentally friendly iodine industry chain, including large-scale cultivation of kelp, extraction of biomass energy from kelp fermentation, manufacture of organic iodine fertilizer, and cultivation of iodine-rich plant foods, etc.

Competing forces of socioeconomic development and environmental degradation on health and happiness: A multilevel analysis of China

Gu L^{1,2}, Rosenberg M², Zeng J¹

¹Central China Normal University, Wuhan 430079, Hubei, China, gulijuan25@mails.ccnu.edu.cn

² Department of Geography and Planning, Queen's University, Kingston, Ontario K7L 3N6, Canada

Abstract

China's rapid socioeconomic development in recent years and its accompanied environmental degradation are altering the conditions of residents' well-being. This paper applies multilevel analysis to 2013 China General Social Survey data on social development and health. Multilevel models are developed to investigate the competing forces of socioeconomic development and environmental degradation on self-reported health (SRH) and self-reported happiness (SRHP) and the unique situation encountered by low, middle and high income groups. Geographical distributions show significant spatial patterns with northern China having the highest levels of SRH and SRHP compared with low SRH in the southwest and low SRHP in southern coastal China. Logit multilevel analysis demonstrates that community environmental hazards mainly harm happiness of low and middle income groups while provincial-level greenspace coverage is linked to good health for all. Contrary to expectations, subjective and objective measures of pollutants are linked to good health, especially for high income groups, and developed provinces are connected to lower odds of happiness. The positive role of government and income on health and happiness are only significant for low and middle income groups. Employment is health protective for all while having basic health insurance is linked to SRHP of the low income group. These outcomes indicate the complex interconnections among economic development, environmental degradation and government policy have differential effects on SRH and SRHP in different parts of China and among different income groups.

Dengue spread in Pakistan; Facts and Factors responsible for the outbreak of this disease and its mitigation strategies

Abdul Ghaffar¹, Bushra Khalid²

¹Department of Meteorology, COMSATS Institute of Information Technology (CIIT), Islamabad, Pakistan, aghaffar@comsats.edu.pk

²Department of Environmental Sciences, Islamic International University (IIU), Islamabad

Abstract

Climate is an important factor as temperature, rainfall, winds and humidity play a crucial role in the vector borne disease outbreak that shows the direct and indirect economic loss of millions of USD each year and are inextricably related to human health as well as human mortality and morbidity. An increase in temperature, rainfall and humidity in Monsoon months in Pakistan has been associated with an increase in the incidence of dengue cases. In north-east Punjab, vector borne disease epidemics increase fivefold in the year following an El Niño event. The present study reveals the Dengue spread in Pakistan from the four big cities at macro-level as well as at micro-level based on the climate, social covariates and on the environmental risk factors. In one part of this study we have presented a data for the four years (i-e 2009-2012) while in second part we have selected a high endemic year of Dengue spread (i-e 2011) and based on the results we have suggested the mitigation strategies as well as the early warning system to save our community from this dreadly disease. Moreover, this study also focuses on the extension of Dengue, based on the above mentioned parameters (climate, social and environmental risk factors) in different regions of Pakistan.

Key words:

Dengue spread; Climate covariates; social covariates; mitigation strategies

Global Environmental Change and Urban Health Analysis: Some Emerging Complexities for Interdisciplinary Discourse

Raheem U.A (PhD) and Awotayo G.P (MSc)

Department of Geography and Environmental Management, University of Ilorin, Ilorin-Nigeria

Abstract

There is a strong scientific consensus that warming of the climate system is a fact that can no longer be ignored for human health particularly in cities of developing countries. For instance, evidences show that climate change is shifting the overall temperature distribution and thus increasing the frequency of heat waves around the world. Despite these evidences and the need for decisive actions on climate change impacts many issues remain as conceptual and methodological complexities that are open for multidisciplinary discourse. These puzzles serve to cast aspersions on the ability of analysts of climate and health relationships to be able to produce concrete and flawless evidences of the postulated impacts. This paper examines some of these puzzles, using the example of urban health analysis in most cases, with a view to challenging meaningful academic discourse in a multidisciplinary environment. The paper draws on grey literature from both the climate and public health sciences to identify largely unresolved issues in the climate change and human health nexus. The implications of the challenges described in the paper are enormous for the kind of progress made in climate and environmental change research particularly as it affects urban health analysis. An immediate implication of the complexity is the development of the climate skeptics who claim that the argument that the present-day processes of global warming are produced by human activity is not proven. The paper posits that it would be profitable to adopt the concept of Global environmental change instead of Climate change. The former is broader and much flexible in interdisciplinary discourse while the latter is narrower and susceptible to dispute by climate skeptics. This will allow us to emphasize the effects of 'Environmental' rather than 'climate' in the issue of urban health.

GEC; Health; Interdisciplinary; methodology

Health and Wellbeing in the Changing Urban Environment: A case study of New Delhi

Dr. Monika Vij

Department of Geography, Miranda House, University of Delhi, monikavij@hotmail.com

Abstract

The world has passed the demographic milestone of becoming predominantly urban. Over half of the world's population lives in urban areas and the urban population is increasing by over 2% annually. Whatever be the size or function, cities are, first and foremost, human habitat-not mere engines of economic production and growth. Understanding of the dynamics of the biophysical components of the city and the way their functioning impinges on people is a vital part of urban studies.

The grouping of people together in confined spaces has always produced discomfort, risks of disease, problems of food and water supply, disposal of waste and so on. As cities have grown, these environmental problems have become so severe that the liberation the cities provide appears to be reduced by the restrictions imposed by the urban environment. Although the urban dweller has benefitted from the greater opportunities for economic growth, cultural enrichment and social enjoyment, the quality of urban life appear to have been deteriorated as the citizen feels more and more threatened by polluted air and water, crowding and noise. Currently there is limited understanding of the complex causal processes that shape urban population health and inequalities in health at local, regional and global scales. Food, nutrition, water, landscape, waste, transport, infrastructure, housing, energy, safety, security, access to health care and the urbanization process itself are interdependently linked to urban health, each influencing the other. Running through all these aspects of health and well being are power inequalities and differential impacts on age, income, gender, race, migrant status and social class.

As India's capital city, New Delhi is experiencing unprecedented population growth. The rise in population has also been associated with growth in economic activities leading to environmental problems. The growth in civic amenities has not kept pace with the rising population. Unabated in-migration has compounded the problem. Land use regulations have been flouted in many cases and the green cover of the area is also dwindling- all raising very serious questions about the sustainability of the city and its resultant impact on the human health. For the purpose of this study following question emerge: How does the urban environment determine the health status of the urban people? What are the correlates and determinants of health and well being in urban environment? How does governance affect the issues of urban health and wellbeing?

Key words:

Governance; climate change

Impact of Drinking Water on Human Health, the Challenges Ahead: A Case Study of Tekelangjun of Karbianglong District

Dr. Hazarika Minakshi P.

JB College, Jorhat, Minakshi_gse3240@yahoo.in

Abstract

Clean and fresh drinking water is one of our most vital resource. The human body is made up of over 70% water and our energy level is greatly affected by the amount of water we drink. Health on the other hand as defined by WHO is “a state of complete physical, mental, social and spiritual well being and not merely the absence of disease and infirmity”. It is experienced by disease free people living in harmony with their environment and with one another. Thus, good health is profoundly influenced by both external and internal conditions of life. External factors of the physical environment are climate, toxins and others, which play an increasingly important role. The accessibility and availability of basic amenities such as water supply is definitely an important indicator of the quality of life. Drinking water is a key factor influencing the health status of an individual and is the most often cause of disease and death especially in developing countries.

This study is done in Tekelangjun area of Karbi-Anglong district in Assam. Generally, fluoride exists fairly abundantly in the earth's crust and can enter groundwater by natural processes. The 1984 WHO guidelines suggested that in areas with a warm climate, the optimal fluoride concentration in drinking water should remain below 1 mg/litre (1ppm or part per million). High concentrations of fluoride occurring naturally in groundwater have caused widespread fluorosis among local populations. Thus, in this paper, the researcher tires to assess the outcome on the health of the residents located on the Karbi Hills with warm sub-tropical climate.

Incorporating Social Vulnerability to Assess Population Health Risk Due to Heat and Cold Stress in China

QIN Wenmin, LIN Aiwen

School of Resource and Environmental Sciences, Wuhan University, Wuhan 430079, China

Abstract

This paper presented a new conceptual framework by taking account of heat and cold stress, social vulnerability, and population exposure. Meanwhile, an index system combining environmental data, demographics data and socioeconomic data has been built for the quantitative assessment of county-level heat stress risk pattern of China. Using a factor analytic approach, the evaluation variables were reduced to fewer independent factors. Felt air temperature index was used to improve the evaluation of heat and cold stress.

Key words:

social vulnerability; population health risk; heat and cold stress; China

Problems and Prospects of Disabled Population in India

Laxmi Kant PremPrakash

Centre for the Study of Regional Development, School of Social Science, Jawaharlal Nehru University, New Delhi, India,
Laxmi.jnu10@gmail.com

Abstract

It is a utopian notion of a 'Harmonious World' until world's 15 percent disabled population (WHO 2015) is developed in all aspects of life. Since the disabled population is subjected to multiple deprivation, they are most oppressed, most backward, weakest of the weakest, utterly neglected, less served, less loved, less respected, in the world. The present paper is an attempt to study the socioeconomic and demographic status of the disabled population in India. The factors associated with disabled have also been discussed. The spatial variation at sub-national level has also been explored with the help of the maps. To accomplish this task, the latest data has been collected from 'Census of India 2011'. The cross tabulations and Arc GIS techniques have been used to meet the objective of the paper. The major findings reveal that the male population is more disabled compared to female disabled population and the percentage of not-movement disabled population is the highest in the country. Findings across the social-strata bring home the glaring disparities on various counts in regard to the disabled population amongst the lowest rung of the society. The larger chunk of the disabled population belongs to the 10-15 years old age group. The illiteracy particularly, female illiteracy and unemployment are the major concern of the disabled population in the country. Maximum disabled population is unmarried and males exceed than that of the females. Loopholes have been identified and Policy implications are well charted out.

Relationship between Deprivation and Population Health Status. Case Study: Ialomița County (Romania), Health and Health Care

Taloș A.M.

Faculty of Geography, Bucharest University, Bucharest, Romania, talos.ana@gmail.com

Abstract

Compared to other European countries, Romania has a precarious health status. One of the main determinants are socio-economic factors (education, housing endowment, occupation, income etc.). The main objective of the present study is to reveal the territorial differences in population health status in relationship with deprivation, trying to demonstrate that socio-economic factors are influencing health status.

The study area is Ialomița county, located in a plain region of SE part of Romania, being characterized by precarious population health status compared to other Romanian counties.

The study was based on statistical and spatial analysis. The territorial differences in health status have been analyzed using a complex aggregated indicator (deprivation index) resulting from aggregation and standardization of different indicators (occupation, housing endowment, education). The outcomes have been processed using the programs Quantum GIS 2.2.

Preliminary results point out a significant influence of socio-economic factors on health status of various groups of population, factors such as education level, housing endowment and occupation could explain the existing differences in population health status.

Key words:

deprivation; population health status; Ialomița county; health indicators; territorial inequalities

The effects of VOCs on cancer rate: evidence from panel data of Chinese cities

Wenbo GUO^{1,2}

¹Department of Urban Planning and Design, the University of Hong Kong, Hong Kong SAR, China, guowen_bo@126.com

²College of Urban and Environmental Sciences, Peking University, Beijing 100871, China;

Abstract

The issue of population health has drawn increasing attention from geographies of health and health. The links between health risks and health responses both at population-level and individual-level within multi-scaled lenses is now becoming critical in geospatial health researches. PM_{2.5} and other pollutants have been extensively explored their relationships between health results, but the relationships of VOCs and cancer rate is far-to-sufficient to be revealed. This paper dissects this question by first stressing the spatial turn in health researches and reviewing the literature of air pollution's health effects on human being mainly based on the work by geographers, and examines the effects of VOCs on cancer rate based on the panel data, of which the VOCs data are collected and modelled into city-level concentration according to the industrial share and GDP contributions, and the cancer rate data are derived from Statistical Yearbook of Chinese cities. On the basis of spatial statistic feature of VOCs and population's cancer rate data, statistic modelling and spatial analysis are employed in revealing the linkage between VOCs and cancer rate. It is demonstrated the effect of VOCs on population's cancer rates and differentiation in different areas.

Urban Health and Well Being: A Case Study of Urban Delhi

Sandesh Yadav*, Prof. Haseena Hashia

Department of Geography, Jamia Millia Islamia, Delhi-110025, India, sandesh_official@yahoo.in

Abstract

The fast pace of urbanization and tremendously increasing urban population have direct impact on the health of urban dwellers. If we go through the World Health Index (WHI), India is lagging behind even than some of the African Countries. The NCT of Delhi is characterized by the 97.5% of urban population and only 2.5% rural population as per census 2011 and such a huge urban population have created enormous pressure on the urban health system which in lieu have resulted in poor health of the urban dwellers. The immigration is an important factor which contributes heavily to this problem in the NCT of Delhi and the risks associated with this migrated population. The deteriorating environmental conditions, creation of different types of wastes and pollutions, continuing social fragmentation and overburdened urban infrastructure are some urban health determinants which got transformed drastically.

The present research study begins with a brief description of the urbanization process in NCT of Delhi. The study moves further to examine the role of urban environments, urban society and urban health systems. In its main course, the research study will focus on the various determinants causing health hazards for urban population, growing disparities in urban health services and role of various agencies including government, which urgently need to be addressed for a future urban health agenda. The research study closes with recommendations and suggestions on the overall urban health status of NCT of Delhi.

Keywords:

Urbanization; World Health Index; Immigration; Social Fragmentation.

Correlates of Caesarean Section Delivery in West Bengal (India): An Analysis Based on DLHS-3

Sk Rayhan, BaruaSomdutta

awaharlal Nehru University, New Delhi, India, rayahangog@gmail.com

Abstract

It has been well recognized that medically unnecessary caesarean section could increase morbidity risks for both the mother and her child and also could put strain on both institutional and individual assets. On the basis of these observations, the present study tried to assess the levels and trends of C-section delivery rates and to examine the factors associated with C-section delivery in West Bengal. Data from the third round of the District Level Health Survey 2007-08, covering 6,447 ever-married women of age 15-49 years has been used. The predicted probabilities from logistic regression analysis have been computed to measure the net effect of independent variables on the dependent variable. The results have shown that about 12 percent women delivered their babies by caesarean section and rest of the 88 percent women delivered their babies normally or through assistance in West Bengal during the reference period preceding the survey (DLHS, 2007-2008). The results of estimated predicted probability computed from logistic regression reveal that delivery in private health facilities, lower birth order and higher level of education are the strongest predictors of caesarean section delivery. Besides, higher number of ANC visits and higher maternal age are also significant factors of caesarean section delivery. For the betterment of women and child health and appropriate use of resources the universal guidelines, protocols and medical audit on caesarean section should be implemented. Further, the maternal and child health related educational programme should be implemented for educated women as well as uneducated women.

Key words:

caesarean section delivery

Geographical Perspectives and Approaches to Human Health and Well Being

Mohd Taqi, Mohd Mazhar Ali Khan

Department of Geography, Jamia Millia Islamia University, New Delhi, 110025, India, taqizaik@gmail.com

Abstract

Geography and health are intrinsically linked. The place where we born, live, and work, the social, built and natural environment which surrounds us directly influences our health and exposure to various diseases. Environmental factors play a fundamental role in shaping human health. A variety of place based attributes like physical (altitude, temperature, water, air, pollution etc.), social (religion, language, race, perception of risk behavior, social access to care etc.), and economic (quality of nutrition, access to better healthcare services etc.) affect health at a greater extend. Understanding the health impacts of these attributes of place is one of the most challenging yet important contemporary geographical problems. Geography has a crucial role to play in advancing understanding of spatial variations in the spread of disease, access to care, treatment and prevention of illness. Various approaches specific to geography can provide insights into locational factors affecting health and diffusion of diseases. In this context the paper aims to explore how and why space and place are important for health and well being and provides an overview of geographical approaches to interpret the complex relationship between health and socio-physical environment. The paper also aims to review a rich body of theory and research to show how attributes of space and place are associated with human health and well being and illness.

Identifying the Spatio-Temporal Pattern of Avian Influenza A H7N9 in China 2013-2014

Zhang P

College of Geo-Exploration Science & Technology, JiLin University, Changchun 130061, China, zp@jlu.edu.cn

Abstract

The novel avian influenza A subtype H7N9 has posed a potential epidemic threat for human beings in both China and the rest of the world. So the whole world has been concerned about it. This paper used *Moran's I* index to analyze the spatial autocorrelation of the avian influenza A subtype H7N9's average annual incidence rates in China, and applied the Bayesian hierarchal model to predict the relative risk of avian influenza A subtype H7N9 infection in human of China at county level during 2013 to 2014. The results showed that the average annual incidence rates of avian influenza A subtype H7N9 at county level had the positive spatial autocorrelation because their *Moran's I* indexes were all larger than zero with their *P*-values not larger than 0.05. And their spatial point pattern took on the clustered distribution. Moreover, the county number of relative higher risks of avian influenza A subtype H7N9 infection in human for the year of 2014 has decreased comparing to those in the year of 2013, with their maximum value and minimum value of relative risk were all declining. It could illustrate that the relative risk of avian influenza A subtype H7N9 infection in human of China at county level had reduced from 2013 to 2014.

Knowledge and Practice of Non Pharmacological Management of Pain among Sickle Cell Clients in Selected Hospitals, Southwestern Nigeria

Adeleke O.O, Oluwafemi O.A,

Oyo State Hospital, Oyo State, Nigeria, toyinfemi007@yahoo.com

Abstract

Nigeria is among the major endemic countries where Sickle Cell Disease (SCD) causes serious psychological pains to the patients. The management of pain in SCD involves multitasking and multidisciplinary approach. Over the years, management of the pains usually involves pharmacological approach; empirical studies have shown that Non Pharmacological Approach has been practised worldwide but still new in tropical sub-Saharan countries including Nigeria. Hence, this study examines the Non Pharmacological approach combines with biofeedback, self-hypnosis, relaxation therapy and cognitive-behavioural interventions. The study adopted a descriptive research design targeted at sickle cell clients between the ages of 10-60 years attending haematological clinics at Obafemi Awolowo University, Ile-Ife and Ladoke Akintola University Teaching Hospital, Osogbo both in Osun State, Southwestern, Nigeria. Sample Size was derived using Taro Yamane's formular with a structured Questionnaire through accidental sampling methods to 200 respondents. The data were analysed using Statistical Packages for Social Providers (SPSS). The study clearly reveals 56% of the total respondents were female clients while 44% were male respondents. The study also revealed that clients engaged in eight major Non Pharmacological Management of Pain (NPMP) with Application of Ice Block to the painful locations of the body with 73%, Massage 68.4%, Dancing 11.5%, Swimming 20.7%, Self- hypnosis 10.3%, Acupuncture 37.9%, Physical Exercise 29.9%, Heater Usage 69.5% and Others 1.1%. The study also revealed that 37.5% of the respondents have poor knowledge about NPMP, 25% with good knowledge, 20% with fair knowledge and 17.5 % with very good knowledge. The study concludes that majority of the respondents are not satisfied with the use of NPMP for the management of SCD. Hence, the study suggest that health providers should take into cognizance awareness campaign on various methods of Non Phamacological Management of Pain (NPMP).

Mapping the Dynamics of Global Physical Aluminium Economy

Liu, G.

Centre for Life Cycle Engineering, Dept. of Chemical Eng., Biotech. And Environ. Tech., University of Southern Denmark, 5230 Odense, Denmark. gli@kbm.sdu.dk

Abstract

Material cycles have become increasingly coupled and interconnected in a globalizing era. While material flow analysis (MFA) has been widely used to characterize stocks and flows along technological life cycle within a specific geo- graphical area, trade networks among individual cycles have remained largely unexplored. Here we developed a trade- linked multilevel MFA model to map the contemporary global journey of anthropogenic aluminum. We demonstrate that the anthropogenic aluminum cycle depends substantially on inter- national trade of aluminum in all forms and becomes highly interconnected in nature. While the Southern hemisphere is the main primary resource supplier, aluminum production and consumption concentrate in the Northern hemisphere, where we also find the largest potential for recycling. The more developed countries tend to have a substantial and increasing presence throughout the stages after bauxite refining and possess highly consumption-based cycles, thus maintaining advantages both economically and environmentally. A small group of countries plays a key role in the global redistribution of aluminum and in the connectivity of the network, which may render some countries vulnerable to supply disruption. The model provides potential insights to inform government and industry policies in resource criticality, supply chain security, value chain management, and cross-boundary environmental impacts mitigation.

Production and Consumption of Calories in India and Implications for Food Security: A Spatial-Temporal Analysis

Bhattacharya R, Ravi J

PhD Candidate, CSRD, SSS, JNU, New Delhi, India-110067, ruchijnu16@gmail.com

Abstract

We attempt to analyse the changing patterns of calorie, protein and fat intake both nationally and regionally for rural India and relate it to the changing patterns of production. We divide total nutrient intake in cereals, pulses, animal and vegetables and observe the change in balance of calorie, protein and fat in household's own production and purchases of food. We observe that consumption of staple calories from PDS and Home grown stock are supplementary. Households with access to these sources purchase a lesser proportion of staple calories from market. In both the irrigated and unirrigated regions there is evidence of overall increase of percentage of non-market consumption between 2009 and 2011. Increase is mainly of consumption from PDS. We also observe that due to changes in content of production towards finer staples and lesser production of pulses or coarse grains household's access to own production has gone down. PDS has not been able to replenish the same. We find an association between regional production and nutrient balance in consumption. The irrigated coarse grain and cotton producing regions produce a higher percentage of protein and lesser percentage of carbohydrate. Consumption of carbohydrate, protein and fat in these regions is close to WHO norm. But the rice growing irrigated and rainfed regions which produce an excess of carbohydrate show imbalance in nutrient intake. The study emphasises the need for procurement of alternative food grains and regional distribution and also coverage of small farmers of non-food crop producing regions in food policy.

Research on the Dynamic Impact of Public Service Expenditure on Residents'

Consumption

Zhuangyuan LI, Jinying WANG

School of Economics, Hebei University, Baoding, 071002, Hebei, China, wangjy369@263.net

Abstract

Consumption, investment and net exports are to promote economic growth in the “three carriages”. Among them, consumer demand is the biggest driving force of economic growth, investment is a kind of consumer demand, if there is no support for consumption, the investment will become invalid investment. For a long time, the final consumption rate of Chinese residents all the way down, from 50% in 1990 down to 46% in 2014, during the period had slipped to 33.8% in 2010.

Scholars at home and abroad through various economic models analysis shows that public expenditure has a certain impact on the consumer. In this paper, we will integrate the financial education expenditure, health-care expenditure and social security expenditure into the public service expenditure, and analyze the mechanism of the impact on the consumption of the residents, based on 31 provincial data of China during 1998-2014, established a quantitative analysis of the impact of the data panel model on the consumption of the residents in China's provincial public service expenditure, and expect to explain the following questions: 1. The public service expenditure of resident consumption in our country has what effect? 2. In the short-term and long-term economic growth, public service expenditures whether can play a role in promoting economic development? What is the meaning and function of? 3. Public service expenditure on residential consumption and economic growth? It is concluded that the increase of public service expenditure promotes the consumption level of residents, and points out that the level of public service expenditure is limited, not unlimited.

Key Words:

Public service expenditure; Residents' consumption; Panel Data

Spatial Analysis of Public Education and Average Private Household Expenditure on Education in India

Bhattacharya R

PhD Candidate, CSRD, SSS, JNU, New Delhi, India-110067; email: ruchijnu16@gmail.com

Abstract

The paper is an attempt to analyse up to what extent free education can reduce households' burden of private expenditure on education. Such an analysis is important in current government policy drive of reducing subsidies from social sectors and providing targeted free education to poor. Analysis on NSSO data on Participation and Expenditure on Education, 2007-08 reveals that free education is available only at elementary level and at that level also free education is not universal. Using decomposed Gini coefficient for free and paid education subgroups we compare up to what extent free education exempts students from private expenditure. Component wise gini decomposition has been used for each state to understand the particular item that is responsible for most of the expenditure and inequality between households. It has been observed that above elementary level free education is almost inexistent and expenditure on education is incurred on all consumption expenditure quartiles. Doing a region specific comparison of supply of public funded education and demand for private education we observe that household private expenditure on education is not entirely "choice" driven. From a policy perspective it comes out that quality of public educational institutions have to be improved so that private tuition does not remain a necessity and overall education from primary to highest level have to be provided by government to relieve households from expenditure burden.

household consumption; education expenditure; free-education; private-expenditure; gini coefficient; gini decomposition

The Study on the Suitable Planning Index System of Non-profit Public Facilities in County Seat at the Eastern of Northwest China

Xin Wu, Peng Cui

College of Urban and Environmental Sciences, Northwest University

Abstract

As an important guarantee of the daily life of urban and rural residents, the non-profit public facilities are the basic instruments to realize public service of government, and promote social fairness and justice. A scientific and rational non-profit public facilities planning is the premise to enhance the level and the degree of equalization of basic public services. A complete specifically planning index system for non-profit public facilities is not exist, the planning indexes are scattered around various related standards. Most of the existing standards on the planning of public facilities is suit for large and medium-sized cities, towns and villages, and is not caring the non-profit public facilities in county seat not only serve the town itself but also the whole county. It also should take some characteristic of the county seat into account in their non-profit public facilities planning, as the limited government investment, lacked county seat construction land and low-level socio-economic development. It is conducive to promoting the region to establish and improve sustainable basic public service system in line with national and region conditions, and gradually promote the equalization of basic public services. This study summarizes and sorts out the related indexes from existing standards, and builds a planning index system of non-profit public facilities. It also has an analysis of the suitability on its use in the county seats at the eastern of Northwest China. Then, the study builds the framework and content of the suitable planning index system, and explores the suitable of the planning index. The index system can be used as guidance to plan and construct non-profit public facilities of countries. It is also the practice of urban planning as a society fair and equitable public policy as well as improving the level of common service, promoting the regional community as a whole, balancing regional development and building a harmonious society. All of these have a very important theoretical and practical significance.

Key words:

eastern of Northwest China; non-profit public facilities; suitable planning index system; county seat

Accessibility and spatial equalization of rural public services in Jiangnan Plains

Luo Jing, Tian Lingling, Zeng Juxin

Hubei Province Key Laboratory for Geographical Process Analysis and Simulation, College of Urban and Environmental Science, Central China Normal University, Wuhan 430079, Hubei, China

Abstract

Public education, health care and culture services are the stable and persistent demands that farmers need, which means that their accessibilities are significant indexes of the rural life quality, and Spatial equalization is the developmental orientation of new village construction. (1) This paper, which focuses on the main rural areas in Jiangnan plains and its representative counties, is concentrating on the public education, health care and culture services in rural areas, taking the administrative villages as basic spatial units. It will found a spatial analysis model on population, settlements, services to exhibit people's public service demand and spatial behaviours, distribution of public facilities and resources, road network structure and mobility pattern in a multi-scale by using the geographimetrics and geovisualization method. (2) The accessibility will be calculated by the integration of availability, proximity and mobility, and will be classified by spatial cluster. Also, the spatial autocorrelation model is to be found to analyse spatial equalization. The above methods are to explore the spatial portfolio and diversity of accessibility and equalization, and thus to detect the shortage areas of public services. (3) According to the project of rural population and demand changes, targeting to the new village construction and equalization of basic public services, and taking the service radius and service population as key index, the project carry out simulation of public service facilities and spatial distribution of resources to analyse the responding mechanism of accessibility and spatial equalization, and thus provide scientific theory and tools to rural education, health care and culture spatial planning.

Key words:

public services; location; spatial analysis model; new village

Study on Spatial Pattern and Spatial Effect of Basic Public Services Supply Efficiency in China

WU Di, ZHAO Lin, LI yang, CHEN siyu, WU Dianting

Beijing Normal University, School of Geography, Beijing, 100875, P. R. China, nk.wd@163.com

Abstract

This paper estimates the provincial supply efficiency of public service in China from 2007 to 2014, based on the super efficiency DEA model, then the exploratory spatial data analysis method is used to discuss its spatial autocorrelation, and finally, uses spatial Durbin model to analyze the spatial spillover effect and influencing factors of basic public service supply efficiency. Research shows that: (1) China's basic public service supply efficiency displayed a "U" type evolution trend from the year 2007 to 2014. Both absolute gap and relative gap among provinces showed a trend that became wider. Areas with low efficiency were still showing a significant difference from areas with had high efficiency. Gap between provinces was kind of revealing a pattern of Matthew effect. (2) Basic public service supply efficiency was showing an uneven characteristic on spatial pattern, a decreasing gradient feature was quite obvious from east to west. Global trend of supply efficiency was showing a falling trend from east to west, as for north-south direction, the pattern was an inverted "U" type. (3) Global autocorrelation analysis showed that the interprovincial basic public service supply efficiency had a positive spatial correlation, a mode of scattered- agglomeration- scattered- agglomeration can be observed as time advances. High-High agglomeration area mainly located in the Yangtze River Delta, the Pearl River Delta and other eastern regions. Low-Low agglomeration area is the west and northeast China. High-Low and Low-High agglomeration were mainly focused on the transition area. (4) Spatial spillover effect of basic public service supply did exist. Urbanization level, industrial structure, the level of opening to the outside world, as well as urban transportation development level, together they had significant positive effect on regional basic public service supply efficiency.

Key words:

basic public services supply efficiency; super efficiency DEA model; spatial pattern; spatial spillover effect

The Spatial Organization of State-owned Bank Outlets in China: Taking Changchun as an Example

CHEN Yan, MEI Lin

School of Geographical Science, Northeast Normal University, Changchun, 130024, P. R. China, chen662@nenu.edu.cn

Abstract

Case studies in select large cities in China have found that bank outlets are usually clustering around the well-developed area and traditional banks are more accessible to high density neighborhoods. However, many analyses neglect the different levels of banking service and the special strategies made by each banking company. This study employs mean center, standard deviation ellipse and Ripley's K to untangle the relationship between the serving levels and spatial distribution and influence factors in Changchun. We found that the serving levels are indeed powerful determinants of bank location, the main four state-owned banks in high levels are all clustering in certain area, while the distribution characters of fringe bank outlets in lower levels are mainly effected by population base, commercial activities, zoning and developmental strategies. Furthermore, the number of bank outlets in both the highest and lowest levels is much smaller than the one in the other serving levels.

Key words:

state-owned bank outlets; spatial organization; serving level; Changchun City

A framework of efficiency and spatial equality analysis on reclassified urban parks in Wuhan

LJ Xing, YF Liu

School of Resource and Environment Science, Wuhan University, Wuhan, 430079, China, flygirlxlj @ 163.com.

Abstract

Urban parks connect natural and city residents, may influence the physical and mental well-being of them. Many researches focus on the fairness of urban parks while limits on the efficiency of actual usage in cities of developing countries. This study establishes a framework of efficiency and spatial equality analysis on urban parks in Wuhan based on the check-in dataset and population census. A multidimensional reclassification of urban parks instead of urban planning classification is first processed by the construction of supply and demand variables including natural features, traffic conditions, policy, social context and people's preference, for different kind's needs of residents may be correspond to different park services. The efficiency analysis using check-in density and equality analysis using Gini coefficient compare the reclassifying and urban planning park types to neighborhood social groups. The result reveals four distinct park types in study area and each with a unique mix of natural, spatial, land cover and building characteristics. The reclassification park types are less efficiency and equality than urban planning types, as well as each different level types. A discussion section probes into the causes of inefficient and inequality. The findings can inform sustainable and equitable urban park policy, planning and management.

Approaching Sustainable Urban Development in China through a Food System

Planning Lens

Scott, S, Zhenzhong Si, Taiyang Zhong

University of Waterloo, Waterloo, Canada, sdscott@uwaterloo.ca

Abstract

After more than two decades of rapid urbanization, Chinese cities now face severe sustainability challenges in terms of balancing economic viability, social justice, and environmental protection goals. While various types of planning have long been adopted to cope with these challenges, food as a centerpiece of daily life and of social and economic activity in cities has rarely been considered as a focus of urban planning in China, despite a lot of recent attention to food waste and food safety concerns. In contrast, over the past decade or more, cities in the west have seen food system planning emerge as a holistic lens to promote multifaceted urban development strategies. Community gardens and neighbourhood farmers' markets are two common examples. In these strategies, food has been recognized as a powerful element that links closely with multiple economic, social, health, and environmental issues. This paper thus calls for an integration of food issues into urban planning in Chinese cities. Our paper provides a preliminary assessment of urban food systems in China. The analysis brings together various priorities: connecting people to the local food system, community economic development, access to healthy food, ecological health, and integrated food policy. By applying this framework to examine urban food systems in China, our paper identifies strengths and challenges in terms of achieving sustainability goals. This analysis also sets the stage for future research on urban food systems in China.

Feedback between Virtual Land Embedded in Food Trade and Farmland Loss of China

Zhiying XU, Taiyang ZHONG, Guoliang XU, Yumei TANG, Qiong HE

School of Geographic and Oceanographic Sciences, Nanjing University, Nanjing, 210023, P. R. China,

xuzhiying1992@163.com

Abstract

China has experienced both notable farmland loss and increases in food imports during past 25 years. Food trade is the transfer of virtual land and water resources that embedded in traded commodities. Existing studies focused on the impact of farmland loss in China on significant increase in virtual land imports, while the impact of virtual land change on farmland loss was ignored. The aim of this study is to reexamine the relationship between the change of virtual land embedded in food trade and farmland loss in China, especially whether a reciprocal feedback exists or not. First, we calculate the virtual land embedded in China's food trade. Then we employ vector error correction (VEC) model and Granger causal analysis to investigate the interaction between them. The results show that China's net virtual land imports embedded in food trade has grown from 2.37 Mha in 1987 to 33.28Mha in 2012, especially a sharp increase since China's entrance into WTO in 2001. The bidirectional causal link between virtual land imports increase and change of farmland occupied for construction suggests positive mutual feedback between them. Specifically, aggravated farmland conversion stimulates net increase of virtual land, which in turn results in a further increase in farmland occupied for construction. Our analysis suggests intense tension exists between economic development and food self-sufficiency in the process of rapid urbanization.

virtual land; food trade; farmland loss; positive feedback; China

Food Safety and Trust: A Survey of Consumer Perception in Hong Kong

Wang, Y.¹, Ng, C. N.²

¹ Faculty of Social Sciences, The University of Hong Kong, Hong Kong SAR, P. R. China, wangyuray@connect.hku.hk

² Department of Geography, The University of Hong Kong, Hong Kong SAR, P. R. China

Abstract

Food safety is concerns people's daily life and health. Yet the issue of food safety only peripherally relates to foods themselves. With social division of labor and globalization, general consumers do not have absolutely accurate and full knowledge about the cultivation, production and distribution process of foods; as a result, their collective behavior of food consumption is essentially affected by an implicit trust placed in various actors in food networks, such as farmers, vendors, retailers, manufactures and regulatory institutions. Therefore, one of the key to disentangling the puzzles of food safety and its implications lies in the underlying mechanisms which account for the general public's trust in food. Trust in food is not only a complex multi-dimensional construct which is built upon diverse trust-relevant attributes (i.e. competence, willingness, care, fairness and openness) of different actors, it also involves an evolutionary process during which consumers' trust varies under a number of social, economic, political and environmental conditions. The Hong Kong Special Administrative Region (HKSAR) is a unique place which vividly illustrates all of the forgoing aspects of trust in food. As a highly urbanized city, Hong Kong has very limited agricultural industry and thus is heavily dependent on imported food. To what extent Hong Kong consumers are trustful in their food and in what ways they react to food safety problems? This study will present preliminary results of a city-wide survey to address these questions.

Key words:

food safety; trust; consumer perception; Hong Kong

Food Safety in Daily Lives: Perceptions, Coping Strategies and Improving Opportunities

Zhenzhong Si

Balsillie School of International Affairs, Waterloo, Canada

Abstract

Food safety has become an increasingly pressing sociopolitical issue in China largely due to the outbreak of food safety scandals in the past 8 years. Existing studies have highlighted the socioeconomic backgrounds of its emergence, and drivers and implications of the heightened food safety anxiety. Yet, few studies have examined the perceptions of food safety conditions and strategies undertaken by consumers in their daily lives to cope with the challenges. Based on a city wide survey of 1200 households in Nanjing, China, this research presents findings regarding Nanjing residents' perceptions of, and strategies to cope with, food safety problems, understanding of traceability, and their trust of certified and imported foods. Coping strategies investigated included Nanjing residents' participation in urban agriculture and alternative food networks. The results of the study enabled a better understanding of how food safety problems play out in people's daily lives. It tests previous assertions about food safety problems (e.g., higher trust of locally produced food; higher trust with clear traceability) and identifies opportunities for future practices. This research also examines various rural issues through the lens of consumer perspectives. These issues include reduction of chemical usage, control of soil and water pollution, traceability of food supply chains, and connections between consumers and producers.

Key words:

food safety; trust; certification; alternative food networks; food system; China

Food Security, Inclusive Growth and Governance of Public Space: The Case of Food Vendors in Nanjing, China

Ning DAI

University of Waterloo, Waterloo Ontario, N2L 3G1, Canada, n3dai@uwaterloo.ca

Abstract

Urban food security is a rising challenge in populous Chinese cities such as Nanjing. Street vendors play an important role in the urban food system by providing affordable and diversified food options. Due to their informal nature, food vendors are perceived as illegal and disruptive to public order in modern Chinese cities. Thus public streets in Nanjing have been restrictive towards food vendors. In recent years the Nanjing government began to relax the restrictions of public space towards food vendors. At the same time, the central government incorporated inclusive growth in the national development agenda. This shift calls for attention to the logic behind the policy changes and the impacts on food vendors, yet few articles shed light on these issues. Through a study of the food vending policies in Nanjing, this research explores the rationale for policy changes and the practice of emerging concepts, including informal economy, inclusive growth and entrepreneurship. This research demonstrates the impacts of policy changes on the geography of food vendors. Street vendors have been resilient in the face of changes in urban governance. They conduct business on a mobile and flexible basis to cope with regulations. By navigating the spatial patterns and mobility of street vendors, the research captures the reconstruction of social norms as an outcome of formal institutions and self-rule. Combining the two findings, this research determines the disconnects between food vendors and policy makers in the governance of public space.

Key words:

Urban food security; street food vending; governance of public space; inclusive growth; Nanjing

Organic Agriculture—alternative way of small-scale farmersto sustainable agriculture: case study in Wanzai County, Jiangxi Province, China

Abstract

Organic agriculture can support and sustain rural development and ease poverty in regions with low economic productivity, as in Wanzai County in Jiangxi Province. Due to the commitment of the local government, parts of Wanzai County have become one of the most important organic agricultural zones in China. By using the Sustainable Livelihood Approach (SLA), a conceptual framework for understanding and addressing poverty, the livelihood situation of organic farmers in Wanzai County from two studies from 2007 and 2014 is compared as well as presented and discussed. Small-scale farmers with less than 0.5 ha of land are still the most prevalent in the region. While their overall household net income has increased since 2007 from USD 2,065 to USD 6,159, it is just enough to meet their basic needs. Furthermore, the share of agricultural income has decreased. However, farmers with one to five hectare of agricultural land get not only more than half of their household net income from farming activities, but also reached the average Jiangxi rural household net income only with profits from cash crops and livestock. This paper analyses the question, which alternatives do small-scale farmers have in their hometown or in the region to improve their livelihood situation.

Organic agriculture; China; Income; Sustainable livelihood approach

Transformation of Rural Livelihoods with the Agro-industrialization and Capitalization of Tea Industry in Tongmu Village in China

Huaqing HUANG

Tsinghua University, Beijing, 100084, P. R. China, huang-hq12@mails.tsinghua.edu.cn

Abstract

This article studies the agro-industrialization and capitalization of tea industry and its influence on rural livelihoods, based on architectural and anthropological investigation of a historical tea village in Fujian, China. Tongmu village boasts the hometown of Lapsang Souchong, whose history of tea production could be dated back to 16th century. Its social and spatial form had barely changed until the 1980s, when the privatization of the collectively-owned tea industry gave rise to transformations in the scopes of socio-economy and agro-food system. Moreover, a luxury tea called “Jin Jun Mei” was successfully developed ten years ago, which not only ignited the prosperity of private tea business, but also paradoxically lead to the “re-collectivization” of local agro-industry when expanding tea manufacturers incorporated other smaller ones, putting the balance of social ecology at risk.

A “food system perspective” is adopted to understand how the transformation of local tea industry has changed the social, ecological and spatial form of the village. It is crystallized in a historical wooden tea factory, “Qinglou”, which is not only where tea is traditionally produced, but also recently recast as a “symbolic capital” of cultural distinction that local tea manufacturers try to sell together to costumers. Through the interpretation of both architectural and social-economic meanings of this industrial space, the article tries to show how tea manufacturers, workers and farmers adapted respectively to the trends of agro-industrialization and capitalization, and further reveal the limitations of agrarian transformation in rural China considering the improvement of rural livelihoods.

Key words:

tea industry; rural livelihood; food system; agro-industrialization

Understanding Community Building and its Impacts on Community Supported Agriculture (CSA) Farms in China

Danshu Qi, Weiping Chen

University of Waterloo, Waterloo, N2L 3G1, ON, Canada, spinach0322@gmail.com

Abstract

In the context of extended food chains, broad use of chemical in farming, and food safety problems, Community Supported Agriculture (CSA) has sprouted and spread quickly in China as a new relationship between farmers and consumers. CSA operators prefer to form a sense of community rather than the transactional relationship with consumers. However, little research has focused on the role of community building in shaping CSAs. In this paper, we explore the community building practices of CSA operators and analyze how community building affects the financial profitability of CSAs, job satisfaction of CSA operators, and relationships with members. This research takes a nationwide survey of 77 CSA operators around China. By using factor analysis and structure equation model, we conceptualize the community building practices in CSAs and explore the influences of community building on performances of CSAs. The result shows that, firstly, community building consists of three components: bonding, participation, and shared values. Secondly, community building influences job satisfaction most strongly, profitability second, and affects relationships with members least. On one hand, the research is valuable for CSA operators who seek to conduct community building in their practices; on the other hand, the research provides insights for understanding future relations between producers and consumers in the pursuit of rural sustainability.

Key words:

Community building; factor analysis; structure equation model; community supported agriculture

Linking Farmer Cooperatives through CSA to Market

Abstract

In a remote mountainous area of Guangxi province, characterized by steep karst mountain formations and fast-running streams, sits the village of Shanggula – a ‘natural village’ in Mashan County. In addition to vegetables, farmers plant maize in minute pockets of soil on the steep slopes between rocks in flat, tiny fields. The topography makes irrigation water scarce. Heavy rains tend to cause floods, regularly damaging field crops. There are no major roads, and access to markets is limited. In recent decades, most households have relied heavily on income from temporary work in cities in south and southeast China.

This situation is starting to change, however, because of the work of a dynamic women’s organization and its collaboration with a non-governmental organization (NGO) in the provincial capital of Nanning, Guangxi province, and a policy-research centre in Beijing. This is the story of this community’s experiences, their laughter and their tears, starting from Participatory plant breeding (PPB), and then in exploring and adapting the Community-Supported Agriculture (CSA) approach to revitalizing agriculture in their village, and now they try to attend a project of Participatory security system (PGS) in Guangxi. Though this initiative is not a CSA in the conventional sense of networked members who pledge to support local farms, those involved feel that the term captures what they are trying to achieve and we have therefore remained consistent with their use of the term. Through this case study, we explore what lessons they have learned and how these may be useful more generally for strengthening sustainable agriculture in China and elsewhere.

Key words:

Community-Supported Agriculture; farmer cooperatives; market

Ensuring Food Security with Lower Environmental Cost under Intensive Agricultural Land Use Patterns: A Case Study on Taojiang County

Xiaoxing Qi^{1,2}, Laiyuan Zhong^{1,3}, Liming Liu^{1*}

³ College of Agriculture, Guangdong Ocean University, Zhanjiang, 524088, China

Abstract

In the context of rapid population growth and environmental deterioration, ensuring food security with lower environmental cost is fundamental to realizing sustainable development in China. To provide an operational approach for regional policymakers to address the twin challenges of food security and environmental sustainability, based on the status of regional natural resources and socio-economic conditions, this paper took the perspective of farmers' decision-making behavior and established four foci-differentiated scenarios to explore how to achieve food security quantitatively with lower environmental cost. The results indicated that increasing grain yield while reducing environmental risks can be achieved when policymakers take differentiated and targeted policies and management measures to impel the transfer of farmland to farmers with advanced agronomic techniques. Meanwhile, actively promoting the construction of agricultural infrastructure would be a useful approach to resisting natural disasters, thereby enhancing the farmers' willingness regarding grain cultivation.

Abstract

In the background of "Internet +" big data, information network has become an important platform for traditional secondary real economic growth. In this paper, we chose used car industry in China as the research object, and made full use of the internet's superiorities of time-sensitive information and wide coverage, and selected the sample data from the five most influential Internet platforms of used car consignment. The mathematical statistics, location entropy index methods were selected, from Jan 25 to 29, 2016, to analyze the spatial characteristics of model, mileage, price, age and brand of used cars among capital cities. The conclusions are as follows: the used car industry in China was dramatically uneven, the agglomeration degree in eastern region was higher than western region, in a few large cities, agglomerations were obvious and typical to gather the saloon cars; used car consignment factors had affecting a certain geographical features, good branding and high price models were more concentrated in the big cities, the distribution of different models had a certain regional directivity, such as aged SUV models and MPV models were concentrated in less developed regions and service-oriented city, respectively. Different factors of agglomeration consignment also owned different characteristics, such as used cars in each province were heavily concentrated in 3 to 8 year-old, prices were more concentrated in 3-100,000 RMB. This study, in the background of "Internet +", is conducive to reveal the spatial layout disciplines and location factors of the traditional industry, provides empirical research foundations to optimize the various elements of spatial layout and promote efficient development of used car industry.

Keywords:

Geography of Adaptation of Industry on the Change of Socio-Economic System in Czechia in 1989

Kopačka, L.

Charles University, Faculty of Science, Department of Social Geography and Regional Development, 128 43 Prague 2, Albertov 6, Czech Republic, kopacka@natur.cuni.cz

Abstract

Process of socio-economic transformation was accompanied by deep changes of structure and geographical distribution of industry after the geo-political break in the contemporary Czech Republic on November 17, 1989. Events like disappearance of bipolar world, division of Czechoslovakia, becoming a member of European Union as well as processes of privatization and massive inflow of foreign direct investment evoked broad scale of concrete adaptations and re-orientation of whole Czech economy (sectors of economy), industry (especially proprietary, organizational and branch structure) and foreign economic relations (foreign trade). Parallel geographical distribution of industrial activities was re-localized substantially (macro-, mezzo- and micro-regional shifts; green-fields instead of brown-fields). Main aim of paper is to illustrate phases of development of industry in the course of transformation, changes and deformations, positive and negative tendencies.

Key words:

Socio-economic transformation; sectors of economy; branch structure of industry; geographical distribution of industry; foreign direct investment; foreign trade

Local Market Effect of Producer Services in Central City, China: By a Firm-level Analysis of Guangzhou

ZHONG Yun

College of Economy, Jinan University, Guangzhou 510632, China

Abstract

The term *local market effect* is got from the one named as *home market effect*, which was proposed in New Economic Geography. Expanding from NEG theory, this paper assumes that once the scale of the local market is large enough and the local network of firms has been set up, the industry will be influenced by the market attractions, therefore, the firms will tend to locate in local market and industrial agglomeration will appear accordingly.

Based on the data got from the questionnaires to the producer services firms in Guangzhou, this paper tries to evaluate the local market effect of producer services and figure out the determinants of the local market effect. Guangzhou is a central city in South China and also a most developed city in China. The contents of the study involves: (1) by exploring the exportation behavior features of the producer services firms, to evaluate the network or the agglomeration of producer services firms in Guangzhou. The question that I try to answer in this part is: while the firms selling more and more of their services to the market outside the local city, will the local market effect still happen in this central city? (2) by setting up an ordinal regression model, to analyze the determinants of the local market effect. Based on the literature reviews, several factors reflecting globalization, governance, local policy, competition and so on will be applied to test the interaction. All indexes for the regression are available from the database of the questionnaires.

To study the local market effect by the producer services firms' behavior in Guangzhou can be helpful to understand the agglomeration of the producer service in China. Furthermore, to evaluate the local market effects by the service exportation can be taken as a new way to assess the development of the producer service, distinguished with the traditional assessment by the statistical data such as value-added and employees of the industry, or the index such as industrial structure and specialization.

Key words:

local market effect; producer services; firm behavior; determinants

Study on Renewable Energy Industrial Clusters in the Hexi Corridor based on CAS

Theory

LV Rui, SHI Pei-ji

College of Geography and Environment Science, Northwest Normal University, Lanzhou, 730070, Gansu, China, ylr0319@163.com

Abstract

Understand the development of renewable energy industry in China from the perspective of evolution of industrial cluster development based on the theory of self-organization theory. To explore the regularity of the different stage of renewable energy industrial clusters in China. Through the analysis of the renewable energy industrial clusters agglomeration degree in the typical area, the development phase and evolution law of the renewable energy industry cluster in the Hexi Corridor are compared. Through the research, it was found that the renewable energy industry cluster in the Hexi Corridor was promoted under the administration of exogenous forces. It has completed the resource elements of self-reinforcing stage agglomeration, is currently in the transition phase from enterprise agglomeration ability self-amplified to cluster system self-adjustment. To speed up the development of new energy industry cluster in hexicorridor should strengthen the government's strategic planning, incentive policy design, financial support and regulatory services. Attract enterprises to the Hexi corridor development while increasing the root of the enterprise, improve the supporting industry to extend the industrial chain, enhance the ability of self-organization of industrial clusters.

Key words:

Renewable Energy Industrial Clusters; Self-organization; the Hexi Corridor; Agglomeration Degree

Technological Relatedness, Regional Institutions and Firm Survival in China

He, C F, Guo, Q

College of Urban and Environmental Sciences, Peking University, Beijing, 100871, China, hecanfei@pku.edu.cn

Abstract

The importance of agglomeration externalities for economic activities is widely recognized. Recent developments highlight the importance of technological relatedness to the performance of firms, industries and regions. This study explores the determinants of firm survival in China and tests the significance of technological relatedness and regional institutions using firm-level data over the period 1999-2007. Technological relatedness is developed from the co-occurrence analysis of paired industries. Results based on Cox regression models show that technological relatedness sustain large firms in China. Technological relatedness plays a larger role in sustaining firms in regions with developed market-oriented institutions and strong economic and political incentives from local governments. Productive firms and market-oriented firms are more likely to exploit technological relatedness to sustain while SOEs have no incentives to do that. This study highlights the significant influence of local forces on firm dynamics and enriches our understanding of regional industrial restructuring in China.

Key Words:

Technological Relatedness; Regional Institution; Firm Sustaining; Firm Heterogeneity; China

The Dynamics of Agglomeration Economies from the Industrial Life Cycle Perspective

Yiwen Qiu, Lin Zhou, Tiyan Shen

The School of Government, Peking University, Beijing, 100871, P. R. China, qiuyiwen@pku.edu.cn

Abstract

With the researches on agglomeration economies going deeper, the industrial life cycle theory has recently argued that the varying role of agglomeration economies emerges from the stage-specific needs within the industrial life cycle and provided an evolutionary view to explore the dynamics of agglomeration economies along the industrial life cycle. Based on the database from China's Annual Survey of Industrial Firms (2000-2011), this paper focuses on three aspects, 'evolutionary patterns of the industrial life cycle', 'characteristics of industrial specialization and diversification' and 'changing benefits of agglomeration along the industrial life cycle' to analyze the industrial heterogeneity and dynamics of agglomeration economies. The results are as followed. (1) Three evolutionary patterns of industrial life cycles are identified (Growth, Regeneration and Stability), and labor-, capital- and technology-intensive industries are characterized by young, stable and mature trends respectively. (2) The industrial specialization and diversification patterns both present the inverted U shape; both specialization and diversification increase as the maturity of labor- and technology-intensive industries increases, but specialization first increases and then declines while diversification presents an opposite trend as capital-intensive industries get more mature. (3) Both localization economies and urbanization economies strengthen as the industrial life cycle evolves from a young stage to a mature one, but generate different benefits across sectors. Finally, the results can be applied in practice to diagnose the problems regarding industrial composition at the regional level and optimize agglomeration economies by adjusting the regional industrial structure in a reasonable way.

Key words:

industrial life cycle; agglomeration economies; specialization; diversification; industrial heterogeneity

The Spatial Polarization and its Influencing Factors of the Service Industry in Xuzhou Metropolitan Area

QIU Fangdao, LIU Jibin, CHEN Yongsheng, WANG Yaoyu, ZHU Chuangeng

Jiangsu normal university, China, Xuzhou, 221000, qiufangdao@163.com

Abstract

Using a statistical panel data in Xuzhou Metropolitan Area from year 1995 to 2012, the spatial difference and polarization characteristics as well as driving factors of service industry are discussed by using the method of spatial polarization and spatial autocorrelation. The results show as follows: (1) The degree of spatial polarization and development difference of service industry showed the trend of fluctuating decreasing, On the contrary, the spatial agglomeration of service industry was improved greatly between the year 1995 and 2012. The service industry development pattern was formed with the core in the area of Xuzhou, Jinxing and Lianyungang urban area. Marginalization phenomenon of service industry was significant in the southern and western area. (2) The spatial polarization had a centre-peripheral pattern with high centre and high peripheral area. From the perspective of polarization direction, the spatial polarization degree was weak from the peripheral area to the core area. Obviously, the service industry centre had not yet formed. (3) The driving factors such as the level of development, industrialization, transportation accessibility and market presented a promoting effect and the level of industrialization was playing the leading role in the spatial polarization development of service industry.

Key words:

service industry; spatial difference; spatial polarization; driving factors; Xuzhou Metropolitan Area

Evolution of industrial structure and spatial-temporal differentiation on environmental effect the traditional industrial area in Northeastern China

LU Cheng-peng, XUE Bing, JIANG Lu, XIE Xiao, REN Wan-xia

Key Laboratory of Pollution Ecology and Environmental Engineering, Institute of Applied Ecology, Chinese Academy of Sciences, Shenyang 110016, China

Abstract

Based on the description of decoupling degrees between Northeastern China's environment and economic development, this paper makes a quantitative analysis of the relationship between the evolution of the traditional industrial area in Northeastern China's industrial structure and environment change. By using industrial characteristic bias(ICB) index and the data of 23 manufacturing sectors of each province in Northeastern China during 2000-2014, the paper emphatically describes the impact of environment-pollution characteristic of industrial structure on the disparities of the regional environmental effect. The results show that the wastewater-discharge intensity of industrial structure reduced during this period, but this trend tended to decrease. The industrial structure had a high level of industry solid waste discharge with constant intensification of the trend of SO₂ emissions. In addition, the paper also employed regression analysis model to analyze the impact of evolution of on the disparities of the regional environmental effect. The results show that the regional industry structure is closely related to the environment quality especially for edge zone which is experiencing a stage of lower economic development level. Finally, the paper brings forward some suggestions on the industrial restructuring and environmental protection policies.

Key words:

industrial structure; environmental effect; spatial-temporal differentiation; industrial characteristic bias index; Northeastern China

Spatial patterns of pollution-intensive industries transfer and its effect on pollution emissions in the Yangtze River Delta, China

Zou H, Duan X J

Nanjing Institute of Geography and Limnology, Chinese Academy of Sciences, Nanjing, 210008, P. R. China,

zoucas@163.com

Abstract

Pollution-intensive industries play an important role in regional economic growth and industrial restructuring, meanwhile they're also a principal source of industrial emissions. Recognition of spatial distribution relationship between pollution-intensive industries (PII) and pollution emissions (PE) contributes to industry transfer guidance and environmental pollution control. The Yangtze River Delta (YRD) is one of the most developed and serious environmental pollution areas in China. This paper takes the YRD as study area from 1999 to 2013. Results show as follows. (1) The proportion of PII output value in gross industrial output value declines. Spatial distribution of PII gradually disperse, spread to southern and northern Hydrostatical distribution of "processing of petroleum, coking and processing of nuclear fuel" industrial sector is most concentrated, "manufacture of non-metallic mineral products" industrial sector is on the contrary. Main cities with PII transfer-out include Shanghai, Nanjing and Wuxi, and main cities with PII transfer-in contain Suzhou, Hangzhou, etc. (2) PE of industrial waste water, COD and SO₂ have been rising trend after falling, PE of industrial waste gas and solid waste continue to rise. PE of COD concentrate mostly, PE of smoke is on the contrary. Shanghai, Suzhou and Nanjing are main industrial pollution intensive cities. Main cities with PE transfer-in main include Suzhou, Ningbo, Nantong and Shaoxing. (3) Impact of industrial transfer on patterns of pollution emissions showed significant temporal and spatial differences. Hence in-depth exploration on pollution-intensive industries transfer from a larger scope (e.g. the Pan-Yangtze River Delta, the Yangtze River Economic Belt) is the further efforts.

Key words:

pollution-intensive industries; industry transfer; pollution emissions; spatial pattern; the Yangtze River Delta

A Conceptual Model for Considering Adaptive Behavior in Studying Human-Nature Interaction

Huang Guangwei

Graduate School of Global Environmental Studies, Sophia University, Tokyo, Japan, huang@genv.sophia.ac.jp

Abstract

In behavioural ecology, an adaptive behaviour is defined as a behaviour contributing directly or indirectly to an individual's survival or reproductive success. Many animal and plant species have adapted to the new stresses, food sources, predators and threats in changing environments, where they thrive in close proximity to humans. However, adaptive behaviour has been given much less consideration in evaluating human's impact on environment. The present study is attempted to develop a conceptual model to consider adaptive behaviour for better environmental impact assessment. It was based on a case study on waterfowl's response to habitat degradation due to dam development. It provides evidence on the necessity of including adaptive behaviour in modelling human-nature interaction. Furthermore, it puts forward a new modelling framework for dealing with adaptive behaviour. It is a new and innovative initiative toward better explaining human-nature relationship.

Key words:

Adaptive behaviour; conceptual modelling; environmental impact assessment

Sociohydrological Modeling to Understand the Coevolution of Coupled Human-Water System

Fuqiang Tian

Department of Hydraulic Engineering, Tsinghua University, Beijing 100084 China

Abstract

Two-way coupling between human and water is much more apparent and influential in the Anthropocene, which calls for a new science, sociohydrology, to study its coupling dynamics. Understanding the emergent behavior from the coevolution of coupled human-water system is a key to move forward the sociohydrology. Models can serve as the diagnosing tools to enhance the sociohydrological process understanding. In this talk a framework for sociohydrological modeling was discussed, which includes hydrological, economic, political, and institutional components. Based on the framework, a simplified conceptual socio-hydrological model based on logistic growth curves was developed for the Tarim River basin in western China. The results showed a costly pendulum swing, an emergent behavior occurring at the century scale, between a balanced distribution of socio-economic and natural ecologic resources among the upper and lower reaches and a highly skewed distribution towards the upper reach. Also, a conceptual socio-hydrological model including four major components, i.e. policy actions, technology, irrigation land use and water use, was constructed to capture the governing rebound effect of technology and adaptation effect of human policy of the irrigation efficiency paradox, an emergent behaviour occurring at the decadal scale, in the Baying Olin Prefecture, Xinjiang Uygur Autonomous Region.

Key words:

Sociohydrology; modelling; irrigation efficiency paradox; pendulum swing

A Theoretical System of Environmental Performance Evaluation Based on Big Data Environment

Malin Song^{1,*}, Qianqian Du¹ and Qingyuan Zhu²

²School of Management, University of Science and Technology of China, Hefei, Anhui Province, 230026, P. R. China

Abstract

Today, environmental issues are one of the key challenges to sustainable development of the social economy of every country in the world. How to effectively solve environmental problems and prevent further deterioration of environment have attracted tremendous attention from scholars. In recent years, Big Data, that is, enormous volume of data, has developed quickly and widely and has brought great challenges as well as unprecedented opportunities to the world. For example, Big Data can be used to predict production processes more accurately. However, they make traditional environmental performance evaluation methods ineffective. Thus, studying and improving environmental efficiency evaluation under the background of Big Data are important to improve environmental efficiency apart from pushing forward discipline development. This study provides a set of scientific and axiomatised conditions for environmental performance evaluation based on Big Data environment. The findings of this study can provide references for environmental performance evaluation in the new era.

Key words:

Big Data; Environmental efficiency; Data envelopment analysis; Life cycle assessment.

Assessing the Combined Impacts of Human Activities on the Environment:

Integrating the Environmental Footprints into a Footprint Family

Fang K

Zhejiang University, Hangzhou, 100101, P. R. China, fangk@zju.edu.cn

Abstract

A growing number of environmental footprints have received considerable interest and discussions from academia, the public, organizations and governments as a tool for assessing the effects of anthropogenic activities on the planet's environment. Despite the worldwide popularity gained in the past two decades, the footprint communities are found to be isolated and disparate at the present moment, such as those of the ecological, water, and carbon footprints. Focusing on single footprints in isolation however runs the risk of shifting the environmental burden to other footprints. To address this concern, this paper conducts an in-depth investigation into the conceptual and mathematical structures behind different versions of the ecological, water and carbon footprints, with the aim of capturing the inherent distinction between various footprint accounts in terms of inventory analysis and impact characterization. On the basis of a dichotomy where environmental footprints are classified into the inventory-oriented and impact-oriented categories, this paper proposes a framework that brings together different impact-oriented footprint indicators into a truly integrated footprint family. A unifying approach for characterization, normalization and weighting of environmental footprints is therefore achieved, whereby the results of inventory analysis are first to be translated into single impact category indicators, and subsequently normalized, weighted and integrated into a composite footprint index. The research can be of great interest to policy makers as it allows for an overall picture of human-induced environmental impacts without losing the complexity of individual footprint accounting, thus contributing to the ongoing discourses on the integrated modelling of the human-nature system.

Key words:

environmental footprints; footprint family; classification; characterization; integration

Evolution of Human-nature Relationship in China's Old Industrial Area

Xue B, Ren W.X., Lu C.P., Li J.Z., Jiang L, Tang C.R., Han B, Huang Y.P.

Key Lab of Pollution Ecology and Environmental Engineering, Institute of Applied Ecology, Chinese Academy of Sciences, Shenyang, 110016, P. R. China, xuebing@iae.ac.cn

Abstract

Understanding human-land relationships is essential for optimizing human activities in order to achieve local and global sustainability. China's rapid urbanization is attracting much global attention; however, one of the challenges to achieve sustainable urbanization in China is to determine appropriate development mechanisms related to human-land relationships. As one of the typical industrial bases in China, the Tiexi District in Shenyang suffered from serious decline but now is shifting its industrial structure from heavy to tertiary industries, along with essential improvement of natural ecosystems and re-structuring of land use. Using Tiexi District as a case study, this paper investigates the evolution of the human-land relationships in the context of urban spatial restructuring based on both qualitative and quantitative analysis of temporal and spatial elements. A database was built based on interpretations of aerial photographs of Tiexi in 2000 and of the Quickbird Images in 2005 and 2010, combined with a survey on existing buildings; spatial-restructuring analysis of human-land relationships was conducted; heavy-metal pollution in a significant brownfield redevelopment site was inventoried and mapped, the enrichment factors, pollution index and integrated Nemerow pollution index were used to assess the pollution levels; a four-level land-use coding system was proposed and may supply more detailed information for land use management and offer a more precious database for measuring performance.

Key words:

human-nature relationship; land use change; ecological risk; land use coding system; brownfield redevelopment; old industrial area; Northeastern China

Evolution of Societal Value on Water for Economic Development and Environmental Sustainability in Australia during 1843-2011

Yongping Wei¹, Jing Wei² and Andrew Western²

¹The School of Geography, Planning and Environment Management, the University of Queensland, Australia

² The Department of Infrastructure Engineering, the University of Melbourne, Australia

Abstract

Introduction: The earth has entered a new epoch, the Anthropocene, when humans constitute the dominant drivers of change to the Earth System (Crutzen 2002). The stress on freshwater resources around the world cast by the human activities now as well as in future requires a radical paradigm shift in approaches to water resources management.

Societal values, a set of common values, belief and attitudes shared by the majority of a regional population, represent the core societal practice within a region (Dietz et al, 2005). Changes in values are seen as leading to changes in decisions and thus to changes in behaviour. However, societal value has not been addressed adequately in current water management studies. For much of the twentieth century water catchment management was dominated by engineers and hydrologists. Hence, it has been blind to changes in the social drivers for, or societal responses to, management decisions. This seriously compromises our capacity to foster social–ecological sustainability of water catchments in the long term.

Aims: This paper aims to understand the evolution of societal value on water resources for economic development versus environmental sustainability in Australia. Newspapers are very commonly used as data sources to track the changes of societal values because news accounts are rich in description and they reflect and influence public values and opinion on certain issues at their time of publication. The Sydney Morning Herald with diversity of coverage and wide readership, one of the oldest continuously published newspaper in Australia is used as the data sources to track the changes of societal values on water resource between 1843 and 2011. Specifically, this paper will address the following three research questions:

- 1) How did the societal value on water for economic development versus environmental sustainability in Australia evolve over timescale of 169 years?
- 2): What was the transition pattern of the societal value?
- 3): In what context such transition occurs, and what factors possibly trigger such transition?

Methods: Three methods were used in this study to address the research questions include: 1) describing evolution of the societal value on water for economic development and environmental sustainability in Australia with content analysis of newspaper; 2) determining the pattern of evolution of the societal value on water for economic development and environmental sustainability in Australia since European settlement with both regression analysis and transition theory; 3) understanding the pattern of evolution of the societal value on water for economic development and environmental sustainability in Australia since 1900 with co-evolutionary framework.

Results: Overall, as shown in Figure 1, percentage of articles dedicated to economic development driven fluctuated throughout the study period. However, when comparing the percentage of attention, the importance of economic development has been declining with the arising attention given to environment. The vision for environmental sustainability were kept at a minimal level at the beginning, and stayed as a relatively low voice in the society until it took off at around 1960s and overweigh the voice of economic development in the last decade.

The regression analysis was conducted for two sets of societal value data. The model with the highest R^2 was considered as the most fitted regression line. The results showed that societal value evolution follows closely in sigmoid function with R^2 equal 0.722. The fitted sigmoid curve for societal value on economic development and societal value on environmental sustainability are described with the following equation (1) and Equation (2) respectively.

$$y = 0.34496 + (0.98654 - 0.34496) / (1 + \exp((x - 1980.5777) / 13.89785)) \quad (1)$$

$$y = 0.65504 + (0.01346 - 0.6504) / (1 + \exp((x - 1980.5777) / 13.89785)) \quad (2)$$

With the fitted transition curve, first and second derivatives were derived to measure the rate and direction of change of these two curves. Then derivatives results were used to explain the stages of social transition if they exist.

According to the derivatives, three stages were identified. The predevelopment stage of societal value on environmental sustainability when changes occurred only marginally was identified as the period during 1843-1961. The take-off stage was considered between 1962-1980. The take-off point was when the rate of change speed is maximized. The acceleration stage was identified during 1981-2011. It is a period of the absolute value of societal value is still increasing, the acceleration rate is negative and the rate of change is decreasing. Around

2000 a new process of the acceleration rate increase started. The stabilization stage did not appear because the rate of change of societal value has not come to zero.

The societal value on water resources in Australia has co-evolved with the variability of rainfall, and management policies and practice reforms.

The co-evolutionary processes are explained according to the stages of societal value transition identified above. They include the predevelopment (1900s-1960s)-societal value on water resources was dominated by economic development; take-off (1962-1980), Societal value on water resources reflected increasing awareness of the environment due to outbreak of pollution events; 1980-2011: Environment oriented societal value on water resources and the Millennium Drought triggered a package of policy initiatives and management practice towards sustainable water resource use.

Discussions and Conclusions: This study developed a new method in combination of qualitative and quantitative approach to measure the change of societal value on water, a "less tangible" variable, and its transition pattern with time. This combination of qualitative and quantitative approach, which enables mathematical analysis of the society value has made the milestone progress in measuring the societal value, potentially making it explanatory and predictable. However, It should be noted that the societal value we identified in this study is only an indicator of the reality. It should be also noted that only one newspaper was used in this study as an example.

In conclusion, we face a future with significant reductions in water availability as a result of a drier climate. Our study provided an understanding of the dynamical mechanism of transitions which can assist policy makers to identify management practices that require improvement by understanding how today's conditions and problems were created in the past. It could help policy makers, to a certain extent, to monitor and guide the societal value transit into sustainability in proactive way. (This study was funded by the Australian Research Council (project number is FT130100274).)

Impact Assessment of Land Use/Cover and Climate co-evolution on water resource in Heihe River Basin of Northwest China

Feng Wu^{1,2}, Jinyan Zhan³, Xuezhen Zhang¹

³State Key Joint Laboratory of Environmental Simulation and Pollution Control, School of Environment, Beijing Normal University, Beijing 100875, P. R. China, zhanjy@bnu.edu.cn

Abstract

This study evaluated hydrological impacts of potential climate and land use co-evolution in Heihe River Basin of Northwest China. The future climate data for the simulation with Soil and Water Assessment Tool (SWAT) were prepared using a dynamical downscaling method. The future land uses were simulated with the Dynamic Landuse System (DLS) model by establishing Multinomial Logistic Regression (MNL) model for six land use types. In 2006-2030, land uses in the basin will experience a significant change with a prominent increase in urban areas, a moderate increase in grassland, and a great decrease in unused land. Besides, the simulation results showed that in comparison to that during 1981-2005 the temperature and precipitation during 2006-2030 will change by +0.8°C and +10.8%, respectively. The land use change and climate change will jointly make the water yield change by +8.5%, while they will separately make the water yield change by -1.8% and +9.8%, respectively. The predicted large increase in future precipitation and the corresponding decrease in unused land will have substantial impacts on the watershed hydrology, especially on the surface runoff and streamflow. Therefore, to mitigate negative hydrological impacts and utilize positive impacts, both land use and climate changes should be considered in water resource planning for the Heihe River Basin.

Integrated Assessment of Climate Change Scenario Modeling and Livelihood Capital Security: A Case study of Himachal Pradesh, India

Singh RAM BABU Singh, Swarnima

Department of Geography, Delhi School of Economics, University of Delhi, Delhi-110007, India, rbsgeo@hotmail.com

Abstract

The study aims at integrated assessment of climate change scenario modeling and livelihood capital security taking empirical datasets of the Himachal Himalaya. In the region, most of the southern and western blocks together with extreme eastern blocks of this region are undergoing the lowest seasonal mean rainfall (<6 mm per day). It has been found that the winter season in this region befitting more snowy and mild whereas the season pertaining to summer months are characteristically getting hot and dry under the A₂ GHG scenario. Under B₂ scenario of GHG emission the general trend is nearly same and the only difference is that extent of change in the value which is quite small than A₂ emission scenario. As per PRECIS simulation the annual rainfall in the Kangra region is likely to vary between 1,268 +/- 224.2 and 1,606 +/- 145.2 mm in 2020s. The projected precipitation is likely to increase by 5 to 17 per cent in 2020s with respect to 1970s in the north-eastern parts, whereas the deficiency in rainfall has become a common feature of central and western parts. The livelihood pentagon has been made to analyze baseline and simulated future climate change scenario. Marked differences were observed between the two agro-climate zones. The composite indices have been presented for the individuals and cumulative livelihood assets. The total livelihood vulnerability has been calculated, grouped and ranked into five categories. The result may be replicated in other parts of the Himalayan region with similar bio-physical and human environment.

Key words:

climate modeling; livelihood vulnerability; integrated modeling; Himachal Pradesh; India

Integrated Modelling of Bioenergy Industry in China

Abstract

Along with our greatly enhanced capability of changing the environment which we rely on, the research on human-nature relationship becomes ever more important and faces a couple of challenges, for example, the existing models can rarely fully represent the interactions and two-way feedbacks between natural and human systems. In order to explore the co-evolution of both systems and meanwhile bring the complex and giant human-nature relationship to a feasible level, we focus on bioenergy industry that bridges both systems and contemplate a decision support system of the industry development.

To alleviate the possible side effects of first generation bioenergy production on food security and environment, this system particularly concentrates on the second generation- the lignocellulosic biomass and covers its entire supply chain from bioenergy feedstock cultivation, harvesting to biomass transportation, and finally to bioenergy products conversion, transportation and consumption. The allocation of natural resources and the socioeconomic behaviors are all set as endogenous and interacted with each other on the bioenergy market. In this way, we create the coupled model of the human-nature system co-evolution.

We further apply this model to the Jiangsu province of China and evaluate two possible directions of bioenergy development incentives: a universal taxation policy- carbon tax and a targeted subsidy- either on farmers or on bioenergy plants operators. The simulation results show that: (1) The policy effects of carbon tax are positively correlated to the imposed level of the tax, which helps biomass-based power plants to cement their leadership in the bioenergy market due to the greater greenhouse gas mitigation potential of bio-power than bioethanol. (2) The financial subsidy on mudflat reclamation has the highest rate of return and smallest scale and benefits both farmers and bioenergy plants operators.

Integrated modelling; human-nature relationship; bioenergy; China; incentive

Integrated River Basin Management Strategies: A Global Perspective

Deng X, Wang P

Institute of Geographic Sciences and Natural Resource Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, dengxz@igsnrr.ac.cn

Abstract

Aimed to integrated river basin management in the arid and rapid developing region, the Heihe River Basin (HRB) in Northwestern China, one of critical river basins were selected as a representative example, while the Murray-Darling Basin (MDB) in Australia and the Colorado River Basin (CRB) in the USA were selected for comparative study. Firstly, the comparable characters and hydrological contexts of these three watersheds were introduced in this paper. Then, an overview and comparison of the river basin management in the MDB, the CRB and the HRB was presented. Based on comparative study, the drought, intensive irrigation, and rapid industrialization were highlighted as challenges for integrated river basin management in the HRB. The river management strategies are compared in three aspects: water allocation, water organizations, water act and scientific projects. Finally, we proposed policy recommendations for integrated river basin management for the HRB: 1) Water allocation strategies based on laws and market on the whole basin; 2) Public participation should be stressed by the channels between governance organizations and local communities; 3) Scientific research should be integrated into river management to understand the interactions between the human and the nature.

Key words:

river basin; river basin management; Heiheriver basin; Murray-Darling Basin; Colorado River Basin

Integrated Water-Economic Model for Simulating Water Use at a River Basin Level

LIU J, Zhao X

School of Environmental Science and Engineering, South University of Science and Technology of China, Shenzhen, 518055, China, liujg@sustc.edu.cn

Abstract

Water has become a key constraint for economic development in many parts of the world, in particular in the arid and semi-arid regions. However, research on how water is interacted with economy is remains rare. In this paper, we integrated hydrological models with economic models to study the water use in different economic sectors for the Heihe River Basin, which is located in the arid Northwest China. We aim to understand: (1) how much water is available; how much water is used and whether such use is sustainable; (3) whether the water-saving society initiative is successful. By comparing water use with water resources, we show that water use in this river basin is not sustainable either on an annual or on a monthly basis. We also find that consumptive water use does not decrease much as expected. The integrated water-economic model show that while technology improvements decreased water use to a large extent, increasing amount of commodity exports from this river basin to other regions increased water use. As a result, consumptive water use did not change much at a river basin level. To implement the water-saving society development, emphasis also needs to be paid to adjustment of commodity trade. For arid regions, a high level of exports may not be sustainable from a perspective of water use.

Abstract

Plants' optimality through adjusting their root systems is a way for plants to adapt to harsh environments. However, most existing land surface models (LSMs) use a prescribed, static root profile, which cuts the interactions between soil moisture and root dynamics. In this paper, we implement an optimality-based model of root dynamics that is capable to adapt to soil moisture dynamics in meeting the water demand for plant transpiration into the Noah-MP LSM. The dynamic root model updates its vertical profile of the root surface area in conjunction with changes in the water stored in plant tissues and the soil moisture profile. Considering direct water uptake by roots from the matrix saturation zone above the water table and the underlying saturated zone, we introduced a "watered" root layer into the Noah-MP scheme to represent the overall root density within these two zones. We have tested the model against observations of a riparian *Tamarix* spp. stand under a hyper-arid climate (approximately 35 mm precipitation per year) in northwestern China. Compared with the original, static root profile, the dynamic root model significantly improves the energy and water flux simulations from the groundwater-soil-plant system to the atmosphere, particularly during the dry seasons. The improved model with root dynamic provides a powerful framework to understand and predict the responses of groundwater-dependent terrestrial ecosystems to climate change and groundwater extraction in arid and semi-arid regions.

Modelling Praxis, Social Learning and Systemic Governance

Ison, R.L.

Applied Systems Thinking in Practice (ASTiP) Group, The Open University, Walton Hall, MK7 6AA UK,

ray.ison@open.ac.uk

Abstract

Modelling, as a practice, is a contested domain of human activity. This is not to question the abilities of the many talented modellers that can be found around the world, but to invite a more substantial reflection on what moves modelling from practice to praxis (theory-informed practical action), and how, if at all it might be effectively used to transform what we humans do in our acts of governing human-nature relations as a co-evolutionary dynamic. This paper describes how modelling can move from practice to praxis, especially praxis that is transformative; this entails shifting the boundary of concern beyond the technicalities of model development and functioning so as to include the modeller and the modelling situation as part of the 'praxis system'. Building on recent research and action the possibilities for designing and enacting systemic co-inquiry laboratories, as platforms for integrated modelling and transformative praxis, are explored. The experiences upon which these design considerations are based arise from 40 years of Systems thinking in practice (STiP) pedagogy at The Open University (UK) and over 15 years researching by the author and colleagues of social learning as an alternative governance mechanism and praxis in the UK, Australia, China and South Africa.

Water governance; structural coupling; reframing; co-inquiry; learning lab; systemic praxis

Optimizing Conjunctive Use of Surface Water and Groundwater for Irrigation to Address Human-Nature Water Conflicts: A Surrogate Modeling Approach

Yi Zheng^{1,2*}, Xin Wu², Bin Wu², Yong Tian¹, Feng Han¹, Chunmiao Zheng^{1,2}

¹ School of Environmental Science and Engineering, South University of Science and Technology, Shenzhen 518055, Guangdong Province, China, zhengy@sustc.edu.cn

² College of Engineering, Peking University, Beijing 100871, China

Abstract

In arid and semi-arid areas where agriculture competes keenly with ecosystem for water, integrated management of both surface water (SW) and groundwater (GW) resources at a basin scale is crucial, but often lacks scientific support. This study implemented physically-based, fully integrated SW-GW modeling in optimizing water management, and performed surrogate modeling to replace the computationally expensive model with simple response surfaces. Water use conflicts between agriculture and ecosystem in Heihe River Basin (HRB), the second largest inland river basin in China, were investigated. Based on the integrated model GSFLOW (Coupled Ground-Water and Surface-Water Flow Model), the conjunctive use of SW and GW for irrigation in the study area was optimized. Overall, the study demonstrated that, with the surrogate modeling approach, an expensive integrated model could be efficiently incorporated into an optimization analysis, and the integrated modeling would make feasible a physically based interpretation of the optimization results. In the HRB case study, the surrogate-based optimization analyses suggested very different time schedule and spatial allocations of water diversion in opposite to the existing ones, indicating the critical role of SW-GW interactions in the water cycle. With an optimization analysis, a basin-scale water saving could be achieved by reducing non-beneficial evapotranspiration. The current flow regulation in HRB may not be sustainable, because the ecosystem recovery in the lower HRB would be at the cost of the ecosystem degradation in the middle HRB. To address the current human-nature water conflicts in HRB, a change of the water management regime is necessary.

The Assessment System of the Water Sustainable Development in Inland Arid

Regions: Taking the heihe River Basin as an Example

Yanqiang Wei, Xin Li, Yingchun Ge

Cold and Arid Regions Environmental and Engineering Research Institute, Chinese Academy of Sciences, Lanzhou
730000, China

Abstract

Sustainable development in inland river basins requires the basin to be considered as a whole, with the relationships between the upstream, midstream and downstream areas of the basin coordinated appropriately and taking the water resources as the heart in the whole basin development. So how to establish an appropriate and scientific assessment system to evaluate the sustainability of the water in the basin is important. The paper takes the fresh water safety and the economic sustainable development in the basin as the targets, by the means of improving water efficiency and maximizing the value of water, taking the inter-sectoral allocation of water as the main approach, to establish an assessment system to evaluate the sustainability of the development in the Heihe River Basin (HRB). Based on the assessment system, the sustainability in the HRB has been evaluated and put forward some advises for the DSS and water management.

Key words:

water; sustainable development; assessment system; inland river basin; Heihe River Basin

The Interrelation between Water and Social Economic Development: an Analysis Based on Water Social Accounting Matrix (WSAM)

Abstract

Water is a significant restraining factor for social and economic development in arid and semi-arid regions, whereas the social-economic attribute of water is rarely recognized. The relationship between water resource and regional industry structure and the social welfare is hardly explored from a macroscopic view. In this paper, the Zhangye City was chosen as the case study area, which is a typical arid and semi-arid region located in Heihe River Basin in Northwestern China. Firstly, we established the county level Social Accounting Matrix (SAM) and added water resource account into it to form the WSAM. Based on the SAM multiplier and decomposition analysis, we found that though the transfer effects of agriculture is small which indicates limited direct promotion in intersectional production, the closed-loop effects is larger than the secondary industry demonstrated that agriculture has the most potential influence on the whole regional economic system for the study area. Furthermore, since irrigation water price is far below the shadow price, and the price reform is considered an effective way to improve water use efficiency. By fully considering the economic attribute of water and its role as a fundamental factor for production, we try to figure out how irrigation water price reform will influence the whole industrial production chain through price multiplier analysis and how farmers' income will be influenced based on the WSAM price model. The results illustrate that one percent water price increase will lead to a 0.03 percent cost increase in agriculture production and 0.005 percent increase in CPI.

Trial of Current China Societal Risk Perception based on Baidu Hot News Search

Words

Xijin Tang, Nuo Xu

Academy of Mathematics and Systems Science, Chinese Academy of Sciences, Beijing, 100190, China, xjtang@iss.ac.cn

Abstract

Current China is undergoing great social transformations and facing tremendous emerging wicked problems across environment, food safety, governance, health, inequalities, national security, population, urbanization, etc. which cover every aspect of social living and timely expose to the public via BBS posts, blogs and microblogs, especially in Web 2.0 era, quickly turn into highlighted events beyond their original region, thus bring big challenges for government administration. Different from those studies on detecting and removing negative public opinions, we try to map those on-line community concerns into respective societal risks and aggregate all risky potentials over the whole concerns as the on-line societal risk perception. We collect the Baidu hot news search words (HNWS) released at Baidu News Portal every hour and map each hot news into either risk-free event or one risk event which belongs to national security, economy & finance, public morals, daily life, social stability, government management, resources and environment based on socio psychological study results. Then the daily risk level with the frequency of daily risky events over the frequency of the daily news is acquired. With the generated 4-year (2012-2015) daily societal risk dataset, not only a rough image toward China's societal risk is acquired from on-line public concerns, but the distributions of different risks events, such as resources and environment, along the time are studied in details. Such an approach may serve as one augment way to harmonious society measurement.

societal risk perception; Baidu hot news words; public opinions; resources and environmental hazards; measure of one harmony society

Assessment of ecological sustainability in arid land, Northern China

Jie LIAN

Cold and Arid Regions of Environmental and Engineering Research Institute, Chinese Academy of Sciences, Lanzhou, 730000, China, lianjeco@outlook.com

Abstract

Soil and water are important elements in ecological processes and have played key roles in structure, development and sustained restoration of vegetation in arid and semi-arid region. In recent years, soil quality degradation and/or water shortage were found more severe in most regions in northern China.

Key words:

arid land; sustainable development; soil quality

Design and Development of a Prototype Decision Support System for River Basin Water Resources Management

Abstract

With the fast economic development, rapid growth of population and climate change, a series of environmental problems, such as the sharp decline in groundwater level, the well is running dry, ecological deterioration, have been caused in many river basins. Those are the results of lacking effective administrative and management of water resources. In this study, a prototype decision support system was designed and developed for supporting integrated water resources management in river basin (RB-WRMDSS). RB-WRMDSS is based on integrating Geographical Information Systems platform (ArcGIS), a database platform (Sql Server 2012) and a development framework of plug-in. Four subsystems are included in RB-WRMDSS, 1) basic information subsystem including spatiotemporal relations of social economy and water attributes; 2) scenarios simulation for change of climate, land and Oasis, industrial development and water resources management policy; 3) Data management subsystem for updating the latest water consumption data, land change data and social economy data to the database; 4) decision support subsystem for visualization and mapping the results of simulation and generate a decision report for decision makers. The prototype RB-WRMDSS was tested with a case study in Heihe River Basin, Northwest China. The developed DSS is very useful to deal with complex water resources management problems in river basin.

Landscapes Management towards Human Well-being: a Case Study in Zhangye Basin Northwest China

Youhua Ran, Xin Li

Cold and Arid Regions Environmental and Engineering Research Institute, Chinese Academy of Sciences, Lanzhou, 730000, P. R. China, ranyh@lzb.ac.cn

Abstract

Ecosystem is essential for human well-being through their provisioning, regulating, cultural, and supporting services. There are increasingly being considered critical for decision making in resource management. Scientific management of water and soil resources by changing landscape configuration is the core of sustainable development, especially in arid region, such as Zhangye basin in northwest China. Due to the complexity of human-natural system, how integrating the ecosystem service into landscapes management practical is a frontier issue in this field. Despite the growing literature on ecosystem services, the study about integrate ecosystem services in landscape management is still limited, especially in developing country. This study provide a case that integrate ecosystem services into landscape management practical by tradeoff ecosystem service in Zhangye basin northwest China. We use the MESH (Mapping Ecosystem Services to Human well-being), an ecosystem service assessment and mapping toolkit developed by Bioversity International, the Consultative Group on International Agricultural Research (CGIAR), and the Natural Capital Project, to map, tradeoff ecosystem service and link ecosystem change to Sustainable Development Goals (SDGs) of United Nations under different landscape management scenarios. Ecosystem service include food production, crop pollination, water purification, habitat quality, wind protection and sand fixation, eco-tourism, and carbon storage are integrated in MESH framework. Water consumption model, landscape nutritional potential, and landscape degradation model are used to modelling the water cost of ecosystem service and ecosystem change. This will provide a useful exploration to support landscape design toward sustainable development in arid area of China.

ecosystem service; MESH; water; remote sensing

Social–Ecological Systems: The Overlapping of Chaos and Quantum

—Re-interpretation of SES Yin-Yang Model Based on the Book of Changes

Zhou Xiao-fang

School of Tourism Management, South-China Normal University, Guangzhou 510631, China, 25785409@qq.com

Abstract

This research sets up the Yin-Yang Model of SES based on the idea of “the separation and joining of Yin-Yang two poles of the Book of Changes from the perspective of the model development status-quo of SES, and interprets this model with the idea of “one begets two; two beget three; three beget all things” in Tao Te Ching. Since this model is three-dimensional, “The Six Directions”, a simple spatial idea of ancient China, is applied to conduct projection simplification to this model from three to two dimensions, thus making analysis and explanation easier. The result of this research indicates, as a complicated system, SES has different manifestations under optional time and space. It is a point on its starting surface, embodies chaotic characteristics on its development surface, and expresses quantum characteristics on its ending surface. The chaotic and quantum characteristics assume an obvious perpendicular relationship. The method of “The Six Directions” reflects the fact that the complexity of SES system not only lies in its own complexity and ever-changing complexity, but also lies in the complexity of optional time and space. Therefore, the complexity here refers to the overlapping of the complexity of the thing itself, the complexity of scale and the complexity of optional time and space.

Key words:

SES Yin-Yang Model; The Book of Changes; One begets two; two beget three; three beget all things; Quantum; Chaos; Complexity

Study on China's Yellow River Delta Social Vulnerability Evaluation and Influence

Factor

School of Geography and Environment, Shandong Normal University, Jinan 250014, Shandong, China

Abstract

Social vulnerability is one of vulnerability connotation's content and vulnerability's research direction, and social vulnerability research can provide guidance and reference for regional sustainable development. Taking ecological vulnerable Human-earth system China's Yellow River Delta as an example, its social vulnerability indicator system was set up from sensibility and responsibility, its social vulnerability and evolvement rule in 2000-2014 were analyzed by set pair analysis method and vulnerability evaluation model, the influence factors of social vulnerability, sensibility and responsibility were analyzed by mult-variable linear return analysis, correlation analysis and disorder degree model. The results show that: (1) Yellow River Delta's sensibility index shows a downward trend, responsibility index shows an increasing trend, social vulnerability index shows an increasing trend. The main reason is Yellow River Delta has been to China's national strategy and its ecological economy has realized development, the coordination degree of economy-society-ecotopes gradually. (2) Responsibility is social vulnerability's major influence factor; economy, society and ecological environment's disturbance to sensibility is balanced, but economic factor is relative prominence; infrastructure construction's hysteresis and industrial structure level's low that restrained by ecological environment are responsibility's obstacle factors. Countermeasure and suggestion were put forward from strengthen infrastructure support, perfect efficient ecological industrial system and cultivate new economic growth point, environmental protection and ecosystem conservation.

Abstract

Fluvial flood is a considerable challenge for urban traffic and residents' livelihoods in many metropolitans worldwide, which makes it a public concern and study interest to discover the most vulnerable links to take adaptive measures. This paper presents a novel approach to simulate the impact of fluvial flood on urban traffic in a local scale network located in Huangpu District of Shanghai, China. Basically, the four-step travel demand forecast model is adopted for *trip generation*, *trip distribution* and *trip assignment*, while *mode choice* is absent given our focus on traffic of individual vehicles and taxis and also for simplicity. A modified A* algorithm is used to calculate the travel routes in a virtual lane-based road topology and change the travel plans as soon as the individuals are informed of road conditions marked as *open* or *block*. The traffic volume is recorded on each road segment separately under a fine weather condition and a fluvial flood scenario. Computing and simulation work are implemented in a prototype program redeveloped based on GIS. Following are three major conclusions. (1) There is an increasing pattern of traffic volume on most non-flooded segments due to the reassignment of traffic flow in the fluvial flood scenario. (2) Minor streets with less utilization in fine weather would more possibly become vulnerable to congestion and bottlenecks in the whole network. (3) With the fluvial flood receding, the traffic volume on a flooded segment could recover in a timely fashion when the road state turns from block to open.

Abstract

Previous studies have suggested that many human and environmental factors have contributed to the spatial expansion and temporal evolution of urban heat islands. However, little research has been directed to the impacts of urban traffic flows on the heat island. This research examines the variation of urban heat island intensity and spatial extent with reference to the change in urban traffic. In this research, daily MODIS thermal data are used to map surface temperature distributions in Beijing metropolitan area, and urban traffic volume was regulated during 2008 Summer Olympics by the “Odd and Even Car Ban (OECB)” policy. The contribution of traffic volume to the urban heat is analysed using spatial statistical models for different parts of the metropolitan area. Our analysis suggests that the decrease in urban traffic volume can significantly reduce the spatial extent and intensity of the urban heat island. The “Odd and Even Car Ban (OECB)” policy is more effective for heat mitigation in inner city than in city outer rings and suburbs.

Abstract

Over the past several decades, anthropogenic production of reactive nitrogen has increased by 120 %, and global nitrogen overload has been identified as a main emerging environmental issue in this century. Much of anthropogenic nitrogen is transported into estuarine and coastal regions via rivers, groundwater and atmosphere, which has already exerted a serious threat to the environmental quality of estuarine and coastal ecosystems. Nitrification, the sequential oxidation of ammonia to nitrite and then to nitrate, is an important bioremediation process in these nitrogen-enriched environments. Excessive nitrogen load in these ecosystems can be greatly reduced via a tight coupling between nitrification and denitrification or anaerobic ammonium oxidation, thereby diminishing the risk of nitrogen pollution. However, the removal of nitrogen from aquatic environments often depends directly on the supply of products (nitrite and nitrate) from nitrification. Thus, nitrification plays a critical biogeochemical role in the estuarine and coastal ecosystems. As the first and rate-limiting step in nitrification, ammonia oxidation has been widely studied because of its ecological significance in the global nitrogen cycle and environmental implications. Ammonia oxidation is known to be mediated by both bacteria and archaea. However, in estuarine ecosystems their relative importance in ammonia oxidation remains more ambiguous and uncertain, which may imply a more complex interaction between dynamics of ammonia oxidizers and associated activity in these environments.

In the present study, diversity, abundance and activity of ammonia-oxidizing bacteria (AOB) and ammonia-oxidizing archaea (AOA) were investigated using ammonia monooxygenase- α subunit (*amoA*) in the intertidal sediments of the Yangtze Estuary. Generally, AOB had a lower diversity of *amoA* gene than AOA in this study. Clone library analysis revealed that AOB communities were dominated by *Nitrosomonas*, while AOA communities were dominated by the Marine group 1.1a. Clone library analysis also revealed great spatial variations in both AOB and AOA communities along the estuary. UniFrac distance matrix showed that all the AOB communities and 6 out of 7 AOA communities in the Yangtze Estuary were statistically indistinguishable

between summer and winter. The studied AOB and AOA community structures were observed to correlate with environmental parameters, of which salinity, pH, ammonium, total phosphorus and organic carbon had significant correlation with the composition and distribution of both communities. Also, the AOA communities were significantly correlated with sediment clay content. Quantitative PCR (qPCR) results indicated that the abundance of AOB *amoA* genes was greater than that of AOA *amoA* genes in 10 of the 14 samples analyzed in this study. Potential nitrification rates were significantly greater in summer than in winter and had a significant negative correlation with salinity. In addition, potential nitrification rates were only correlated strongly with archaeal *amoA* gene abundance but not with bacterial *amoA* gene abundance. However, no significant differences were observed between rates measured with and without ampicillin (AOB inhibitor). These results implied that archaea might play a more important role in mediating the oxidation of ammonia to nitrite in the Yangtze estuarine sediments. This work may provide novel insights into the biogeochemical cycle of nitrogen in estuarine and coastal areas.

nitrogen; ammonia-oxidizing prokaryotes; intertidal marshes; Yangtze Estuary

Differential Exposure to Flood Risk in Coastal Mega-Cities

de Sherbinin, A.M.

Center for International Earth Science Information Network (CIESIN), Columbia University, Palisades, NY 10964, USA,
adesherbinin@ciesin.columbia.edu

Abstract

It is generally understood that selected population groups (the elderly, children, the poor, or those with health conditions) are more vulnerable than others to certain climate impacts, and that the specific vulnerability characteristics may differ from one type of impact to another (e.g., between flood and heatwaves). However, while it is often asserted that the poor or more vulnerable populations are disproportionately represented in highly exposed areas – what some have termed a poverty exposure bias – this assertion has rarely been tested empirically. The purpose of this paper is to present results of empirical testing of differential exposure to floods in three coastal mega-cities: New York, Mumbai, and Shanghai. Specifically we examine whether the most exposed populations are also the most socially vulnerable. First, we develop Social Vulnerability Indices (SoVIs) for each city with census data. We then overlay the SoVI scores onto modelled or actual flood extent maps for major flood events in each city. Results suggest a degree of differential exposure in New York, especially in the highest flood risk areas, and fairly clear evidence for differential exposure in Mumbai. (Results for Shanghai are pending.) The paper also explores how differences in the input resolution and confidence in the data sets across the cities affects the results. The paper concludes with a discussion of policy implications and data needs for urban spatial vulnerability assessment.

Downscaling Land Surface Temperature by Fusing VIIRS and Landsat-8 Data

JiaYF, Yu BL, HuangY, Wu JH

Key Laboratory of Geographic Information Science (Ministry of Education) and School of Geographic Sciences, East China Normal University, Shanghai 200241, China, blyu@geo.ecnu.edu.cn

Abstract

Land surface temperature (LST) is a key parameter for urban heat researches, especially for the Urban Heat Island (UHI). However, no single satellite sensors can provide TIR data at both high temporal and spatial resolution. I.e. TIR band from Landsat 8 has the spatial resolution of 30m, but its temporal resolution (16 days) is too coarse to be applied in researches of urban environment. Visible Infrared Imaging Radiometer (VIIRS) can provide daily TIR data but the spatial resolution is about 375m. To our knowledge, VIIRS TIR data had never been used in data fusing in TIR bands. This study generates daily LST images at Landsat-8 resolution by fusing the VIIRS and Landsat 8 data for the first time. The Spatial-temporal Adaptive Data Fusion Algorithm for Temperature mapping (SADFAT) was applied in this article, VIIRS and Landsat 8 data are used for predicting daily TIR radiance images with resolution of 30 m, with the generally single channel (SC) algorithms, the daily LST images of high spatial resolution can be retrieved. A case study was conducted with seven pair's data of Landsat 8 and VIIRS in Beijing, China from April 2014 to April 2015. Prediction accuracy for this study area was about 1 K to 2 K, and the correlation coefficients varied from 0.7116 to 0.8948. Results show that VIIRS data can be used in urban heat environmental study, especially in which require higher temporal resolution.

Effect of Snowpack On the Concentrations of Pahs in The Soils

ZuchengWang, ShashaLiu, BaohuaCai

Institute for Peat and Mire, Northeast Normal University, Changchun, 130024, P. R. China, wangzc100@nenu.edu.cn

Abstract

The release of PAHs from a melting snowpack can result in temporary concentration peaks in urban environment. In this study, the concentrations of 16EPA priority PAHs in snowfall and snowpack are investigated, as well as those in soils before and after snowmelt. The concentrations of PAHs in snowfall range from 1100 to 7200ng L⁻¹ for dissolved phase and from 240 to 410μg g⁻¹ for particulate phase, respectively, reflecting various PAHs concentrations in the atmosphere during winter. The concentration of dissolved PAHs in snow increases in the first few days of snow accumulation, indicating absorption of gaseous PAHs to fresh snowpack. The decreased particulate PAHs in snowpack with time may be attributed to the photolysis, which can also be induced from low ratio of BaA to Chr in particles. The percentages of 2-4rings PAHs in both dissolved and particulate phase increase in snowpack comparing with those in new snowfall, suggesting faster loss of 5-6rings PAHs in snowpack than 2-4rings PAHs. The concentrations of PAHs in soils without plants and with buildings covered increase from 3.5 and 10.1μg g⁻¹ to 34.7 and 63.3μg g⁻¹ after snowpack melted, respectively, whereas those in soils with plants covered rarely change. Although 2-4rings PAHs account for more than 90% of both particulate and dissolved PAHs in snowpack, 5-6rings PAHs are dominated in soils. These results indicate that 5-6rings PAHs from snow pack may remain in soils in the end during snowmelt, while 2-4rings PAHs may be absorbed by plants or enter into water body with melt water.

polycyclic aromatic hydrocarbons; snow; snowmelt; soil

Effects of Thiamphenicol on Nitrate Reduction and N₂O Release in Estuarine and Coastal Sediments

Guoyu Yin, Lijun Hou, Min Liu

East China Normal University, gyyin@geo.ecnu.edu.cn

Abstract

Nitrate overload is an important driver of water pollution in most estuarine and coastal ecosystems, and thus nitrate reduction processes have attracted considerable attention. Antibiotics contamination is also an emerging environmental problem in estuarine and coastal regions as a result of growing production and usage of antibiotics. However, the effects of antibiotics on nitrate reduction remain unclear in these aquatic ecosystems. In this study, continuous-flow experiments were conducted to examine the effects of thiamphenicol (TAP, a common chloramphenicol antibiotic) on nitrate reduction and greenhouse gas N₂O release. Functional genes involved in nitrogen transformation were also quantified to explore the microbial mechanisms of the TAP influence. Production of N₂ were observed to be inhibited by TAP treatment, which implied the inhibition effect of TAP on nitrate reduction processes. As intermediate products of nitrogen transformation processes, nitrite and N₂O were observed to accumulate during the incubation. Different TAP inhibition effects on related functional genes may be the microbial mechanism for the changes of nutrient fluxes, N₂ fluxes and N₂O release rates. These results indicate that the antibiotics residues in estuarine and coastal ecosystems may contribute to nitrate retention and N₂O release, which could be a major factor responsible for eutrophication and greenhouse effects.

Abstract

With the development of nanotechnology, more and more nanoparticles (NPs) will be inevitably discharged in the environment. Sediments could act as a significant sink of NPs, further control the stability, fate and toxicity of these NPs. Analytical methods to detect and characterize NPs at low concentrations, and in complex environmental matrices, such as sediments, are urgently needed. In the present study, we aim to develop a method to quantify and analyse the size distribution of NPs at low concentration in sediments, based on a new technique -- single particle inductively coupled plasma mass spectrometry (SP-ICP-MS). Sediments from Yangtze River Estuary were taken as a representative environmental matrix. NPs were extracted from sediments via ultrasonic with different water solid ratio. 60nm and 100nm citrate-stabilized Ag-NPs were spiked into the sediments to determine the extraction efficiency and recovery of ultrasonic extraction, including the optimized ultrasonic power, ultrasonic time and solid water ratio considering various NPs (such as Ti-, Fe-, Pb-, Zn-NPs) presented in sediments. Overall, SP-ICP-MS is an efficient approach and shows significant advantages over other techniques when sizing NPs consisting of various elements in environmental matrix, such as sediment in the present study.

Abstract

Rapid urbanization has brought great pressure to the sustainable development and the global climate. Mapping multi-temporal urban extent distributions on a global scale is significant to extract urban areas. Closely related to human activities, the stable nighttime light (NTL) data from the Defense Meteorological Satellite Program (DMSP) Operational Line-scan System (OLS) provide a straightforward and convenient way to map the global distribution of urban areas. Considering the problems in the thresholding method and the characteristics of urban development in time and space, we proposed an method for global urban extents extraction from 2002 to 2012 based on support vector machine (SVM) and Markov random field (MRF) using the DMSP/OLS stable NTL data, the moderate-resolution imaging spectroradiometer (MODIS) enhanced vegetation index (EVI) data and the MODIS normalized difference built-up index (NDBI) data. Some urban and non-urban pixels were selected first as training seeds, and a SVM classification was used to identify urban pixels from unclassified ones according to the data combinations. Then, The MRF was adopted to make the temporal and spatial corrections, ensuring compliance with the law of urban development. The extracted urban areas were validated using the existing global land cover data and Landsat ETM+ images. The results showed that our proposed method is effective and efficient for time-series urban area extractions on a global scale.

High-Resolution Modeling of Human and Climate Impacts on Global Urban Areas

Wada Y

Center for Climate Systems Research, Columbia University, 2880 Broadway, New York, NY 10025, USA., Y.Wada@uu.nl

Abstract

The number of global hydrological models (GHMs) have been developed in recent decades in order to understand the impacts of climate variability and human activities on water resources availability. The spatial resolution of GHMs is mostly constrained at a 0.5° by 0.5° grid ($\sim 50\text{km}$ by $\sim 50\text{km}$ at the equator). However, for many of the water-related problems facing urban society, the current spatial scale of GHMs is insufficient to provide locally relevant information. Here, using the PCR-GLOBWB model we present for the first time the analysis of human and climate impacts on global urban areas at a 0.1° by 0.1° grid ($\sim 10\text{km}$ by $\sim 10\text{km}$ at the equator) in order to depict more precisely regional variability in water availability and use. Most model input data (topography, vegetation, soil properties, routing, human water use) have been parameterized at a 0.1° global grid and feature a distinctively higher resolution. Distinct from many other GHMs, PCR-GLOBWB includes groundwater representation and simulates groundwater heads and lateral groundwater flows based on MODFLOW with existing geohydrological information. This study shows that global hydrological simulations at higher spatial resolutions are feasible for multi-decadal to century periods. Higher spatial simulation can distinctively identify urban water issues such as water scarcity and groundwater depletion more accurately.

Impervious Surface Mapping: A Multivariate Regression Approach Employing Population Density

Dhorde A A

Department of Geography, Nowrosjee Wadia College (affiliated to SP Pune University), Pune, 411001 India, anarghawakhare@gmail.com

Abstract

Present research involves assessment of land use/ land cover modifications with respect to increase in population density and its impact on impervious cover in one of the urbanized watersheds (Mula-Mutha watershed) using IRS LISS-III (2008) and Landsat TM images (1989). The extraction of impervious cover is performed with the help of multiple regression model having various parameters like band values (band 1 to 4), NDVI, tasseled cap (band 2) values, population density, slope and elevation. Final output predicts the percent area that is covered with impervious surfaces at pixel level. During the assessment period (1989-2008) it was observed that the watershed experienced significant growth in population impacting the land use pattern. Major increase in population density was noticed in the central region (Pune-Pimpri-Chinchwad area) where the population increased by 7-8 times. Built up area increased significantly by 10% in and around Pune city and Pimpri-Chinchwad. On the other hand barren land drastically decreased (13.16%) due to increasing demand of land for residential and commercial purposes. More than 75% impervious cover is observed in centre of the watershed whereas surrounding villages are having moderate (40-60%) imperviousness. Along the major transportation routes, the land use pattern changed rapidly which is reflected in high imperviousness. The changing land use pattern observed in the Mula-Mutha basin may lead to changes in the watershed and its hydrological parameters. Thus conservation and proper management of the natural resources with their optimum use is required for the balanced growth of an area.

Integrating Multidisciplinary Data to Address Complex Urban Challenges in a Changing Global Environment

Chen RS, Yetman G, MacManus K

Center for International Earth Science Information Network (CIESIN), The Earth Institute, Columbia University, Palisades, New York 10964 USA, bchen@ciesin.columbia.edu

Abstract

The world's cities are facing multiple challenges coming from a variety of directions, ranging from continued urban population growth, rapid economic change, and aging public infrastructure to new public health crises, changing political, cultural, and ethnic landscapes, growing threats from terrorism and conflict, and unprecedented environmental stresses, including climate change. Integrated approaches to urban risk management and sustainable development are essential for coping with these challenges—including managing interactions between them, avoiding disastrous outcomes, and developing and maintaining sustainable, equitable, and liveable cities. One necessary ingredient to such integrated approaches is the ability to pull together diverse types and sources of data – not only from the natural and social sciences but also from the engineering and health fields—into forms useful for analysis and decision making. Because of the different scientific and technical traditions of these fields, varied spatial and temporal scales and units of analysis, and diverse needs for data by different stakeholders, data integration is itself a major challenge, requiring significant effort to address issues of access, quality and provenance, interoperability, compatibility, and usability. We report here on a number of efforts to integrate urban data across disciplines, develop useful decision-focused data products, services, and indicators, and deliver geospatial information to scientists, decision makers, and the general public. Data types include high-resolution remote sensing imagery; georeferenced administrative data; model estimates and projections; scenarios of future population, economic development, and climate change; individual- and household-level social and health data; crowd-sourced data; and engineering and operational data on urban infrastructure.

Mapping and Geospatial Analysis of the Model Estimates of Emissions from Fossil Fuel Power Plants and Impacts to Urban Population in China

Xing, X.¹, Brugère, E.^{2,3}, Mendeloff, D.¹, Wang, W.²

¹Center for International Earth Science Information Network (CIESIN), Earth Institute, Columbia University, New York, USA, xxiaoshi@ciesin.columbia.edu

²École Polytechnique, Paris, France

³École des Ponts ParisTech, Paris, France

Abstract

Since 1990s China has experienced rapid urban development as a key driver for the growth in electric power demand and supply. Fossil fuels are the main sources for power generation. Emissions from combustion have imposed great impact on the environment and human life, especially, of urban population. This study assesses major fossil fuel power facilities based on their capacities and other physical factors. In order to estimate power production and emissions, we use and optimize the model of Multivariate Adaptive Regression Splines (MARS). Based on officially disclosed data for all of the plants in the US, the physical specifications are adapted to the Chinese plants, such as age, capacity, technology and presence of control devices. The model is fitted on the data from the American plants for estimates of those in Chinese plants. The geospatial analysis is then conducted by combination of geolocations of the facilities and distribution of population. 700 Gigawatts (GW) plants are precisely geocoded and verified by remote sensing imagery. The distribution of the Chinese most polluting power plants is superimposed to population grids from the latest version of Gridded Population of the World (GPW) and Global Rural-Urban Mapping Project (GRUMP) created by CIESIN at Columbia University, USA. The results indicate that the power plants under operation are mainly installed in the most populated areas and that the planned plants in the future follow the same trend. Further analysis estimates that a significant portion of the urban area and population are exposed to the health hazards.

power plant emissions; urban; model optimization; geospatial analysis and mapping

Mapping the Spatial-temporal Dynamics of Global Cement, Steel, and Aluminum In-use Stocks Using Nighttime Light Data

Deng SQ¹, Liu G², Yu BL¹, Yang CS, Wu JP¹

¹Key Laboratory of Geographic Information Science (Ministry of Education) and School of Geographic Sciences, East China Normal University, Shanghai 200241, China, blyu@geo.ecnu.edu.cn (Yu BL)

²Centre for Life Cycle Engineering, University of Southern Denmark, Odense5230, Denmark

Abstract

Urbanization around the world largely relies on materials consumption, and in-use stock of materials can be an effective indicator to measure the level of urbanization. Therefore, spatial distribution of materials in-use stocks and their temporal dynamics are essential to the research on urbanization and sustainability. However, there is still a lack of spatially explicit and long-term time-series estimations of in-use stocks on the global scale. In this study, we collected global statistics of in-use stocks of aluminum, cement, and steel at country level. Utilizing DMSP/OLS nighttime light data, we build up a double-log linear relation between nighttime lights and in-use stocks based on strong positive correlations. Then we applied the model to estimate global distribution of in-use stocks. With time series of in-use stocks data and nighttime light images from 1992 to 2010, we conducted long period estimations of in-use stocks and mapped global in-use stocks distributions. Using the estimated result maps, the aggregation and dispersion of in-use stocks can be easily observed. Around the world, cities are holding the majority of in-use stocks which have been rapidly increasing in recent years and the disproportion of distribution can be discovered under a smallerscale. In-use stocks is a fundamental composition of urban facilities that support cities to work and a direct symbol that indicates urban developing level. With global in-use stocks estimations been conducted, we can understand urbanization more deeply viewed from material stocks.

Modelling the Influence of Urbanization on Urban Rainstorm Waterlogging: A Scenario-Based Case Study in Shanghai, China

HUANG QY^{1,2}, WANG J^{1,2}, DONG JG^{1,2}, LI MY^{1,2}

1. School of Geographic Sciences, East China Normal University, Shanghai, 200241, P. R. China, jwang@geo.ecnu.edu.cn

2. Key Laboratory of Geographic Information Science of Ministry of Education, East China Normal University, Shanghai, 200241, P. R. China

Abstract

Rapid urbanization has brought great developments and challenges to Shanghai in the last few decades. This paper focuses on the influence of urbanization on rainstorm waterlogging which caused severe damage especially in the central urban area. In general, we quantitatively evaluated the impact of urbanization on the risk of urban waterlogging using method of scenario simulating. The involving scenarios were designed by incorporating two environmental variables (land subsidence and land-use/land-cover (LULC) change), three time points (2000, 2006 and 2012) and four degrees of rainfall intensity (with 5-, 10-, 50- and 100-year return period, respectively). A toolset was developed for modeling the hydrodynamic process of waterlogging. Inundation area and the average depth were selected as indices to estimate the severity of waterlogging. Besides, the corresponding F statistic and the Root Mean Square Deviation were employed to quantify the changes with the impact of all scenario variables.

Results suggest that the impacts of land subsidence and LULC change are the function of precipitation intensity, and display a spatial disparity across the entire area. LULC change is the key factor contributing to the risk of waterlogging, for all magnitude precipitation events. Nonetheless, the effects of different land use types are distinctive. Inundation aggravates within land use for industries and transportation, while alleviates within green land and waters. Besides, except for a slight change captured in the local water depth, the risk of waterlogging is less sensitive to the impact of land subsidence with the precipitation magnitude varying when compared to the LULC change.

Abstract

Nanoparticles (NPs) resulting from urban road dust resuspension are an understudied class of pollutants in urban environments with strong potential for health hazards. The objective of this study was to conduct a comprehensive investigation of PM_{2.5} generated in the laboratory using a novel aerosolization technique, paying particular attention to the NP-fraction of the resuspension. This was accomplished in this study using road dust collected throughout the mega-city of Shanghai (China). Sixty-six samples were collected and aerosolized in the laboratory. The samples were characterized using an array of techniques including inductively-coupled plasma mass spectrometry, aerosol size distribution instrumentation, and scanning and transmission electron microscopy coupled with elemental characterization. Principal metal concentrations were plotted geospatially. Results show that metals were generally enriched in aerosolized samples relative to the bulk dust. Elevated concentrations of metals were found mostly in downtown areas with intense traffic. Fe-, Pb-, and Ba-containing NPs were identified using electron microscopy. Pb-containing NPs were often associated with Sn and possibly originated from an e-waste plant. Size distributions of most aerosolized samples presented a peak in the ultrafine range (< 100 nm). We estimate that 3.2 ± 0.7 µg/mg of dust may become resuspended in the form of PM_{2.5}. Aerosolization, as done in this study, seems to be a very useful approach to study NPs in dust.

Nitrate Reduction Processes and Associated Contribution to Nitrogen Removal in the Yangtze Estuary

Hou Lijun, Liu Min, Yin Guoyu, Zheng Yanling

State Key Laboratory of Estuarine and Coastal Research, East China Normal University, Shanghai, 200062, P. R. China,

Ljhou@sklec.ecnu.edu.cn

Abstract

Denitrification, anaerobic ammonium oxidation (anammox) and dissimilatory nitrate reduction to ammonium (DNRA) are important nitrate reduction processes, which play a crucial role in determining nitrate dynamics and fate in estuarine and coastal environments. However, the dynamics of these processes and controlling mechanisms remain unclear for a specific aquatic environment. In this study, we examined potential rates of denitrification, anammox and DNRA in the sediments of the Yangtze Estuary via slurry experiments combined with isotope-tracing techniques to reveal their respective contributions to total nitrate reduction in this hypereutrophic estuarine ecosystem. Measured rates of denitrification, anammox and DNRA ranged from 0.06 to 4.51 $\mu\text{mol N kg}^{-1} \text{h}^{-1}$, 0.01 to 0.52 $\mu\text{mol N kg}^{-1} \text{h}^{-1}$, and 0.03 to 0.89 $\mu\text{mol N kg}^{-1} \text{h}^{-1}$, respectively. These potential dissimilatory nitrate reduction process rates correlated significantly with salinity, sulfide, organic carbon and nitrogen. Denitrification contributed 38 – 96 % total nitrate reduction in the Yangtze Estuary, as compared to 3 – 45 % for DNRA and 1 – 36 % for anammox. In total, the denitrification and anammox processes removed approximately 25% of the external inorganic nitrogen transported annually into the estuary. In contrast, most external inorganic nitrogen was retained in the estuary and contributes substantially to the severe eutrophication of the Yangtze Estuary.

Key words:

Nitrogen; Denitrification; Anaerobic ammonium oxidation; Dissimilatory nitrate reduction to ammonium

Occurrence and Concentrations of Antibiotic Resistance Genes in the surface sediments of the Yangtze Estuary

Xingpan Guo, Yi Yang*, FeiyunTou, Min Liu

School of Geographic Sciences, East China Normal University, Shanghai 200241, China, yyang@geo.ecnu.edu.cn

Abstract

As emerging environmental pollutants, antibiotic resistance genes (ARGs) could cause serious effect on the security and stability of ecosystem in natural environment. To investigate the occurrence and concentrations of ARGs in the surface sediments of the Yangtze Estuary, the qualitatively and quantitatively analysis of the 16s rDNA genes, sulphonamide-ARGs (sul1 and sul2), tetracycline-ARGs (tetA and tetW), Quinolone-ARGs (aac(6')-Ib and QnrS), β -Lactam resistance genes and class 1 integrons (int1) were conducted. Furthermore, the correlation between the TOC, particle sizes, heavy metals, pH, salinity, DO and the concentration of the tested ARGs were analyzed. Results showed that all tested ARGs were detected in the eight samples taken along the Yangtze Estuary, except the plasmid mediated resistance gene QnrS, which had a lower concentration in SDK and WSK samples. Statistical analysis of the results indicated that the particle sizes, pH, salinity and several metals were correlated with the concentrations of tested ARGs in different degrees. However, there was no significantly correlation between the ARGs and the concentration of TOC, which suggested that the ARGs may exist in different forms. Furthermore, the abundance of sul1 and sul2 were as high as 10^7 copies/g, and significantly correlated with the abundance of 16s rDNA which suggested that the propagation of sulphonamide-ARGs was affected by bacteria in estuary environments.

antibiotic resistance gene; the Yangtze Estuary; sediments; heavy metal

Polycyclic Aromatic Hydrocarbons and Heavy Metals: Pollution, Ecological Risk and Impact On Microbial Community in Yangtze River Estuary

LIU Xinran, CHEN Xing, LIU Min

School of Geographic Sciences, East China Normal University, 500 Dongchuan Road, Shanghai, 200241, P. R. China, xrliu@geo.ecnu.edu.cn

Abstract

Estuarine sediments are both sinks and secondary sources of terrestrially derived pollutants like PAHs and heavy metals. Yet the synergistic pollution pattern of pollutants and their impact on the estuarine microbial community have scarcely been studied. We thus investigated the latest pollution state of 16 priority PAHs and 7 heavy metals in the surface sediments of 11 sampling sites along the Yangtze River Estuary. Results showed that PAHs concentrations ranged from 195.5 to 4377.6 ng/g, with a mean content of 1770.3 ng/g. The pollution level of both PAHs and heavy metals showed a general trend that concentrations in fresh water area > transition area > seawater area. Source apportionments revealed that Cu, Zn and PAHs may have common anthropogenic sources (i.e. industrial production). The ecological risk associated with the heavy metals and PAHs in sediments was rated as low to moderate level using methods of Potential Ecological Risk Index (R_i) and mean Sediment Quality Guidelines (mSQG), Ni, Zn and Hg are crucial pollutants in the studied area and should be put enough attention. Salt water area and transition area were found to have more similar microbial community, while fresh water area had a different community. pH values, TOC, N, P, PAHs and As concentrations were found strongly influenced the microbial species composition in sediments. For example, PAHs had a positive relationship with the diversity and abundance of microbial community of Jinshan, Fengxin, Luchaogang, Donghai, Chaoyang and Bai long gang, but have a negative relationship with that in Liuhekou, Qiyakou and Shidongkou.

Satellite Altimetry for Flood and Storm Surge Studies in Waterfront Cities

Ming Pan

Department of Civil and Environmental Engineering, Princeton University, mpan@Princeton.EDU

Abstract

Satellite remote sensing has been transforming the way we monitor and assess our environment in recent decades. One of the forefront of these applications is to use satellite altimetry sensors to monitor (and subsequently forecast) the height (level) of waterbodies like rivers, lakes, reservoirs, and coastal/near shore sea. Nowadays, a large number of cities are located along the waterfront, e.g., next to a major river, lake, river delta, or sea coast, for the benefit of abundant water resources supply, convenient transportation, scenery values, easier storm water/sewage management, and so on. At the same time, the growing urban population and steep concentration of assets has tremendously increased our stake/risk in these areas when natural disasters like flood or coastal storm surge strike. For example, when Hurricane/Super Storm Sandy hit the east coast of United States, hundreds of thousands of houses were damaged (due to a combination of coastal surge, river flood, and wind damage) and the loss amounted to billions of US dollars. Therefore, large-scale monitoring of these waterbodies can provide a large amount of critical information for us to analyze and understand the underlying physical processes, as well as to forecast and mitigate these risks. Here we give a brief introduction to this developing field of satellite altimetry, including the past efforts, current research, and new sensor technologies to be deployed in the very near future. We will also try to highlight the great opportunities in urban studies brought forth by the development and operation of new-generation satellite altimetry technology.

The Risk of Sea-Level Rise for Coastal Cities

Brown S, Nicholls R J, Reeder T and Haigh I D

University of Southampton, Southampton, SO17 1BJ, United Kingdom, sb20@soton.ac.uk

Abstract

Understanding and planning for the consequences of sea-level rise requires long lead-in times due to the complex political, financial, social and physical interactions happening at the city scale. Cities can evolve rapidly, with many new, large cities being built within the last few decades. This trend is likely to continue, with many new cities emerging, particularly on the Chinese coast. Simultaneously, cities evolve over long time scales and contain culturally important values and assets. Sea-level rise, potentially up to 1m by 2100 (with some high-end projections higher again) threatens low lying cities. Even if we mitigate for climate change, sea-levels will continue to rise due to the time lag between atmospheric temperature rise and oceanic response. With sea-level rise, flood risk levels increase as it raises the likelihood of extreme events, leading to increased damages. Without adaptation to existing infrastructure and integrating the threat of sea-level rise when planning new infrastructure, cities will be at risk from increasing saltwater intrusion and flooding. Past extreme events, such as Hurricane Katrina (2005) affecting New Orleans and Superstorm Sandy affecting New York provided a wake-up call for the need to adapt. This could mean increasing defence standards of improved emergency planning. Despite the need for adaptation action, climate change adaptation is slowly moving onto the political agenda. Yet still there remains physical/engineering, economic/financial and social/political limits to adaptation. The presentation discusses these challenges in relation to cities, focusing on Shanghai, New York and Kolkata.

Sea-level rise; coastal cities; New York; Shanghai; Kolkata

Understanding the Impact of Sea Surface Temperature Variability on the Climate of New York City on the Interdecadal Scale

Liu H, Zheng X

The Lamont-Doherty Earth Observatory, Columbia University in the City of New York, Palisades, 10964, USA,
haibo@ldeo.columbia.edu

Abstract

New York City is located at the meeting of the Hudson River and the Atlantic Ocean; its climate patterns are affected by the Atlantic Multidecadal Oscillation (AMO), which influences the frequency and severity of hurricanes and coastal storms. Among many variables, the most dominant factor is the sea surface temperature (SST). To understand the impact of SST on the City's climate on the interdecadal scale, we analyze the Last Millennium Experiment (LME) conducted by the Coupled Model Inter comparison Project Phase 5 (CMIP5) program. There are seven models supplied the experiment results available to public. We propose a new method that uses data from all seven models to estimate the contribution of decadal noise to the interdecadal variability of climate variables, the decadal variability associated with the potentially predictable slow processes. Our analysis shows large potential SST interdecadal predictability in the extratropical region in both hemisphere, as well as in the subtropical/tropical Indian Ocean, the western Pacific and the Atlantic. In the tropical eastern Pacific, interdecadal variability is dominated by unpredictable decadal noise. The two leading unpredictable modes of interdecadal variability have features related to the two leading ENSO modes, and the PDO. The four leading potentially predictable modes of interdecadal variability are shown to be related to the external forcing, the IPO, inter-hemisphere SST fluctuations and the AMO, and decadal/multi-decadal AO/NAO variability.

² State Key Laboratory of Estuarine and Coastal Sciences, ECNU, Shanghai

Abstract

Since the end of the 20th century, more and more people have been moving into the city, thereby increasing the complexity of relationship between the human and physical environments. Along with the urban development, the natural water system has been heavily modified, the natural topography has been levelled off, natural vegetation has been replaced, the regional climate has been changed by the built environment, and the river system has been severely polluted affecting drinking water. The significant changes in the natural environment of city require a comprehensive assessment to review and evaluate the impact of urban development and the changing nature of interactions and interrelationships between the human and physical environments. The occurring of problems of physical geography in urban areas shows a new stage of the evolution of human-earth interaction. Thus Urban Physical Geography, as a new discipline has been developed, which concentrates on the research of the spatial and temporal changes, evolution processes of natural elements, mutual coupling effects between physical environments and human activities, the response mode of urban system against physical environmental changes, and mutual feedback influencing mechanism in urban system, then makes simulation, prediction, and adaptation for urban development and management. Its main task is to study the evolving characteristics and the mechanisms of changed physical geography, to explore the changes in the level of physical geography elements, the functioning processes and mechanisms, as well as the relations and effects of mutual restraints, and to seek the sustainable development of the relationship between human and environment in urban areas. This study presents the concept, disciplinary system and framework, new developments, and future trend of Urban Physical Geography.

Abundance and diversity of polycyclic aromatic hydrocarbon degradation bacteria in urban roadside soils in Shanghai

Xiaofei Li¹, Lijun Hou², Min Liu¹

¹College of Geographical Sciences, East China Normal University, Shanghai 200241, China

²State Key Laboratory of Estuarine and Coastal Research, East China Normal University, Shanghai 200062, China

Abstract

Understanding the impact of polycyclic aromatic hydrocarbons (PAHs) on soil environments is of increasingly important concern. Therefore, the microbial degradation of PAHs in soils has drawn considerable attention, but little is known about the PAH degradation genes in urban soils. In this study, we examined the diversity and abundance of the PAH degradation bacteria and evaluated whether the specific bacteria can reflect PAH contents in the soils from urban roadsides directly receiving traffic emission. The results of phylogenetic analysis indicated that low PAH degradation bacterial diversity occurred in the urban roadside soils, only including *Mycobacterium* sp., *Terrabacter* sp., and one novel cluster. The community composition diversity of PAH degradation bacteria did not show a significant difference across the sampling sites. The abundance of PAH degradation genes ranged from 5.70×10^6 to 6.44×10^7 gene copies g⁻¹ dry soil, with an average abundance of 1.43×10^7 gene copies g⁻¹ dry soil, and their spatial variations were related significantly to PAH contents in the soils. The *Mycobacterium* sp. was the most widely detected and estimated to occupy 65.9–100 % of the total PAH degradation bacteria at most of the soil samples, implying that the *Mycobacterium* sp. might play a primary role in degrading PAHs in the contaminated urban soil environments.

Correlations of Global Sea Surface Temperatures with the Solar Wind Speed and Its Effect on Local Urban Environment in East China

Limin Zhou¹, Brian Tinsley², Xiangmin Zheng¹, Ziniu Xiao³

¹ Key Laboratory of Geographic Information Science, Ministry of Education, East China Normal University, Shanghai, China, 200062

² University of Texas at Dallas, Richardson, TX, 75080

³ State Key Laboratory of Numerical Modeling for Atmospheric Sciences and Geophysical Fluid Dynamics, Institute of Atmospheric Physics, Chinese Academy of Sciences, Beijing, China, 100910

Abstract

A significant correlation between the solar wind speed (SWS) and sea surface temperature (SST) in the region of the North Atlantic Ocean has been found for the Northern Hemisphere winter from 1963 to 2010, based on 3-month seasonal averages. The correlation is dependent on Bz (the interplanetary magnetic field component parallel to the Earth's magnetic dipole) as well as the SWS, and somewhat stronger in the stratospheric quasi-biennial oscillation (QBO) west phase than in the east phase. The correlations with the SWS are stronger than those with the F10.7 parameter representing solar UV inputs to the stratosphere. SST responds to changes in tropospheric dynamics via wind stress, and to changes in cloud cover affecting the radiative balance. Suggested mechanisms for the solar influence on SST include changes in atmospheric ionization and cloud microphysics affecting cloud cover, storm invigoration, and tropospheric dynamics. Such changes modify upward wave propagation to the stratosphere, affecting the dynamics of the polar vortex. Also, direct solar inputs, including energetic particles and solar UV, produce stratospheric dynamical changes. Downward propagation of stratospheric dynamical changes eventually further perturbs tropospheric dynamics and SST, whose effects on local urban environment in East China were addressed.

Diversity, Abundance, and Distribution of *nirS*-encoding Denitrifiers in the Coastal Wetlands of China

Juan Gao¹, Lijun Hou¹, Yanling Zheng^{1, 2}, Min Liu¹, Guoyu Yin^{1, 2}, Xiaofei Li², Xianbiao Lin², Chendi Yu¹, Rong Wang¹, Xiaofen Jiang¹, Xiuru Sun²

¹State Key Laboratory of Estuarine and Coastal Research, East China Normal University, Shanghai 200062, China

² College of Geographical Sciences, East China Normal University, Shanghai 200241, China

Abstract

For the past few decades, human activities have intensively increased the reactive nitrogen enrichment in China's coastal wetlands. Although denitrification is a critical pathway of nitrogen removal, the understanding of denitrifiers dynamics remains limited in the coastal wetlands. In this study, the diversity, abundance, and distribution of *nirS*-harboring denitrifiers in China's coastal wetlands were analyzed to reveal their variations along the latitudinal gradient. Diverse *nirS* sequences were obtained and most of them shared considerable phylogenetic similarity with sequences obtained from aquatic systems (marine/estuarine/coastal sediments and hypoxia sea water). Clone library analysis revealed that the distribution and composition of *nirS*-harboring denitrifiers had significant latitudinal differentiation, but without seasonal shift. Canonical correspondence analysis showed that the community structure of *nirS*-encoding denitrifiers was significantly related to temperature and ammonium concentration. Q-PCR results revealed that the *nirS* gene abundance ranged from 4.3×10^5 to 3.7×10^7 copies g^{-1} dry sediment with a significant spatial heterogeneity. Among all detected environmental factors, temperature was a key factor regulating not only the *nirS* gene abundance but also the community structure of *nirS*-harboring denitrifiers. Overall, this study provides valuable insights into the composition and dynamics of denitrifying community in the coastal wetlands of China.

Denitrification; reactive nitrogen

Extreme Climate Event, Urban Social-Ecological Systems and Disaster Resilience in Coastal Cities: A Comparative Study

Ruishan Chen

School of Geographic Sciences, East China Normal University, Shanghai, 200241, P. R. China, chenrsh04@gmail.com

Abstract

The intensification, changing frequency and duration of climate extreme events such as heavy precipitation, tropical cyclones and intensified heat waves is currently emerging as one of the most important facets of climate change. The losses from extreme climate events are increasing in coastal urban area and urban societies are becoming more vulnerable to these events given their location, high concentration of people, and increasingly complex and interdependent infrastructure. And among these climate extremes, the compound or concurrent extreme event is most destructive and draw more attentions. Coastal cities in different countries have different capacity to cope with the disasters related to extreme climate event. This paper examine the history of extreme climate events in Shanghai and New York, the possibilities and magnitude of compound extreme events in these two cities, and the resilience of urban social-ecological system after mega events which illustrated with two extreme cases of Hurricane Sandy and Typhoon 9711. Impacts of Hurricane Sandy, and Typhoon 9711 demonstrate not just failures in built infrastructure, they highlight the inadequacy of institutions, resources, and information systems to prepare for and respond to events of this magnitude. Joint learning from the experiences of adaptation in two cities can make the cities stronger and more resilient.

Extreme climate event; social-ecological system; vulnerability; cascading impacts; disaster resilience

Health Risk Assessment of Soil Heavy Metals in Housing Units Built on Brownfields in a City in China

Chen X^{1,2}, Liu M¹, Ma JH^{2, *}, Liu DX², Chen YF²

¹College of Geographical Sciences, East China Normal University, Shanghai 200062, P.R. China

²Institute of Natural Resources and Environment, Henan University, Kaifeng 475004, P.R. China

Abstract

Nine housing units built on different brownfields in a city in Henan Province in China were chosen to investigate the health risks of soil heavy metals (As, Hg, Pb, Cd, Ni, Zn, Cr, and Cu) in 41 surface soils. Concentrations of soil heavy metals were measured by AAS, ICP-MS, and AFS. Based on the health risk models recommended by the US EPA, carcinogenic and non-carcinogenic health risks of soil heavy metals were assessed. Our results showed that compared with the original brownfields, soil heavy metal concentrations and their health risks in housing units built on brownfields have been improved after soil remediation. Nevertheless, the concentrations and health risks of soil heavy metals in these housing units are all higher than those in non-brownfield housing units. The hazard quotient (*HQ*) and hazard index (*HI*) values of soil heavy metals in each housing unit are lower than one, which indicates that there are no non-carcinogenic risks for the residents. However, the values of carcinogenic risk (*CR*) and total carcinogenic risk (*TCR*) are slightly higher than the standard suggested by the US EPA, indicating that there are slight carcinogenic risks for the residents in these housing units. The *HI* value of the heavy metals for children is exactly seven times higher than for adults. The contribution of *HQ*_{As} to *HI* is approximately 53%, and the contribution of *CR*_{As} to *TCR* is approximately 80%, indicating that arsenic is the crucial heavy metal for carcinogenic and non-carcinogenic risk in the residential quarters of the city.

Investigation on Atmospheric PM_{2.5}-borne PAHs in Eastern Cities of China: Concentration, Source Diagnosis and Health Risk Assessment

Li Y, Liu M, Liu XR, Li XF

School of Geographic Sciences, East China Normal University, Shanghai, 200241, P. R. China, liye1219aaa@hotmail.com

Abstract

This study has investigated on PM_{2.5}-PAHs associations collected from Beijing, Jinan and Shanghai in Eastern China. Results indicated that PM_{2.5} concentrations of Beijing, Jinan, and Shanghai were 126 $\mu\text{g m}^{-3}$ (19~356 $\mu\text{g m}^{-3}$), 116 $\mu\text{g m}^{-3}$ (44~345 $\mu\text{g m}^{-3}$) and 85 $\mu\text{g m}^{-3}$ (24~233 $\mu\text{g m}^{-3}$) respectively. The PAHs concentrations in PM_{2.5} of Beijing, Jinan, and Shanghai ranged from 23 to 820 ng m^{-3} , 26 to 727 ng m^{-3} and 9 to 134 ng m^{-3} , separately. PAHs concentrations were found to be positively correlated with PM_{2.5} concentrations in Beijing and Shanghai. The compositions of PAHs in PM_{2.5} in Beijing and Jinan were almost the same: 11% of low ring, 80%~82% of middle ring and 7%~9% of high ring. Yet Shanghai has a different composition. Source apportionment indicated that incomplete combustion of coal and diesel and gasoline emissions were main sources of PAHs in PM_{2.5} in all three cities, while Shanghai has more contribution of liquid fossil fuels. The values of health risk assessment estimated by benzo[a]pyrene equivalent concentration of Beijing and Jinan were 2.39×10^{-6} and 2.57×10^{-6} , exceeding the 1×10^{-6} (USEPA), likely posing inhalation cancer risk to people. Shanghai has a risk estimate of 5.05×10^{-7} , which is still in a safe range. This study is first to simultaneously monitor the PAHs in PM_{2.5} in three cities of Eastern China and points to a long-range transportation of PM_{2.5}-PAH from Beijing to Jinan, and partially to Shanghai.

Key words:

PAHs; PM_{2.5}; sources; Eastern China; health risk assessment

**Modelling the Anthropogenic Impacts on Fluvial Flood Risks in A Coastal Mega-city:
A Scenario-Based Case Study in Shanghai, China**Jie Yin¹, Dapeng Yu², Zhane Yin³, Jun Wang¹, Shiyuan Xu¹¹Key Laboratory of Geo-Information Science of the Ministry of Education, East China Normal University, China²Centre for Hydrological and Ecosystem Science, Department of Geography, Loughborough University, UK³Department of Geography, Shanghai Normal University, China**Abstract**

This paper describes a novel approach to the evaluation of anthropogenic impacts on flood risks in coastal mega-cities by incorporating three anthropogenic variables (land subsidence, urbanization and flooddefence) within a scenario-based framework where numerical modelling was undertaken to quantify the risks. The evolving risks at four time points (1979, 1990, 2000 and 2009) were assessed for the Huangpu River floodplain where the city of Shanghai is located. A 2D hydrodynamic model (FloodMap-Inertial) was used to estimate the flood risks associated with each scenario. Flood events with various return periods (10-, 100- and 1000-year) were designed based on a one in 50-year flood event that occurred in Shanghai on August 1997. Results demonstrate the individual as well as the combined impacts of the three anthropogenic factors on the changing fluvial flood risks in the Huangpu River basin over the last three decades during the city's transitional economy (1979–2009). Land subsidence and urbanization were found to lead to proportionate but non-linear impact on flood risks due to their complex spatial and temporal interaction. The impacts and their sensitivity are the function of the rate and spatial distribution of each evolving factor. While the pattern of response to individual anthropogenic variables is largely expected, the combined impacts demonstrate greater spatial and temporal variation. Flood defences offer considerable benefits in reducing the total inundated areas in the Huangpu River basin over the periods considered, for all magnitude floods. This, to a large extent, alleviates the adverse impacts arising from land subsidence and urbanization.

Nitrogen Mineralization and Immobilization in Sediments of Shanghai River Networks: Spatiotemporal Variations and Environmental Implications

Xianbiao Lin¹, Lijun Hou², Min Liu¹

¹College of Geographical Sciences, East China Normal University, Shanghai 200241, China

²State Key Laboratory of Estuarine and Coastal Research, East China Normal University, Shanghai 200062, China

Abstract

Nitrogen (N) mineralization and immobilization play crucial role in the N cycle in river sediments. Although these processes are critical to understand the N budgets and maintain the ecological environment security in river ecosystem, few studies have investigated them in the urban river networks of Shanghai. Sediment-slurry incubation experiments combined with ¹⁵N isotope dilution technique were conducted to quantify the potential rates of N mineralization and immobilization in surface sediments. The gross N mineralization (GNM) and gross ammonium immobilization (GAI) rates ranged from 0.1 to 11.1 mg N kg⁻¹ d⁻¹ and 0.2 to 12.83 mg N kg⁻¹ d⁻¹ in surface sediments, respectively. In general, both the potential rates of GNM and GAI were greater in summer than in winter, and the relative high values were mainly detected in urban area. Both the rates of GNM and GAI were related closely to sediment temperature, pH, NH₄⁺-N, NO₃⁻-N, and TOC and TN contents in urban and suburban areas. In addition, the total mineralized and immobilized N in the were estimated to be approximately 1.3 × 10⁵ t N yr⁻¹ and 1.4 × 10⁵ t N yr⁻¹, respectively. Compared with general dissolved inorganic nitrogen (DIN) fluxes from other sources, the potential mineralized N could become an important DIN source in the urban river networks of Shanghai, and N immobilization is crucial for maintaining the ecological environment security.

Abstract

Understanding the spatio-temporal distribution and sources of PAHs in sediments of urban rivers has been raised recently. In this work, principal component analysis with multiple linear regression model, hierarchical cluster analysis and diagnostic ratios were conducted to identify the potential PAHs source. The results indicated that total concentrations of PAHs ranged from 723.25 ngg⁻¹dry weight (dw) to 38541.61 ngg⁻¹dw with mean value of 7611.91 ngg⁻¹ dw in the dry season, while the average value of 1113.4 ngg⁻¹ was observed in the wet season. Generally, the concentrations of PAHs were higher in mainstreams than in the tributaries. The PAH compounds was dominated by 4-ring PAHs, contributing 42.41%±6.81% and 44.70%±7.73% of total PAHs, respectively. On the base of statistical methods, the sources of PAHs were mixed and derived mainly from vehicular emission, coal combustion and wood combustion. Risk assessment results indicated that the toxicity was higher in drought season than in wet season. Additionally, the BaP contributed (59.88%-55.91%) to TEQ_{PAH} at most sites.

Bank Erosion along Lower Subansiri River, Assam: A Geospatial Analysis

Bora, Amritee^{1*}, Mipun, B.S. ^{2*}

Department of Geography, North-Eastern Hill University, Shillong-793022, Meghalaya,
amritibora@hotmail.com&bsmipun@hotmail.com

Abstract

Subansiri is the largest tributary of the river Brahmaputra and second largest river in Assam contributing as much as 11 percent of the total flow. The maximum discharge recorded at Chowldhoaghat is 18799 cubic meters per second in the year 1987 during its peak season. It is one of the most dynamic and unstable river originating in the Eastern Himalayan Region. Flood and drainage congestions are the major problems in the plains of the Lower Subansiri. The hydrological characteristics of the river and the geology of the surface indicate that it is an active zone of river bank erosion. The study shows that between the years 1956 to 1990 the annual rate of erosion is about 8.3 square kilometres. During the years 1990 to 2000 the annual erosion rate has gone up to 19.51 square kilometres. In the last decade, from the year 2000 to 2010 the annual erosion rate has decreased to 6.07 square kilometres. Every year a considerable amount of land loss has been due to bank erosion in the flood plain region. The primary aim of the present study is to assess the amount of land loss caused by the Lower Subansiri River and map the erosional areas between the years 1956 to 2010. The methodology is based on RS and GIS techniques with mathematical as well as statistical analysis. The channel behaviour and configuration of river undergoes dramatic changes in response to variation in flow regime. The study aims to project future bank erosion areas.

Changes of Siltation in Main Sediment Sinks and Sediment Load of the Yellow River

Changxing SHI

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, P.R. China, shicx@igsnrr.ac.cn

Abstract

The Yellow River is one of the gigantic sediment delivery systems on the Earth. This study investigates the changes of siltation in three principal sediment sinks and sediment load of the river in history. It is displayed that the sediment load of the river undergone an accelerating increase after the Song Dynasty mainly resulting from a gradual enhancement of human activities and a decrease tendency in recent decades as a result of climate change and soil erosion control and water conservation practices. Before the middle of the 20th century, siltation in two sediment sinks (including the lower Yellow River and the lower Wei River and the Xiaobeiganliu reach of the middle Yellow River) showed an increase trend accompanying with the accelerating increase of the river's load. In recent decades, siltation rates in the two sediment sinks undulated due to the promotion of flood control capacity of artificial levees, changes in pool level of Sanmenxia Dam, and variations in the river's load. The sediment storage in the two sinks has continuously decreased since 2003. The Hetao plain is the largest sediment sink in the upper Yellow River. Siltation in the sink was approximately 900 million tons annually on average of over 400 years before 1949. In over 50 years after 1950, the mean siltation rate in the sink was higher than that before and rose and fell for two cycles due to changes in incoming sediment coefficient. It is low in recent years.

Channel Patterns and Their Transformation in The First Bay of the Yellow River**Suiji Wang**

Key Laboratory of Water Cycle and Related Land Surface Processes, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, wangsj@igsnrr.ac.cn

Abstract

The Yellow river is famous in the world because of its high-concentrated flow and high sedimentary rate on the channel bed of the lower reach. Furthermore, various channel patterns can be found along its trunk channel and many tributary channels. The first bay of the Yellow River, located in an intermountainous alluvial region of the eastern Qinghai-Tibetan Plateau, at least has three different channel patterns in a channel long about 200 km. Based on satellite images and field investigation, anastomosing, meandering and braided channel patterns have found in the first bay. Specially, although the anastomosing channels shows typical planform of anastomosing pattern, the sediments of channel bed and in channel bank-bottom are gravel materials which are different from the sediments on sandy bed and in muddy banks of reported anastomosing river systems, respectively. The channel pattern transformation in the first bay shows two modes, from anastomosing to meandering and from meandering to braided. The series transformations present a tend from very stable to very unstable channel patterns that is reverse with the normal trend from unstable to stable channel patterns downward stream in the world. These transformations are influenced by crustal rise, restriction of the gorges in upper and lower reaches of the first bay, hydrodynamic characteristics, sediment difference of channel boundary and regional distribution of vegetation cover. In the future, it needs to reveal the cause of formation of the anastomosing channel pattern with gravelly bed and bank-bottom.

Criticality in the Cutoff Behaviour of the Ganges River Meanders

Carling, P.A., Gupta, N., Atkinson, P.M., Huang, Q. H.

The Geographical Society of China, Beijing, 100101, P. R. China, igc2016@igsnr.ac.cn

Geography and Environment, University of Southampton, Highfield, Southampton, SO17 1BJ, UK

Abstract

Changes in the planforms of large rivers often are considered unpredictable. In contrast, we demonstrate that the cutoff behaviour of meanders in the wandering Ganges is highly predictable. Historical maps indicate cutoffs occurred at intervals defined by multiple decades. Recent remote-sensing data indicate that four self-similar meanders cutoff, or attempted to cutoff, after approximately 31-35 years, primarily due to channel-aggradation. Meander planform behaviour is a form of self-organised criticality. As main-channels aggrade, sinuosity is maximized for broad channel widths (B) and small radii (r) of curvature and relaxes for bends of greater radii. Maximized form resistance occurs close to criticality and super-elevated flows develop along the outer banks of bends that promote cutoffs. Avulsions lead to main channel narrowing and prevent further bend tightening, relaxing the system by reducing sinuosity. Thus, wandering rivers oscillate in space and time from a more ordered to a more chaotic state. Planform behaviour is described using the Jerolmack-Mohrig mobility number and the Parker stability criterion. These parameters well-define the behaviour of the Ganges meanders as they approach criticality and then relax via partial or completed avulsions. In conclusion, the behaviour of the Ganges in the study reach is predictable in space and time. The results have significance for river engineering management and such an approach could be of practical value when predicting the behaviours of other major wandering rivers.

Criticality; Meander; Avulsion; Wandering; Anabranching

Influence of Cascade Hydropower Development on Fluvial Morphology Diversity in the Yellow River Source Zone

Huan HONG, Jinming HU

Institute of International Rivers and Eco-security, Yunnan University, Kunming, 650091, P. R. China, jhuynu@163.com

Abstract

Fluvial morphology in the Yellow River Source Zone (YRSZ) has received more attention for its unique diversity. However, the newly planned Cascade Hydropower Development on the mainstream of the YRSZ will potentially change its fluvial morphology. Based on river patterns, the mainstream of the YRSZ between the Longyangxia and Huangheyuan reservoirs was divided into 14 sections. We adopted 8 indicators to establish an index system reflecting the spatial, inter-channel lands and boundary features for each section. DEM data, the location of dams and their normal pool levels were used to simulate the flooding impacts on fluvial morphology from the cascade reservoirs. Results document a huge change of fluvial morphology between pre- and post-dam construction. The length ratio of unnatural, multiple and single channels will be altered from 1:6:8 (now) to 9:5:1, with a greater rate of decrease (87%) of single channels than multiple channels (20%). The unnatural channels will account for 60% of the reach between the Longyangxia and Huangheyuan reservoirs. The sinuosity of the flooded sections will decline, and more than 50 km² of inter-channel lands will be submerged. To protect fluvial morphology diversity and the vulnerable river ecosystem, we need effective actions before the cascade dam construction.

Yellow River source zone; fluvial morphology diversity; cascade hydropower development

Network Evolution and Fluvial Process of the Tarim River in China

Yu GA, Huang HQ, Disse M

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China,
yuga@igsnrr.ac.cn**Abstract**

Historical literature/maps, gauged hydrological data and satellite images are analyzed to examine how river network and fluvial morphology of the Tarim River, the longest dryland river in an extremely arid region of China, have changed in recent centuries, particularly in the last decades due to ever-increasing human impacts. Gauged hydrological data from the past five decades shows an obvious reduction in runoff and sediment load in the Tarim River, even though the runoff from source tributaries exhibits a gentle increase. The annual occurrence of low flow events shows a significant increase, while the occurrence of moderate-high flow events follows a gentle decrease. The river network has disintegrated from a historically '(quasi-) centripetal' system with nine tributaries into several isolated branches, which have mainly developed since the 20th century. Currently, only four tributaries flow into the main river, leading to the development of a braided channel pattern in the upper reach and a meandering pattern in the middle reach. The braided reach is wandering and in aggradation. The mean width of the braided channel in the upper reach follows a gentle decrease mainly due to the reclamation of river flood plains into farmlands and embankments. The sinuosity of the current Tarim River channel is distinctively lower than those of the old channels that were abandoned decades or centuries ago, even though the sinuosity of the current channel exhibits a gentle increase in recent decades due to the increased occurrence of low flow events.

Abstract

Studies on the behavior of anabranching rivers have been dominated with empirical analyses and it has not been clear so far how this type of rivers responds to environmental changes. For anabranching rivers formed of islands of a particular shape, this study applies a variational analytical approach to explain the morphology of the islands. A model is developed based on observations from the upper Yellow River and the middle and lower Yangtze River which alternate between single channel and two-channel anabranching with islands approximately triangular in planform. The equilibrium condition of the model river is derived from basic hydraulic relationships of flow continuity, channel boundary resistance, bedload transport and energy conservation in the model anabranching river. It is shown that when such an anabranching river reaches stationary equilibrium, the planform of the island is determined by the proportions of water and sediment discharges passing through the two channels. In comparison with field observations in the middle and lower Yangtze River, a remarkable consistency is achieved between theoretical predictions and the measured morphologies of islands.

Fluvial Response to Climate Variability and Human Interventions in The Damodar Valley, India During Anthropocene

Ghosh PRASANTA KUMAR, Bandyopadhyay SUJAY, Jana NARAYAN CHANDRA

Department of Geography, The University of Burdwan, Golapbag, Burdwan, Pin: 713 104, West Bengal, India,

gprasanta05@gmail.com

Abstract

Field mapping, sedimentologic investigations and geomorphological analyses in combination with a series of temporal ancillary data i.e. hydro-meteorological data, sand excavation data and satellite data define a record of Anthropocene landscape change along 282.7 km stretch of the Damodar River in West Bengal, India. During the 20th Century, the Damodar Valley Corporation (DVC) came into existence and the Damodar basin was extensively engineered for irrigation and flood control. Since that time up until the present time, the hydrology and morphology of Damodar River has been controlled by dams and embankments, with these, now another intervention i.e. large-scale excavation of river sand has been added. The floodplain undergoes great changes as a result of the confinement of river flow due to construction of embankment. Through historical satellite image, hydro-meteorological data, and cross sectional surveys, we demonstrate that the influence of the upstream dam, embankment and sand mining is still a major control of river dynamics and adjacent landscape. Human alterations and their impacts on the system's ecology have also been considerable. In addition, sand mining disturbs the equilibrium of a river channel because it intercepts material load moving within a dynamic system and triggers an initial morphological response to regain the balance between supply and transport. The methodology also adapts various statistical approaches like Mann-Kendall test, Sen's Slope estimator to detect the possible trend in stream flow pattern. The results of this study would help in maintaining the health of rivers in the Anthropocene world.

Abstract

Land surface is of temporal-spatial heterogeneity. Terrestrial system (TS) comprehensively studies on land surface and physical regionalization objectively describes geographical zonation of the system. China has vast area with apparent spatial variations in resources and environment conditions, which highly influence on social economic development. In this paper, progress of TS studies in China is overviewed and research priorities in the near future are prospected. Since 1950s, China has paid high attention to TS study as its social economic construction developing, and implements the researches on physical geographical regionalization, eco-geographical regionalization and comprehensive regionalization. Along with the deepening of global change research, dynamic of TS has been highly concerned. During the studies, methodology has been developed from qualitative research of integration of experts' brainpower gradually to quantitative research based on field observation and experimentation of the natural processes, including physical, chemical and biological processes, as well as application of information technology and mathematical simulation. In the near future, TS would combine with the ideology, objectives and key researches of Future Earth program, to focus on the mechanism and regional effects of interaction among land surface elements, the responds of TS to global change, the quantitative recognition on regional unit boundary, and the application of TS in sustainable social economic development.

Abstract

The micro-topography features in riverine system can be the controlling attributes to induce the different patterns and magnitudes of hyporheic water exchange. The objective of study is to determine how hyporheic water exchange is affected by the meandering banks and riparian vegetation at small scales. The one dimensional heat steady-state transport model is applied to identify and quantify the hyporheic water exchange fluxes along the meandering bank and straight bank segmentations in January and July 2015, respectively. Moreover, on the basis of the curvature formula and the fitting mathematical equations, the curvatures are calculated. The results demonstrate that all water exchange patterns in test site are upward in both test times, and the higher fluxes mostly occur in January 2015. There are significant spatial variations for the water exchange fluxes along the different river banks. In terms of convex banks, larger curvatures of the measurement points along the either sides of convex bank are inclined to induce the higher fluxes, and the significantly higher water exchange fluxes would occur near the apex of bends. Additionally, a flow pattern from river bank discharging into stream is illustrated during the campaign in July 2015, and significantly higher fluxes are obtained along the straight bank where more riparian vegetation is adjacent to the bank line. It can be suggested that the bank curvatures, riparian vegetation are considered as the crucial attributes influencing the hyporheic water exchange.

Abstract

The innovation study is becoming more and more attention from western human geography scholars, and has become the new direction of western human geography studies in recent years. The paper chooses Web of Science (WOS) as the literature search engine, and 14 geography journals indexed by SSCI among the top 500 journals which published articles with innovation as the theme as literature sources. The data covers a total of 2,048 English literature records associated with the innovation topic from 1982 to 2015. The paper made co-occurrence analysis and cluster analysis for key words based on the platform of CiteSpace and Carrot2 to make the innovation knowledge mappings of western human geography, which made the knowledge base, development vein and research frontier visualized. We found that: (1) innovation studies of western human geography shows continuous development trend after the rise since the 1990s, the branches or gaps doesn't appear, and the research perspectives make a gradual transition from surface phenomenon to deep mechanism. (2) The research contents are broad and the research topics are not centered, and nine clusters has formed currently, including "market intelligence", "knowledge spillover", "region influence", "collective learning processe", "spatial technological adoption", "terra incognita", "multi-actor network analysis", "regional innovation system", and "literature review". (3) Recent research hotspots point to keywords "city", "firm", "technology", "research and development", and "network". (4) The researchers mainly from the UK and the US, researchers from Spain, Germany, Italy, and Sweden are also more active recently.

A Partition-and-Filter Model for Crowdsourcing GPS Trace Data Filter

Xue Yang, Liliang Tang

Wuhan University, yangxue@whu.edu.cn, tll@whu.edu.cn

Abstract

Owing to the popularization of GPS, a massive amount of spatiotemporal GPS traces collected by mobile devices are being as a kind of new big data source for urban geographic information extraction. However, the quality of GPS data collected through crowdsourcing way is low, thus making it difficult to mine high-precision road information such as centerline-level, carriageway-level and lane-level road map. Therefore, it's very important and challenging to filter high quality GPS data from the crowdsourcing GPS trace based on its positional accuracy. To address the challenges, this paper proposes an efficient partition-and-filter model to filter trajectories, which includes trajectory Partition with Position and Angle Constrain algorithm (*PPAC*) and Trajectory Filtering with Expected Accuracy method (*TFEA*). For the partition part, *PPAC* is used to partition a trajectory into a set of sub-trajectories based on distance and angle constrains. Then, the *TFEA* is used to filter the sub-trajectories according to the similarity between GPS tracking points and GPS baselines constructed by random sample consensus algorithm (RANSAC). Experimental results demonstrate that the proposed partition-and-filtering model can effectively filter the high quality GPS data from various crowdsourcing trace data sets with the expected accuracy.

An Improved Method Based on Spatial Proximity Model to Discover the Urban Functional Areas Using Pedestrian Trajectories

SONG Xuetao¹, PU Yingxia^{1,2,3}

¹ Institute of Geographic and Oceanographic, Nanjing University, Nanjing, 210023, P. R.

China, xuetaomagicson@gmail.com

² Jiangsu Provincial Key Laboratory of Geographic Information Science and Technology, Nanjing, 210023, P. R. China

³ Jiangsu Provincial of Collaborative Innovation Center of Geographic Information Resources Development and Utilization, Nanjing, 210023, P. R. China

Abstract

Mining the urban functional structure contained in a large amount of residents' moving trajectories is meaningful in the current big-data era. However, existing methods rarely take into account of the spatial association relationship among these functional areas during the classification process by using machine learning. In this paper, we propose an improved framework based on Spatial Proximity Model to identify the functionality of urban areas using GPS trajectories and POIs. We firstly apply a series of mathematical morphology operators to partition road network into basic semantic regions. Then we add spatial dependence of each region as a nonlinear factor to our classification model. The spatial dependence among each region and its neighbourhoods consists of two kinds of spatial proximities, one is spatial autocorrection and the other is co-location. After that, resilient backpropagation algorithm is applied to solve the model. The classification accuracy is verified with Moran's I index and BW joint count statistic. We demonstrate the framework using 100 thousand trajectories during three months and 46,000 POIs in Hefei city, China. The results show that the spatial dependence improves the precision of the classification significantly. We also discover the urban structure of the study region is in accordance with the classic concentric zone model.

Spatial Proximity Model; Machine Learning; Co-location; Spatial Autocorrection; Trajectories Mining; Urban Functional Area

Applications and Challenges of GIS in the Era of Big Data

Gefei Wang¹, Peiyun Zhang¹, Liwen Liang¹, Jie Wang², Shiqiang Zhang¹

¹Northwest University, Xi'an, 710000, P.R. China, zhangsq@lzb.ac.cn

²Institute of Water Resources and Hydropower Research of Yunnan Province, Kunming, 650228, P.R. China

Abstract

With the rapid development of network infrastructure, the emergence of the new social networks and the coming of the intelligent devices, the number of mobile internet devices, equipments of the Internet of Things and high-definition cameras rises sharply. The data volume shows the trend of explosive growth. The era of big data is coming. And 80% of data produced in human life are closely related to spatial location, which has brought opportunities and challenges to the application of geographic information. This paper first explains the definition and characteristics of big data, and then discusses the application of GIS in the era of big data through several typical examples. Next it analyzes the challenges of GIS in data acquisition, data storage, data processing and analysis. Finally, the paper points out that the tight integration between GIS, mobile internet and decision support system is the key to improve the coupling of big data and GIS based on data filtering on the theory of probability, distributed cloud storage and data instant analysis.

Assessment of Water Quality for Irrigation and their Impact on Cropping Quality Pattern using LISS-IV Sensor's based Geospatial Techniques

Kumar Amit, Tomar Vandana

National Institute of Technology, Kurukshetra, India, 136119, amitkumar8530@gmail.com

Haryana Institute of Public Administration, Gurgaon, India, 122015

Abstract

The words "water quality" is a widely used expression, which has an extremely detailed scale of meanings. Green revolution introduced worldwide in preview of high crop yield. The Utilization of agricultural land efficiently for the production of the crops requires knowledge of the nutrient inconsistency. Geomatics has proven to be the pre-eminent technique to retrieve the synoptic and substantial changes in cropping pattern. Groundwater quality and crop yield potentials in Katihar and Bhagalpur districts of Bihar, India has special significance and needs great attention of all concerned since it is the major alternate source of domestic, industrial and irrigation water supply. The present study monitors the irrigation water quality, relates it to the crop production and maps such quality using geospatial techniques through LISS-IV sensors. Thematic maps for the study are prepared by spatial interpolation method and enhanced LISS-IV imagery using ERDAS IMAGINE and ARC/INFO software. Physico-chemical analysis data of the groundwater samples collected at predetermined locations forms the attribute database for the study, based on which, spatial distribution maps of major water quality parameters are prepared using inverse distance weighted (IDW) method in ArcGIS software. Water Quality Index (WQI) was then calculated to find the suitability of water for irrigation purpose. Using ground truth information, satellite images were analyzed and hazardous locations were determined to cultivate the selected crops in the study area. The EC map, WQI distribution map, pH map were overlaid and analyzed in GIS media to estimate the effect of water quality on crop yield potential.

Basin Approach to The Analysis of Environmental Problems of the Amur River

Egidarev E

Pacific Institute of Geography, FEB RAS, Vladivostok, 690041, Russia, egidarev@yandex.ru

Abstract

This reporter views various methods of collection, storing and analyzing spatial data pertaining to the Amur River Basin for the purpose of solving a number of conservation tasks. For many years the Pacific Institute of Geography together with international conservation organizations such as WWF, WCS and others, has been monitored ecological problems and the sustainable use of natural resources in this transboundary region. The report demonstrates the use of the basin approach for the creation of GIS which contains the most important data units regarding environmental condition and change of this large transboundary river. Such GIS with remote sensing data has been successfully used for environmental assessment in the areas of gold mining, hydropower, water use etc. Furthermore, the paper discusses the importance of the Amur River system for the neighbouring countries (Russia, Mongolia and China) from the natural resource and socio-economic point of view. The designing of a common geoinformation space for the unitary transboundary GIS on the Amur River Basin is an important task. It will serve as an informational basis for a sustainable natural resource use project that would take into consideration the principles of ecological safety adopted in transboundary regional planning and scientific research.

A GIS-based Framework of Process Model for Soil Erosion

Zhang Chuancai, Qin Fen

College of Environment and Planning, Henan University, Kaifeng, 475004, China, zccai1205@163.com

Abstract

Modularization or componentization of the process model for soil erosion can improve the efficiency of the development of new soil erosion model, but the large granularity components of the process model for soil erosion will limit the improvement to the model. GIS and the process model for soil erosion have extremely different data structures, which limits the integration of the two applications. This paper builds a framework of the process model for soil erosion to solve the two problems mentioned above. The framework of process simulation for soil erosion includes mainly two aspects: the first, Fine-grained decomposition and composition of the model, the second, the shared data model of GIS and the process model for soil erosion. Formal concept analysis method is used to decompose and modularize the process model for soil erosion. Using the object-oriented model design method, the paper designs a shared data model in the level of data structure in order to facilitate the GIS and soil erosion model to access data efficiently each other on the basis of Arc Hydro data frame. On the basis of fine-grained decomposition of the process model for soil erosion, the paper improves the slope downscale method based on fractal theory, and then implements the scale transformation of the slope as internal parameters in the process model for soil erosion. Finally, the paper verifies the effectiveness of the framework of the process model for soil erosion by integration of scale transformation method and soil erosion model.

Advances in Technology and Methods of Land Disputed Area Demarcation Based on GIS

Changqiang Feng, Nan Jiang, Pei Wang

Institute of Geospatial Information, Information Engineer University, Zhengzhou, 450000, P. R. China,

luckystar1682006@126.com

Abstract

Under the era theme of peace and development, delimitation negotiation becomes the preferred method to resolve the territorial disputes. With the development of computer, database, GIS and so on, the demarcation method of disputed area has developed from manual demarcation based on paper maps to computer-aided demarcation relying on digital maps, which could effectively conduct organization, storage, management, analysis and visualization of delimitation data. Firstly, this paper summarizes the history and development of land dispute district demarcation. Secondly, it mainly introduces the automatic generation of delimitation line considering many constraints (such as agreed area ratio, the ascription of special area and unilateral demands for resources), the optimal adjustment of delimitation line making it go along with actual terrain features like ridge and valley under the constraints of agreed area ratio, and the evaluation of demarcation scheme taking into account important resources and agreed area ratio. Thirdly, comparisons and analyses are made among different methods of each technique above in terms of algorithm principle, performance and application, which reveal the essential characteristics of different methods. Finally, this article forecasts further studies on techniques and methods of land disputed area delimitation.

Key words:

disputed area; computer-aided demarcation; automatic generation of demarcation line; optimal adjustment of demarcation line; evaluation of demarcation line

Construction and Precision Analysis of Isostatic Free Air Gravity Anomaly Model

WangK, Wu X, Liang Z ZH, Zhang L

Beijing special engineering design and research institute, Beijing, 100028, P. R. China, 18510410410@163.com

Abstract

Isostasy is widely used in the construction of gravity potential models and the estimation of gravity anomaly where no measurement data available. With the Earth divided into land area and ocean area, the series expressions of the first order derivation of exterior gravitational potential are derived, separately. The application of topographic data with different resolutions is studied, and the influence of the depth of compensation is analyzed. Finally, the spectrum characteristic of the estimated model is discussed. Results show that the best depth of compensation studied here is 30 km, of which the average difference towards that of EGM2008 is less than 1 mGal. The precision falls obviously with the growth of the depth of compensation.

Key words:

Isostatic model; isostatic free air gravity anomaly; depth of compensation; radius derivation

Despeckling Algorithm of High-Resolution Synthetic Aperture Radar Images Based on Partial Differential Equations Methods and Non-Local Means Filters

Sun Z G¹, Yang L²

¹School of Computer Science, Shaanxi Normal University, Xi'an, 710119, P. R. China, duffer2000@163.com

²College of Computer Science and Technology, Huaqiao University, Xiamen, 361021, P. R. China

Abstract

Synthetic aperture radar (SAR) has been widely used in the ecology, hydrology, geography, ocean monitoring, terrain mapping and so on, with virtues of all-day, all-weather, multiple perspectives and penetration. However, owing to the coherence from radar waves, SAR images are inevitable to produce some speckle. The speckle makes it difficult for the understanding of images, and thus the features of targets are not easy to describe correctly. Especially for the high-resolution SAR images, the mechanism of imaging is much more complicated to that of the low-resolution SAR images. Therefore, it is worth constructing a new despeckling algorithm appropriate for the high-resolution SAR images.

Activated by partial differential equations (PDE) methods and non-local means (NLM) filters, how to achieve satisfying despeckling results for high-resolution SAR images is discussed in this paper. In PDE methods, AA model is popular despeckling method for SAR images, because it can effectively suppress speckle in homogeneous regions. However, the AA model usually owns poor performance in keeping edge information. On the contrary, the NLM filter has well performance in keeping edge information, but poor performance in suppressing speckle in homogeneous regions. Therefore, considering the AA model as well as the NLM filter, a new despeckling method is proposed with well balance between speckle suppression and edge preservation. Firstly, the non-local dirichlet function is taken as a linear regularization item, which constructs the weight by measuring the similarity of images. Then, the proposed despeckling model is constructed by combining the regularization item and the data item of AA model. Lastly, an iterative equation is deduced to numerically solve the new despeckling model. Despeckling experiments show that, compared with the AA model and NLM filter, the proposed model can not only suppress speckle effectively but also preserve edge information well, leading to satisfying despeckling performance for the high-resolution SAR images.

Key words:

high-resolution synthetic aperture radar images; despeckling algorithm; partial differential equations methods; non-local means filters

Progress of Research on Information and communication Geography in China

Zhongwei SUN

The Geographical Society of China, Shijiazhuang, 050035, P. R. China, sunzhongwei@126.com

Abstract

Research on information and communication geography in China derived from three aspects: the historical background of great development of worldwide information and telecommunication technologies as well as arriving information society, introduction and response to relevant research conducted by European, American and Japanese geographers; and reflect on how Chinese scholars carry out follow-up research. Till 1989, China saw the first paper on information and communication geography research, while research results of two primary subjects, i.e. information industry and telecommunication geography sprung up after 1995. In 2000, research on information and communication geography in China entered the age of the internet/cyberspace. In the later decade, Chinese scholars conducted research on seven fields, specifically, internet geography of exterior level, new spatial form and spatial structure change, relationship between informatization and regional economic development, effect of ICT on urban internal and external space structure, reform of ICT and enterprise spatial organization, effect of ICT on human spatial behavior, website online services and location selection. With the arrival of big data era, information and communication geography research in China has entered big data stage over the past five years. The research results concentrate on five levels, i.e. enterprise location and spatial structure change, urban inner space organization and smart city construction, multi-perspective city network and grading, and regional digital divide and spatiality of social networks. In addition, Sun Zhongwei et.al systematically sorted out relevant research at home and abroad, and attempted to present subject name and subject nature.

Spatial-temporal Evolution of Malls in Guangzhou and Its Impact on Urban Commercial Spatial Structure

ZHANG Xiao-ying

Guangzhou Academy of Social Sciences, Guangzhou, Guangdong 510410, China

Abstract

Employing ArcGIS and Spss to conduct spatial and statistic analysis, respectively, this article explores the spatial-temporal patterns of the development of shopping malls in Guangzhou City and their relationship with the change of urban commercial spatial structure. The following conclusions have been drawn from the research: Firstly, the increase in the number and scale of shopping malls takes on a cyclical and jumping pattern, which is closely related to urban development. As to the spatial pattern, they originally concentrated in the urban center and gradually diffuse outward to the urban outskirts over time. Analysis of the elements underlying the spatial-temporal evolution of shopping malls reveals that population size is positively correlated with the number and scale of shopping malls, while correlation between population density and distribution of shopping malls is not obvious. Their locations almost coincide with the places with good transportation accessibility. The location of metro stations greatly influence the spatial distribution of shopping malls. Secondly, the spatial-temporal pattern of shopping malls is also greatly determined by the government's strategy over urban spatial structure and the change in land uses. Thirdly, the rising of the commercial style of one-stop and experiential consumption also imposes large impact on the pattern. Finally, the paper examines the impacts of the development of shopping malls on urban commercial spatial structure. A flat ranking system of urban commercial centers has been brought about by the development of shopping malls, promoting the formation of polycentric urban commercial system and the upgrading of commercial levels.

Key words:

The Prediction of Spring Drought of the Typical Areas of Hulun Buir Based on the Grey Sequence Forecast Model

Liu Kun, Wang Ning, Yang Lingbin

The Northeast Normal University, Changchun, 130000, P. R. China, yanglb872@nenu.edu.cn

Abstract

Drought is the most common, the most widely distributed and the most affected kind of meteorological disaster in Hulun Buir, Inner Mongolia autonomous region. Humidity index is an effective index to divide the drought level in Hulun Buir area. In this paper, we use the grey sequence forecast model (GSFM) to analysis the humidity index of 4 typical areas of Hulun Buir, and predict the times which may occur spring drought in the 4 areas by using the grey system GM (1, 1) model in DPS. The research results provides theory basis for the prevention of spring drought in Hulun Buir area.

Key words:

Spring drought; humidity index; grey sequence forecast model

Topic Modelbased Classification of Moderate-resolution Remote Sensing Images

Shao H¹, Li Y²

¹ School of Geomatics, Nanjing Tech University, Nanjing 211816, China

² Key Laboratory of VGE, Ministry of Education, Nanjing Normal University, Nanjing 210023, China

Abstract

Represented by Latent Dirichlet Allocation (LDA) model, probabilistic topic model showed a great success in the field of natural language processing and image processing, which can be used to effectively overcome the gap between low-level features and high-level semantic. In recent years it has also been introduced into remote sensing image analysis field, while most of the research focus on the analysis of high-resolution remote sensing images. This study analysed the weakness of traditional probabilistic topic model in reduced resolution remote sensing image classification and points out that low segmentation scale makes the image objects small and containing less pixels. We learn from the ability of inferring the semantic of sparse documents of Biterm Topic Model (BTM), which directly model the generation of word co-occurrence patterns in the corpus, making the inference effective with the rich corpus-level information. By segmenting the remote sensing image in two scales and regarding the image objects at two levels as short documents and visual words respectively, we introduce BTM to the classification of moderate resolution remote sensing image. We propose to use space adjacent visual word pairs as the observations in BTM called S-BTM reduces the quantity of observation objects. This framework turns to be effective solution in the target task, achieving better result than LDA model. Experiment results also show that S-BTM achieved a higher classification accuracy with a smaller amount of computation when using space adjacent word pairs than BTM.

Key words:

probabilistic topic model; moderate resolution; remote sensing image classification; biterm topic model

Characteristics of Bacterial Community and The Influencing Factors in an Urban River Water

Peng Wang, Bo Chen, Chuangqiong Li, Yan Li

School of Geography and Environment, Jiangxi Normal University, Nanchang 330022, P. R. China,

wangpengju@jxnu.edu.cn

Abstract

Bacteria play a critical role in environmental and ecological processes in urban river ecosystems. We studied the bacterial community in Ganjiang River, a major tributary of Yangtze River, when it flowed through Nanchang City, the largest city in Ganjiang River basin. Water was sampled at five sites monthly in wet season, and bacterial community was characterized using Illumina high-throughput sequencing. A total of 811 operational taxonomic units (OTUs) were observed for all samples, ranging from 321 to 519 for each sample. The bacterial communities were maintained by a core of OTUs that persisted longitudinally and monthly. *Actinobacteria* (41.17% of total sequences) and *Proteobacteria* (31.80%) were the dominated phyla, while *Firmicutes* became the most abundant when there was a flood. *Proteobacteria* (specifically *Betaproteobacteria*) was the only phylum whose abundance showed significant difference among sampling sites, and no significant difference among months. Temperature and runoff, rather than the water chemical parameters, were the main influencing factors of bacterial community in river water. Temperature had a higher correlation with the OTUs abundance, and runoff had a higher correlation with bacterial phyla community. The influence of urban landscape on the bacterial community was consistent with the river length through urban area, and the degrees of influence were estimated to be 17%-34%.

Key words:

bacterial community; Ganjiang River; high-throughput sequencing; influencing factors

Identify The Key of Ecological Land Based On GIS in The Valley: A Case Study of Xingyun Lake

Guan Chengwen, Li Yimin

College of Resource Environment and Earth Science, Yunnan University, Institute of Geography Yunnan Province, Kunming, 650091, China, 315046707@qq.com.

Abstract

With the acceleration of urbanization process in China, human activities extended to the scope of basin. It has serious effects on the critical watershed ecological land. How to coordinate watershed economic development and ecological environment security has become a hot topic. Xingyun lake basin in Yunnan province as the study area, based on GIS spatial analysis technology, it uses service value calculation methods and the comprehensive index methods about Chinese terrestrial ecosystem, implements ecosystem services value estimation of land utilization and spatial distribution of ecological vulnerability index, and comprehensively identifies basin key of ecological land. Aiming at sustainable development of river basin and ecological security pattern can provide a scientific reference to build.

Abstract

The ecological environment of lake–river ecotone is an important water purification area and pollution buffer zone, where the microorganisms play an important role in the mediation of material cycle, nutrition transfer, and element transformation. Microbial groups is sensitive to environmental changes. In this study, twelve water samples from the lake–river ecotone of the Poyang Lake in China were collected to determine microbial gene sequences employing next-generation DNA sequencing techniques. The results showed the major Poyang Lake has the largest microbial population, followed by Yao River, Gan River and Rao River. Based on the Shannon and Simpson Index, major Poyang Lake has the largest biodiversity of microbial communities, followed by Gan River, Yao Lake, and Rao River. Microbial characteristics vary with the TN and TP concentration, for instance, the nitrifying bacteria were relatively rich in Yao Lake and Ganjiang River ecotone, and the polyphosphate-accumulating organisms in Rao River were richer than those in Ganjiang River. The Tags number of Euryarchaeota, Acidobacteria, Chlamydiae and Proteobacteria in Gan River were more than in Rao River, while significant differences were found between the major Poyang Lake and other lake–river ecotone, the Operational Taxonomic Units number of major Poyang Lake have 3 047, which was far more than the others. The study indicates that the Poyang Lake serves as a huge microbial gene pool, including a large number of DNA from ammonia oxidizing bacteria to ammonia-oxidizing archaea. An Efficient Hybrid Classification Approach for Assessment and Monitoring of Wetland using LANDSAT ETM+ Sensors

Tomar Vandana, KumarAmit

Haryana Institute of Public Administration, Gurgaon, India, 122015, vandana7232@gmail.com

National Institute of Technology, Kurukshetra, India, 136119

Abstract

Geographically isolated wetlands are a unique and significant part of the nation's wetlands resources and provide vital habitats for fish and wildlife. Wetlands are most prolific ecosystems besides being a rich repository of biodiversity and are known to play a significant role in carbon sequestration. Wetlands are halfway world between terrestrial and aquatic ecosystem and share properties of both. Wetland vegetation provides a natural barrier to fast moving water and therefore aids in flood speed reduction. A multiple purpose wetland inventory is being developed and promoted through partnerships and specific analyses at different scales in response to past uncertainties and gaps in inventory coverage. A partnership approach is being promoted through the Ramsar Convention on Wetlands to enable a global inventory database to be compiled from individual projects and analyses using remote sensing and GIS. Remote sensing offers a cost effective means for identifying and monitoring wetlands over a large area and at different moments of time. The present research paper describes the assessment and delineation of wetland area for Ranchi city of Jharkhand state for the year 1996-2015. The signatures of wetlands and associated land features are identified in hybrid and unsupervised classification approach based on their DN value using LANDSAT ETM+ sensors data. There are drastic change in between 1996 and 2015. The spatial distributions of the NDVI values were evaluated to determine the cut-off points for the water bodies, and wetted area.

Key words:

Abstract

Map matching is an important prerequisite for map integration, map updating, change detection and so on. The amount of volunteered geographic information (VGI) has increased in recent years, and VGI is drawing great attention with its superiority for map updating. In order to achieve the matching of VGI road network and the professional road network, this paper proposes a map matching algorithm based on radial basis function (RBF) neural network. It takes distance, orientation, shape and length as the evaluation factors to determinate whether the two road arcs are the same road or not. Add a scaling parameter to the basis function of the hidden layer to make the RBF neural network anisotropy and utilized sigmoid function in the output layer to make the calculation results normalization. Firstly, select samples from the professional road data and the VGI road data, calculate the four feature similarities of these samples, these four similarities with addition of the matching rate serving as learning modes. Secondly, calculate the mean value and variance of the each feature similarities. Thirdly, input the learning modes to train RBF neural network, get the connection weights between the hidden layer and the output layer. At last, input the VGI road network and the professional road network, calculate the matching rate of road arcs. Result shows that our algorithm achieves good performance even the quality of VGI data is not so good, besides, utilized RBF neural networks has a better efficient than utilized BP neural network in matching road networks.

Key Words:

map matching; RBF neural network; RBF; VGI road networks

Image Fusion Based on Landsat and Images Derived from Unmanned Aerial Vehicle

Myungsik Cho, Kangsan Lee, Jinmu Choi

The department of geography, KyungHee Univ., Seoul, Korea, gismyungsik@gmail.com

Abstract

Image fusion refers to the acquisition, processing and synergistic combination of information provided by various sensors or by the same sensor in many measuring contexts. The aim of this paper is to suggest the image fusion between Landsat Images and UAV images for meaningful usages in various areas. The Landsat Images are obtained by a multi-sensor and free for use, but characterized as low-resolution in spatial and temporal. In contrast, images derived from UAV have high-resolution in spatial and temporal, but limitation to the few sensors because of costs for equipping sensors and safety, like high-risk, of the UAV. For overcoming weaknesses in the both images, fusion can be facilitated. Since low-resolution and few sensors are supplemented image fusion, integrated images can have high-resolution and properties of the multi-sensor. Through this method, researchers can utilize UAV more in various areas.

Key words:

Remote Sensing; Image fusion; Landsat Images; Unmanned Aerial Vehicle

Suitability Assessment for cassava cultivation in Nigeria

Abstract

Identifying the best region for agricultural crops is an important step to ensure food security and enhance food sustainability. This study therefore modelled an agro-climatic zonation for cassava production in Nigeria using the similarity of soil conditions and their suitability potentials for cassava cultivation as selection criteria. Pattern of yield-climate and yield-soil relationships across the different agro-ecological zones were also assessed to map the climate-edaphic zonation for the crop. The study showed that soil conditions exert more influence on cassava yield performance than climatic conditions in Nigeria, and that the guinea savanna and upper region of the rainforest zones were the most favourable locations for cassava production in Nigeria. The mangrove swamp is the least suitable while the suitability of the remaining regions of Nigeria can produce from marginal to good rate of the crop. The study revealed the decision-support capacity of the geospatial approach to agricultural land selection. The study concluded that agricultural capacity of Nigeria can be enhanced by balanced informed decision based on geospatial information results such that best suitable crops can be cultivated at the different agro-ecological zones in the country.

Abstract

Soil moisture plays a significant role in the ecological system, which is not only a key variable in the energy exchange regulating the air temperature, rainfall and the stability of the atmospheric boundary, but also an important part of the hydrology cycle providing essential materials for the vegetation and organisms in soil.

In this study, ECV_SM (European Space Agency's Climate Change Initiative soil moisture product) from January, 2003 to December, 2010 over china was down-scaled to 1km resolution based on the methods of multiple step-wise regression and moving window. And two land surface parameters (NDVI and LST), the antecedent precipitation index (API), three terrain factors (DEM, SLOPE, ASPECT), two soil texture factor (SAND, CLAY) and brightness temperature (BT) were chosen as the model parameters. The down-scaling results of soil moisture were validated using in-situ observations and the spatial-temporal characteristics during the period 2003-2010 were analyzed.

It is discovered that the general spatial pattern of soil moisture in China is decreasing from the wet southeast to dry northwest; The spatial distributions of soil moisture varies in different land cover types, and the soil moisture is lower in the sparse vegetation area while higher in the dense vegetation area; Changes with seasons, soil moisture is generally low in winter and high in summer. But the trend of soil moisture varying as seasons in bare lands and sparse vegetation areas is not obvious.

Unifying Inconsistent Multi-source Geospatial Data Through Conflation

Dan Lee and Nobbir Ahmed

Geoprocessing, Esri, Inc, Redlands, USA, dlee@esri.com; nahmed@esri.com

Abstract

Good quality of geospatial data is essential to geographical analysis and mapping. However, many GIS organizations, mapping agencies, and data providers are facing a common problem: the geospatial data they have don't always line up with those they acquire from another source and need to use jointly. For example, roads owned by a local government or a company may differ in shape, position, and level of detail from those obtained through another source or agency; rivers or other features in one data area may not properly connect when crossing into adjacent data area. It is a challenge to identify the misaligned features, resolve the conflicts, and harmonize the needed features from various datasets for the intended analysis and mapping purposes.

The solution to such problems is conflation, which reconciles multi-source data for the best accuracy, completeness, and consistency. With the release of a set of conflation tools in ArcGIS Desktop 10.2.1, a number of use cases have been examined; workflows for specific tasks have been built and tested. This paper discusses a few typical conflation scenarios and presents the processing workflows and results. Some of the workflows involve spatial adjustment to bring spatially inconsistent data together; others transfer needed attributes between correspondent features. The conflation tools are built based on highly automated feature matching techniques, which we continue to improve. Efforts are also being made to evaluate the conflation results and facilitate post inspection and editing processes, which will be described in the paper.

Key words:

Conflation; geospatial data; feature matching; spatial adjustment; attribute transfer

Application of Geospatial Technology for Site Suitability Analysis of Overhead Tank Installation & Water Supply Line Alignment in Rural Chhattisgarh

Abstract

Over Head Tanks are one of the vertical assets which are regarded as one of the backbone of the water utility network. Site suitability analysis is an analytical technique used to present a coherent picture of how well particular location is suited for a specific purpose. The study proposes the existing gaps available in the area and suggests the government to construct the OHTs and suggest sites for OHTs on the basis of site suitability analysis. Thus, government can bridge the gap of water scarcity by constructing the tanks on proposed locations. The study area has been chosen as a part of rural Chhattisgarh. Two types of data has been used for the study are primary and historical data. Elevation profiles were taken from DEM along driven pipelines to verify feasibility of flow with respect the slope along which they are planned to build. Remote Sensing data can be very helpful in mapping existing OHTs shape, size, shadow, contrast, tone, texture. Age of OHTs can be estimated from temporal satellite images. Technology used for mapping existing OHTs includes DGPS, GPS, GIS and Interpretation of high resolution of satellite images. According to the study the most suitable sites for water tank is near to settlements as well as waste or open land. The study focuses on development of remote sensing and GIS based analysis and methodology in artificial groundwater recharge sites.

Abstract

Recent developments in 3D virtual reality (VR) and augmented reality (AR) technologies have already begun to transform segments of industry, research, and education, and will soon affect, more so than before, the spatial sciences. While around for decades, the new ease of accessing 3D information through environmental sensors (such as LiDAR or 360 degree cameras) combined with geospatially aware 3D modelling software such as ESRI CityEngine or Google SketchUp, mean that efficient workflows from environments to digital, interactive 3D models are beginning to emerge. In parallel, VR and AR are beginning to enter both mainstream entertainment and academic research in unprecedented ways. New VR technologies such as Oculus Rift and Samsung GearVR provide compelling immersive and augmented experiences at a price point within reach of millions of consumers and researchers. Even though much of the VR/AR developments have been technology-driven, the opportunities for GIScience research and application are vast, and may result in nothing less than a paradigm shift in how we communicate and understand spatial environments. The immersive but relatively unconstrained nature of these environments allow for the exploration of unreachable spaces (e.g. under the oceans) and times (e.g. historical Rome) in engaging and natural ways. The talk will provide an overview of research activities in ChoroPhronesis addressing topics such as the value added by immersiveness, the visualization of LiDAR data in VR, the modeling of historic campuses at Penn State, and mobile VR applications.

Case-Based Method of Using Knowledge of Digital Terrain Analysis – Illustrated by Drainage Network Extraction

Abstract

Digital terrain analysis (DTA) in application relies heavily on the domain knowledge on the match between the chosen algorithm (and its parameter-settings) and the application context (such as the target task, terrain condition of study area, DEM resolution, etc.), so-called application-context knowledge. However this type of knowledge in DTA has not been formalized to be available for inference in existing DTA-assisted tools. Therefore, DTA modeling process is still not easy for users, especially for non-expert users. In this abstract we propose a case-based method of using the application-context knowledge in DTA. The basic idea is to solve problem through referring the solution of a new problem to the solution of existing similar case. We take drainage network extraction, a typical DTA application, as example to evaluate the performance of the proposed method. The case base was prepared by extracting DTA application instances on determining the catchment area threshold for extracting drainage networks from the articles published in the peer-reviewed journals. The experimental result shows that the proposed case-based method can conduct reasonable result in general and thus is suitable for formalizing the application-context knowledge in DTA and using it to reduce the modeling burden greatly for users.

Abstract

Big Data (BD) is an important phenomenon of the development of contemporary science and technology. Many scientists believe that it is continuation of the development line started by information superhighways through digital and intelligent data to Big and Smart Data. There is not exact definition of BD, the most famous says: "There is no rigorous definition of big data. Initially the idea was that the volume of information had grown so large that the quantity being examined no longer fit into the memory that computers use for processing, so engineers needed to revamp the tools they used for analyzing it all" (Mayer-Schönberger and Cukier, 2013). But almost all researches agree with definitions and importance of "V's": "three Vs": *volume*, *velocity* and *variety* (structured) and unstructured data, described in various publications. The next very important fourth "V" is veracity. In order to harness true benefits, big data needs to be turned into actionable and smart data, with a clear focus on the purpose, (combined) insights, actions and resulting outcomes (Siemens) in both, business and science.

BD is a broad term including complex challenges which must be prioritized and addressed – such as "Fast Data" and "Smart Data." "Smart Data" (SD) means information that actually makes sense. SD is data from which signals and patterns have been extracted by intelligent algorithms. Collecting large amounts of statistics and numbers bring little benefit if there is no layer of added intelligence. By "Fast Data" we're talking about as-it-happens information enabling real-time decision-making (Alissa Lorentz, AUGIFY). But still in geography, geoinformatics and cartography is very important visualization and cross cooperation of the non-traditional disciplines and finding new solutions and explanations.

Virtual Geographic Environments (VGEs) are built on the foundations of geographic information systems (GIS) and geographic information science (GIScience) in which considerable attention is paid to the user in terms of the manner in which they interact with the software. User interaction is thus a key component of such systems (Li, Batty, 2008). The degree to which users are immersed in such systems defines major differences between VGEs.

In the situation we have BigData, we want transform them to Smart (Spatial or Geospatial) data and we are looking for more effective modelling, visualization and effective decision making based on inclusion of users, customers and generally inhabitants to the all process, authors of the paper would like to describe some basic principles and potentials of integration of existing approaches and their interpretation with assistance of context-based and adaptive approaches with support of Virtual Geographic Environments (VGE).

Key words:

Big Data; Smart Data; VGE; visualization; context-based and adaptive cartography

Knowledge Representation and Management in Virtual Geographic Environments Populated with Intelligent Agents

Mehdi Mekni

St. Cloud State University, St. Cloud, Minnesota, 56301, United States of America, mmekni@stcloudstate.edu

Abstract

In this paper, we propose a novel approach using Virtual Geographic Environment (VGE) models to effectively represent, integrate and manage knowledge about the environment and hence support agents' cognitive capabilities and spatial behaviours. Unlike conventional VGE models involving geographic data representation and manipulation for spatial analysis purposes, our approach evolves a new generation of decision-support oriented VGE models populated with cognitive situated-agents. This approach relies on well-established theories on human spatial behaviours and specific ways people apprehend the spatial characteristics of their surroundings in order to navigate and interact with the physical world. The main contributions of this paper include: (1) knowledge about the environment represented using Conceptual Graphs (CG); (2) tools and mechanisms allowing intelligent agents to acquire knowledge about the environment and the various geographic features it contains; and (3) capabilities for intelligent agents to reason about this knowledge and autonomously make decisions and finally act with respect to both their own and the virtual environment's characteristics.

Key words:

Virtual Geographic Environments; Knowledge Representation and Management; Intelligent Software Agents; Conceptual Graphs

Maintenance Mechanism of Microbial Community Biodiversity Resulted from Niche Construction

Dawei HU, Jinhui ZHANG, Xiaojie DU, Kai WANG

Institute of Environmental Biology and Life Support Technology, School of Biological Science and Medical Engineering, Beihang University, Beijing 100191, P. R. China, hudawei@buaa.edu.cn

Abstract

The phenomenon of microbial niche construction has been discovered in our former works, namely the microbes can secrete extracellular enzyme to corrode surrounding materials for substrate production as food shortage, and the competitive exclusion between species significantly decreased in the course of niche construction, caused biodiversity characteristics in microbial community.

In this paper, we used system dynamics and cellular automata to model and simulate the formation process of microbial community biodiversity resulted from niche construction. Firstly, a highly valid system dynamics model expressing by continuous ordinary differential equations was developed to describe the local population quantity variation based on the relationships between neighboring species (such as competition, cheating and cooperation) and species characteristics (such as dispersal, kin selection, exclusive substrate storage and niche construction). Secondly, the continuous ordinary differential equations model was discretized to difference equations as update rules for cellular states calculation and transition. Finally, a microbial community composed of 10^6 species was seeded on a grid, the cellular automata simulation shows that whatever the initial structure of species network in microbial community, the number of microbial species is far more than the number of available substrates made by niche construction, derogating from the principle of competitive exclusion. Furthermore, depended on initial network structure of species and their initial population, different microbial community succession patterns are exhibited in the process of biodiversity formation caused by niche construction, such as asymptotic stability, periodical stability and chaotic stability.

Mobile Sensing based VGE for Regional Simulations

CHE Weitao¹², LIN Hui¹², HU Mingyuan¹²

¹Shenzhen Research Institute, The Chinese University of Hong Kong, Shenzhen, China, cheweitao@cuhk.edu.hk

²Institute of Space and Earth Information Science, The Chinese University of Hong Kong, ShaTin, N.T., Hong Kong, China

Abstract

Mobile sensing has been gradually applied for collection of environmental data with multiple granularities in space and time to improve the update frequency and reduce the cost of environmental data collection. However, mobile sensing data are generally contributed by vehicles or pedestrians at arbitrary locations and times in most cases. Consequently, collected samples are randomly distributed in space and time, thus making processing and management of these data difficult, especially for the purpose of supporting simulations. Therefore, effective organization and management of these mobile sensing data are needed to further support the data input for regional simulations.

This topic presents VGE for bridging the gap between mobile sensing. The aim of this topic is to effectively organize the mobile sensing data by VGE, and then to use the models managed by VGE to support regional simulations. In this topic, we first discuss mobile sensing system (MMS) and its potential limitations. Next, we introduce the VGE platform and its advantages of not only data handling but also model management. In which, mobile noise and air quality data are taken as examples. Spatial and temporal characteristics of the data are systematically investigated and spatio-temporal patterns are analyzed. Then these data are reorganized by using data reconstruction methods. After that, regional simulations based on the reconstructed data is processed. (The work was supported by National Key Basic Research Program of China(2015CB954103) and National Natural Science Foundation of China(41401459))

Abstract

Along with the development of Web Service and Internet Technology, sharing variety geo-analysis models as model services (also called as geo-processing) has been widely approved as an efficient way to help researchers more conveniently work together. Through this Service Oriented Architecture (SOA) based approach, researchers from all around the world can more conveniently access and make use of different model resources, data resources and other modeling-related resources. For example, the Web Processing Service (WPS) specification proposed by the Open Geospatial Consortium (OGC) is one of the prominent studies that aimed at providing analysis abilities as web services. Based on these geo-analysis models resources, the integration of different model services is an efficient method to solve complicated geo-problems and simulate synthetic environment (given that the integrated models are scientific logical). Different from the traditional model-integration methods (executed in standalone computer) studied in the Integrating Model Framework (IMF) field, the integration of model services can take full advantage of the distributed resources and support modelers collaborate with each other. Many studies about the integration of different model services have been conducted (such as the geoprocessing web, service orchestration, services chaining, etc.).

However, these studies mainly focus on the linking and executing of variety model services, the modeling results are presented as workflows only. Modelers still meet difficulties when conduct some exploratory model-integration experiments (which means the workflow that contains different model services is unknown and a modeler tries to build a rational model-integration scene through a range of different models). In this paper, we proposed a scenario-based approach for orchestrating distributed geo-analysis models services in an open and collaborative modelling environment. The modeling work is treated as building a scenario to simulate the real geographic world. With this scenario-based approach, the exploratory modeling-integration

study is divided into three basic steps: the conceptual modeling step, the diagram modeling step and the workflow processing step.

In the conceptual modeling step, the method to construct the basic logical scenarios is studied. In the diagram modeling step, the method to build a scenario-based workflow is studied. In the workflow processing step, the method to execute the workflow is studied. By using the proposed method, a reusable model service architecture can be more easily constructed, and the difficulty of sharing and integrating geo-analysis models in web environment is reduced. Finally, a prototype system is established, the methods are implemented to verify the capability and practicability of such scenario-driven approach for orchestrating different model service.

geo-analysis models; model sharing; model integration; model service

Simulation of Three-Dimensional Distribution of Light within Virtual Canopy Model

Tang L Y, Chen C C, Huang H Y, Lin D, Zou J, Yang Y F

National Engineering Research Center of Geospatial Information Technology, Key Laboratory of Spatial Data Mining

& Information Sharing of MOE, Fuzhou University, Fuzhou, 350002, P. R. China, tangly@fzu.edu.cn

Abstract

Light distribution plays an important role in interaction between tree physiological processes and natural environment. However, the complexity of tree architecture and long growth period makes it difficult to measure light distribution in a real tree. In this paper, we combine three-dimensional (3D) tree architectural model, raytracing algorithm, turtle algorithm, and photosynthesis model to provide better quantitative analysis of light distribution within canopy and light interception. The detailed organ-based 3D canopy was built using ParaTree software (Tang et al, 2011). With a 3D virtual tree model, a ray tracing algorithm and turtle algorithm were utilized to simulate the 3D distribution of direct- and diffuse- radiation respectively. Furthermore, the photosynthetic active radiative (PAR) for each leaf unit can be calculated, which offers an opportunity to calculate photosynthesis rates. Taking young Chinese Fir (*Cunninghamia lanceolata*) and peach (*Amygdalus persica* L.) as examples, we built detailed 3D tree models. According to the sunlight properties, latitude, order of the day in a year and time in a day, the PAR at the top of the canopy was estimated. We estimated the net production rate at the whole canopy scale and the average net photosynthetic rate per unit leaf area at specified time step. Compared to other literature, the simulation result of net photosynthesis rate was reasonable. Light interception in canopy is the basis of further plant research. We believe that the proposed approach is useful for biomass estimation, ideotype design, growth simulation and remote sensing inversion.

light distribution; Virtual plant; canopy architecture; simulation

Spatial Behavioral Simulation Using Abstraction of Virtual Geographic

Environments

Mehdi Mekni

St. Cloud State University, St. Cloud, Minnesota, 56301, United States of America, mmekni@stcloudstate.edu

Abstract

In this paper, we address two challenging issues underlying spatial behavioral simulation using software agents immersed in Virtual Geographic Environments (VGE). First, the way to describe virtual VGE models using exact spatial decomposition approaches and graph theory techniques. Second, how to apply graph abstraction techniques to support realistic and efficient advanced navigation and path planning capabilities for software agents while considering the VGE's characteristics. In order to illustrate our contribution to the growing field of spatial behavioural simulation, we present and discuss a case study involving an urban VGE model populated with various agent types autonomously and differently interacting with multiple abstractions of the same physical environment.

Virtual Kyoto based on Digital Humanities

Yano K

Ritsumeikan University, Kyoto, Japan, yano@lt.ritsumeikan.ac.jp

Abstract

Virtual Kyoto is a virtual time-space created on the computer for the purpose of investigating the past, present and future of the historical city, Kyoto. Using the cutting-edge technologies in GIS and VR, we have conducted Virtual Kyoto as a 4D-GIS that comprises a series of 3D-GIS at various points in time. From a viewpoint of Digital Humanities, Virtual Kyoto is an infrastructure to place numerous digitally archived materials associated with the city, and to disseminate Kyoto's cultural assets to the world over the Internet (Yano et al., 2007; Yano et al. 2011). Virtual Kyoto consists of a wide variety of GIS-based geo-spatial data of Kyoto, whose most important data sources are historical maps and landscape paintings. A genre of screen paintings captures in detail Kyoto's famous temples and shrines, the Imperial Palace, warrior residences, and various shops as well as the townspeople (Kano, 1997). The collections were painted during the transition from the late Middle Ages (Muromachi era; 16 century) through the Modern Ages (Edo era; 18 century). At the moment, there still remain about 200 folding screens of *Rakuchu rakugai-zu*, owned by museums both in Japan and abroad. We are negotiating to use digital images of theses *Rakuchu rakugai-zu* for creating their portal site, and the Web-GIS-based application for comparing folding screens of *Rakuchu rakugai-zu* with maps. This paper explores Virtual Kyoto as historical VGE using *Rakuchu rakugai-zu* based on the context of Digital Humanities as well as spatial humanities.

A Study on Drought Risk Assessment of Pastoral Area in Xilingol

Li SZ, A LTTY

College of Geographical Science, Inner Mongolia Normal University, Hohhot 010022, China, 920194467@qq.com

Abstract

Being a key element in all over the world, drought disaster is the second natural disaster in the world, which bring great harm to human's survival. Drought occur frequency, high intensity, long duration and large range, which caused huge losses. Drought caused lack of water resources, crops are die of dry. Ecological deterioration has threatened food security and social and economic development seriously. Xilingol league area is located in northern China-- the central part of Inner Mongolia autonomous region, which is a strong ecological security barrier in north China. Based on theory of regional natural disaster system, meteorological climatology, natural geography and disaster science and so on, the data concludes the environment essential graphic document of Xilingol, weather data of 29 stations from 1980 to 2013 around Xilingol, statistical annual social economy data in 2013 and the disaster data of Xilingol. The statistical analytic method, the superimposition analytic method and AHP are used to do the research. The natural factors which include landform, climate, soil, vegetation, water, temperature and precipitation are composed of drought risk system assessment. The humanity factors include the first industry, total cost of the first industry, animal husbandry quotas, population loss, livestock losses and economic damage. Hazard-formative environment, reciprocity among hazard and hazard affected bodies are used to establish the drought subsystem and evaluate indicator system. Then to analyze the drought subsystem, drought system, synthesizes the district, the appraisal district in Xilingol. Finally, the pastoral areas were conducted by the comprehensive assessment of drought risk, evaluation of comprehensive partition and partition management respectively in Xilingol.

Analysis of Different Terrain Factors in Abaga Banner'S Vegetation Index of Its North Central Region

Gaosurigug, Wulingdi

School of geography science, Inner Mongolia Normal University, Hohhot, 010022, China, 1102529891@qq.com

Abstract

The vegetation index is an important parameter to describe the degree of vegetation. In this paper, we take North Central Plains of Abaga banner as the study area. In July 2002 and May 2007 and August 2011 we checked NDVI vegetation index by TM remote sensing image as remote sensing data sources by using envi software. NDVI was extracted from remote sensing images, and by using ArcGIS of NDVI spatial distribution characteristics of the research. Then, on this basis, combined with the altitude, slope geological factors, correlation between spatial distribution and NDVI respectively. The results show that the NDVI in the study area and elevation on the whole has a positive correlation, namely NDVI increased with increase of the elevation, and slope has no relationship with it, but in the local area have certain correlation. The research results are beneficial to the management department to grasp the distribution of vegetation in the area, and provide scientific basis for enhancing the vegetation protection of the grassland.

Key words:

the North Central Plains; NDVI; AcrGIS;

Analysis of Land Use Change with Its Policy Driving During Recent Sixteen Years in Horchin Desert: An Example of Ar-Horchin Banner in Inner Mongolia, China

WuLanTuYa, ChaGanTuYa

College of Geographical Science, Inner Mongolia Normal University, Hohhot 010022, China

Abstract

Horchin, originally as a tribe name of Mongolian ethnic, gradually being the name of grassland where the tribe was distributed. Here, the name of Horchin generally indicates the desert located in eastern Inner Mongolia, China. The modern agricultural prescribed form of the Horchin desert was formed in the middle Qing Dynasty, and then it developed through 20 century. The increasing or decreasing of farming area, increasing or decreasing of intensity of agricultural activities, are the direct causative factors for the land use changes in this region. Consequently, these factors caused quantitative and qualitative changes of grassland and farming area, being as the most intuitive expression of the Horchin desert land use changes.

The Ar-Horchin banner is located in the northern part of the Horchin desert. In this region, cultivation began in 1905, but only 5 period of assart were conducted up to the establishment of the Inner Mongolia Autonomous Region in 1947. In this study, we selectively analyzed farm land changes in Ar-Horchin Banner in recent 60 years using statistical data of farm land from 1946 to 2013, LANDSAT-5 TM images of 1986, 1996 and 2006, LANDSAT-8 OLI images of 2013; meanwhile, we discussed the driving relationship between the land policy changes and farm land, and we concluded as below.

(1) In recent 60 years, the area of reclamation in the Ar-Horchin has been gradually northing to high latitude region, and the farm land area has been increased, the scale of farm land area has been experienced a severe process. In the early stage of the establishment of Inner Mongolia Autonomous Region, the farm land in Ar-Horchin region was mostly distributed in the southern area from $N43^{\circ}40'$, but had been enlarged to $N44^{\circ}20'$ in 1986 and now, it has reached to about $N45^{\circ}00'$ in the north part of the region. During from 1946 to 2013, the farm land has been increased 932.42 km^2 , in which, once in 1998, the farm land area had been reached to 1018.69 km^2 , as its peak within the 20 century. Now, the farm land has been driven into its new cycle of increasing.

(2) From the establishment of Inner Mongolia Autonomous Region, the principle policies for agriculture, such as "The Land Reform" (from 1947 to 1952), "The Agricultural Collectivization" (from 1953 to 1977), "The Household Contract Responsibility System" (from 1978 to 1999), "The Return the Grain Plots to Forestry and Grassland" (from 2000 to now), have been conducted in the study area. For the agriculture itself, it has been expressed as "The Prohibition of Reclamation" or "the Encourage Reclamation". From the analysis, we can find the during the early 50s in 20 century of "The Agricultural Collectivization" and "The Return the Grain Plots to Forestry and Grassland" in 21 century, the scale of farm land in the Ar-Horchin Banner had been clearly

decreased. However, in the period of “The Household Contract Responsibility System” and after the end of the policy of “The Return the Grain Plots to Forestry and Grassland” in 2007, say now, the farm land is in its tremendous increasing period.

(3) Seen from the result of farm land scale change coincident with the tightness of agricultural policies in the study area, we considered the level of economical development, the consciousness of residents for ecological and environmental, agricultural technologies are also factors that cannot be ignored for land use change in the study area. Further work will be done on these subjects.

Analysis of West Ujimqin Barner Land Cover Change in Recent 40 Years

TANA

School of geography science, Inner Mongolia Normal University, Hohhot, 010022, China, 626716944@qq.com

Abstract

In this paper, we take West Ujimqin barner as the study area, use the 1975,1990,2000,2005,2009,2015 five times sensing image as data source analyze the land cover change for nearly 40 years. This paper adopts the Dynamic model of a single land use type to analyze the land cover change process. And then, we get the transformation between land cover types from transfer matrix by using the ArcGIS soft. According to the number characteristics of land cover types change from 1975 to 2015 shows that nearly 40 years, the variation trend of grassland, forest land, water land area is decreasing and farmland, unutilized land is increasing. by using the transfer matrix, analysing land cover types change shows that the mainly transformations are transformation from grasslands to the sandy lands; from grasslands to the farmlands; and between farmland and forests. The driving force factors of land cover change is divided into natural and human factors.

Carrying Capacity Study for Stockbreeding Population in Pastoral Areas in Xilin Gol

WuYinga, Hugejiletu

College of Geographical Science Inner Mongolia Normal University, Hohhot, 010022, P. R. China,
149755088@qq.com

Abstract

After the politic of “The responsibility in contract of grassland and livestock” in the pastoral areas in Inner Mongolia, herdsman are required to graze in fixed meadows and the number of livestock should suitable for the carrying capacity of pasture. Livestock are the main economic source of herdsman, and there must be a certain area for livestock in grassland pastoral area. In order to improve the life qualities, they can only increase the number of livestock. However, due to the limited carrying capacity of grassland, the number of livestock are restricted. This is the reason why some herdman become poor as well as the deterioration of the contradiction (Land-Man-Livestock), lead to pastoral areas cannot achieve an overall well-off. The scientific prediction of population carrying capacity of animal husbandry and the innovative system utilizing pasture has great significace to achieve the sustainable development in pastoral area. The result of this paper show that the well-off population carrying capacity in animal husbandry is one person 153 hectare in southern Xilin Gol, while this figure in northern Xilin Gol is one person 350 hectare, which means there are marked differences in the southern and northern. The south region should merge the pasture and work together and transfer the remaining herdsman, because it is severe over-loading. However, the north region should develop the domestic pasture or work together to manage the grass resources.

This paper based on the theory, "man-land relationship", and main ideas, “output of grass decided the livestock number, number of livestock decided population”, measure the population of hersdman carrying capacity in different region in Inner Mongolia, and hope to provide a scientific basis for “aiding the poor” as well as to achieve a well-off in pastoral area.

Change Detection of Desert Steppe Ecosystem by Spatiotemporal Analysis Based on Estimated Net Primary Productivity in Inner Mongolia, China

Wuliangha B, Han W, Sun G F, Chen J B

College of Geographical Science, Inner Mongolia Normal University, Hohhot, 010022, P. R. China, bayaer_90@126.com

Abstract

Desert steppe ecosystem belongs to one of the fragile terrestrial ecosystems and it is easily affected by climate changes and human activities. Net primary productivity (NPP) is a quantitative measure of the carbon absorption by plants per unit time and space. NPP is defined as the accumulation of dry matters by green plants per unit time and space, and is equal to the difference between gross primary production (GPP) and autotrophic respiration. So NPP is a key indicator to evaluate the productivity of vegetation communities in the natural environment, and it could be an indicator to represent ecological situation of terrestrial ecosystems. This study performed change detection of desert steppe ecosystem during eighteen years from 1998 to 2015 in the Inner Mongolian Desert Steppe region of China through GIS spatiotemporal analysis based on estimated annual NPP for eighteen years which are derived from multiyear 10-day SPOT VEGETATION NDVI data and PROBA-V NDVI data, and meteorological observation data using a modified Carnegie-Ames-Stanford Approach (CASA) model. The study area Inner Mongolian Desert Steppe region (IMDSR) is located in the western part of the Inner Mongolia Autonomous Region, China, between 105°07'E and 115°12'E, and 37°37'N and 45°08'N. The final results show that the NPP had many obvious spatiotemporal changes during the period from 1998 to 2015 in the Inner Mongolian Desert Steppe region.

Comparison of Drought Monitoring Method in Pastoral Areas Based on the Meteorological Data: A Case Study of Xilingol League

A LTTY, Tu Y, Su YLT

College of geographical science, Inner Mongolia Normal University, Hohhot, 010022, China, altty@imnu.edu.cn

ChiFeng NO.10 Middle School, Inner Mongolia, 024000, China,

College of Life Science and Technology, Inner Mongolia Normal University, Hohhot, 010022, China,

Abstract

Xilingol League belongs to arid and semi-arid regions, which the drought occurred in high frequency, widespread and long duration. Selecting scientific methods and collecting accurate information to monitor drought can reduce the impact it brings at the lowest limit and also has a propound influence on protection of eco-environment and the further development of husbandry production in pastoral area. Currently, there are various kinds of drought detection methods and metrological data. But due to the different formation mechanisms of drought, distribution characteristics of observation data, mathematical principles and assumptions, the outcome and applicability of drought index have showed some certain differences. This paper studies the Xilingol League in the territory of 15 meteorological stations monthly precipitation data for nearly 50 years and calculate five drought index, such as precipitation anomaly percentage, precipitation standard deviation index, Z index of precipitation, standardized precipitation index, precipitation percentile index. Furthermore, from the aspect of mathematics, choosing the 16 consistency tests to check-up and comparing with the results of remote sensing inversion from the point of surface characterization and also matching from the effects of the drought disaster situation respectively, and comparing such a variety of methods and aspects, the paper selected the most suitable drought index of the study area for drought monitoring. It is the Standardization Precipitation Index(SPI). The conclusion of this paper has high application value and practical significance to improve the accuracy of drought monitoring.

drought index; consistency check; drought index of temperature and vegetation; disastrous situation

Ecological Mechanisms of Nomadic of Production in Mongolia Plateau

Haishan

Geography Science College of Inner Mongolian Normal University, Huhhot, China

Abstract

In the past over thirty years, the drastic deterioration of grassland eco-environment in Inner Mongolia pasturing areas not only endangers the North ecologic safety, but also affects the eco-environment safety of neighboring countries; therefore, it has aroused great attention of people at home and abroad, especially academic circles.

With the deterioration of grassland eco-environment, reasons of grassland eco-environment deterioration have been become a focus of debate. And there are some theories about deterioration reasons, such as theory of over-grazing, theory of extensive management, theory of drought, theory of population overloading, theory of disappearance of nomadic (change of culture), theory of traditional nomadic, theory of meadow property rights, theory of goat-eating and theory of development of society and economy. In this all, the theory of over-grazing become the mainstream point and the fundamental basis for rules and policies by government.

By contrast the actual and theoretical animal number of the grasslands in Inner Mongolia for the past fifty years, we can draw a conclusion: the basic reason of the deterioration of grassland eco-environment in Inner Mongolia pasturing areas is “located herd” mode of production by the system of grassland contracted to households and un-herdsman destructive activities such as grass mowing, medical materials digging, unauthorized and wasteful mining; not overgrazing by herdsman and livestock. Especially, “located herd” mode of production by the system of grassland contracted to households is the basis; other predatory activities are appeared on the precondition of the policy of grassland contracted to households.

Some pursuing national policies is not fundamental control measures, such as Treatment Project of Sandstorm Sources of Beijing and Tianjin, keeping the balance of grassland and livestock, rest-grazing in spring, forbid-grazing and fencing and population migrating. Government must adapt policy about the pasturing areas. First, by grassland shareholding and national support, establish modern nomadic management, rebuild benign running mechanism of man-land relationship of pasturing areas, raise the overall efficiency of animal husbandry and recover dry grass layer of meadows. Second, issue certificates to certify the right to use the land that collectively owned by herdsman, resolve the main body to original herdsman. Third, the grassland is protected by government legislation. Government must improve the ecological efficiency compensation and

control mechanism, prohibit any destructive activities of grassland eco-environment.

College of Geographical Sciences in Inner Mongolia Normal University, Huhhot 010022, China

Key Laboratory of Remote Sensing and Geographic Information System in Inner Mongolia, Huhhot 010022, China

Abstract

In this paper, the altimetry data of ICESat/GLAS was used to approach the precise water level of the Hulun Lake during 2003-2009 to help reveal its variation. The inlier points of 31 tracks were employed by RANSAC process for detailed study to eliminate abnormal values introduced by outlier points. In addition, the NDWI method was proved the most appropriate method to obtain the area of water bodies and was then applied to study the area change of the lake. The research revealed that: (1) In spatially, during the study period, the shoreline of Hulun lake was mainly retreat, especially, in the south area. (2) In temporally, the area of Hulun lake was shrinking fast and the reduced rate is $49.52\text{km}^2/\text{a}$ in 2003-2009. (3) Water level decreased with volatility from 530.72 m in 2003 to 529.22 m in 2009 and the mean decrement was 0.0759 m/a. (4) The decrement of volume experienced three stages: sharp, slight and then sharp. The general decrement was caused by high temperature, massive evaporation and low precipitation. Reduction of runoff was another reason. Fluctuation or even slight increment of water level was due to the intra-annual temperature drop, decreased evaporation and slightly increased precipitation. Meanwhile, anthropogenic factors including overgrazing and agricultural irrigation accelerated the decrement of water level. The variation of water level at Hulun Lake is a comprehensive result of compound factors of both nature and human beings.

Inter-Decadal Spatiotemporal Variations of Aridity Index Based On Temperature and Precipitation in Inner Mongolia, China

TONG Siqin^{1,2,3}, ZHANG Jiquan¹, BAO Yuhai^{2,3}, Hasi¹

¹ School of Environment, Northeast Normal University, Institute of Natural Disaster Research, Northeast Normal University, Jilin Changchun 130024, China

² Inner Mongolia Key Laboratory of Remote Sensing and Geographic Information System, Hohhot 010022, China

³ College of Geographical Science, Inner Mongolia Normal University, Hohhot 010022, China

Abstract

The study result was indicated that the mean aridity degree was increasing as west to east and was mainly characterized by moderate aridity; from 1961 to 2010, the change of aridity was decreasing while the aridity was increasing especially after the abrupt changing point at 1995. What's more, the decreasing area of aridity was taken up 82.6% as the increasing area was only occupied 17.4% of the whole area. During the 50 years' timescale, the annual mean aridity oscillation periodicity was at the 49a, 25a, and 7a. And Inner Mongolia was still at the stage of aridity and might last for a long time. As the different decadal, the climate of Inner Mongolia was relatively humidity in 1980s, however, as the time went by, the area of moderate aridity degree was increasing while the humidity area was decreasing entering the early 21st century. Therefore, it was clear that the climate was becoming dryness year after year. From 1960 to 2010, lower than 30 contour shift toward longitude direction and that of greater than 30 moving toward latitude direction.

climatic aridity index; spatiotemporal variation; aridification; Inner Mongolia

The Study on GIS Based Simulating Spatial Distribution of Mongolian Population in Inner Mongolia Region

Mu XYL, A LTTY, Wu D

College of geography science, Inner Mongolia Normal University, Hohhot, 010022, China, 489334963@qq.com

Abstract

Population data is one of the important indicators which reflect sustainable development of national, regional economy and culture. The spatial distribution of population means the distribution status in various regions based on a definite time and space and a form of expression in space of population data. Combining with the social and economic elements which include situation of study area and population, accurate and detailed spatial distribution information is an important component of the risk management of natural disaster in Inner Mongolia. Among of them, Mongolian population are the deeply affected objects of most important natural hazards in Inner Mongolia. Therefore, it is also the paramount basis on disaster prevention and mitigation process. Furthermore, to engage in effective disaster early warning and risk identification need to obtain accurate spatial distribution of risk population. Whether in theory or in practice, the traditional statistic methods of population distribution with administrative boundaries has many limitations. But, spacialization of statistical population data is an effective way to integrate statistical data and natural factors.

With Inner Mongolia autonomous region as research unit, this paper makes an elementary study on simulating spatial distribution of the Mongolian population in a large scale. By filtering the available data of Mongolian population distribution based on Inner Mongolia population census data in 2010, and making the correlation analysis combined the GIS spatial analysis function with SPSS software, found that strong correlation exists between the distribution of Mongolian population in different areas in inner Mongolia and macro-influence elements including altitude, land-use (farmland, construction land), climate condition, road and river system ,and it also found that the impact of vegetation and soil types on the distribution of Mongolian population are more obviously. Meanwhile, residential point is an important indicator to distribution of Mongolian population. Based on it, Weight values of affecting factors are assigned objectively and multiple sources data fusion technology is applied to spatialization of population census data. Finally, a rasterized Mongolian population density map for Inner Mongolia district with a resolution of 1km×1km was calculated to verify and evaluate the accuracy and effectiveness of the Mongolian population spatial distribution simulation. It is found that the method can produce better simulation results and the operation is

of great significance in the practice application. The method used in this paper can be referenced by applied researches for county-scale Mongolian population distribution. At the same time, it is a great important significance for socio-economic development and ecological balance in Inner Mongolia Autonomous region.

What Matters Most in Institutional Design for Community-Based Rangeland Management in Mongolia?

Ulambayar, T.¹ and Fernandez-Gimenez, M.²

¹The Institute of Geography and Geoecology, Mongolian Academy of Sciences, Ulaanbaatar, Mongolia, utungalag@hotmail.com

²Dept. of Forest & Rangeland Stewardship, Natural Resources, Fort Collins, USA

Abstract

This study tested the effect of institutional design principles on social outcomes of evolving pastoral institutions in post-socialist Mongolia. Using data from 77 community-based rangeland management (CBRM) groups and 392 member households, we examined the effect of donor facilitation on institutional design. We found that donor facilitation approach significantly influenced group attributes and their external environment, but not institutional arrangements. The study confirmed that small group size, homogeneous interests, and heterogeneity of well-being are important group characteristics that predict higher levels of information diversity, leadership, and income diversity. Institutional arrangements such as the presence of sanctions, group-devised rules, frequent meetings, and recording documents increased cooperation, rules, and information diversity. Similarly, access to training and local government support provided a favourable external environment for increasing social outcomes. Furthermore, group characteristics such as dependence on livestock, homogeneity of interests, and leader legitimacy were critical for increasing social capital, livelihoods, sustainable rangeland practices, and proactive behaviour of members. More frequent meetings of leaders were the most influential for these outcomes. Local government support and available donor support were associated with increased trust and norms of reciprocity, sustainable rangeland management practices, proactiveness, and livestock holdings. Lastly, group attributes and external environment influenced social outcomes of pastoral CBRMs in Mongolia more than institutional arrangements.

Abstract

Grassland fire disaster are devastating burning of grasslands that bring some loss to grassland ecosystem and people. Providing information quickly and accurately for fire fighting and rescue work, using multi-source remote sensing data to monitoring the fire information. Comprehensive analysis multi-source satellite remote sensing data of MODIS data, meteorological satellite data(FY-3A/B), environmental disaster reduction satellite data(HJ-1A/1B) and conventional meteorological observation data(wind direction and wind speed), in total at 20 different time points during April 13-17, 2015 by fire point monitoring , sub-pixel fire area and burned scar region estimation method for dynamic monitoring of the process of cross border fire disaster on April 13, 2015 in Hulunbeier. Monitoring results indicated that, using multi-source satellite remote sensing data to dynamic monitoring the grassland fire disaster can be more accurate and comprehensive understanding of the process of cross border grassland fire. And the proposed monitoring method to provide the latest fire point information for the fire risk early warning.

Spatiotemporal Characteristics and Driving Mechanism of Xilingol League

Settlement Since 1990

A Rong, CHEN Cai, LIU Ji-Sheng

School of Geographical Science, Northeast Normal University, Changchun, 130024, P. R. China, P. R. China, ar327@nenu.edu.cn

Abstract

With the rapid urbanization and industrialization, researching the temporal differentiation characteristics of settlement landscape in pastoral areas and driving mechanism can provide the scientific basis for settlement layout, reconstruction of settlement system and the close relationship of settlement system in pastoral areas. In this article, by using GIS spatial analysis, spatial statistics and landscape patterns, to analyze the evolution of the pastoral areas settlements, and their spatial distribution, scale of landscape pattern from 1990 to 2015, and to explore the main driving factors on the development of pastoral areas settlement in Xilingol league. (1) The total area and scale of pastoral area settlements in Xilingol league expanded significantly from 1990 to 2015. The shape of pastoral area settlement patches tend to be complex irregular development, there is not obey the rules of the objective of local conditions, its development has a certain randomness and leadership subjectivity. On the spatial distribution, the pastoral area settlement patches were characterized by obvious agglomeration situation. There was an obvious positive correlation between the density distributions of settlement patches and settlement patches of size distribution, specifying that there was a high density distribution of mass size settlement patches and a low density distribution of small size settlement patches. During 1990-2015, there was a small change in overall of pastoral settlement, but a change of local areas. These spatial patterns of settlement patches in pastoral area were affected by road adjacent advantage and water system, and socio-economic factors played an important role, by studying the driving mechanism, it was agreed that dynamic mechanism including regional economic development, industrial structure adjustment, urbanization and industrialization advancement and government policy and other macroeconomic regulation and control function.

Abstract

Snow cover information has important significance to determine the scope of the snow disaster and its classification in temporal and spatial monitoring of regional scale. In this paper, we put the cross-border area of Mongolia and China region as study area, include Mongolia and parts of Inner Mongolia, for the Inner Mongolia part, consist of Alxa League, Bayannao'er City, Baotou City, Xilin Gol League, Chifeng City, Xing'an League and Hulunbeier City in total of 7 League and City, at the same time, involving a total of 47 municipal districts and banners; Mongolia involving four League and City, distributed from east to west are Umnugovi, Dornogovi, Sukhbaatar and Dornot.

We using the MODIS snow products in recently 14 years and synthesis as method of monthly maximum area to analyze snow covered area from spatial and temporal variation in cross-border region of Mongolia and China. In time scale, the change of snow cover area began to accumulate in October, snow cover increased volatility before January, snow cover into the stage of melting after January. From the perspective of spatial, Mongolia's steady snow mainly distributed in Dornot, Sukhbaatar and Umnugovi-N in the northwestern part of the region. The region of stable snow in Inner Mongolia, mainly concentrate on the northeast and central Inner Mongolia regions.

³ Grassland Research Institute of Chinese Academy of Agricultural Sciences, Hohhot 010010, China, liugx804@163.com

Abstract

Snow cover information has important significance to determine the scope of the snow disaster and its classification in temporal and spatial monitoring of regional scale. The snow cover temporal and spatial dynamics monitoring in the past 10 years (2003 - 2012) was investigated in the specific study. In time series period, the snow cover area changed significantly within an individual year, and the maximum snow cover area occurred in January and the smallest snow area occurred in October. In recent years, the total snow cover area of Inner Mongolia has a reducing trend and the annual average reduced rate was about 7km². The first snow date was delayed and the snow end date became earlier and earlier. It indicated that the snow cover time period has reduced significantly. The annual average snow depth ranges from 2.29cm to 3.9cm. The snow cover has a maximum depth in 2003 and has a minimum depth in 2008. The average snow depth also has a slightly decreasing trend and its reduce rate was about 0.56cm/10a. In spatial distribution, the snow cover area changes in Xilinguoluo and Wulanchabu grassland were dominated the total snow cover area fluctuation in Inner Mongolia. In Inner Mongolia, the spatial covered more than 10cm snow depth were mainly distributed in Greater Khingan Range mountain area and this area has an early beginning snow date and late date of ending snow cover. So this area has a longer snow cover days.

Key words:

spatial and temporal changes; snow area; snow cover time; snow depth

What Explains Positive Social Outcomes of Community-Based Rangeland

Management in Mongolia?

Abstract

The collapse of state cooperatives in early 90s created a gap for formal institutions of rangeland management in Mongolia. By 2007, 14 different donor programs supported formation of over 2000 herder community groups with the goals of effective resource management and livelihood improvement. However, results of donors' efforts have not been consistently successful, yet little is known about the factors that influence success or lack thereof. This research examined causal relationships of variables that influenced socio-economic outcomes of community groups. We studied 142 pastoral groups in 36 soums (counties) of 12 Mongolian provinces, where 77 of them were donor supported groups. We examined how the effect of formal organization on social outcomes was mediated by four intermediate variables, namely, information diversity, leadership, knowledge exchange and agreed rules given four different ecological regions. We found that traditional and innovative rangeland management practices, proactiveness and social networks were significantly mediated by the intermediate outcomes, while the same mediators did not influence levels of trust, norms of reciprocity and assets. Moreover, among these four interdependent mutually-enforcing mediators, information diversity had a triggering effect on other three variables creating a causal chain of information diversity→leadership→ knowledge exchange→rules. The study also revealed importance of ecological zone in achieving better social outcomes such as traditional and innovative rangeland practices, social capital and assets. However, a negative effect of rules on trust and norms of reciprocity as well as assets was a contradictory finding to the prevailing understanding in the field of the commons.

Development of heritage conservation in Saudi Arabia

Makki, M S

The Saudi Geographical Society, P.O. Box 2456, Riyadh 11452, Saudi Arabia, sgs@ksu.edu.sa

Abstract

This paper attempts to consolidate the architectural heritage in the Kingdom of Saudi Arabia by giving examples of the components of urban civilization dating back to ancient times, then move to the gaps and discontinuity between the authenticity of this heritage and urban updated strange combinations on the local environment and that created some disharmony in cities components. There is an attempt to identify the causes of this disharmony.

Also the paper exposed to modern efforts formal and informal to create a kind of harmony in the cities combinations by undertaking several policies to maintain the architectural heritage. In spite of these efforts, it seems that there is a lot of work required to achieve balance in the urban growth that combines conservative and modernity for the benefit of human and place.

Riyadh and a Dramatic Increase in Tourism Attractiveness by 2020

Dr. Mohammed Saad Almogarry

Geography Dept. King Saud University

Abstract

Riyadh has seen rapid growth in both population and urbanize during the second half of the twentieth century; making it one of the fastest growing cities in the world. But since the beginning of the third millennium, responsible authorities for the development of the city, continued in collaboration with the private sector, in implementation of major sustainable development projects of the city, it became a modern city, comparable to major cities in the world.

This research concerns with major development projects that are being implemented at present, and will completed by or before 2020. God willing. One of the main objectives of the review of the following major development projects:

- Transport Infrastructure projects, it comprises a huge and sustainable development projects, the most important of these projects is Riyadh Metro, and developing road network in the city, and projects to development of King Khalid International Airport.
- Hospitality projects.
- Recreational projects.
- Shopping and hospitality projects.
- Museums and educational projects.

In the same time, there is more concern about eco-tourism, and elements of natural and historic attractions. In Addition to the concern about the integration between the elements of human and natural attractions. Thus after completion of those major development projects in the city on or before 2020, it will become more attractive to tourists, in which they can meet the desires such as recreation, shopping, and education.

Therefore, Riyadh city in 2020 will have a variety of human and natural attractions, which will dramatically increase its attractiveness to tourists, either from Saudis and other residents, or from other countries.

Key words:

Riyadh; Saudi Arabia; tourism; sustainable development

The Prospects of cultural tourism in the Kingdom of Saudi Arabia: Rock Arts as a Model

Alfaqueer B

King Saud University, Riyadh, Saudi Arabia, dr.balfaqeer@yahoo.com

The Geographical Society of China, Beijing, 100101, P.R. China, igc2016@igsnr.ac.cn

Abstract

Saudi Arabia has abundant cultural resources, which include archaeological and historical sites, architectural heritage sites, sites in the depths of the seas that contain monuments in the sunken ships in the territorial waters of Saudi Arabia, the folkloric and literary heritage sites, museums and others.

The thousands of rock arts sites that abound in the territory of the Kingdom of Saudi Arabia are of the most important cultural heritage components in the Paleolithic, prehistoric and historic times and that they prove to be one of the first man habitations and corridors, which perpetuate their role in the march of international civilization.

Rock arts groups made up of two groups differ in their colors and techniques, the first group which is the largest of arts, executed by engraving, pecking, slitting and erosion on the surfaces of rocks. The second group, which is small, it had been painted with shades of red and yellow, in addition to the black color, which is mainly concentrated in the mountain caves.

Topics covered by numerous rock arts sites are multiple and can be classified according to the following groups: Animals arts group, human arts group, Different human activities arts such as hunting, dancing, dueling and others group, Signs, symbols such as hands, feet, tribal marks, plants and others. This precious archaeological inventory is an inexhaustible source for the archaeological and geographical researcher attempting to understand the nature and history of the region in the past centuries.

Abstract

Urban Agglomeration (UA) is now considered to be the elementary regional unit for China to participate in the global labour division and market competition. Relations among cities of an UA may form a complex network which causes difficulties for researchers and policy makers to study its spatial structure and make reasonable spatial policies accordingly. In this paper, we develop a novel algorithm to analyse the complex relational network among an UA and convert it to a hierarchical spatial structure. Firstly, overall capacity of each city and interaction between each city pair in a UA are estimated. Then an algorithm is developed to construct a so-called Hierarchical Spatial Structure Tree (HSS-Tree) from the relational network. Finally, the HSS-Tree is visualized and interpreted based on the UA map. The HSS-Tree generated describes a hierarchical spatial structure of a UA. In the end we applied this method to Guanzhong UA scenario, and results show that due to Xi'an's high overall capacity, cities around it have more interactions with it than among themselves. It is recommended that secondary-level core cities are needed to share the service provision burden of Xi'an. The HSS-Tree of Guanzhong UA could be of great help to understand the spatial structure of this area, and provides a good reference for the authority to draw regional policies.

Abstract

Since 2014, China has entered 'New Normal' which means a new stage different from that in the past 30 years. So, it is essential to find out new driving forces for China's economic growth. As the basic factor of the long-term economic performance, institutions play fundamental roles in regional development. The study firstly reviewed the central and local automobile industrial strategies in China since 1978 and then compared formal regulations, business culture and conventions of the main provinces and municipalities for automobile manufacturing including *Jilin*, *Hubei*, *Shanghai*, *Guangdong*, *Zhejiang*, *Jiangsu*, *Beijing*, *Chongqing*, *Anhui* and *Shandong*. Lastly, different responses to the institutional changes and their impacts on regional development were discussed. The results showed that (1) since 1978, the institutional change shows the dynamic relationship between the central government and local authorities in orienting foreign direct investment and training the native enterprises. (2) Different responses to the national strategies induce different developmental outcomes. Relying on training native enterprises during the decentralization of the central governments, *Zhejiang*, *Jiangsu*, *Anhui* and *Chongqing* have grasped the opportunities to regional development while some regions like *Jilin* missed the chance to improve the automobile industry. (3) In the same provinces or municipalities, the informal institutions such as local convention and business culture have profound influence on regional development, especially in *Jilin*, it is difficult to change it in a short time. This study will help the central government and local authorities to make effective policies and select differentiated solutions for regional development.

² Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing 100101, China, liuh@igsnr.ac.cn

Abstract

The "Belt and Road Initiative" is and will continue to be an overall strategy of China's all round opening-up for a long time into the future. It will have great impacts on China's regional development disparity. This study examines the influence of the "Belt and Road Initiative" on China's regional development with regard to the all round opening-up, improvement of facilities connectivity, changes of energy supply system, trade, and social and culture exchanges. Based on the great international transport and economic corridors proposed by the Chinese government in the "Vision and Action on Jointly Building Silk Road Economic Belt and 21st-Century Maritime Silk Road," this article also analyzes the impacts of different international economic corridors on territory development in different regions. The main results are as follows. (1) Although different international economic corridors influence different regions, the western region of China will benefit the most from the "Belt and Road Initiative", which is beneficial to reduce regional disparity in China. (2) The "Belt and Road Initiative" will facilitate the formation of several metropolitan economic areas and economically highly developed areas in the inland area that open to the outside. (3) The "Belt and Road Initiative" will accelerate the development of port of entry and inland border cities and promote the development of cross-border economic cooperation areas, which will drive the development of border areas.

Abstract

Analysis of the latest Census data for 2000 and 2010 shows that 88 out of 336 prefecture cities suffered population loss at different levels. These cities are mainly located in the Northeast, East Coast, South Coast, and Middle Yangtze River regions. A General Ordered Logit model captures scalar processes of total, urban and Hukou population loss, which are associated with economic state, low population production, economic growth, de-manufacturing, and promoting services at different courses and different levels. The complex and varied mechanism leading to population shrinkages are revealed, which offers a preliminary analysis, but calls for future studies and policy modification against past growth-themed China.

Key words:

city shrinkage; China; ageing; city and regional development; general ordered logit model

Small Hydropower and The Making of China's Rural Green Development Model

Harlan, T.

Department of Geography, University of California, Los Angeles, Los Angeles, USA, trharlan@ucla.edu

Abstract

What is the 'China model' of rural development? This question, long the subject of scholarly work, has more recently garnered interest from those seeking to replicate China's successes in other countries. Amidst the many reports on China's rural reforms, a recurring theme – though an often overlooked one – is the government's extension of electricity access to 99% of rural households, much of this through small hydropower (SHP). SHP holds a special place in China as a symbol of rural self-sufficiency, even as grid extension has replaced its role supplying power for villages and industry. In the last decade, however, the government has re-framed small hydropower as a clean energy source for 'green' development, resulting in a construction spree by private investors. Meanwhile, the government and international agencies have begun promoting SHP in other countries as a clean, low-carbon technology for rural development and poverty alleviation, and one in which China has recognized expertise.

This paper investigates how small hydropower is implemented in rural China and packaged as a set of 'green' technologies and practices that other countries can follow. I argue that the official view in China of rural development as a staged process affects the kind of small hydropower practices Chinese officials promote, and the impacts that result. Drawing on interviews with officials, investors, and international training staff, I suggest that the green rural development advocated by Chinese actors does not match China's own experience; rather, it serves as a way to internationalize China's SHP industry.

Key words:

Green rural development; China; renewable energy; small hydropower; international aid

The Emergence of Local Product-Service Industry for A Second-Ranked City-Region: A Case Study of Xi'an-Xianyang-Xixian New Area, China

Song T, Liu W D, Chen M X, Liu Z G*

Key Lab of Regional Sustainable Development and Modelling, Institute of Geographical Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China, liuzhigao@igsnr.ac.cn

Abstract

This article examines the role of urban product-service industry in the economic transformation of a second-ranked city, developing a conceptual framework that identifies the spatial expanding and industrial features of urban product-service industry to enhance a city's global status and manufacturing competitiveness. The paper focuses on a case study of Xi'an-Xianyang-Xixian New Area, China. It is argued that the latest urban product-service industry might serve as a boost for diverse local interests to achieve a more competitive development, which could be seen as an aspect of China's decentralization. However, various political divisions of government make this race uncompetitive and unsustainable on contemporary city-regions.

Key words:

Product-service industry; Fragmented governance; City-region; Globalization

Abstract

In the neoliberal age many commentators have argued that laissez-faire capitalism offers the only route to economic development. The state is portrayed as an obstacle to development, and wasteful in allocating scarce resources. Yet in practice state governance can play a crucial role in initiating development, although the strategies adopted in different settings are necessarily variegated, being framed with respect to local laws, policies, culture, and histories. In recent years, China's spatial governance has continued to evolve. Since China's Western Development Plan was launched in 2000, the central government has encouraged western governments to take local initiatives. An example is Chongqing Municipality and its strategy for developing a notebook computer cluster. These initiatives in some ways resemble Foucault's interpretation of governmentality as a set of organized practices involving ways or thinking, types of rationality and techniques through which subjects are governed and govern themselves. These practices and governance tools reflect however the specific configuration of the Chinese state system and are therefore an example of variegated governance.

The Pattern and Type of “China’s New Normal” from The View of Economic Geography

Mingxing Chen, Dadao Lu, Yinghua Gong

Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing, P. R. China, chenmx@igsnrr.ac.cn, mengmengff@hotmail.com

Abstract

In face of the decreasing external demand and the population, resources and environment bonuses, the economic growth in China will gradually dipped to a low growth. The researches on objects and pattern of “China’s New Normal” from the view of Economic Geography have great influence on the development of China. Through certain key indexes, this paper focused on the trend of economy and the regional type in the 31 provinces. The result indicated that: In the past few years, the growth rate of fiscal revenue, electricity consumption, and volume of railway freight has declined sharply, and meanwhile, many primary industries and “three carriages” (fixed asset investment, export, and total retail sales of consumer goods) as well. Many provinces have the same tendency as the whole China. Moreover, the total 31 provinces are divided into three types: relatively fast growth, light downward pressure, and great downward pressure individually. Provinces with great downward pressure are further divided into four types: developing regions, overall declining regions, energy-owned regions, and others. The same type of regions is geographic agglomeration obviously. Faced with this round of economic downside, different regions should take different measures, and the developing risks of Northeast China and energy-owned regions such as Shanxi should be emphasized on.

Economic Geography Study in Modern Times and the Spatial Pattern of Chinese

Economy

Wu Songdi

Fudan University, China

Abstract

In recent years, with the series publications of China's economic geography in modern times (9 volumes), we had comprehended basically both the economic spatial pattern in modern times and the factors of Chinese economic spatial pattern from modern times to right now. Up until recently, many aspects of China's economic spatial pattern, such as the regional economic differences, the direction of spatial economic development, the formation and expansion of urban agglomeration, are all subject to the constraints of modern economic geography. Therefore, we should understand further both the economic geography in modern times and its influence on current economic development.

Key words:

Chinese Economy; Spatial Pattern

Family Geography and Genealogy: Can Assemblage Thinking Aid the Understanding of the 'Social World' of 18th Century Ballinakill, Ireland?

GaleR

Interdisciplinary Environmental Studies, Sydney, Australia, r.gale@unsw.edu.au

Abstract

A framed, embroidered, 1815 map of Ireland passed down through successive generations is in my charge. The name of the small 1612 'charter town' of Ballinakill, Queen's County, stitched on the map – almost as the centre of Ireland – is a cultural statement of attachment to place. Drawing on genealogical, census and property records, I report some surname geographies and show how attachment to place might be problematic for a given family with a mere one hundred year history living in the area.

Given the relations between power, politics and space, my interest in the 'social world' of Ballinakill can quickly become a quagmire of fixed notions of Irish identity in nationalist historiography. I test a view that assemblage affords a more processual and socio-material perspective in my argument that 'family geography' is less about heritage and more about situational place-based change, and that 'family geography' can augment traditional 'family history' studies of lineages based on marriage and progeny in genealogical research.

The study reveals Ballinakill to be both a real and imagined place. It is real because of British military rule, large estates, landed gentry, middle class merchants, vast poverty, the Great Frost famine of 1739-1741, and the 1798 rebellion. It is imaginary because it is historical and British rule no longer exists. The vestiges and imprints of 18th century life, which are still physically present in the landscape and archives, mean that a genealogical inquiry can be given a geographical interpretation aided by insights from assemblage thinking.

Family geography; surname geography; historical geography; genealogy; assemblage; Ireland; Place

Geographical Education and Its Impact on Colonial Taiwan China and Korea

YEH, Chienwei

Ibaraki University, Mito, Japan, chienwei.yeh.j@vc.ibaraki.ac.jp

Abstract

This paper discusses the role of geography education upon the development of colonialism and its impact on the people of Japanese colonies: Taiwan China and Korea. Taiwan was the first colony of Japan from 1895-1945 and Korea from 1912-1945. Taiwan China and Korea were, as Peattie (1984) put it, 'the most important colonies' where 'were well populated lands whose inhabitants were racially akin to their Japanese rulers with whom they shared a common cultural heritage'⁷. Taking advantage of this cultural affinity, Japan developed a unique colonial policy: Pan-Asianism. The Japanese aimed to assimilate the colonized people and transform people into 'Japanese'. Education was one of the key factors in Japanese colonial policy to promote the assimilation and geography was a core subject in elementary school education to foster patriotic spirit among children in the colonies. Although both Taiwan China and Korea were 'assimilated', their development of colonial policies and the way of acceptance/resistance by the people were different in each colony. The difference was also reflected in geography education.

By comparing geography textbooks and educational policies in Taiwan China and Korea, I will discuss how the geography education and its difference affected on the development of colonialism and the people in each colony.

Key words:

colonialism, geography; elementary school; education; Taiwan China; Korea

⁷Peattie, Mark R. (1984) Japanese Attitudes Toward Colonialism, 1895-1945. In *The Japanese Colonial Empire, 1895-1945*, edited by R. H. Myers and M. R. Peattie. Princeton University Press.

Multi-Agent Model-Based Historical Cropland Spatial Pattern Reconstruction:

Methods and Case Study

Abstract

To advance the research of global land use/cover change (LUCC), biodiversity, global carbon cycle, and other aspects of the earth system, it is essential to reconstruct changes in historical cropland cover with long time series and high-resolution grid. Currently, it is a general approach which is based on the view of combining the overall control of cropland area, selecting grid of high land suitability, and 'top-down' decision-making behaviors to reconstruct the historical cropland. Considering various factors that influenced cropland distribution, including behavioral agent's selection by itself and the limitation of nature and human factors, a spatiotemporal dynamical reconstruction model of historical cropland based on the multi-agent systems has been developed from the perspective of 'bottom-up', which combine macroscopic and microscopic decision-making behaviors of agents to simulate the government and farmer autonomously implementing the selection behaviors of farming area. Taking Shandong Province as the study area, this model was used to imitate its cropland spatiotemporal pattern with 1km grid-resolution from 1661 combining the contemporary pattern and reconstructed amount of historical cropland as a maximum potential scope and control variable of reconstruction model, respectively, furthermore, followed the accuracy valuation and comparative analysis. The reconstructed results show that: 1) It is properly suitable for Multi-Agent to simulate and reconstruct the spatial distribution of historical cropland; 2) Compared with historical map datasets (1930s) from the view of point to point, the correctly classified producer accuracy, user accuracy and overall accuracy of reconstructed result totally up to 59.09%, 80.62% and 62.31%, respectively, and shows our reconstruction map achieved a better agreement with the historical maps; 3) From the view of grid-level or county-level, our reconstruction approach can effectively keep away from the grid with mountain-hilly and easily flooding probability, it showed a good similarity and higher consistency when compared with the research result based on archives and historical records in overall pattern and tendency of cultivation, and difference error decrease gradually, moreover, the cultivation ratios in county-level is more close to the historical situation.

Key words:

Multi-Agent; historical cropland; reconstructing spatial pattern; Shandong Province

The Study of the Dissemination and Distribution of the Catholic Church in Northwest Yunnan in Late Qing Dynasty

Xiaohong Zhang

The Institute of Chinese Historical Geography, Fudan University, China

Abstract

In the late Qing Dynasty, there were about three kind of forces in Northwest Yunnan: one was the Buddhist which expanded during Ming and Qing Dynasties from Tibetan Plateau and had acquired a monopoly in the area; one was the Catholic Church which missionaries came from France had spread in the lower classes by renting the farmland to the poor; one was the local government who were going to bulldoze through national authority. In the struggle among the three forces, the Catholic Church united with the local government and diminished the power of Buddhist, so that the Buddhist had to share the local power with the Catholic Church and local authority. In the political pattern in the area, there was no clear and definite geographic border line between the distribution of the Catholic Church and Buddhist. And the corresponding relationship between the religion and the ethnic group was broken out. The geographical distribution of the religion and ethnic groups in the area had been changed and showed a mosaic pattern.

Key words:

Catholic Church; Distribution; Northwest Yunnan; Late Qing Dynasty

Vernacular Culture Regions in China: Its Forms and Indicators

Zhang Weiran

Institute of Chinese Historical Geography, Fudan University, Shanghai, 200433

Abstract

As an academic item, the concept of Vernacular Culture Region came from America. It is perceived to exist by its inhabitants, as evidenced by the widespread acceptance and use of a special regional name. The most popular case is “Dixie” region which was formed since Civil war in south-eastern of United States. It is determined by “Dixie” symbol appeared in telephone directories as part of the name of business establishments, and so it has no clear bounds, no central points. According to its definition, in China, there are many alike cultural regions such as Qin (秦) cultural region, Chu (楚) cultural region and so on, which come from some traditional region concepts. Another kind of such regions is determined by some physical symbols such as mountains and rivers. For example, Jiangnan, Shandong and Jiangnan. Differing from it in United States, most of such regions in China have notable edges and remarkable central places. And most of them had very deep relationship with administrative regions.

A Study on the Age of Ancient City Bajiaocheng in Gansu Province, Northwest China

Qiang Wang, Dongju Zhang*, Duo Wu, Yanwu Duan, Fahu Chen

MOE Key Laboratory of Western China's Environmental System, Lanzhou University, Lanzhou, 730000, P. R. China,
wangq2010@lzu.edu.cn

Abstract

Bajiaocheng, a well preserved ancient city, located in Xiahe County Gansu Province, was one of the important cities on the western road of Chinese ancient Silk Road. It has great value not only in the history of the relationship between central government and northwest minorities but also in the architectural significance. The city was built and occupied by ancient Tibetan Empire for a long time, however, when the city was built is still unclear as both the Western Han Dynasty based on some archaeological artifacts inside and outside the city and the Northern Song Dynasty according to some local historical documents are possible. Here we try to use chronology method to confirm the accurate age of the city. After investigating Bajiaocheng city, around 36 plant remains and charcoal samples were collected from main body of the wall. In order to obtain the age of the city, 8 of them from the base of wall were picked for radiocarbon dating by using accelerator mass spectrometry (AMS) method. Combined with the dating results and historical documents, we finally draw a conclusion that the Bajiaocheng city was built at least in 766 (± 47) AD which is corresponding to Chinese Tang Dynasty.

Folk Belief and Village Boundary: A Study Centered on Fenghuang Village, Chaozhou, Guangdong Province

Feng Huang

Sun Yat-sen University, huangf33@mail2.sysu.edu.cn

Abstract

This paper is a comparison of the folk religious activities in Fenghuang Village and other 4 nearby villages. By taking the God Games as an example, to throw light on the significance of folk religion in constructing internal identity as well as outer boundary for a village. Folk religion is an important factor in internal identity, which makes sense in the promotion of the integrity of a village. Also, it is an important factor in the construction of the boundary of a village. The otherwise vacancy of group activities has been filled by the folk religious activities during the traditional festivals. Individual, families and villages are reunited by such folk religious activities at which expressions of care for the fortune of the village can be readily found. In addition, relationship between villages can also find its expression at the games which is an opportunity to coordinate village relations and construct boundaries.

Key words:

folk religion, village boundaries, sacrificial offering circle, God Games

Multi-Ethnic Residential Segregation in Urumqi, China, 1982-2010

LI Song A, ZHANG Xiaolei B, Li Shoushan C, DU Hongru D, Zhang Lingyun E

Xinjiang Agricultural University Management college, Urumqi 830052, P.R.China, lisong821314@163.com

Abstract

The ethnic landscape of Urumqi has undergone significant changes since 1980's, which has fostered greater ethnic diversity. However, little is known about the changing patterns of spatial differentiation among ethnic groups. Using the Urumqi census data from 1982 to 2010, we examine the level of residential segregation of Uighur from Han and the level of residential segregation of Kazak, Hui, Mongolia and other ethnic minority groups from the majority Han and Uyghur population by the indices of dissimilarity and exposure. We then assess a regression between residential segregation and the percentage of the ethnic groups. Finally, we find out whether a regression between residential segregation and the percentage of the ethnic groups. The result reveal that Kazak population are most segregated group from Han and Uyghur, although, the level segregation have declined from 1982 to 2010. Uighur people experienced lower level of segregation from Han between 1982 and 2000, but has gradually increase, particularly from 2000 to 2010, this unexpected change of the segregation for Uighur group might be associated with 7.5 events. The findings of the study show the growth of the Han population negatively associated with segregation of the ethnic groups in a district, and that the association between the percentage of population and segregation was uniform for Uighur, Hui and Kazak: the higher percentage of an ethnic group in a district, the lower level of segregation.

³ Economy Management Department, Huanghuai University, Zhumadian, 463000, Henan, China

Abstract

Based on space syntax theory and “convex space model”, this paper measured the courtyard space structure of typical traditional vernacular dwellings of Henan province, analyzing its spatial features and elucidating its regional cultural connotation. The results are as follows: ①The four dwellings bear some similarities. *GI*: central axis or node > courtyards > entrance; halls > principal rooms > wing rooms. *LI*: halls > principal rooms > wing rooms in the back yards > wing rooms in the front yards. ②The distribution of the convex spaces with higher *LI* deviate from the convex spaces with higher *GI*, existing a “Core-periphery” phenomenon. ③Different building structures have strong or weak coupling relationships with different residential cultures: “living in the west and worship in the east”, “family glory”, “living in the central”, “the Confucian culture”, “the spatial culture of taking advantage of the terrain”, “cultivation and read to bequeath to the family”, “the concept of no financial exposure”, appearing different characteristics of regional cultures.

Key words:

traditional settlements; space syntax; spatial integration; regional culture; Henan province

Sustainable Development or Resilience: a Model of Social-Ecological Systems Based on the “One Begets Two” Theory of Yin-Yang in the Book of Changes

Zhou Xiao-fang

School of Tourism Management, South-China Normal University, Guangzhou 510631, China

Abstract

Nowadays, the theory of Resilience encounters the same plight that the theory of Sustainable Development and becomes a targeted and descriptive concept which continuously endows human value. The reason lies in that these two theories are based on the hypothesis of human center. With the help of the Yin and Yang ideology in the traditional Chinese culture of the Book of Changes, this thesis establishes and analyzes the Social–Ecological Systems (SEs). First, with the method of bisection (“one begets two” of Yin-Yang), this thesis corrects the error of the theory of Resilience and Sustainable Development centering on human society, and takes the Yin-Yang ideology which is both mutually-centered and non-mutually-centered as the hypothesis for setting up the socio-ecosystem model. Next, the thesis sets up the socio-ecosystem model with the help of the division-combination relationship of Yin-Yang after “one begets two”. Then, based on the “six-directions” projection of the model, the thesis acquires the development track of SEs, the Yin-Yang unification line and the “mutual promotion and restraint” line of SEs, and nonlinear power and chaos features of the SEs as a complicated system. Researches show that Sustainable Development is the Yin-Yang unification line in essence, and Resilience is the Yin-Yang mutual promotion and restraint line in essence. That is to say, there is a vertical relationship between sustainable development and resilience.

Yin-Yang; the Book of Changes; Social–Ecological Systems (SEs); Sustainable Development; Resilience

The Sustainable Development of Historical and Cultural Resources of the Yellow River Estuary

Liu CC

Capital Normal University, Beijing, 100101, China, 2543100514@qq.com

Abstract

Historical and cultural resources are an important part of human historical and cultural heritage of many entities, which possesses unique features, the value of modern wealth, can also be developed and used by scientific and rational ways, and even sublation and sublimation. The sustainable development of historical and cultural resources for the development of the economy, education and spiritual civilization construction is of great significance. Selecting the Yellow River estuary as demonstration area, using the method of spatial analysis and combining with the relevant data, studying the situation of the historical and cultural resources and researching the advantages and difficulties of historical and cultural resources faced by the development, summing up the historical and cultural resources of the Yellow River mouth still exist many problems in the process of sustainable development. And giving countermeasures and suggestions from three aspects including increase investment, build the Yellow River estuary's cultural card and promote the development of the cultural industry of the Yellow River mouth, which can promote the sustainable development of historical cultural resources of the Yellow River estuary.

Key words:

historical and cultural resources; the sustainable development; the Yellow River estuary; spatial analysis

Technosols Classification in Areas of Old Municipal Solid Waste Deposits in

Presidente Prudente - São Paulo-Brazil

Antonio, J. N., Tommaselli, J. T. G., Metternicht, G. I

University of New South Wales (UNSW), Sydney, Australia and janaina51@gmail.com

Abstract

The purpose of this study is to develop a method to classify technosols in areas of old municipal solid waste in Presidente Prudente – São Paulo – Brazil. The technosols are a new category of soils with its natural characteristics modified by anthropogenic activities. These soils are characterized by the presence of artefacts and technic hard materials composed of different materials among them there may be to occur toxic materials. In this study we are evaluated areas which have been used for the disposal of municipal solid waste and it caused changes in your landscape. Currently there are several problems for the people who lives nearby. To verify the changes in the landscape were used aerial photographs of the area in the years 1962, 1995, 2000 and field work to verify these changes. The area is on the course of the river which was grounded by solid waste and currently the area has many problems such as erosion and soil contamination. Additional relief data are being used to make the classification of technosols such as geomorphometric data obtained from a DEM as slope, curvature, aspect, flow direction and added chemical and physical analysis of soils in order to verify the area of influence of contamination of these soils. The application of a methodology for technosols classification can be applied in other areas and can be used for purposes of planning and land use planning as well as for other activities and studies.

Key words:

Technosols; geomorphometry; landscape; soil contamination

The Red Book of Soil in Landscape Protected Area

Guseinov A.N, Robert A.E.

Abstract

The standard SPNR conditions do not prevent soil degradation and its destruction as well as do not take into account the specific basic role of the soil in ecosystem components protection (plants, birds, animals etc.). Here we can ask an appropriate question – is it possible to protect plants, animals and mushrooms simultaneously without taking care of their natural surroundings – the soil? Today, the danger of non-refundable extinction of some kinds of soil seems real. «Tepliy Stan» landscape protected area was chosen as a model for the research, which is located in the south-west of Moscow and its soils suffer from an intensive recreational influence in all the seasons. On the ground of field works was compiled and digitized the soil map in scale 1:10000. The map showed 3 types of soil: podzolic, soddy and inundable (alluvial). We researched the affinity coefficient as the most accurate index of recreational influence and it made a foundation to create a recreational influence map in scale 1:10000. During the field ecological works we discovered some fire-pit locations and put them on the same map. Sod-podzolic soil areas suffer from maximum anthropogenic influence where affinity index is from 3000 to 4200 m / 0,08 km². According to this as well as the data of fire-pits locations and intended for construction areas locations, these sod-podzolic soils were brought to extinction category. We believe that the proposed approach will have significant implications for similar ecological studies, and to open a new washed SPNR.

Changing Regional Division of Labor between Hong Kong and the Pearl River Delta: From “Front Shop, Back Factory” to “Front Office, Back Desk”?

Yeh, A.G.O., Yang, F.F.

Department of Urban Planning and Design, The University of Hong Kong, Hong Kong SAR, China, Anthony.Yeh@hku.hk

Abstract

Hong Kong and the Pearl River Delta (PRD) has developed a well-known collaborative relationship, namely the “Front Shop, Back Factory” (FSBF) model, since the 1980s. However, the effects of this partnership have been in a process of decline over the past decade as a result of economic transition and rapid growth of producer services in mainland China. This paper examines the industrial linkages of producer services between Hong Kong and the PRD to see whether a new type of regional division of labour exists between these two places. The emphasis is placed on the utilization of producer services from Hong Kong and the competitive advantages and disadvantages of Hong Kong suppliers in the mainland. We find out that a “Front Office, Back Desk” (FOBD) pattern between the two sides of the boundary is emerging but its effects are not as significant as that of the FSBF model. In the theorization of international division of labour, the interconnectedness of the global economy is based on comparative advantages arising from geographically differentiated labour power. This study not only reveals some new tendencies of development, namely the connection of producer services between two places on a basis of competitive advantages, but also unravel the impacts of the difference in politico-economic context on the competitive performance of producer service suppliers.

Key words:

regional division of labour; Hong Kong; the Pearl River Delta

Eco-City in the Making: The Ambiguity of Environment and the Planning Practices in the Cities of the Pearl River Delta

Chen Yanyan

Department of Geography and Resource Management, the Chinese University of Hong Kong, Hong Kong, P. R. China,
chnyanyan@gmail.com

Abstract

After decades of rapidly economic growth, the cities of the Pearl River Delta have confronted with a dilemma of treating environment: to prioritize high-speed economic growth by ignoring environment or to address environment and its relationship with development before it is too late. Since 2000, the jurisdictions in the Pearl River Delta have spent numerous efforts in making so called 'Eco-city', attempting to integrate more environmental concerns into development strategies. A series of new vocabularies related to ecological development are adopted in such massively planning activities, such as Ecological Corridor, Eco-Park, and Greenway. Nevertheless, the meanings of these environment discourses adopted in the planning document are ambiguous, and even contrasting, resulted in problematic planning practices in realities. On the hand, the environment discourse denotes a place where primitive nature is well preserved because of its lack of development; On the other hand, the environment is taken as a branding cover of development projects which require more natural space. This study attempts to examine how the municipal governments in the Pearl River Delta have adapted to the changing environmental problems through urban planning in the past two decades. The specific focus is on the incompatible meanings of environment implied in the planning policies, and the relevant environmental practices. Through an engagement with the discussion of discourse, the argument is made that the conflicted discourse should not simply taken as a result of incompatible desires of the jurisdictions, but a mechanism for the municipalities to flexibly rework their powers to reconstruct the cities to counter the backward economy as well as to meet the challenge from other competitive cities.

Key words:

Environment discourse; cities of Pearl River Delta; Eco-city

Finding the Fix in Changes and Flows: The Urban Political Ecology of Greenway Development in the Pearl River Delta

Chung, CKL

Bartlett School of Planning, University College London, London, WC1H 0NN, United Kingdom, calvin.chung.14@ucl.ac.uk

Abstract

From the perspective of urban political ecology, the search for a sustainability fix to cities confronted by the dual imperative to promote economic growth and champion environmental qualities involves the provision of new physical infrastructure to mediate the socio-ecological metabolism of nature upon which urban fortunes predicate. This paper draws on such perspective to offer a critical interrogation of the extensive development of greenways in the Pearl River Delta (PRD) since 2010. It argues that, to fix the sustainability demands on the urbanisation of PRD cities, the Guangdong provincial government has heralded greenways as 'metabolic vehicles' which, in three ways, facilitate and enhance the transformation and circulation of part and parcel of the rural environment as object and idea. To urban dwellers, greenways serve as cost-effective conduits to replenish their severely strained supply of collective consumption with rural open spaces. To rural villagers, greenways as spaces of movement of people create opportunities for the commodification of the idyllic beauty and soil fertility of their territories. And to property developers, greenways provide them with the imaginary threads to capitalise on the rural nature at a distance. These findings enunciate the promise to contour in a more nuanced manner the political and economic dynamics of the development of the PRD, as with any other hotspots of urbanisation, by giving analytical attention to their biophysical embeddedness.

Key words:

urban political ecology; sustainability fix; urban metabolism; Pearl River Delta; greenway

Going beyond the Politics of Scale: Planning Intercity Railway System in China's Pearl River Delta

jiangxu@cuhk.edu.hk

Abstract

There is a recent blossom of scholarly work on the political-economic approach to scale by human geographers who study the changing state spatiality in China. This research explored the social construction of scale to overturn the old-fashioned conception of scales as neutral, pre-given, fixed, and external to social activities. In its arguments, scale is relationally produced. Thus, it is essential to deploy a relational thinking to understand the dynamic and fluidity of scale in the policy process of Chinese state regime. Such highly illuminating work of political economy of scale is inspiring, but it might place too much emphasis on the ontological (or material) existence of scale while ignoring the epistemological construction of scale (scale as social practice or a representational trope). Using the 'scale politics' thesis which combines the sensible arguments of both political economic tradition and post-structuralist approach, this presentation will use the intercity railway systems (ICRS) in China's Pearl River Delta as an example to illustrate the two moments of scale in policy process – i.e. scale as material political-environmental relations being shaped and as device shaping political-environmental relations. The impacts of such 'scale politics' will also be discussed using a recent large-scale questionnaire survey on Guangzhou-Zhuhai Line.

Key words:

Scale politics; Intercity Railway System; Pearl River Delta

Urban Development and Land Use Governance in the Pearl River Delta: A Regional Perspective

Chan, Roger C K

Department of Urban Planning and Design, The University of Hong Kong, Hong Kong, China. hrxucck@hku.hk

Abstract

The process of land development has close linkages and interactions with politics, society, economy and urban form. Land development process has been the driving force behind China's economic and urban development, as illustrated by the experience in the Greater Pearl River Delta region. The process has brought about changes in the land tenure and management system, which are due to the fiscal relationship between the central and local governments and the resulting adoption of land-based local finance. Increasing capitalization of land has generated huge demand for development. This paper will probe into how the land tenure and management system may be improved and the direction for changes to the current relationship between local governments' land-based fiscal policy and urban development.

Urban Shrinkage in the Pearl River Delta: Pattern, Typology and Influencing Factors

Li xun, Yang jinkun

Sun Yat-sen University, Guangzhou, P. R. China, 515692285@qq.com

Abstract

In an increasingly urbanised world, the coupling of urban growth and shrinkage has been a common phenomenon. Relative to urban growth, urban shrinkage has often been understudied by most mainstream scholars. Since China's reform and opening-up, while the Pearl River Delta (PRD) is usually being described as “a miracle of growth”, the problem of urban shrinkage has also become apparent in parts of the region. Drawing on China's 5th and 6th national censuses data, this paper investigates the current situation of urban shrinkage in 595 towns across the PRD. By assessing the effects of changing resident population, permanent population and urbanised areas on the shrinkage of the PRD region, this research aims to reveal its shrinking feature and pattern. Based on cross tabulation analysis of population loss and the extent of urban expansion, this research has categorized all territorial units at town levels in the PRD region into the following four types: Type I (significant loss of population with noticeable expansion), Type II (significant loss of population with insignificant space expansion), Type III (slight loss of population with noticeable expansion), and Type IV (slight loss of population with insignificant spatial expansion). On the basis of this typology, an attempt has been made to offer some theoretical explanations for the influencing factors of such urban shrinkage.

urban shrinkage; Pearl River Delta; typology; influencing factors

Industrial Agglomeration Models' Experiences of Some Famous Bay Areas in the World and Their Enlightenment Function to the Development of Guangdong, Hong Kong and Macao Bay Area

Han W., Cai J.M.

Institute of Geographic Sciences and Natural Resources Research, Beijing, 100101, P.R.China, han_wei1987@126.com

Abstract

This paper takes industrial cluster as the theoretical framework and analyzes the industrial agglomeration models of San Francisco Bay Area, New York Harbor, Tokyo Bay area, Port of Rotterdam and some other world-famous Bay Areas in order to provides ideas and suggestions for the development of Guangdong, Hong Kong and Macao Bay Area. The analysis revealed that this bay area had some problems like the different constitution, unclear labor division and other issues. There are three aspects given by this paper to improve the industrial models of Guangdong, Hong Kong and Macao Bay Area: 1) correct understanding the position of Hong Kong, 2) a reasonable improvement of regional division, 3)actively promoting production city integration of the whole region.

Key words:

bay areas; industrial agglomeraion models; industrial development experiences

Are People Less Likely to Own Cars in a City with More Bus Stops?

Fenglong Wang

Institute of Urban Development, East China Normal University, Shanghai 200062, P. R. China, wfldragon@yahoo.com

Abstract

Car ownership is increasing rapidly in urban China. This is considered as an important contributor to the serious traffic congestion and air pollution. Therefore, control of car ownership is an hot topic in many Chinese cities. Development of public transportation is usually adopted as an important policy for this aim. However, not many studies have examined the relationship between car ownership and accessibility to public transportation empirically. In this paper, we explored the effects of accessibility of bus stops on car ownership using a linear regression model at the city level and a multi-level logistic regression model at the household level. The results suggest that accessibility to bus stop is a factor when people considering to own a car. However, the effects are differential in different regions. We believe the finding in this paper have significant implications for policy makers and urban planners.

Key words:

Car ownership; built environment; bus stop; urban China

Becoming Active Traveler in Urban Space: The Use of Social Media Data in Public Housing Estates of Guangzhou

Abstract

This study investigates the interaction between the travel behavior of public housing residents and the Internet in Guangzhou, China. It examines how the public housing residents make use the Internet and weave it into their everyday life (including working trip & non-working trip) to improve active travel. The study analyzes the use of social media (like wechat, QQ, weibo) with a special reference to Guangzhou, based on the analysis of computer-assisted monitoring online communication platform from September to December 2015, and in-depth interviews. We argue that the social media provide a platform within which information exchange, organization of collective actions, and social interactions to tackle the difficulties of travel because of a disadvantaged location of public housing. In addition, residents' activity pattern and routes become more flexible in pursuit of the Internet. The emergence and use of social media is one of attempts and endeavors by public housing residents to improve their quality of life under new public housing regime. The findings would facilitate an understanding that a quantitative assessment of the use and impact of the Internet on people's time and space is needed in the future research, and provide some recommendation on urban planning and housing policy.

Key words:

Travel; Social media; Public housing residents; Guangzhou

Built Environment, Non-Work Activity Participation and Travel: A Case Study of Suburban Beijing

Abstract

Urban planning have been trying to create relatively compact and complete communities in order to facilitate non-work activities in daily lives. However, so far many studies have focused on reducing the motor travel, but few focus on opportunity to engage in activities. This studies examines the impact of built environment at micro level on participation and related travel of out-of-home non-work activities using an activity diary survey data collected in suburban Beijing. The participation in non-work activities are measured using the episode and location and tours of out-of-home non-work activities after work. After descriptive analysis, we explored the relationship between the residential built environment and participation in non-work activities by regression models, controlling for social-economic attributes. The expected research findings are that suburban residents engage in few out-of-home non-work activities after work and most of the non-work activities are conducted during commuting. Neighbourhood characteristics have significant influence on participation in non-work activities, but the influence varies among social groups. Taken together, our results suggest that if cities use urban planning and policies to facilitate activity participation should also consider the attributes of residents.

Key words:

Space-time behaviour; non-work activities; built environment; suburb; Beijing

Built Environmental Impacts on Individual BMI: Evidence from China

Abstract

Although the link between obesity and the built environment has long been of research interest, how the built environment affects health in China, which has a 37-percent obesity and overweight rate, has rarely been studied. By applying a structural equation model on the data from China Family Panel Survey, this paper examines the effects of neighborhood built environment on the body mass index (BMI) in China. We find that controlling for socio-economic attributes, population density and the densities of public service facilities and retail shops have positive influence on BMI, which is inconsistent with the findings in developed countries. The further analyses show that higher densities in population and public service or retail businesses indeed increase the likelihood of choosing active travel modes including walking and cycling which show negative association with BMI in the estimation, but at the same time, lead to shorter travel distance. The positive relation between density and BMI may result from the net effect dominated by travel distance. In addition, the distance to the nearest bus station positively influences non-transit mode choice and negatively influences BMI controlling for mode choice. This again indicates the role of travel distance on BMI. The different findings in China from developed countries can be attributed to the fact that most neighborhoods in China are characterized by high density and compact development pattern.

Key words:

built environment; BMI; travel distance; mode choice; China

Carbon Emissions from Shopping Trips to Different Commercial Centers on Weekend

Li J

Northeast Institute of Geography and Agroecology, CAS, Changchun, 130102, P. R. China, lijingsara@iga.ac.cn

Abstract

The objective of this study was to estimate carbon emissions induced by shopping trips to different commercial centers in Shenyang, one of the most important metropolitan areas in China by the questionnaire surveys and interviews on weekends. Results showed that firstly shopping carbon emissions to the two professional wholesale commercial centers were the highest, about 312.73g and 274.57g per capita on average. The carbon emissions induced by suburban shopping center of Hunnan was relatively higher than commercial centers of Middle street and Taiyuan business street in downtown. And the regional traditional commercial centers of Xita-Beishi, Beihang and Tiexi in inner city produced least carbon emissions, about 184.14g, 134.43g and 115.80g per capita on average. Secondly, for the total commercial centers, private car emitted six times more carbon emission than those by public transport. Thirdly, there were particular characteristics of high-income, undergraduate or above education level and typically white-collar individuals that explained the likelihood of using private cars for shopping. We concluded that rational distribution and balanced development of commercial centers in downtown, inner city and suburbs, improvement of urban public transit and low carbon education of citizens would be a feasible and effective strategy to reduce urban transport emissions.

Key words:

transport carbon emissions; shopping; commercial center; travel mode

Characteristics of Commuting Pattern in Xining: Based on the Comparison of Different Types of Urban Communities

Abstract

Since the reform and opening up, with the disintegration of the Chinese Danwei welfare housing system and the deepening reform of urban land and housing market, the process of rapid suburbanization and urban sprawl, great changes have taken place on jobs -housing spatial origination in Chinese city , which has already led to commuting problems and changes of urban commuting pattern. Based on the survey in 11 typical communities of Xining in 2013, this paper describes basic features of commuting behavior of Xining citizens, and focuses on the comparison of the disparity of commuting pattern by five types of communities, trying to reflect the micro process of jobs-housing relationship changes. Our study shows that, firstly, obvious differences on commuting pattern lie in different types of communities. Secondly, the residues and invisibility of Chinese Danwei welfare housing system still has a significant impact on residents' commuting pattern in Xining. Thirdly, the facts that about one fourth surveyed residents in in central city community who are experiencing long distance outward commuting, as well as a higher proportion of residents in suburb communities experiencing long distance inward commuting, may show that the separation of home and work has already come into being in Xining.

Key words:

commuting pattern; urban structure; comparison of different types of urban communities; Xining

Abstract

Travel experience has increasingly become a debatable issue among human geography and transport studies. The relationship between travel behaviour and subjective wellbeing has been revealed from many aspects, however less is known about the role of out-of-vehicle travel time use (walking, waiting, transferring, etc.) on individual satisfaction. Out-of-vehicle travel time use are usually considered as an index reflecting the effectiveness of transit travel, but this “onerous” process could be explored of its effects on in-vehicle experiences for travels taken subsequently. This paper examines this question by reviewing the literature on the role of out-of-vehicle travel time use and travel-related subjective wellbeing, and offers insights into the role of out-of-vehicle time use on travel satisfaction. The data will be derived from the Beijing 2012 GPS-based activity-travel diary survey, and out-of-vehicle travel will be analyzed in three categories of walking, waiting and transferring. The out-of-vehicle time use and travel satisfaction are first demonstrated through descriptive statistics, and the relationships between out-of-vehicle time and travel satisfaction are explored by deploying a structural equation model. Individual and household socio-economic information are set as exogenous variables, and the effects of out-of-vehicle time on satisfaction with travel are examined separately in three categories in regards to their effects on subsequent travels under different travel modes and travel purposes. It is revealed the difference in direct/indirect effects of three different out-of-vehicle time use on travel satisfaction, and the limited effect of out-of-vehicle time on intermodal transition.

Abstract

Studies on travel characteristics benefit understanding of travel status quo, trends, and driven forces. Traditional researches mainly focus on travel survey data. Nowadays, the emerging of big spatiotemporal data gives us an opportunity to explore travel characteristics in finer granularity both in space and time. This research explores the spatial and temporal variation of public transit passengers' travel characteristics with smart card data of Shenzhen. Travel movements are firstly inferred from long-time smart card transaction data of metro and bus. Then indicators of travel characteristics like travel volume, average travel distance and time are extracted at traffic analysis zone (TAZ) level from derived movements. To explore the spatiotemporal variation of passengers' travel characteristics, comparisons between temporal and spatial changes are made, and further analysis is conducted on these indicators to measure spatiotemporal autocorrelation using method of the improved Moran's I index. The results illustrate that, in the study area, the inhabitants' travel characteristics vary in space and time noticeably, and travel generation exhibits significant spatial cluster patterns with temporal changes. This research not only helps to better understand the spatiotemporal variance of travel characteristics, but also explores the possibility of the use of spatiotemporal smart card data.

Abstract

Understanding spatio-temporal dynamics of urban function is essential for urban planning and urban governing. The explosive big spatio-temporal data, such as mobile phone location data and social media data, have the potential to capture city-wide human activities interacted with urban regions. In light of the close correlation between urban functional regions and human activities, this article proposes a novel bottom-to-up approach to infer urban functional regions dynamics by aggregating human activities identified from mobile phone location data and social media data. Activities at home and working places are firstly extracted from mobile phone location data with spatial-temporal regulations. Other social activities are then labelled by a temporal-varying hidden Markov model combining with social media data. By aggregating identified human activities at base tower station level, city-wide spatio-temporal dynamics of urban functional region is revealed. An experiment in Shenzhen, China was conducted and the obtained result illustrated the presented approach can uncover the spatial and temporal dynamics of urban functional regions. Spatio-temporal activity pattern analysis verified that our approach can uncover more detailed human dynamic across space and time than traditional land use. The proposed approach and the obtained results provide a new perspective to bridge the gap between land use and human dynamics and benefit both long term policy-making in urban planning and short term decision-making in urban governing.

Lost in Urbanization: the Employment Outcomes of Land-lost Farmers in China

Pengyu Zhu, Hui Wang, Xiao Chen, Sarah Swider

Department of Community and Regional planning, Boise State University, USA, pengyuzhu2002@yahoo.com

School of Public Affairs, Zhejiang University, China

Abstract

With the acceleration of industrialization and urbanization in China, large amounts of rural land are expropriated and a growing number of farmers have lost their farmland. As of 2012, it is estimated that the number of farmers who have lost their farmland has exceeded 60 million, excluding those caused by illegal land expropriation. The governments at all levels introduced various employment policies for land-lost farmers to help their transition, encourage their reemployment in the non-agricultural sectors, and solve related economic and social problems. These employment policies include government organized job training, job recommendations from government, preferential employment licenses, preferential employment agreements from the land using business, as well as small loans and tax exemptions to start their own business. Through empirical analysis, the paper examines the effectiveness of these employment policies implemented by local governments. This study uses data collected from a survey conducted in four major economic regions in China in 2009. We use multinomial logit model to investigate the impact of local government's employment policies on the employment outcomes of farmers who have lost their land during land requisition.

Modeling Household Residential and Mobility Decisions: Household Time Allocation

Approach

Yao M.Z., Wang D.G.

Department of Geography, Hong Kong Baptist University, Hong Kong, P. R. China, dgwang@hkbu.edu.hk

Abstract

Household residence and car ownership problem have been widely explored over the past decades. However, individual differences and intra-household interactions in these important household decisions jointly made by household members have rarely been considered. In this paper, we develop a multi-dimensional household decision model that consolidates the correlated long-term residential choice, middle-term car ownership decision and short-term time allocation decision, explicitly incorporating interactions among household members by adopting group decision approaches. Both the selection of residence and car ownership level are supposed to be collective decisions made by household members so as to meet their mobility and amenity preferences. Meanwhile, these two decisions are explored from the perspective of household members' time allocation patterns, because they may directly influence their travel-based activities through travel distance and travel speed. In families with tightened monetary budget, the tradeoff between housing expenditure and car ownership expenditure is captured to investigate their complex interrelationship. Data collected in Beijing will be used to calibrate parameters in the proposed simultaneous multi-dimensional decision model. Findings from this study are expected to provide insights on how residence-related urban form influence household car ownership and household members' lifestyle in terms of their time allocated to various daily activities.

residential selection; car ownership; time allocation; intra-household interaction

Real-time Interactive Space-Time Integration and the Spatiotemporal Data

Explosion

Douglas Richardson

American Association of Geographers, United States

Abstract

Real-time spatiotemporal data are now being generated almost ubiquitously, and their applications in research and commerce are widespread and rapidly accelerating. However, the ability to continuously create and interact with fused space–time data in geography and GIScience is a relatively recent phenomenon, made possible by the invention and development of real-time interactive (RTI) GPS/GIS technology and functionality in the late 1980s and early 1990s. This innovation has since functioned as a core change agent in geography, cartography, GIScience, and many related fields, profoundly realigning traditional relationships and structures, expanding research horizons, and transforming the ways in which geographic data are now collected, mapped, modeled, and used, both in geography and in science and society more broadly. Real-time space–time interactive functionality remains today the underlying process generating the current explosion of fused spatiotemporal data, new geographic research initiatives, and myriad geospatial applications in governments, businesses, and society. This presentation addresses briefly the development of these real-time space–time functions and capabilities; their impact on geography, cartography, and GIScience; and some implications for how discovery and change can occur in geography and GIScience and how we might foster continued innovation in these fields.

Redefining the Concept of Daily Activity Area and its Depiction: From Perspective of Individual Behavior

Sun Daosheng, Yanwei Chai

Department of Urban and Economic Geography, College of Urban and Environmental Sciences, Peking University, Beijing 100871, China, sundaosheng@foxmail.com

Abstract

Marketing-oriented and giving priority to efficiency, China's urban planning and construction of the space organization takes more consideration of production and functionalism from a macro-scale, and less concerns about the urban residents' daily lives from a micro-scale. But it cannot be ignored that the behavioral characteristics of residents and their concrete day-to-day life demand should be taken into account of as a ruler to advance the innovation of planning from below. Focusing on life space based on the individual behavior, taking a new understanding of the suburban space, and conducting neighborhood community planning around the daily life of residents, is response to social transformation, and an important idea to guide Chinese cities as human centered.

This research firstly put forward the concept of neighborhood life area after combing the development of the concept of life area abroad and home. Then on the basis of the aforementioned concept, this paper applies one-week GPS-facilitated activity-travel survey data obtained in Beijing Qinghe area in 2012, with ARCGIS visualization methods, conducts the empirical definition of daily activity area of suburban residents, and analyze their basic features. The results show that, in accordance with the different nature of the activity and its spatial accessibility, activity area of suburban communities can be divided into neighborhood activity area, commuting activity area, extended activity area three spheres. In addition, the study also found that after the superposition the neighborhood activity areas of residents in one same community, the spatial extent of common usage selected by a certain percentage threshold, can be used as the basic unit of community living space planning.

Refueling Behavior Identification and Fuel-Consumption/Emissions Estimation from GPS Trace Data

Luliang TANG, Zihan KAN, Qingquan LI

Wuhan University, Wuhan, 430079, China, kzh@whu.edu.cn

Abstract

The accelerating urbanization indicates the prominence of problems of urban transportation and environment issues. Reports show that 20%—30% of the total production of greenhouse gases (GHGs) is released from urban transportation operation. Energy consumption and polluting gases releasing from urban transportation represents a severe challenge. To deal with this challenge, we propose approaches for understanding the patterns of energy consumption, emissions as well as refueling activities in urban transport system.

First of all, we represent vehicles' traces with their space-time path and study the characteristics and patterns of vehicles' refueling behaviors under Time-geography frame. Second, we identify and detect refuelling behaviors of vehicles from their space-time paths. Finally, taking the refuelling behaviors as anchor points of their belonging traces, we estimate the energy consumption and emissions between anchor points. As a result, energy/emissions in different scale (from a single trace to a city level) can be estimated and revealed.

With GPS-tagged trace data from taxis in Wuhan, China, we detected their refueling behaviour successfully. Energy consumption/emissions were then obtained in individual level, street level and city level. This study holds the potential of accessing information about vehicles' energy/emission in various scales, and supporting strategies and policies about the energy, environment and transportation network operation.

Key words:

Research on Traffic Impact of Commuting Behavior of Suburban Mega-Community Residents: Evidence from Sanxiangsiji Community in Shanghai Songjiang New Town

Lizhi MA, De WANG, Wei ZHU

Tongji University, Shanghai, 200092, P. R. China, 2006linzhma@tongji.edu.cn

Abstract

Performance evaluation of suburban new town development has been widely concerned by researchers after its initiative more than ten years ago in China. The traffic impact of population suburbanization is one of the hot topics, existing literatures on commuting widely assumed that its impact is negative, because population suburbanization (1) caused jobs-housing imbalance problem in urban areas even worse, which led to significant increase in residents' transportation costs (include commuting time and fees) (2) caused rapid expansion of car transit, which resulted in greater traffic congestions in urban area (3) generated more public transit, thus added pressure and challenges to urban public transit. Whereas, these arguments are derived from personal observations more than empirical study, especially, case studies on residents' dynamic commuting behavior change between before and after their migration to suburban community. Besides, studies based on traffic statistical data usually neglect personal behavior and socio-economic related analysis, as well as specific community group analysis. This paper takes a mega-community which is located in Songjiang new town-a far-suburban new town of Shanghai metropolitan area as a case, collects the first-hand data through household questionnaire survey. First, this paper analysed the dynamic changes of residents' job-work relationship, commuting behavior of all population groups, then different population groups, results indicate that (1) residents' jobs-housing imbalance increased about 8% (2) average commuting time and fees increasing slightly, separately 3 minutes and 2 yuan, while 54.5% residents' travel tools did not change (3) there are significant variations among different populations of their commuting time, fees and travel tool choices. Furthermore, the behavioral impact of residents come from central city-because it plays a major role-is investigated in this paper, by four aspects of commuting time, fees, car dependency, public transit dependency. The results demonstrate (1) Suburbanization may not lead to the increase of residents' commuting time and fees, as well as dependence on cars (2) Even there is a high degree of dependence on cars, the condition of traffic congestion in central city may not be aggravated. On the contrary, it can play a role in alleviating the bad situation (3) Suburbanization does not result in a significant increase of dependence on public transport (actually only increased by 0.1%), but it leads to great changes in the composition and structure of public transport, the dependence on bus and rail transit get a 11.5% increase and 11.6% decrease respectively, which make the rail transit toward to the suburban new town become very crowded. The research results may provide basis for policy decision-making on far-suburban new town housing and transport development.

Key words:

Mega-community; commuting behaviour; traffic impact; Suburban areas of Shanghai metropolitan

Spatial-Temporal Figures of Suburban Workers' Daily Activities from the Perspective of Employment Suburbanization: Case of Shangdi-Qinghe Area in Beijing

Wenrui Ma, Yanwei Chai

College of Urban and Environmental Sciences, Peking University, Beijing 100871, P.R.China

Abstract

With the rapid change of socio-spatial structure in urban China, the issue of employment suburbanization has drawn increasing attention from urban geographers. The limited supply of shopping, leisure and transportation facilities in suburban areas are faced with great mismatch with the fast-growing demand of suburban workers. However, the spatial-temporal demands of suburban workers are often overlooked by researchers and planners. Individual spatial-temporal figures are able to reflect the needs of urban space utilization, and to indicate accessibility and reach by suburban workers.

The study employs the data of 2012 GPS-based activity-travel survey in Beijing, and the samples include 203 workers in Shangdi who live in suburban area. By combining urban social geography, time geography, and using methods of statistics and space-time GIS, this paper describes the spatial-temporal figures of workers' daily activities, and analyze their demands under employment suburbanization. Based on the findings, suggestions for optimizing urban space and managing time are provided.

The study shows that 1) suburban workers work longer with more regularity; 2) the work places, downtown and large shopping malls in suburbs are the main places where suburban workers' daily activities take place; 3) due to the strong restriction by work, their non-work activities happen closer to the working places on work days, but take place far from both homes and working places on weekends. The findings confirm that urban sprawl structure of Beijing is still dominated by inner city and that suburban employment and supporting facilities greatly lag behind the industrial development.

Key words:

suburban workers; employment suburbanization; daily activity; spatial-temporal features

Study on the Representativeness of Mobiles Positioning Data to Tourists in Tourism City

ZHAO Ying, ZHANG Chaozhi, JIN Yuhan

Assistant Professor, School of Tourism Management, Sun Yat-sen University, Guangzhou, Guangdong, P.R. China (Email: zhaoy233@mail.sysu.edu.cn)

Abstract

As the popularization of mobile communications and mobile Internet, big data which carries a number of geospatial information has taken more attention of human geography scholars. However, it's also questioned about the hybridity and applicability of big data. This research focus on the value of mobile positioning data in tourism research, based on the case study of Wulingyuan district and Cili county of Zhangjiajie. It uses aggregated mobile positioning data from China Mobile and China Unicom, and analyses the characteristics of the mobile positioning data of tourism area and residential area by analyzing the time rhythm of the roaming user number and the amount of mobile positioning data. It establishes a correlativity among actual visitors and telephone traffic and internet traffic to explore the representativeness of mobile positioning data to tourists. It is pointed out that the characteristics of the mobile positioning data has significant differences between tourism area and residential area. The roaming user number has a larger volatility and the time rhythm of mobile positioning data is more convergent in a single day in tourism area, which means the mobile positioning data is more representative for the fluctuation of tourists in tourism area. On account of the habit that tourists use mobile phones during visiting, internet traffic is more representative for actual visitors than telephone traffic, even if the telephone traffic and internet traffic is highly positively correlated. The findings provide a reference for us to comprehend the application value of big data in tourism and scientifically establish tourism statistics system based on the mobile positioning data.

Key words:

big data; tourists; internet traffic; telephone traffic; correlativity; Zhangjiajie

Study on the Travel Elasticity Based on IC DATA in Beijing

MENG Bin, YIN Qin

College of Arts and Science of Beijing Union University, Beijing 100191, P. R. China, mengbin@buu.edu.cn

College of Environment and Planning, Capital Normal University, Beijing 100048, P. R. China, yinqin123@126.com

Abstract

Along with the rapid development of city transition, more and more researches focus on the travel problems in the city. The spatial-temporal data provides a special perspective for travel behaviour research. Based on the IC data of subway passes in Beijing, this study analyses the elastic spatial-temporal characteristic with the statistical and spatial analysis. We define the elasticity and formula from the perspective of probability, the result has confirmed that this method's validity in dealing with travel problem with big data. As a whole, the residents' elasticity of departure time choices is more flexible and more elastic in Beijing. We also find that the elasticity of departure time choices has clear temporal and spatial differences. It reflects the temporal and spatial differences of residents' travel behaviour in Beijing. Based on the research of travel elasticity, it is helpful to further interpret different residents' social behaviour characteristics. The relationship between commuting distance and elasticity is inverted "U" type. Which means that the short distance traveller (commuting time takes 45 minutes or less), the shorter distance, the smaller elasticity. For long distance traveller (more than 45 minutes commuting time), the longer distance, the smaller elasticity. The elasticity of departure time choices is not only affected by the residents' individual characteristics, and also closely related to its spatial features. The elasticity is affected by many factors, mainly includes the traveller attribute, travel characteristic, transportation system, social economy, and other related environmental factors.

Key words:

Travel elasticity; travel behaviour; spatial-temporal characteristics; IC DATA; Beijing

The Effect Model of Multilevel Variables and Mechanism on Car Travel of Residents' Working-Day Activities in Guangzhou

Song Jiang Yu, Zhou Suhong, Song Guangwen

School of Geography and Planning, Sun Yat-sen University, Guangzhou, 510275, P.R. China, eeszsh@mail.sysu.edu.cn

Abstract

Urban residents' working-day activities are the direct reason for car travel. Under the stronger market effect on urban residential space, differentiation of residents' travel mode appears between communities inevitably. Previous stress on traveler individual attributes to explain the influence of car travel fatigue. And the existing residents travel data acquired by the method of stratified sampling, which results in its multilevel structure and statistical bias. For the sake of further analysis on car travel of work activities and maintaining activities in working day, it is necessary to build a Logit multilevel model which contains individual variables and community variables. It is concluded that urban residents' working-day car travel is influenced by multilevel variables. As for the individual level, lower personal income level, collective unit profession, less minors in a family, less family housing area and shorter travel distance may help refrain the choice of automobile travel. As for the community level, improving bus stops density, floating population proportion may help reduce car use ratio of two types of activities' travel. The community elderly population increase to reduce car use in work activities while it has less impact on maintaining activities' travel. The increased land mixing degree and decreased business center distance may reduce automobile travel in maintaining activities, while these don't have significant impact on work travel. These conclusions help us to have a deeper understanding of the mechanism behind the urban residents' working-day car travel and provide suggestions to alleviate the traffic problem by adjusting the multilevel variables.

car travel; community differentiation; multilevel variables; GuangZhou

The Relationship between Icts and Flexibility of Daily Activity and Travel: A Case Study of Beijing, China

Yue Shen, Na Ta, Yanwei Chai

The Center for Modern Chinese City Studies, School of Urban and Regional Science

East China Normal University, Shanghai, 200062, China, shenyue0519@163.com

Abstract

Information and communication technologies (ICTs) are playing a significant role in everyday life, and the relationships between ICTs and daily activity-travel behavior have been studied extensively. ICTs, especially mobile ICTs, make it possible to rearrange activity schedules more often, so it is argued the use of ICTs allow more flexibility in the spatiotemporal distribution of daily activities. However, the direct empirical studies are not sufficient, and how the use of ICTs influence temporal and modal flexibility of travels are still not clear.

This study examines how ICTs become embedded in the practice of everyday activities and travels, and how ICTs influence the flexibility of individuals' activities and travels. 7-day activity-travel diaries of 709 respondents in Beijing suburbs collected in 2012 were used, and the use of ICTs for each activity or travel was asked. Using multilevel models, this study discusses how daily ICT use influence the flexibility of individuals' daily schedule, and how ICT use influence the flexibility of activities and travels, after the socio-economic attributes of individuals and the attributes of activities and travels are controlled for. The role of ICTs in everyday lives and some possible application directions are discussed.

ICTs; activity; travel; flexibility; Beijing

The Social Implications of Home-Work Separation: Investigating the Links of Commuting and Neighborhood Social Capital of Low-Income Residents in Beijing, China

Liu, Z., Zhang, Y.

School of Public Policy and Management, Tsinghua University, Beijing 100084, China, zhilinliu@tsinghua.edu.cn

Abstract

In developed and developing countries alike, scholars have endeavored to theorize and test the adverse impacts of urban spatial restructuring on the daily life of low-income residents. Recently, empirical literature has shown that Chinese urban residents also began to suffer from declined job accessibility and endure longer commuting amid dramatic urban expansion. However, empirical evidence is often limited to commuting behavior without fully accounting for how commuting may link to the social experiences of low-income residents.

In this paper, we seek to extend from this literature by further revealing the adverse impacts of home-work separation on neighborhood-based social capital building of low-income residents in urban China. Using data from a household survey in nine low- to moderate-income neighborhoods in Beijing in 2010, we examine to what extent longer commuting may lead to a lower level of neighborhood-based social capital and sense of attachment possessed by a low-income resident? Statistical analysis from structural equation modeling reveals that those low-income residents who have never moved since 1988 or those who relocated only because of government housing programs tend to endure longer commuting distance and time, and that long-distance or ‘early-bird’ commuters are less active in neighborhood-based social interaction, thereby possessing a lower level of neighborhood attachment. Planning measures aiming at reducing home-work separation may lead to such additional benefits as to mitigate the decline of neighborhood social capital in Chinese cities, thus contributing to the human-oriented, harmonious urbanization agenda.

Key words:

Spatial mismatch; commuting; neighborhood social capital; low-income residents; Beijing

The Study on the Temporal-spatial Characteristics of the Activities of Quanzhou Residents at Night

Chen jing, Zhou C S

School of Geography and Planning, Sun Yat-sen University, Guangzhou, 510275, P. R. China, 751372996@qq.com

Abstract

This paper is concerned with activities at night, which has long been neglected in geographical studies in china. Based on the questionnaire survey and interviews of Quanzhou residents, the authors analyzed the type of the activities at night, especially their temporal-spatial characteristics. Consumer activities, leisure activities and learning activities are the main types of activities of Quanzhou residents at night. Further, the author made correlated analyses in terms of residents' attributes. The characteristics of these activities of Quanzhou residents at night can be summarized as follows:(1)the consumer activities of Quanzhou residents at night flourish in general and the average consuming time does not last long and the frequency of consuming activities at night is relatively low; and(2)the spatial characteristic of leisure activities at night is according to the distance decay law and can be abstracted as a concentric circle structure; and(3)the learning activities affected by the distance is not obvious, and the time characteristics of learning activities is fixed; and(4) the activity space of different types of activities at night also varies.

Key words:

activities at night; time rhythm; spatial structure; Quanzhou city

Three Types of Commuters towards Suburb and Their Commuting Behavior

Features: A Case Study of Shangdi-Qinghe Area in Beijing

MA Xinlin, Chai Yanwei

College of Urban and Environmental Sciences, Peking University, Beijing, 100871, China, maxinlinpku@foxmail.com, chyw@pku.edu.cn

Abstract

In the process of functional transfer of job centres, from inner city to suburb area in urban China, supporting service and facilities lags far behind the development of industry. As a result, it creates diverse commuting patterns, including reserve commuting (from suburb to inner city), parallel commuting (from suburb to suburb), and traditional ones (from inner city to suburb). To depict these three types of commuters helps us understand commuting space, suburb area centred.

This research carries out a case study of a typical suburban new town in Beijing, resulting from the GPS-based activity diary data collected in 2012 and the data of transportation network and POIs. The paper applies a spatial-temporal analytical method, along with proposing a conceptual model. It aims to reveal the commuting features, of 229 suburban job seekers of three types, who work in Shangdi-Qinghe area. Further, to illustrate their status of job-housing balance, to demonstrate the interaction of suburban commuting space and its geographical background.

This empirical study was found that 1) public transportation is the first choice of suburb commuters, especially the traditional commuters; 2) among parallel commuters, stationary activity tends to be more varied and frequent in the evening; 3) commuting time and distance is largely affected by commuting patterns, following are income, age and gender. The findings confirm that urban sprawl structure of Beijing is still dominated by inner city, suburban employment and supporting facilities greatly lags behind the speed of industrial development, which leads to the dislocation of the living space and employment space, traffic congestion and so on.

Key words:

space-time behavior; commuters; suburban China

Understanding the Suburbanization of Daily Activity Space: Case Studies from Three Suburban Areas in Beijing

Zhang Y.¹, Chai Y. W.²

¹ The Institute of Beijing Studies, Beijing Union University, Beijing, 100101, P. R. China, yanzhang@buu.edu.cn

² College of Urban and Environmental Sciences, Peking University, Beijing 100871, P. R. China, chyw@pku.edu.cn

Abstract

In the last three decades, there have been experiencing rapid suburbanization in most large Chinese cities, such as Beijing, Shanghai and Guangzhou. A large number of studies had already focused on the suburbanization process of urban population, manufacturing industry, office industry, retailing industry et al. and its implications on the changing urban spatial structures at the macro-level. However, less attention had been paid to the suburbanization of daily activity space at the individual level, which revealed the functional link between the suburb and the other urban space through individuals' activity and travel pattern.

This paper attempts to reveal the relationship between suburban areas and other parts of urban areas in Beijing by investigating the space-time activity and mobility pattern of the inhabitants of suburban districts. How individuals' daily activities were spatially and temporally allocated at different urban space, such as their homes, suburban neighborhoods, other suburban areas, central area, city center? And how individuals traveled among these territories to fulfill different activities? Are there any differences between weekdays and weekends? The empirical data utilized in this paper are primarily based on two GPS-facilitated activity-travel survey datasets successively collected at Tiantongyuan and Yizhuang in Beijing in 2010 and at Shangdi-Qinghearea in Beijing in 2012. Everyday context, geographical context as well of social context of resident's daily activities were visualized and made comparisons within time-geography framework. Finally, we found these three suburban areas were quite different from each other in the degree of suburbanization of everyday life and in term of suburb-city relationship.

²Department of Urban and Economic Geography, College of Urban and Environmental Sciences, Peking University, Beijing 100871, China

Abstract

Recent urban development in China suggests significant departure from the traditional high-density, pedestrian- and cyclist-oriented urban form that used to characterize Chinese cities. While there are many differences between Chinese and U.S. cities, the rapid rate of suburbanization and increase in car dependence in China seem to be leading to urban issues that are also common in U.S. cities. These issues include worsening jobs-housing balance, longer commute time and distance, traffic congestion, and air pollution. This presentation explores how urban form, car ownership, household structure, and individual attributes like gender may influence people's activity-travel behavior and activity space in the context of suburban China. Based on recent case studies of cities in China and the U.S., it explores the implications of recent suburbanization trends for sustainable urban development in China.

Analysis of the Built Environment of Urban Primary School Service Circle Based on Household Pick Up Behavior

WANG X,

Xi'an University of Architecture & Technologies, Xi'an, 710055, P. R. China, wangxia@xauat.edu.cn

Abstract

Urban primary schools are social public welfare resource whose spatial allocation has great influence on social justice, family life quality and urban structure. The spatial allocation principles of China's primary school are greatly affected by "neighborhood units", and the regional and scale spatial allocation is based on service radius and service population over a long period of time. However, it lacks the viewing on the rationality of public service facilities layout from the behavior pattern of residents. In recent years, urban built environment are changing greatly and the ways of traveling between home and school are becoming diverse. Taking Xi'an as an example, the study selected three types of urban primary school on a basis of different built environments and attributes of urban primary school, and defined the research scope of urban primary school service circle as a range of 15 minutes walking or public transportation. It analyzed the influence of the built environment on travel behavior of home-to-school to establish the foundation for the improved urban primary school layout which promotes household low-carbon travels. (Foundation: National Natural Science Foundation of China, No 51178371)

² Wuhan Urban Planning and Land Administration Information Center, Wuhan, China

Abstract

Jobs-housing spatial distribution is one of the most important factors for shaping a city's spatial structure. In the past decades, researches mainly concern with the distribution and the dynamic change characteristics of jobs-housing space, urban commuting, and the population and land use. Less study has been carried out on the spatial relationship between employment and residence.

Based on Wuhan Social Security Information, the sixth census and the third economic census data, the study is carried out from the systematic maxims, such as the total jobs-housing ratio, independent index, outgoing commuting rate, and inward commuting rate. The paper analyzes and evaluates the spatial features and jobs-housing matching relations in the peripheral areas, main city, and new town groups of Wuhan, summarizes and tests the problems existing in the jobs-housing space.

Through the results we found that: The jobs-housing mismatch situation of Wuhan is not serious, but not better than that of based on the questionnaire; Population and employment are still concentrated in the central city; Residents are still gathering in the main city; Different spheres of the jobs-housing space match well generally; The functional groups of main city is quite different; walking and public transportation are major means for urban commuting, which happens in the contiguous town groups.

Jobs-housing characteristics have great impact on urban distribution and mobility. Reasonable spatial distribution of employment and residential location needs to be achieved by improving urban land use planning, housing policies, and urban transport networks.

Key words:

jobs-housing space; jobs-housing characteristics; jobs-housing mismatch; Wuhan

Comparative Research of Cross-Strait Industrial Community Form- Illustrated by Two Industrial Communities in Beijing and Kaohsiung

Chang Chiao-Fen, Chai Yenwei

Department of Urban and Economic Geography, Peking University, Beijing, 100871, China, jovanna1015@gmail.com

Abstract

Since the Nationalist Government moved to Taiwan in 1949, cross-strait policy regimes have been deeply impact on local development and residential forms. Also, there are special close relationships between the differences of residential forms and the life style of the residents. Research of the urban space relies on the relationship between human and society-space, it is the container of people's social life, but it also restricts people's social life style. Therefore, research on community forms must take the human-centered guideline and consider the fundamental problems such as the mutual relationship between individuals and between human and environment.

This article focuses on cross-strait industrial communities which emerged during the industrialization periods. We select two cases, one is Kaohsiung Refinery of CPC Corporation in Taiwan and the other is Beijing No. 2 Textile Factory in Mainland. We merge the behavioral geography research method into the Conzenian approach in urban morphology. To understand the relationships between the work, shopping, travel, leisure behavior and the land use. To conclude how the non-physical factors such as economy, culture and policy affect residents' behavior. To clarify the relationships between residents and environments, and interpret the interaction mechanism between residents' behavior and the urban community form from a microscope perspective. Further reflects on the city's growth and spatial evolution of cross-strait, and puts forward a new view point of urban morphology studies: the comprehensive urban morphology could be composed by behavioral space and physical space.

Key words:

cross-strait; industrial community; urban morphology; Conzenian; behavioral space

Considering the Fast Charging Duration and Queue Time in Locating Electric Vehicle Charging Stations

S.L. Zhang, K. Liu, J. Pang

School of Transportation and Logistics, Dalian University of Technology, Dalian, 116024, P.R. China,

18940845076@mail.dlut.edu.cn

Abstract

As a key feature of Electric Vehicles (EVs), the relative longer charging duration aggravate the uncertainties of temporal and spatial energy demands distribution. Therefore, the precise prediction of EV charging duration definitely have a significant influence on the EV charging station launching strategy, which will help energy providers to make a feasible plan for network design. However, the feature mentioned above is always ignored in previous models. This paper presents an integrated model that combine a duration model for predicting fast charging duration and queue time and a multi-agents simulation based optimization model for location charging stations. A total of 209 EVs' GPS tracking data were recorded from Japan, which is used for understanding the duration time of fast charging and the choice of charging stations. To develop the duration prediction model, this study utilizes the Gamma accelerated failure time (AFT) model to investigate the relationship between the fast charging duration and the impact of factors, such as residual SOC, charging quantity, usage of air condition and heater, expected remained distance and so on. The proposed model aims to reproduce the EV drivers' choice behavior during the fast charging and, therefore, to optimize the locating problem.

Key words:

ElectricVehicle; fast charging duration; AFT model

Differentiation in Daily Activity Spaces of Residents on the Scale of Residential Area in Transitional Xining, China

LIU Bochu¹, Chai Yanwei^{2,1}, Wang Xiaomei², TAN Yiming¹

¹School of Urban and Environmental Sciences, Peking University, Beijing, 100871, P.R.China, hjjf@pku.edu.cn

²School of Life and Geographical Sciences, Qinghai Normal University, Xining, 810008, P.R.China

Abstract

From the perspective of daily activity space, we can explore social space differentiation of Xining city in transition from individuals with the aid of indicators measuring activity space, as well as reveal the roles Danwei and new town development play in differentiation of social space. In this paper, where 5 different types of residential areas are surveyed and analysed, trend surfaces of spatiotemporal activities illustrate spatiotemporal distribution of daily activities, and indicators of activity space demonstrate characteristics in area, spatial concentration and relationship to residence. Research shows that unique built environment in Xining city leads to more short-distance and directional travel of residents. The location and socio-economic properties of residential area are important factors influencing the range of areas representing residents' activity spaces. Activity spaces of residents in Commercial Housing Residential Area coverage those of Danwei and Compound Residential Area; activity spaces of residents in Danwei Residential Area appear higher spatial concentration than those of Commercial Housing and Compound Residential Area. It is implied that residents in suburban residential area acquire greater range of area of activity space than urban residents while residents living in the city gain higher rate of spatial concentration than suburban residents.

Key words:

daily activity space; differentiation; residential area; residents; Xining

National Demonstration Zone of Ecological Protection and Construction of "Production-Eco-Life" Space Optimization Analysis: A Case Study of Ji'an City in Jiangxi Province

Huang K-C, Ma D-G

Jiangxi Normal University, Nanchang, 330022, P. R. China, dgm7799@163.com

Abstract

The combination of ecological protection, urban development, spatial distribution and other related theories, scientific definition of production space, living space, meaning on the basis of ecological space, based on Ji'an city, profile, based on space evaluation model of the "San Sheng" spatial Division index system, using technologies such as GIS, remote sensing and mathematical statistics methods, quantitative delimitation "San Sheng" space. Through field research, combined with the Township development planning system, amended the programme in township on quantity, resulting in Ji'an city, "San Sheng" spatial Division. Eventually construct "San Sheng" legal guarantee system for spatial, ecological assessment mechanism; clear compensation rules, building ecological compensation policy platform and red line, ecological constraints, such as the red line, aimed at building intensive and efficient production of Ji'an city spaces, livable a moderate amount of living space, a beautiful eco-space, in order to achieve the optimal development of their production, living and ecological space.

Key words:

spatiotemporal analysis; ecological space; urban development

Overview of Residents' Daily Activity Spaces Research in the Perspective of Space-Behavior Interaction

Jian Jiao

College of Architecture, Xi'an University of Architecture & Technology, Xi'an Shaanxi, 710000, P.R.China,
13759915102@163.com

Abstract

In the process of transformation from quantity expansion to quality improvement, how to improve the quality of urbanization and the quality of residents' life has become the focus of academic research in China. As the projection of residents' daily activities, daily activity space reflects the quality and space utilization of urban space directly and meanwhile is an important medium to understand the interaction between living activities and urban space, associated with sustainability issues such as social exclusion, transportation equity and social isolation, and thus received attentions from human geography, urban planning, sociology and other fields. The domestic researches on daily activity space is developed under the support of the theory of behavioral geography and activity-based approach in the West. This paper reviews the evolution of research contents, methods and theoretical foundations of daily activity space and summarizes the existing problems in the current researches and challenges, to provide inspiration and reference for future research of space-behavior interaction.

Key words:

daily activity space; behavioural space; behavioral geography; space-behavior interaction

Product Follows Behavior: A Tourism Time Product Planning Approach

Xiaoting Huang

Shandong University, Jinan, 250100, P. R. China, satinhuang@sdu.edu.cn

Abstract

By discussion about the relationship between tourist spatial-temporal behaviour and tourism products, this paper puts forward the concept and logical framework of tourism time product advocating planning idea of “Product Follows Behaviour”, and shows the feasibility of the new tourism time product planning approach using a case study of Ocean Park Hong Kong. Based on the GPS tracking investigation and analysis of the tourists in Ocean Park, subject areas and product types of Hong Kong Ocean Park which need to be adjusted are recognized according to the spatial and temporal distribution characteristics of tourists and tourist spatial-temporal behaviour patterns. And then a preliminary tourism time product plan and combination of tourism product plan are proposed as to the data analysis results. From the perspective of methodology, this paper contributes a new approach of tourism product planning under the framework of tourism time planning, which diversifies the theories and methods of tourism product planning. From the perspective of planning practice, the approach of tourism time product planning provides a new perspective and tool for the tourism product planning practice, which supports the innovation of tourism product planning theoretically and technically.

Key words:

tourism time product; tourism time product planning; tourism planning method; tourist spatial-temporal behaviour

Research of Spatiotemporal Variation Characteristics of Dunhuang's Night Market

DONG Xiao-feng^{1,2}, ZHENG Yi², LI Yan-yan¹, HU Wen-bo¹

¹School of Architecture and Design, Urban Planning and Design Research Institute, Beijing Jiaotong University, Beijing 100044, China

²College of Earth and Environmental Sciences, Lanzhou University, Lanzhou, Gansu 730000, China

Abstract

Many foreign cities have made the night economy as the important strategy of urban space rejuvenation and economic revitalization. The night economy is a focus and a new research hotspot of domestic and international urban development. The night economic activities have obvious characteristics of the time, but they have intersections in the space and the city during the day and space in economic activity, it is also influenced by the climate and other environmental conditions, and makes the time and space of the night economy with different characteristics. The night economy of the tourist cities is the most typical type, and their space and time of the activities are closely related to the tourist activities. The night market in Dunhuang is a beautiful landscape in Dunhuang, and the regularity and climate of the tourism industry in Dunhuang night market are more and more evident.

Based on the social investigation method, this paper provides the market research and questionnaire analysis, discussing the spatial structure features in Dunhuang night market, the operations and customer activity rules, from the 'daily cycle', 'half of the week - week in short-term cycle', 'annual cycle' of three typical time scale in the tourist season in Dunhuang. This paper analyses the operations and customer behavior of the time and space characteristics, revealing the characteristics and rules of time and space in Dunhuang night market.

The results show that, 1) The Dunhuang night market plays an important role in economic development and urban construction in Dunhuang; 2) the night market is comprehensive and functional zoning; 3) The development in Dunhuang night market is suffered indignities about temperature environment effect, and it changes periodically; 4) The night market structure of the time and space continues to adapt the demand in the market and reform perfectly.

Key words:

night economy; spatial structure; temporal-spatial change; Dunhuang night market

Research on Temporal and Spatial Decision-Making Process and influencing Factors of Residents' Comprehensive Shopping Behavior: A Case Study of Guangzhou Based on Consumer Survey in 43 Shopping Malls

Chenhao Fu, Suhong Zhou

School of Geography and Planning, Centre of Integrated Geographic Information Analysis, Sun Yet-sen University, Guangzhou, 510275, P. R. China, 806400070@qq.com

Abstract

In China, urban residents' consumption is experiencing a shift from single shopping function to comprehensive consumption combining shopping, catering, leisure and recreation. In this context, temporal and spatial decision-making process of shopping behaviour has become a focus of certain fields such as urban geography, urban planning, urban sociology and urban economics. Although scholars both at home and abroad have discussed whether the different factors, such as social and economic properties, commercial location and commercial space characteristics, have significant roles in the decision-making process of shopping behaviour, they failed to explain whether there is a mutual influence between the certain factors, as well the research on the impact of emerging influencing factors, such as online shopping, development of emerging business format on shopping location decision is relatively lack. In this paper, we conclude the related influencing factors of residents' comprehensive shopping behavior decision-making and then put forward the conceptual model on temporal and spatial decision-making process of shopping behavior. Based on the residents' shopping decision-making theory, the data from the interview and questionnaire survey on residents' shopping behavior in 43 shopping malls, and the established structural equation model, this paper analyses the residents' decision-making process and its influencing factors in the following four aspects: shopping starting time, shopping destination, shopping travel mode, and potential scope of shopping activities. Conclusions of this paper can provide theoretical suggestions on optimizing the urban commercial space hierarchy, improving shopping transportation and promoting the quality of residents' daily life.

Key words:

comprehensive shopping behavior; temporal and spatial decision-making process; structural equation model; shopping mall; Guangzhou

Scaling Law between Mobility and Facility: Spatiotemporal Data Mining of Guangzhou Subway Data

Shili CHEN, XunLI, HaohuiCHEN

Sun Yat-sen University, Guangzhou 510275, P.R. China, slchen@126.com

Abstract

With the acceleration and intensification of China's urbanisation as well as its continuing urban population growth, needs for necessary city facilities have been changing accordingly. While relevant research has pointed to a correlation between urban population and the associated facilities, this paper takes Guangzhou as an example and explores the scaling relationship between census data and the point of interest (POI) data at the street-office/town level across the city. Drawing on statistical data from every subway station in Guangzhou, it makes use of correlation analysis and multiple regression model to investigate the correlations between various POIs surrounding the subway station, the dynamic data of subway mobility, and the power law exponent of static population data. Research findings show that: (1) there exists a relationship of $D \sim \rho^{2/3}$ between the population in every street-office area/town and the amount of its urban facilities across Guangzhou; (2) the types of facilities provided near and around subway stations have indicated a similar pattern; and (3) the power law relationship between the dynamic data of subway mobility and the POIs from subway surroundings is rather insignificant. This research reveals that the density of not-for-profit facility tends to decrease along with the increase of population, whereas for-profit facilities bears a super-linear relationship to population. As people's mobility pattern is an indication of whether facilities are appropriately provided in the city, this research represents an effort along this line to offer some useful evidence for better urban planning.

Scaling law; subway data; point of interest; dynamic mobility; Guangzhou

Scenario Simulation and the Prediction of Land Use and Land Cover Change in Beijing, China

Huiran Han^{1,2}, Chengfeng Yang², Jinping Song²

¹College of Territorial Resources and Tourism, Anhui Normal University, Wuhu, 241002, P. R. China, hanhuiran@163.com

²School of Geography, Beijing Normal University, Beijing, 100875, P. R. China, phoenixycf@mail.bnu.edu.cn; songjp@bnu.edu.cn

Abstract

Land use and land cover (LULC) models are essential for analyzing LULC change and predicting land use requirements and are valuable for guiding reasonable land use planning and management. However, each LULC model has its own advantages and constraints. In this paper, we explore the characteristics of LULC change and simulate future land use demand by combining a CLUE-S model with a Markov model to deal with some shortcomings of existing LULC models. Using Beijing as a case study, we describe the related driving factors from land-adaptive variables, regional spatial variables and socio-economic variables and then simulate future land use scenarios from 2010 to 2020, which include a development scenario (natural development and rapid development) and protection scenarios (ecological and cultivated land protection). The results indicate good consistency between predicted results and actual land use situations according to a Kappa statistic. The conversion of cultivated land to urban built-up land will form the primary features of LULC change in the future. The prediction for land use demand shows the differences under different scenarios. At higher elevations, the geographical environment limits the expansion of urban built-up land, but the conversion of cultivated land to built-up land in mountainous areas will be more prevalent by 2020; Beijing, however, still faces the most pressure in terms of ecological and cultivated land protection.

Key words:

LULC change; spatial pattern; CLUE-S model; Markov model; scenario simulation and prediction; Beijing

The Socio-Spatial Dimension of Behavior Analysis: Frontiers and Progress in Chinese Behavioral Geography

Yanwei Chai^{1,2}, Na Ta³, Jing Ma⁴

¹Department of Urban and Economic Geography, College of Urban and Environmental Sciences, Peking University, 100871, P. R. China

²Qinghai Normal University, Xining, 810008, P.R.China, chyw@pku.edu.cn

⁴School of Geography, Beijing Normal University, Beijing, 100875, P.R.China

Abstract

The interaction between urban space and individual behavior has led to essential social, economic and environmental consequences. Behavioral geography provides a new effective theoretical and methodological framework to investigate behavior patterns in cities. In recent years, behavior approach has become an influential analytical paradigm in Chinese urban geography, as urban geographers and planners have attempted to interpret the dynamic interactions between individual life experiences and urban socio-spatial transformations. This paper provides an overview of behavioral geography research in China, by introducing the theoretical and empirical progress in behavior analysis. It is argued that behavioral approach offers a new perspective to understanding China's urban socio-spatial reconstruction and addressing social and environmental issues at micro scale. This paper also provides an overview of new trends in Chinese behavioral geography that has started to apply the behavioral approach to urban social, economic and environmental issues. It is suggested that social dimensions of behavior should be addressed more comprehensively and rigorously by using interdisciplinary theoretical and methodological frameworks, to better understand the critical social and environmental issues of Chinese cities.

Key words:

Behavioral geography, socio-spatial reconstruction, urban sustainability, Chinese cities

The Time-space Matching of Community Facilities Supply and Residents' Demand in Beijing Suburbs

Yibo Duammu, Yanwei Chai

College of Urban and Environmental Sciences, Peking University, Beijing 100871, P.R.China

Abstract

The community is the basic space carrier for people's daily activities and the smallest unit in urban planning. The supply of facilities is closely related to the quality of life of residents. Most of the community planning practices in China are according to 'Thousands of indicators', which overlooking the residents' demand, and cause many problems such as mismatch of community facilities supply and residents' demand, ignoring of the facilities' opening time and so on.

The study employs the data of 2012 GPS-based activity-travel survey in Beijing, and the samples include 480 residents in Qinghe who live in suburban area. By combining behavior geography, time geography, and using methods of statistics and space-time GIS, this paper analyses the spatial and temporal characteristics of residents' outdoor activities, and the residents' demand of different kinds of facilities. Based on the findings, this paper chooses a community, which named Qing-Shang Park, as a sample to analyze the spatial and temporal characteristics of community facilities supply and the demand of residents. By comparing the facilities supply and demand, this paper tries to find out whether the facilities supply can fit residents' demand in this community.

The study shows 1) there is a strong corresponding relationship between the distribution of different kinds of activities and the related facilities; 2) the demand structures of residents from different communities are different; 3) the demand structures of residents varies in a day, for example, the demands for restaurants concentrate in the moon and evening. The findings can guide us to achieve a more rational allocation of community facilities supply in time and space.

Facilities; Activities; Space-time Behavior; Supply and Demand Matching

Transformation Pattern and Influential Factors of Mature Coal Resource-based City Based on the Perspective of Social Space: A Case Study of Huainan city in Anhui province

HuafuJIAO, JiliXU

College of Territorial Resources and Tourism, Anhui Normal University, Wuhu, Anhui,, 241003, P. R. China,

jiaohuafu@263.net

Abstract

Under the background of new industrialization, new-type urbanization and ecological civilization construction, comprehensive transformation and sustainable development of resource-based city has become a significant strategy. Avoiding transformation of mature resource-based cities will effectively promote the prospective, scientificity and operability of resource-based cities' transformation development. Based on the perspective of social space, taking Huainan city as an example, dividing urban regional function structure, analyzing urban transformation-level and exploring influential factors. Results indicate that: 1) Urban regional function structure of Huainan city consists of five functional groups, polarization effect of urban transformation has not formed, single approach, dependent path, limited space and hysteretic notion make up the overall pattern, 2) Administrative clerk, commercial service staff, people who get a graduate degree, 20-39 year-old individuals, exotic shifting people and purchasing commercial houses are the main 5 factors which drive transformation, the path should be converted from service as a single drive to technology and innovation as multiple drives, it is considerable to positively boosting the process of new city areas, urban-rural integration and rural towns' living quality in mining districts, 3) Social service industry staff drive rural commercialization and agricultural modernization, young people lead social culture and elaboration of mining industry, exotic people promote the status of third and alternative industry and propel multi-core transition of urban space will become effective scientific transformation paths of Huainan city in the future.

Key words:

Resource-based city; Coal resource-based city; Social space; Urban transformation; Huainan city

A Comparative Study for the National Man-land Relationship

Zhang L¹, Liu Y¹, Yang B²

¹ Institute of Geographic Sciences and Natural Resources Research/Key Laboratory of Regional Sustainable Development Modeling, Chinese Academy of Sciences, Beijing 100101, China

² Beijing Academy of Social Sciences, Beijing, 100101, China, yangbo@igsnrr.ac.cn

Abstract

As a part of the earth's living creatures, our human has been making use natural resources and environment as its first need for survival and development, and this remains all the same, even in the modern period. In fact, with the rapid growth of social wealth and population, maintaining a stable of the so-called man-land relationship is always the primary task and basic goal for national sustainable development, especially for big countries. An integrated factor analysis covered natural endowment (fresh water, arable land, grass land, wood land, energy and minerals) and human activity (population, GDP and CO₂ emission) shows that there has one thing in common for all the 11 selected countries (>100 million people). Under the polarization effects of natural resources use, the national man-land relationship of these countries today have been proven to be aggravating and worsening in various degree, although the characteristics of their natural endowments are very differences. Regarding such changes, the Japanese practice is of the most convincing.

Key words:

national man-land relationship; natural endowment; integrated factor analysis

A Dea-Based Analysis for Regional Eco - Efficiency of China from 2005 to 2014

Xiaoxue Zhou, Jiancheng Chen, Guo Feng Wang

College of Economic Management, Beijing forestry University, Beijing, 100083, China, Chenjc_bjfu@hotmail.com

Abstract

Eco-efficiency is an instrument for sustainability analysis, indicating how efficient the economic activity is with regard to nature's goods and services. This paper conducts an eco-efficiency analysis for regional socio-economic, resource consumption and environmental management in China by developing data envelopment analysis (DEA) based models, which reflect the efficiency of utilizing natural resources and improve the estimation accuracy. From a macroscopic point of view, the measure and evaluation were made upon regional eco-efficiency in 30 provinces in china from 2005 to 2014. Special attention was paid to resources and energy consumption, waste emissions as inputs, Gross Domestic Product as outputs. The results also show that, Beijing, Tianjin, Shanghai, Guangdong and Hainan are relatively eco-efficient, and provinces with higher level GDP per capita will have higher eco-efficiency than other regions. The study provides the updated data with high equality and makes comparative and complementary for other researches.

Key words:

Eco-efficiency; Data envelopment analysis (DEA); environmental management; China

Adaptive capacity based water quality resilience transformation and policy implications in rapidly urbanizing landscapes

Yi Li¹, Jan Degener¹, Matthew Gaudreau², YangfanLi³, Martin Kappas¹

Abstract

Resilience-based management focuses on specific attributes or drivers of complex social-ecological systems, in order to operationalize and promote guiding principles for water quality management, and predict potential threats and vulnerabilities of the urban system. We therefore propose a resilience lens drawing on adaptive capacity theory to evaluate the urban resilience between water quality and land use type in relation to urban development plans. Our findings show that: (1) The resilience of water quality variables, which were calculated based on their adaptive capacities, showed adaptive and sustainable trends with dramatic fluctuation; (2) NH₃-N, Cadmium and Total Phosphorus experienced the most venerable shifts in the built-up area under rapid urbanization; (3) Analogous resilient transition states occurred in the agricultural and bare land; (4) National and regional planning practices (City Development Plan and China's Five-Year-Plan) contribute to ongoing shifts (Ammoniacal Nitrogen, Cadmium, Total Phosphorus and Oil) in different resilient transition states. Ultimately, we pointed to political underpinnings for building and managing resilient urban system in a particular coastal urban setting.

Abstract

China's urbanization has faced serious water problems as a result of economic growth and some development projects and it is widely thought that integrated management, including socio-economic factors in each basin unit, is effective. Hence, the target of this paper is to evaluate the structures of water demand and water pollutant discharge with socio-economic activities in the City of Shanghai. First we have developed a methodology for estimating water demand and water pollutants (carbon, nitrogen and phosphorus) based on an input-output analysis model, and then applied it to the City of Shanghai. As a result, we conclude that industry is the largest source of water demand and water pollutants in the City of Shanghai and accounts for more than 50% of the total of each. Water demand from agriculture, forestry and livestock accounts for 35% of the total, and about 20% of water pollutants are discharged from agriculture, forestry and livestock. Furthermore, water pollutants from households constitute more than 20% of the total in the City of Shanghai though water demand and wastewater account for less than 15% of each total. In addition, it becomes clear that about 20% of the water demand and water pollutant discharge in the City of Shanghai is caused by other provinces and foreign countries, with most of the demand and discharge being industrial.

Assessing spatial vulnerability from rapid urbanization to inform coastal urban regional planning

Yangfan LI¹, Xiaoxiang ZHANG²

¹ Key Laboratory of Coastal and Wetland Ecosystems (Ministry of Education), College of the Environment & Ecology, Xiamen University, Xiamen, 361102, P. R. China, yangf@xmu.edu.cn

² Institute of Geographical Information Science & Engineering, Hohai University, Nanjing, 211100, P. R. China

Abstract

This study delves into the development of a Geographic Information System (GIS) based vulnerability assessment tool for assessing coastal vulnerability and making prescriptive recommendations on urban planning in coastal regions at a local level. The framework of "exposure-sensitivity-resilience" (ESR) is not only applied, but also improved and refined to take into account a suite of social-ecological indicators. The results demonstrate that vulnerability was not evenly distributed across Haikou's coastal zones, which may be linked to the different stages of ongoing urban planning for coastal Haikou. For the case study areas, vulnerability tends to increase with higher levels of urbanization, but may decrease once the speed of urban expansion is under control. The most vulnerable area is the main city zone where urban residents are concentrated and a developed transportation network exists. Our study contributes to the development of a general methodology to assess vulnerability in rapid urbanization and to apply it to coastal cities around the world.

Abstract

Insitu urbanization is a phenomenon of population and settlements transition from rural pattern to urban or quasi urban pattern without large scale migration. In southern Jiangsu area, Cutinisation is one of the significant characteristics of insitu urbanization, which is also a considerable cause of timing and stage diversities of urbanization on employment, residence and social security dimensions. This paper conducts in-depth analysis on insitu urbanization characteristics of local family based on a case study of Xinjie township and its surrounding villages in Yixing, Wuxi City. The research reveals that during insitu urbanization process, the township has been expanding with mainly industrial lands, and some commercial housing estate and resettlement communities emerge recently, while the villages have always been all residential lands. The huge influx of external population and arrangement for relocation household has complicated the social space instead of displacing local residents. It is remarkable that the identities of local rural family members are transiting from farmers to citizens reflected by three aspects: (1) Most local family members are able to obtain jobs and education in need within 30-minute distance. while a few members of some families still have to migrate far away for better or higher education; (2) Housing Demolition and Relocation is the main reason that forced local families to migrate to township, which is rarely consistent with neither their will of choice nor their consumption capacity; (3) Urban social insurance coverage for rural families has been increasing, though, the gap between family members still remains significantly.

Citizenization; Local Family; InSitu Urbanization; Rural Area

Demodernization and Development: Transformations of Uzbek Urbanism

Wolf, G

Manchester Architecture Research Centre, The University of Manchester, Manchester, England,
Garrett.Wolf@postgrad.manchester.ac.uk

Abstract

This research looks at the co-production of urban space and urban everyday life in Uzbekistan during the periods/processes of demodernization and urban development that followed the fall of the Soviet Union. These processes lasted approximately from 1991-1998 and 2008-present respectively, and involved significant changes to the production of urban space and urban everyday life.

Using spaces and structures this study looks at how networks produce physical, mental and the social urban spaces in Samarkand and Tashkent. I analyze changing networks, and processes of demodernization and urban development, since the fall of the Soviet Union, and how they altered how space is conceived, perceived, and lived in urban Uzbekistan. Samarkand and Tashkent possess diverse urban forms resulting from varied histories and Soviet interventions, and thus differing relations of social and spatial production. Samarkand retains much of its historic urban form, which is predominantly influenced by Persianate urbanism. The city of Tashkent, following extensive damage by an earthquake in 1966, was then rebuilt by the Soviet government, and remains a prime example of a Soviet built city.

Exploring how urban everyday life in Uzbekistan interacted with the form and the condition of urban Uzbekistan in various periods of time and undergoing various processes allows us to see how urban transformations impact form and practice of the urban. This comparison across both space and time can illustrate changing relations of actors and how space and practice interact within these relations to co-produce urban spaces and structures in Uzbekistan.

Dynamic changes of ecological footprint and its component analysis response to land use in Wuhan, China

Xiaowei Yao

China University of Geosciences (Wuhan) , yaoxwcug@hotmail.com

Abstract

Human's demand for biological resources and energies has always been increasing, whereas evidence has shown that this demand is outpacing the regenerative and absorptive capacity of the planet. Since China is experiencing unprecedented urbanization and industrialization process, how much impact it imposed on the earth system during economic development is worldwide conspicuous. Therefore, we tried to examine the environmental impact in detail and track its changes in a typical city of Central China, Wuhan, based on ecological footprint analysis. Generally, the ecological footprint increased in fluctuations from 1.48 gha per capita to 2.10 gha per capita. The research revealed that the footprints of the productive lands increased most of the time in the region, especially the grazing land, water bodies, carbon uptake land and built-up area, showing there is greater impact on the ecosystem induced by human's manufacturing and consumption. Among the six footprint components, carbon footprint contributed most within the whole time period, implying a relatively high level of energy consumption. Comparing to the declining biocapacity, it was found that there existed gradually aggravated ecological deficit in the region, which increase from 1.12 gha per capita in 1995 to 1.79 gha per capita in 2008. As the population grows in the city, which already reached 10.33 million in 2014 from 8.33 million in 2008, the quick growth of energy consumption may lead to exaggeration of carbon footprint in future. The results implied that cutting down the consumption of fossil fuels could play a very important role in reducing the overall ecological deficit of the city.

ecological footprint; carbon footprint, biological resource; urbanization; Wuhan

Eco-efficiency assessment of cities in China: a stochastic metafrontier approach

Yuping Bai^{1,2,3}, Xiangzheng Deng^{1,2,*}

¹Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, China, dengxz.ccap@igsnr.ac.cn

²Center for Chinese Agricultural Policy, Chinese Academy of Sciences, Beijing, 100101, China

³University of Chinese Academy of Sciences, Chinese Academy of Sciences, Beijing, 100049, China

Abstract

With the rapid development of urbanization, inefficient natural resource utilization and massive energy consumption exerts great pressures on ecological environment. In this context, tremendous efforts have been devoted to seeking opportunities to reduce environmental impacts and improve productivity simultaneously, whereby assessing eco-efficiency has received more and more attentions by researchers and policy-makers alike. But to our knowledge, a common limitation of several previous studies is that they hardly take the variation of technologies caused by regional difference into account, thereby leading to the biased estimates and misleading policy implications. Moreover, conventional measures in China tend to focus on the provincial differences and almost no studies have researched at the urban scale. But in fact, urban eco-efficiency is more worthy of attention towards more efficient and sustainable urban development. In this paper, we measured eco-efficiency of China's 282 cities over the period from 2003 to 2012, using a parametric approach of stochastic frontier analysis (SFA). For further analysis, we introduced a meta frontier approach which assumes that a meta-technology-frontier exists and represents potential outputs available to all cities given inputs. The metafrontier is for four city groups, 1st-tier cities, 2nd-tier cities, 3rd-tier cities, and 4th-tier cities. We found that 1st-tier cities have the highest eco-efficiency score and take the lead in terms of metatechnology ratio while the 4th-tier cities is particularly low due to their backward technology. Moreover, the general approach of SFA, which ignores the technological difference among the groups, is prone to underestimate the eco-efficiency.

Ecological constraints of urban sprawl and land intensive use model - a case study of Dianchi Lake

Hong ZHANG, Jie JIN

Yunnan University of Finance and Economics, zhanghong0957@sina.com

Abstract

The sustainable development of regional economy and urbanization in Plateau Lake basins must limit the scale of City-Town-Village (CTV), conservation and intensive land, keep the ecological land and green space, in order to maintain a sound ecological system of Plateau Lake. In this paper, taking Dianchi River as an example, through constructing a theory framework that the ecological constraints of urban sprawl and land intensive use model, designing four scenario model of CTV' land use: the natural development、ecological constraints, intensive development, and the ecological-intensive development, using SLEUTH model to make empirical study. The results show: the ecological-intensive development scenario model is the optimal model, which coordinates the CTV' land intensive use and protection of the ecological environment in a plateau lake basins, and presents the relevant policy suggestions for the development of CTV in Dianchi basin. From the view of land use to explore a new approach of economic development and ecological protection in plateau lake urbanizing area.

Ecological Intercorrelation in Urban-Rural Development: An Eco-City of China

Zhan Wang^{1,2}, Xiangzheng Deng^{1*}, Pei Wang³, Jiancheng Chen²

¹ Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China, wangz@igsnrr.ac.cn, dengxz.ccap@igsnrr.ac.cn

² School of Economics & Management, Beijing Forestry University, Beijing 100083, China

³ Zhongnan University of Economics and Law, Wuhan 430073, China

Abstract

This study reveals that ecological intercorrelation in urban-rural area is a key role in changes of unobserved environmental effects of urban environmental pollution, energy use inefficiency, and cultivated land loss. In a deductive model, we find that inequivalent economic growth in urban-rural area results in the variability of eco-efficiency of industrial production in urban area, which increases the risks of environmental effect in adjacent suburban and rural area, and directly affects changes of unobserved environmental effect spatial-temporally. Through ecological intercorrelation, both observed and unobserved environmental effects in this dynamic mechanism are formed, consequently intensify the regional inequality of environmental pollution, and frustrate the future coordinative development of regional economy. By employing the data of a case study area in Gaoyou of China, estimations show that observed eco-efficiency is getting better but unobserved eco-efficiency is getting worse until this place becomes an eco-city. This study proved that ecological intercorrelation in some extent sustains unobserved environmental effects to affect regional environmental degradation.

Economic dynamics, value chains and metabolisms of urban and peri-urban agriculture in Sub-Saharan Africa: a review

Follmann, A., Willkomm, M. & Dannenberg, P.

University of Cologne, Cologne, Germany

Abstract

Different types of urban and peri-urban agriculture exist in the Global South, in particular in Sub-Saharan Africa. Besides positive impacts on urban food security, empirical studies have documented an increasing economic potential of urban and peri-urban agriculture in the Global South. Dynamics of urbanization and agricultural intensification at the rural-urban interface result in changes in flows and metabolisms which have social-ecological effects on urban and regional sustainability and human health. Based on extensive literature review and explorative studies on medium-sized Kenyan cities (Nyeri and Nakuru), the paper discusses emerging economic dynamics of urban and peri-urban agriculture with a special focus on the diffusion of supermarkets and their impacts on value chains in the fresh fruit and vegetable production (FFV) sector. First findings suggest that an intensification and commercialization of agricultural production is evident which in turn is linked to the adaption of technologies (e.g. greenhouses, vertical farming) and increasing inputs including pesticides, mineral fertilizers, irrigation systems and wage labour. Overall, the paper aims to contribute to a better understanding of urban and peri-urban agricultural production systems and their associated flows and metabolisms in the context of dynamic urbanization in Sub-Saharan Africa.

Abstract

Urban metabolism is a self-organizing system within materials, energy, money and human labor flows, which can be used as an index of urban sustainable development. Based on the emergy theory, we analysed the structure, intensities, environment pressures and output efficiencies of urban metabolic emergy system at country level between 2005 and 2013. The primary results are as follows, the import and export emergy growth contributed mostly to the emergy consumptions of Beijing metabolic system. Emergy use intensities of Beijing had increased with the rapid rise in the non-renewable resource emergy and import emergy, which resulted in the increasing environmental pressures and gradually declining of output efficiency and sustainability. Facing the growing resource and energy shortage, Beijing should encourage the exploitation and utilization of renewable resources and energy, increase the consumption efficiency of non-renewable resources and energy, establish the mechanism to use wastes of resources and energy to promote the urban metabolism in Beijing.

Energy consumption and greenhouse gas emissions for transmission infrastructure in China: from a micro-to-macro perspective

W.D. Wei¹, X.D. Wu², G.Q. Chen², G.P. Li¹

¹ College of Government, Peking University, Beijing, 100871, P. R. China, weiwendong@pku.edu.cn

² College of Engineering, Peking University, Beijing, 100871, P. R. China

Abstract

In recent years, the ultra-high-voltage electricity transmission and strong smart grid projects have gained wide exposure in China. It serves a strong impetus to safeguard urban electricity security, optimize urban energy structure and invigorate urban industry development, which helps build a solid consolidation for new urbanization and smart city progress. To optimize the structure and comply with the low-carbon strategy, this paper has for the first time undertaken a comprehensive accounting for the energy consumption and greenhouse gas (GHG) emissions of transmission infrastructure from a micro-to-macro perspective. Supported by the ecological input-output database and state grid data, the energy consumption and GHG emissions for micro grid projects in different terrains and voltage classes are calculated. The result suggests that under the same voltage, grid network across the plateau and river swamp seem to be with the highest energy cost and GHG emissions for per unit distance. Besides, based on regional input-output table and provincial grid data, we further account for the energy cost and GHG emissions that are induced by macro regional grid construction and the incremental economic benefits in various sectors. By taking the year 2007 as a case study, the energy consumption and GHG emissions triggered by direct investment of China macro grid are respectively calculated to be $7.88\text{E}+17\text{J}$ and $8.50\text{E}+07\text{tCO}_2\text{ Eq./t}$. Meanwhile, for investment pulling, spatial spillover effects could be witnessed between the different provinces. The outcomes will be provide valuable policy implications and scientific basis for grid infrastructure and spatial planning for building low-carbon cities.

Ultra-high-voltage electricity transmission; smart grid; energy consumption; greenhouse gas emissions

Future Urbanization and Climate Change Related Heat Risk in Asia

Peter J. Marcotullio, Carsten Kessler

Hunter College, CUNY, Department of Geography, New York, USA, peter.marcotullio@hunter.cuny.edu

Abstract

We present a spatially explicit urbanization scenario baselines for Asia to 2100 and relate these findings to projected temperature increases. Using GRUMP (global rural urban mapping project) data for the identification of urban areas and national boundaries (2000) and GPW4 (Gridded Population of the World Version 4) data on land mass and population values (2010), and UN data for population to 2100 and urbanization to 2050 along with our own series of urbanization estimates from 2050 to 2100, we project the spatial distribution of urban population across the region in 10 year intervals. We spatially allocate population based on three different methods: random by urban-non-urban split, by current share of total urban population, random by urban-non-urban split but constrained by cell densities. These baseline data provide a starting point for more detailed urbanization modeling. With these preliminary data, we associate population levels for Asian cities with average temperature model outputs from over 30 GCMs for 2030, 2050 and 2080. We choose the three hottest consecutive monthly temperatures per year and average them for each model and then spatially associate these values with urbanization scenario data to identify potential future locations of urban climate change vulnerability. We find that by 2050 a large and growing urban population may be experiencing average summer (3 months) temperatures of over 35° C (95° F).

Abstract

Based on ecological footprint, which has been extensively applied in recent years to quantitatively measure human pressure on ecosystems, this paper combined urbanization level with ecological tension index to analysis the impact of urbanization on ecological security. Jing-Jin-Ji region was taken as the study area, which is one of the most rapid economic regions in China. Firstly, the paper analysed urbanization level selecting per capita GDP, urbanization rate, non-agriculture payroll employment, household consumption, proportion of built-up land and energy intensity and so on. Then, ecological tension index, which was on the basis of the ecological footprint theory, was calculated to assess the ecological security. Finally, the relationship between urbanization level and ecological security was conduct to analysis the impacts of urbanization on ecological security. The result shows that the urbanization has a negative impact on ecological security. Economic structure and consumption structure should be improved so that the ecological security could be harmony with urbanization process. The study will provide academic references of ecological security analysis, sustainable development evaluation to our country and other fast-urbanizing regions in the world. As well as to offer the scientific basis and decision support for ecological construction in these areas.

Abstract

Ecosystem services research is a hot and key issues at home and abroad. With the intensification of human activities, the structure and function of ecosystem affected by the human activities are more profound. Urbanization is the most typical representative of the natural process of human interference, with the acceleration of urbanization, domain of landscape types and the landscape structure inevitable great changes, also inevitable of regional geophysical processes and earth chemical process and biological process produced a corresponding impact. It will inevitably affect the quality of the regional ecosystem services. Pakistan is located in South Asia, is China's land neighbors, and is "The Belt and Road" construction in key areas and start, also the target area of "Pakistan Economic Corridor" construction. With the implementation of "The Belt and Road" and Pakistan Economic Corridor", Pakistan will face a huge infrastructure construction and urbanization. Under this background, the research is of great significance to influence of Pakistan's urbanization construction of Pakistan ecological system. So this paper chooses Pakistan as the study area, using GIS as a platform, predict Pakistan land use change by DLS model. At the same time, application the InVEST model and combined with land use types and other factors, conduct an in-depth investigation on ecosystem services in Pakistan and realizes spatial quantitative assessment of ecosystem services.

Mapping dynamic and growth of class 1 cities in India

Chowdhary Ravindra, Kumar Rakesh

International Institute for Population Sciences, Mumbai , chowdhary1191@gmail.com, rakesh@iips.net

Abstract

Using the available source of census data on relevant context. This study examine the dynamic change and growth of class I cities in India. Over the last decade it has been observed that the population of class I cities increasing as compare to other class at very high proposition. The reason behind this may be urbanization process and employment opportunities in the cities. Using secondary census data sets of (Town directory) 2001 and 2011 respectively with the several indicator like hospital facilities, infrastructure (road, railways, availability of government and Private College, and other facilities etc.). However allocate the actual location and identify the regime of urban process with the help of ARC GIS tools and technique. Mapping the growth of class I cities will be helpful for town or urban planner as well as government body to apprehend the real change of urban dynamic. Result indicate that there are some class I cities have better advancement of facilities attract more number of people. 264.9 million Persons, constituting 70% of the total urban population, live in these Class I UAs/Towns. The proportion has increased considerable over the last Census. Million plus UAs/Towns: Out of 468 UAs/Towns belonging to Class I category, 53 UAs/Towns each has a population of one million or above each Known as Million plus UAs/Cities, these are the major urban centres in the country. 160.7 million Persons (or 42.6% of the urban population) live in these Million plus UAs/Cities. 18 new UAs/Towns have been added to this list since the last Census.

Patterns of household transport and domestic energy consumptions and policy implications, a perspective of fast developing City

Huang J, Cheng J, Zhang Y

School of Science and the Environment, Manchester Metropolitan University, Manchester, M1 5GD.

J.cheng@mmu.ac.uk

Abstract

There have been numerous studies in the literature on urban household energy consumption in Chinese cities but very few studies are focused on the interactions between household transport and domestic energy consumptions and particularly at micro level. This study, to fill the gap defined above, is based on a large-scale household questionnaire survey conducted in 2010 across Wuhan city that is a mega city in Central China. 1200 questionnaires, based on a stratified random spatial sampling strategy, were validly collected and processed with numerous items included, such as demographic, travel, domestic energy spending, employment, spatial proximity, local environment, and neighbourhood. First of all, both transport and domestic energy consumptions at household level are estimated for the entire survey population. Second, the statistical and spatial patterns of each type of energy consumption and their relationships are analysed using statistical and GIS (geographic information system) methods, aiming to detect any hidden interaction and differentiation. Third, all the households are classified into four categories (high in transport and domestic, high and low, low and high, and low and low). The different demographic, economic and environmental determinants between the four categories are modelled to reveal the roles of these factors in shaping the interaction patterns. All these results are utilized to analyse the policy implications for urban planning and management, and examine if Chinese cities demonstrate different patterns of energy consumptions from the developed countries. These may contribute to the global understanding of urban energy and transport poverty.

Rethinking Sustainability in a More Urbanized World: Comparison in “BIC”

Countries

Chen Zeng^{1,2}, Xiangzheng Deng¹, Jianing Dong², Peiying Hu²

¹Institute of Geographical Sciences and Natural Resources Research, Chinese Academy of Sciences, 100101, Beijing, China

²Department of Land Management, Huazhong Agricultural University, 430070, Wuhan, China

Abstract

The urbanized world has brought social, economic and environmental sustainability into more challenged surroundings which necessitate the exploration on their intertwined relationships, in the rapidly rising countries in particular. In our study, we used Brazil, India and China as “BIC” countries to be our representative study areas for the investigation of sustainability in the context of rapid urbanization. In general, we synthesized our studies into a comparison framework from four aspects: rural-urban relation, industrial development, city development and urban landscape pattern. Through the exploration of the trajectories of urbanization and related sustainable issues in these three countries, distinguishing features are revealed for comparisons and policy implications. We found that urban-rural dichotomy exists in all these countries with India and China to a higher degree. China is revealed to be manufacturing-based in the past half-century whereas service sector turns out to be the primary industry in Brazil and India. The distribution of large cities follows regional pattern with Brazil northeast-focused and China southeast-focused whereas it is comparatively balanced in India. The Amazon forest in the north brings great challenges to Brazil with respect to the conservation of the biodiversity and eco-environment. India and China encounter with tremendous urban expansion/sprawl in the past several decades and the loss of arable land has made food security a critical issue for the large and growing population. In the end, we summarized the sustainability issues in social, economic and environmental aspect for Brazil, India and China in the context of rapid urbanization to provide references for other countries.

Songdo (South Korea), a mega-project in the making: residential neighborhoods of an urban utopia

Geléezeau, V.

École des hautes études en sciences sociales (EHESS), Paris, France, valerie.gelezeau@gmail.com

Abstract

Near Seoul (South Korea), a new city emerges on a vast reclaimed zone from the sea: Songdo, a mega-urban project that is to house about 200 000 inhabitants by 2020. In the globalized competition of large metropolises and global cities (Sassen), this new “International City” is part of the South Korean public policies that try to promote the Seoul capital region as a major hub in North East Asia. The development of Songdo also derives from the opening to foreign investments that followed the financial crisis of 1998 and is at the core of so-called “IFEZ” (Incheon Free Economic Zone). In the programmatic or analytic discourse of planners and developers, Songdo appears as an urban utopia of the 21st century, combining digital technologies (“U-City”, “smart city”) and sustainable development (“green city”). Today, over 70 000 people already settled in – and live between construction sites, brand new skyscrapers, or a public space often referring to foreign locations (the “Central Park”).

This paper intends to expose the preliminary findings of a research aiming at discussing the process of place construction in a mega-project considered typical of Asian contemporary urban development within globalization (KIM Jun-Woo & Ahn Young-Jin 2012). Anchored in the perspective of cultural geography and grounded on ethnographic research crossing planning narratives with dwellers’ residential trajectories, it will particularly focus on the production dynamics of residential neighborhoods where the planning of housing and public facilities meets the actual practices of the pioneering residents of the new city.

²Department of Geography, Taiwan University, China

³Chinese Academy of Sciences

Abstract

It has been reported that, from 1970 to 2000, China had the highest rates of urban land expansion in the world, ranging from 13.3% for the coastal areas to 3.9% for the western regions annually. Although China accounts for less than 20% of the global urban population at present, close to one third of the global urban population growth between 2000 and 2010 was realized in China.

Because of the rapid rate of urban land expansion and its implications in China, compact city and sustainable urban growth has also received attention in the literature (e.g., Chen et al., 2008; Zhao et al., 2011).

Urbanization has been linked to a variety of resource and environmental problems worldwide such as habitat loss, species extinction, land-cover change, and alteration of hydrological systems (Seto et al., 2011). In China, because large amounts of agricultural lands have been converted to urban land use, food security can also become an important issue in the future (Angel et al., 2011; Wang and Fang 2011).

Our presentation proposes different methods for measuring and modelling urban sprawl (urban expansion rate and intensity, weighted expansion intensity etc.) using built-up area data on prefecture level from 2004 and 2013. Comparison of different growth speed of population and built-up area on prefecture level in China provide a picture about sustainability of urban growth and we can understand better the development stages of urban land use intensity on the coastal, central and western regions of China.

Urban land expansion (UR) measures the average expansion rate in a given time period (Schneider and Woodcock, 2008; Seto et al., 2011; Xu and Min, 2013); urban expansion intensity (UI) quantifies the average expansion intensity in a given time period (Schneider and Woodcock, 2008; Seto et al., 2011; Xu and Min, 2013); population growth rate (PR) measures the average growth rate in a given time period; population growth to urban expansion ratio (PU) is the ratio of PR to UR; and urban population density (PD) is calculated by dividing the total urban population divided by the total built-up area (i.e., urban land) in a year. We are using hot spot analysis to understand the different spatial pattern of built-up area and population growth on prefecture level in China.

To understand the processes on closer range, we will also cover case studies of selected cities from the coastal, central, and western regions. As urbanization continues at a fast pace in China, the findings from this comparative study can help us better understand urbanization and sustainable urban growth in different parts of the country focusing on urbanization and sustainable urban growth in different parts of China.

Study on Ecology Efficiency in Rapid Urbanization Area

Gui Jin, Zhaohua Li

Hubei University

Abstract

With the rapid development of urbanization in China, spatial problems such as deterioration of ecological environment, unbalanced development between the urban and rural areas are getting increasingly serious, becoming the major obstacles of sustainable development. How to obtain the biggest economic and social benefits with the minimum ecological loss is an important basis for optimizing development of national spatial territory. Taking Hubei province as the study area. There is a link-up between land use and eco-economic benefits from the perspective of ecological efficiency. We consider the NDVI as the ecological variable by utilizing cross-sectional data in county scale. Based on SFA (Stochastic Frontier Analysis), we not only make measurement on ecological efficiency, environment performance index and total factor productivity but also quantitate the relationship between the land use ecosystem service which aims to analyze the interactive mechanism and balance their conflict. Research results can provide reference for socio-economic development and sustainable development of territorial resources.

Ecology Efficiency; Rapid Urbanization Area

Study on economic development model of Ordos

Rui Dong^{1,2}, Yun-hu Xie¹, Chun-xing Hai^{1,2}

¹Institute for the History of Science and Technology, Inner Mongolia Normal University, Hohhot, 010022, China, dongrui2001@126.com

²College of Geographical Science, Inner Mongolia Normal University, Hohhot 010022, China, cxieyhsd@126.com

Abstract

Mineral resources are occupying dominant in the process of industrialization and urbanization in terms of city development law. Ordos, with the enrichment of mineral resources, which located in the southwest of Inner Mongolia in China, with the help of the opportunity of the national macro-economic policy and the domestic coal market integration, realized the leap forward development of Ordos economic. This article analysis the relationship among economic development of Ordos, national macro-economic policy, resources development, informal finance and estate with the methods of document inquiry, statistical analysis, comparative analysis and field tripping. Finding that it has formed a giant circle of funds among the private lending activities, resources development and estate, and the industrial structure is excessively single, it exists huge risks of economic development, and had fall into the dilemma of financial crisis. Future Ordos will has a new development cycle through the transformation of economic structure, the sustainable development and use of coal and nature gas, and the development of coal gas and Shale gas in Ordos which resources are so rich.

Supporting the Development of China's Urbanization: A Review of Trends and Knowledge Gaps in Urban Studies

Qian Zhang, Xiangzheng Deng, Karen C. Seto

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, zhangq.ccap@igsnrr.ac.cn

Abstract

The magnitude and extent of China's urbanization is unparalleled anywhere in human history. Studies of the nation's urbanization have consequently caught the interest and close attention of international and domestic researchers, Chinese officials, and the public. The objective of this review paper is to synthesize the key findings and gaps in knowledge concerning China's urbanization and environmental change as revealed by projects funded by scientific foundations since 2010. This review provides an additional channel for examination and communication as well as a fresh, comprehensive, and timely insight into urban studies in China beyond the more conventional review mode involving journal publications. The review demonstrates that urbanization and environmental studies projects funded by China have made considerable contributions in the categories of urban transportation, spatial dimensions, processes, and mechanisms of urban development, as China experiences rapid and early-middle stage of urban development. In spite of the fact that a "people-centered" urban development pathway has been highlighted in China's New-type Urbanization Plan, research on the quality of life in urban areas is very limited. The review also indicates that it is imperative to systematically examine the coupled natural-human urban system beyond the individual case studies. The prevalent specific-problem-oriented way of thinking in Chinese studies should be transitional to a systematic way of thinking and the adoption of comprehensive strategies from multiple perspectives to tackle the problems. The findings should shed light on current and future urban development and issues not only in China but also in other rapidly urbanizing countries.

The study on ecological sustainable development of Chengdu

Li YF, Zhan JY, Zhang F, Deng XZ

Beijing Normal University, Beijing, 100875, P.R. China, liyf_simlab@163.com

Abstract

Since the concept of sustainable development of urban was put forward, quantitative measurement of urban sustainable development has become one of the main research contents of relevant scholars in various countries. Ecological footprint method is one of the most important cases in it. However, the traditional ecological footprint method focuses on the static measure of the sustainable development of the city at the present stage, and it can not to predict the development of ecological footprint dynamically. At present, the trend prediction method has not considered the impact of economic development to the calculation index, which leads to inaccurate prediction results. And in this study, we using the traditional ecological footprint method to calculate the ecological footprint supply and demand of Chengdu in 2013. And considering the impact of economic development on the selected indicators, we using the system dynamics (SD) software STELLA to predict the ecological deficit of Chengdu city in 2013-2021, which results shows that the degree of ecological deficit in Chengdu was reduced from 1.43 million hm^2 to 1.24 million hm^2 in 2013-2018. And after 2018, it began to increase, which is 1.32 million hm^2 in 2021.

Abstract

Uganda is the world's second most populous landlocked country in East Africa which is the only region where the population is projected to keep increasing throughout the 21st century. Uganda is one of the countries which have the lowest level of industrialization and its urban population will increase from six million in 2013 to over 20 million in 2040. About 60% of the population still lives in the countryside with a poor life, less employment opportunity, low per capita income and poor infrastructure, thus a large number of rural population rushed into cities to seek more job opportunities. With expanding built-up area and rising urbanization rate, Uganda becomes one of countries with the fastest urbanization process in Africa. However, lots of problems need to be solved in the process of urbanization in Uganda. Our research indicates shows there is an urgent need for decision makers in Uganda to act now to ensure that this rapid population and urbanization are managed well to grantee its sustainable and inclusive development.

Urban Transition in West Bengal, India: ‘Polarization Reversal’?

Guin, D

Centre for the Study of Regional Development, Jawaharlal Nehru University, New Delhi, India,
debarshi.guin.1988@gmail.com

Abstract

Contemporary urbanization in India is in transition which along with the continuation of ‘top heavy’ urban structure and gradual deindustrialization is characterized by faster growth of informal employment, declining trend of urban-ward migration of the males, slowing down of the growth of cities and towns and emergence of new urban centres among others. Given this backdrop, the paper, in relation to the ‘polarization reversal’ theory, examines the contemporary processes and emerging form of urban transition in West Bengal which has a longstanding history of ‘mono-centric’ urbanization. The study is based on secondary data about urban population, migration, employment and unemployment situations, industrial dynamics and investment patterns collected from various sources like population census, National Sample Surveys, Annual Survey of Industries and Centre for Monitoring Indian Economy’s CapEx database. It reveals that the demographic process and emerging form of urbanization indicate a tendency towards ‘polarization reversal’ where large cities are growing at slower rate than the towns and a polycentric urban system is emerging. But the underlying factors of this transition are not associated with similar dispersion of economic activities and employment opportunities away from the metropolitan core and its immediate surroundings as prescribed in the above mentioned theory. Thus, the contemporary urban transition in the state reflects a pseudo ‘polarization reversal’. Furthermore, the study is sceptical about the significance of this emerging form of urbanization fuelled by the growth of small cities and towns which have weak economic base, crisis of urban governance and inadequate access to basic amenities.

Key words:

‘polarization reversal’; polycentric urban form; census towns; deindustrialization; urban governance

The role of greenspace in regulating land surface temperature in the megacities of Southeast Asia

Estoque RC, Murayama Y

Faculty of Life and Environmental Sciences, University of Tsukuba, Tsukuba City, Ibaraki 305-8572 Japan,
rons2k@yahoo.co.uk

Abstract

Urban greenspaces (e.g. forests, grasslands, etc.) are the main ‘provider’ of various urban ecosystem services, including their role in mitigating urban heat island effects. This study aims to examine the role of greenspace in regulating land surface temperature in the megacities of Southeast Asia (Bangkok, Thailand; Jakarta, Indonesia; and Manila, Philippines). Specifically, it aims to determine the relationship between the mean land surface temperature and the density of greenspace and impervious surface based on grids and along the urban-rural gradient. Landsat 8 imagery and geospatial techniques (multiresolution grid-based and urban-rural gradient analysis techniques) were used to facilitate the analysis.

Key words:

land surface temperature; urban heat island; greenspace; remote sensing; spatial analysis; ecosystem services; Southeast Asia

Study on population - economy - space perspective of space-time evolution of urbanization in Shandong province

Gao Baodi, Wang Chengxin, Cui Xuegang

College of geography and Environment, Shandong Normal University, Ji'nan, China

Abstract

Urbanization, is a "population - economy - space" 3 d integration process, and its internal coordination or not is the key to sustainable urban development. Based on the retrospective analysis of the existing about the quality of urbanization, the urbanization, the urbanization process of each subsystem, on the basis of related research, from the economic urbanization, population urbanization, space urbanization three dimensions and its related relation, establishes the evaluation system of urbanization. This article selects 2006, 2013, two years of data, using the mean square error method and coupling analysis method, studies the Shandong province coupling coordination degree of population, economy, urbanization and the temporal and spatial evolution. The research results show that the urbanization level of Shandong province has rapidly developed in recent years, but the current is still in town into a dominant population, in the stage of rapid development of urbanization. Urbanization degree of coupling in urban systems, but the coupling level is not high. It is still in the stage of development of antagonism, and gradually tend to be coordinated development. However, in the west of Shandong Liaocheng, Heze, development level, degree of coupling between subsystems there is still a large gap compared with the eastern cities. Finally, from the scientific planning and population development, economic development, urban space in Shandong province using four aspects proposed "the population - economy - space" the coordinated development of the related countermeasures.

Key words:

The population - economy - space urbanization; The evolution of time and space; The coupling coordination; Shandong province

Territorial strategies of the Madrid Metropolitan Region universities: the establishment of business schools and MBA offer

Rubén Camilo Lois González, Guillermo Morales Mato, M. Ángeles Piñeiro Antelo

University of Santiago de Compostela

Univesity Carlos III

Abstract

During the last years, educational offer has significantly grown in the Madrid Metropolitan Region. The increase number of private universities and centres is to be highlighted, accompanied by a dynamic of segregation with regard to public and private universities. In this context, the growth of private business schools, addressed to specific social groups of the Madrid Metropolitan Region, reinforces the “elite” aspect of this offer.

The localisation of these private business schools will be analysed. They are usually a) around the more valued areas in the city centre and the metropolitan region (North and West); b) in coincidence with the localisation of the private universities of the metropolitan region.

As regards to MBAs, concurrence is even stronger, as some public universities seek to offer these prestigious courses. It will be analysed if the localisation of public and private MBAs register the same segregation process of the one identified between public and private universities.

Abstract

In this paper we propose our conception of city nodal areas (CNA) and how neoliberal globalization changes them. CNA is a territory which plays the leading role in the urban structure because of processes, essential for city vital functions are focused there. These are cross roads of material and spiritual ways, people streams and traffic roads, information and communication links, meeting centers of different ownership interests, places where conflicts are occurred and resolved. The processes intersection leads to the concentration of specific functions (transportation, cultural, social, management, communication, etc.). We outline the main features of CNA. They include: pedestrian and transport accessibility, historical formation, individuality, specialization, attraction to any kind of activities, social value domination, a high risk of conflicts and self-development. Some CNA hasetherealization function and becomes the spiritual center of the city (L.Mumford). Theoretically, because of the historical significance, CNAs have to acquire more cultural and symbolic value. However, we select and analyze the 6 types of CNAs in Kyiv and discover functions replacement and constant dynamic spatial changes there. Neoliberal urban functions displace less relevant for business ones. Service and commercial functions, spatial homogenization and loss of public spaces inherent for most number of Kyiv CNAs. Luxury mall Mandarin Plaza in the city center caused the social fragmentation. The distinctive identity of Kyiv depends upon CNAs, but these spaces are the most vulnerable now. Citizens should perceive their right to the city and responsibility for its development towards future generations.

City nodal area; urban structure; spatial transformation; distinctive identity; neoliberal functions; spatial homogenization; cultural value

Modernizing Urban Villages in Transportational Corridors: A Study in Delhi, India

Mohan, J. A.M., Mohan

B.R.Ambedkar College, University of Delhi, Delhi.INDIA.11005, jmanjana@yahoo.com

Abstract

Urban villages, located along the major transport corridors in Delhi are perpetually in a stage of transition. Villages that are part of the proposed urban extension area or fall within the existing urban area, also faces the threat of losing their character or identity due to the market forces. The urban villages of Delhi carry 5-6 times more the population density than the non-village areas and caters for mixed land use, with residential, commercial and also, industrial (small or household industries), based on the demands of the surrounding localities. "Unfortunately, the urban villages suffer from a lack of infrastructure such as sewerage, water, power supply - due to non development of infrastructure within these areas. The acuteness of the situation is magnified by the high population densities, and leads to horrible living conditions during periods of seasonal stress as in high summer or heavy rains." (Hindustan Times, 24 May, 2003, hindustantimes.com). The study area of east Delhi is very vast. There are national highways passing through it (GT road cuts it through the middle). But accessibility to the villages varies from area to area. Three villages form the study area have been chosen to show case the transition of a rural area into a totally urbanized village due to the dominating role played by the proximity to metalled roads. The three villages - Badarpur Khadar, Garhi Mendu and Shamaspur Jagir- represent the three stages development of a village into an urban area respectively- its rural stage; the middle stage and the totally urbanized stage. The locations of the villages are slightly away from the main road, slightly away but an important road passing through it; and the third village is located on the main National Highway 24. It is a totally urbanized village with little or negligible agricultural land remaining. The paper highlights the unmistakable differences in the skylines, landscapes and the resident socio-economic character of the population brought out through personal interviews and pictures. The paper also tries to suggest policy decisions so as to level out the differences in villages and their planned overall development. Keywords: transport lines, differential urban transformation.

Key words:

Urban villages; converting land uses; transportation lines

Spatial Expression of Inequalities in Kolkata City: the Political Economy Perspective

Firdos, SOHEL

Associate Professor, Department of Geography, Sikkim University, INDIA, sfirdos@hotmail.com

Abstract

Anyone who moves through cities, not only knows that space organises and strengthens inequalities between urban areas, but also can observe the contrast between the rich and poor within them, perhaps more so than even before. In this paper, we discuss about inequalities and their spatial expressions - segregation in Kolkata, one of the largest metropolitan cities located in the eastern part of the country. We introduce the vertical and horizontal paradigms for understanding social structure in this city. Then, we discuss segregation, suburbanisation, gentrification and ghettoisation theories as they aim to explain the spatial expression of stratification in contemporary cities. We show also how these processes have created similarities among social strata across cities in various parts of the world and huge distances between them within cities. As we see, the vertical paradigm points us to socio-economic status hierarchies, now often expanded to include not just income or assets but also forms of social, economic and political capital, resulting in a perspective of capabilities and resources informed by scholars such as Amartya Sen. We note that the spatial expression of inequalities in Kolkata was initially the product of colonial urbanisation but subsequently has been strengthened by capitalism, including its supportive patriarchy, and government as supporting the capitalist system. Subsequently, we employ socio-spatial perspective to ask what role economic, political and social institutions play in creating and changing settlements, and through what processes they are given meaning by local residents.

Key words:

Spatial expression; inequality; Kolkata; political economy

Strategy for Municipal Solid Waste Management for Class II Towns of Uttar Pradesh, India: A Case Study

SIDDIQUI Masood Ahsan, SIDDIQUI Lubna, DEVI L. Mirana, SAJJAD Haroon

Department of Geography, Jamia Millia Islamia, New Delhi, India, siddiqui.jmi@gmail.com

Abstract

The economic development, urbanization and improved living standards in cities increase the quantity and complexity of generated solid waste. If accumulated, it leads to degradation of urban environment, stresses natural resources and leads to health problems. The study deals with management of solid waste in an emerging class II town of Uttar Pradesh, India. The focus of the study is to examine the existing solid waste management system and to estimate the municipal waste generation per head per day in Akbarpur town with the aim to identify suitable sites for waste disposal. The spatial and non-spatial data has been obtained from Survey of India and Census of India respectively. The primary data regarding income, solid waste generation, collection, transportation and disposal has been collected through ward wise household sample survey with the help of structured questionnaire. For the identification of new disposal site constraints mapping was done to minimize the search area. The study illustrates that the town generates about 18 tons of waste daily i.e. 206 grams per head per day. The collection and disposal efficiency is quite low. The civic agency has been collecting and unhygienically disposing about 55 per cent waste. There is neither a defined landfill site nor transportation route. The waste is generally dumped in ditches along roads and low lying areas. Two engineering dump sites have been identified and subsequently collection and disposal routes are identified. It has been estimated that if the proposed plan is implemented the collection and disposal efficiency will be increased by 75 per cent.

Key words:

solid waste; constraint mapping; landfill site; route planning

The Addis Ababa Urbanism: Poverty and Momentum

Givental, E

California State University East Bay, Hayward, 94542, U.S.A., elena.givental@csueastbay.edu

Abstract

Addis Ababa, the capital of Ethiopia, the tenth largest city in Africa, is the indigenous African creation in the country that had never been colonized but endured almost two decades of a violent military regime implementing a command economy. Most research on African urbanism is conducted from the perspective of post-colonial development in the conditions of neoliberal globalization. Though Addis Ababa provides a research fabric for different path dependence, it demonstrates urban attributes typical for the majority of urban areas in the developing countries, such as high slum incidence, informalization, and vast income inequality. On the other hand, Addis Ababa is a vibrant evolving metropolis that is an epitome of 21st century African momentum. The convergence of Addis Ababa's urban traits with those of many post-colonial African cities indicates a possible link between the production of poverty and poor governance in non-democratic authoritarian regimes resulting in lack of investment in public housing and infrastructure. While Addis Ababa's urbanization creates a positive uplifting momentum for Ethiopia, country-wide economic and city-specific urban policies are required for poverty reduction. The author's recommendations include increased investment in residential construction and infrastructure, promotion of foreign direct investment, and creation of jobs in manufacturing sector.

Key words:

Addis Ababa; urbanism; slum incidence; informalization; foreign direct investment; infrastructure; urban policies

Urban Sprawl and Transport Blockages in Developing World: A Case Study of Ranchi City in India

Prasad S, Sen A

Department of Geography, Delhi School of Economics, University of Delhi, India, surajprasad27@gmail.com

Abstract

Post-liberalisation, India has witnessed high economic growth associated with rapid Urbanisation. However, urbanisation in India has more been a product of haphazard rural to urban migration than some planned growth of urban area. This has given rise to the phenomena of Urban Sprawl. Urban sprawl is a multifaceted concept, which includes the spreading outwards of a city and its suburbs to the low-density, auto dependent outskirts, that encroach upon rural land and encourages car dependency. However, urban sprawl without proper planning, and devoid of good transport infrastructure, results into traffic congestion and bottleneck and other transportation issues. The present study will assess the pattern of urban growth in the previous decade and find out the planning gap through the case study of Ranchi district. Since becoming the capital of the newly formed state of Jharkhand, Ranchi has witness rapid economic and urban growth that has turned the small town of Ranchi into an urban behemoth of Jharkhand. The objective of this paper is to determine the specific impact of urban sprawl on daily life in Ranchi by assessing the Land Use / Land Cover change in Ranchi through LANDSAT images of 1995 (TM), 2005 (ETM+) and 2015 (OLI), and to find out the measures that should be taken to tackle these issues efficiently and in a cost effective manner.

Key words:

Urban Sprawl; Transportation; Migration; Ranchi

The Viability and Necessity of Smart City in the Third World

Jiang QY^{1,2}, He ZW³, Zhu S¹

¹College of Earth Sciences, Chengdu University of Technology, Chengdu, 610059, China, 735848299@ qq.com

³Key Laboratory of Land and Natural Resources to Spatial Information Technology, Chengdu, 610059, China

Abstract

Smart City is the advanced stage of urban informatization development following the digital city, which is designed for people to create a better living environment and for the benefit of mankind. With the development of science and technology, the realization of digital city and the emergence of the combination of Internet, Internet of things and other network and cloud computing make the construction of smart city possible. The third World refers to more than 130 developing countries in Asia, Africa and other regions. For developing countries, almost cities are in a state of sprawl. Through a summary of previous researches, we realized that the urban sprawl tends to stimulate economic growth and the improvement of social living standard. But at the meanwhile urban sprawl has brought about a series of problems: the large area disappearance of arable land and greenbelt, river pollution and other environmental problems, thus people have to be faced with the increasingly severe headaches of the world, like resource constraints, environmental pollution, population growth, traffic congestion and etc. The smart city is a kind of powerful weapon to solve the problems above. In this paper, to solve traffic congestion, we divided the development of intelligent transportation into three stages: traffic Internet based (primary), traffic intelligent(intermediate), auto-pilot(advanced)by combining analysis of the Internet technology, networking, GIS, RS, big data and communications technologies. And we also describe the objectives with their viability and dependent technique at each stage respectively.

Key words:

Smart city; The third world; urban informatization development; Urban sprawl; traffic congestion; intelligent transportation

Urban Services Provision in the Peri-Urban Areas of Faridabad City, India: Issues and Challenges

Bali, B.

Department of Policy Studies, TERI University, New Delhi-110070, India, bhawna.bali@teriuniversity.ac.in

Abstract

Cities in the Third World are on account of rapid urbanization are expanding and encroaching upon the surrounding rural areas, thereby, obscuring the distinction between the urban and rural. Villages at the periphery of large cities whose agricultural lands have already been acquired and the villages which are facing imminent acquisition of their agricultural land are witnessing transformations in their socio-economic, cultural and natural environments. The study aims at examining the existing situation of urban services, and governance issues in selected peri-urban areas of one of the major industrial cities in north western India and soon to be developed as a smart city in the State of Haryana-Faridabad. The study is based on secondary data on the household amenities and facilities, and field work based information generated through semi-structured interviews and discussions with peri-urban residents on urban services provision. The study identifies that unregulated building activities within and outside the *abadis* (inhabited areas) proliferate to the detriment of healthy living conditions, in particular the provision of basic services. The heightened focus on the Smart Cities Mission and in making India clean under the Swachh Bharat Abhiyaan, it is expected that the peri-urban areas will receive attention of planners, policy makers and implementing agencies.

Key words:

Peri-urban; governance; urban services; Smart Cities Mission; Swachh Bharat Abhiyaan

Abstract

The study of Urban Heat Island (UHI) is important as it affects health, comfort and energy consumption in urbanized areas as the city's temperature is modified by the human activities. In this study, the hourly temperature differences between City Hall (urban) and Okeafa (rural) in Lagos, Nigeria were calculated using one year of meteorological observation, from June 2014 to May, 2015. The two sites were carefully selected to match the exact representative of their climate zones. Results on the Lagos UHI shows that it varies with days of the week, seasons, solar radiation, direction and speed of wind as well as noon and midnight conditions. The UHI exists throughout the day in the rainy season but both the UHI and Urban Cool Island (UCI) occurs during the day and night respectively in the dry season and in the pre-rainy/dry season transition months. The UCI occurs between 5-6 hours in the afternoon in the dry season and transition season. During weekdays heat island intensity of 7.0°C at midnight on Fridays and as high as 8.3°C early morning on Mondays have been observed. The heat island effect is observed at midnight in all months of the year with the maximum of 6.5°C in January (dry season) and minimum of 0.7°C in June (rainy season). However, at noon, both the UHI and UCI effect were observed.

Keywords:

Cities and Climate Changes

Ghourchi.M, Samadi.R

Master student of Geography & Urban planning of Iran, Tehran, Iran, samadi.roghayeh@yahoo.com

Abstract

Urbanization has enormous environmental consequences, both global and local. Already city dwellers are thought the responsible for up to 70% of the world's greenhouse gas emissions. Sprawling urban development consumes arable land and vital green spaces. Growing numbers of city residents put pressure on energy and water resources, waste management, sewer systems, and transport networks. Therefore, in order to tackle climate change, avoid lasting damage to vital ecosystems and improve the health and wellbeing of billions of people, solutions to these problems must be sought at the municipal level. At the same time, environmental sustainability must go hand-in-hand with other important goals such as promoting economic development, reducing poverty and improving quality of life. Indeed, the green agenda is a necessary part of holistic, city-led strategies for economic, social and environmental sustainability.

Key words:

environmental consequences; greenhouse gas emissions; green spaces; climate change; quality of life; green agenda

Heat Vulnerability and Adaptation Solutions for Shenzhen

Miaomiao XIE, Yun GAO, Yucong TANG

China University of Geosciences (Beijing), Beijing, 100083, P. R. China, xiemiaomiao@cugb.edu.cn

Abstract

With increasing evidence of global warming, many cities have focused attention on assessing heat vulnerability and its solutions. We developed a heat vulnerability index based on sensitivity, adaptability and exposure, which is suitable for a rapidly urbanized city in China. Different causes of high vulnerability were distinguished for choosing adaptation solutions. ASTER image, data of China Population Census-2010, standard land price etc are the data source of heat vulnerability index.

The results indicate that, urban heat vulnerability in Shenzhen western is medium and the value distributes uniform. Local spatial autocorrelation analysis reveals that the spatial distribution of heat vulnerability hot spots shows an aggregative pattern. In consideration of land use types, dominant factor analysis of heat vulnerability indicates: sensitivity is the dominant factor of heat vulnerability in the south of study area because this area lives much more extreme heat sensitive people. There is almost no large hospital in the area of Longhua center, so adaptability is the dominant factor in this area. Industrial park, aviation land, port, and logistics land is the main land use patterns in the west of study area. Western Industry Cluster which result higher impervious surface area and lower vegetation coverage, so exposure is the dominant factor in the western study area. These can provide reference for urban heat wave hazards mitigation and adaptation solutions.

Abstract

Urbanization has effect on urban microclimate through increasing air and surface temperature, which impact on increasing energy demand. Urban Heat Island is created when natural surface is replaced by manmade surfaces like Asphalt, Cement, paving. Today the urban heat island phenomenon is one of the greatest challenges, regarding the sustainability of cities and settlements. The first for detect heat islands Landsat-8 satellite images (OLI and TIRS bands) is used. Then, images of the Earth's surface temperature were normalized and these normalized images were divided into five categories of thermal class. At last, LST is obtained from Landsat-8 in daytime is compared on LST results of MODIS in nighttime. The results of processing images show in the cool season, city area has average temperature less than surrounding nature areas. During daytime, downtown in parts where the vegetation has been appropriate and minimum barren lands are obtained Lower temperatures and are showed cool islands. However, this pattern is vies versa at night so that city area is shown the formation of heat island. It seems UHI in cities are located in desert and arid climate zones have different pattern in comparison on the UHI in moist areas. With overlaying LST and Land use, were identified surface characteristics of lands is showing with high temperature. Bare-lands in the suburban area have high temperature in daytime, built up spaces, vegetation and water bodies recognised by low temperature. Nevertheless, on night built up spaces have inverse condition.

Parisian eco-districts: Low energy and "affordable" housing?

Machline, E., Pearlmutter, D., Schwartz, M. Author A

Urban Planning and Design, Blaustein Institutes for Desert Research, Ben Gurion University, Israel,
elise.machline@gmail.com

Abstract

From the 1960's onward, many middle and working class households have left Paris. The deindustrialization of the city explains why many of the working class households have left it and are unlikely to come back. The middle classes, however, have been driven away by the city's high housing costs. To prevent Paris from becoming 'a city just for the "richest and the poorest"', the new socialist city council (since 2001) has officially pursued a housing policy of social diversity. Social housing has been its main policy tool. The Municipality has become involved not only in its location, but also in its allocation. In France, public housing supply is legally mandatory and compared to international standards, the income ceilings for having access to it are very high. This allows to house families who have no need for state subsidy to access housing. Thus in working-class neighbourhoods, the Municipality is pursuing urban renovation policy and constructs social housing for the middle classes to replace sub-standard buildings previously populated by low-income populations. Furthermore, as part of its sustainable urbanism policy, the Paris municipality has implemented few eco-district projects called "ecoquartiers". In that national eco-district program, the neighbourhoods must meet environmental performance criteria, show potential for economic development and, provide social and functional diversity. Thus housing location and price must meet the needs of the residents. This paper attempts to explain how national policies aimed at providing housing and especially green housing to the poor and thus intended to prevent "greentrification" are subverted to serve specific Parisian goals of retaining the upper middle class in the city by providing it with green housing while promoting the "greentrification" of lower class neighbourhoods.

Abstract

Climate is one of the prominent and persistent factors affecting the human settlement configuration. During the civilization especially the recent 100 years, human society has left remarkable environment footprints including those on the global climate. In the predictable future, human have to make adaptations to accommodate to the macro- and micro-climate changes that emerging globally and locally.

Besides the global vision, it's also essential for urban planning decision-maker to contextualize physical environment and climate changes mutually. The latter usually are due to local development rather than global changes, with the causality relatively easy to detect and measures necessary to take. Peculiar of loose fabric, the open spaces play important role as air shed and flow corridor, many of which are featured of such climatic amenity.

The microclimate especially airflow patterns inevitably be shaped by surrounding environments, which usually means agglomerated development and potentially affect the public life. Investigating such circumstance will provide knowledge for sustainable and reasonable urban design.

Based on modeling and simulation, this paper compares the instant winter and summer wind patterns of four predominant open spaces in Nanjing at 1930s, 1960s and 2000s. The results indicate that the airflow pattern complexity increased gradually, the outdoor comfortability degraded dramatically in some areas, the environment inequity may be deteriorated too. The researchers suggest to put climate issue firmly on the agenda of public policy, support the public involved in the evaluation and urban design code with technical and social assets, hence advance the social and ecologic sustainability of the open space and surroundings integrally.

open space; wind simulation; micro-climatic amenity; urban form; Nanjing

Simulation of Airflow around Xi'an City Wall and Ventilation of Surrounding Residence Using CFD

LU Qian, YANG Lu

School of Architecture, Tsinghua University, Beijing, 100084, P.R.China, iluqiani@163.com

Abstract

Xi'an City Wall was constructed in the 14th century Ming Dynasty. It is not only the most well-kept ancient China city wall to date, but the largest in scale among intact ancient military constructions in the world. With the fast urban expansion of the Xi'an city in recent years, however, the city wall has become the boundary between the inner and outer city and a part of the central city as well. With a height of 12 meters and a circumference of approximately 14,000 meters, the city wall could significantly disturb the airflow around them. Therefore, the low-rise high-density residence adjacent to the city wall could be largely influenced by their huge-volume neighbour. The study of the airflow around the city wall is thus of great significance in terms of the relation between the urban wind environment and cultural heritage in Xi'an City. Airflow around Xi'an city wall is simulated using CFD technique in the aim of investigating the influence of the city wall upon the wind microclimate. Both 3d and 2d airflow simulations of wind flow are conducted and the results from the research scenarios are used for the analysis of air velocity and pressure distribution. Based on the overall research findings, recommendations for the future low-rise residential design in surrounding areas will be provided for a better urban wind microclimate.

A case study: Evaluation of the groundwater quality in shallow and deep aquifers

Battuya B

Department of the Water resource and Water utilization, Institute of Geography and Geoecology, Mongolian Academy of Sciences, Ulaanbaatar 15170, Mongolia, battuya55@yahoo.com

Abstract

The essential and vital component of natural life support system is groundwater. The groundwater resources are being utilized for drinking, irrigation and industrial purposes. There are increasing problems with deterioration of groundwater quality owing to geogenic and anthropogenic activities.

Groundwater, being fragile must be carefully managed to preserve its purity within standard limits, especially in Mongolia. Because the scarcity appears in the spring season is proved by the monitoring of the ground water level. Therefore, to assess the quality for human well-beings, the groundwater from the shallow aquifers and deep aquifers.

We have measured pH, total dissolved solids (TDS), fluoride, total iron and electrical conductivity (EC) content of groundwater samples, which collected from the shallow and deep aquifers in the Southwest side of Ulaanbaatar, Mongolia. Related to the urbanization affect the shallow aquifers water of the study area have poor water quality than those of the bore-wells from the deep aquifers of the Tuul river basin in the alluvial zone. The result reveals the groundwater of both aquifers is found to be slightly alkaline in nature with an average EC value of less than 500 μ S/cm. For the dug-wells, the observed average TDS was 317 mg/L, but pollution level unsuitable for human health besides 586 mg/L for the deep aquifers. In general, the concentration of EC and TDS in the groundwater of the shallow and deep aquifers reveals the shorter groundwater-rock-contact time. The study involved evaluation of groundwater quality both in shallow and deep aquifers in May and September 2015.

Key words:

Groundwater quality; deep aquifer; pollution; urbanization

Climate Change Adaptation in Developing Countries of Southeast Asia: Challenge and Opportunity

Wijaya, NURROHMAN

Study Programme of Urban and Regional Planning, Institute of Technology Bandung, Bandung, 40132, Indonesia,
nuroc_2000@yahoo.com

Abstract

During the last few decades, climate change (CC) phenomenon has significantly become a global environmental issue. Its impacts can be more perceived in urban coastal areas, especially in developing countries of Southeast Asia (SEA). To minimize the impacts, national governments and local authorities have given attention to climate adaptation planning. This paper investigates the challenge and opportunity of climate change adaptation (CCA) at national level in Indonesia, Vietnam, and Thailand, and at local level in several selected coastal cities. Case study approach is conducted. The results reveal that at the national level, CCA becomes more concerned to all respective state governments. Although in the beginning of planning and implementation, mitigation is further getting attention rather than adaptation. In most cases, plans for adaptation have focused on coping with or minimizing the impacts of future CC. However, available long-term climate projections may not be detailed or reliable enough to support an action plan. At the local level, the common situation has given an indication that the impacts of CC have been occurred. The adaptation planning is varied in each coastal city depending on the level of vulnerability and adaptive capacity as well as the institutional and financial capacity. Adaptation strategies should consider approaches to development that increase resilience to climate risks. In this context, CC becomes a key factor in sustainable urban development planning. Mainstreaming adaptation into urban development planning is therefore a main concern.

case study; climate change adaptation; Southeast Asia; urban coastal area

Climate Change and Human Mobility: An Urban Intervention

Tuitjer, A. L.

Department of Geography, Durham University (UK), PhD Candidate 2nd year, L.A.G.Tuitjer@durham.ac.uk

Abstract

This paper seeks to engage with the evolving literature on the “climate change and migration” (ccm) nexus, by re-orienting the polarized debate towards examining the spatial imaginations and subsequent political consequence informing it. While previous reviews of the literature have mostly focused on highlighting the divergent views of *conceptualising the link* between climate change and migration as either causal/deterministic or complex/messy; this review seeks to focus on how the literature is informed by a particular *spatial imagination with political consequences*. It is argued that the ccm debates predominantly discuss urban centres either as sights of vulnerability and origins of out-migration, or as unproblematic receiving sights for economic integration of climate migrants.

Given the problems of uncontrolled urbanisation in many Asian countries, uneven development within the urban terrain, tight funds and political wariness of integration policies for internal or international migrants, and a growing effort to implement urban climate change adaptation/mitigation strategies in the continent, this paper seeks to start re-thinking the significance of the urban sphere in developing, testing and contesting politics and practices that relate to ccm. By redirecting the debates towards urban terrains, the ccm literature is assessed along wider debates of climate change adaptation, urbanisation and more mundane questions of everyday mobilities that are already shaped by changing climatic conditions in Asian cities.

The review proposes an urban intervention that involves a shift from empirical to qualitative methods and ethnographic research and illustrates the points argued with data collected during a six month research period in Bangkok, Thailand.

Urban studies; climate change; mobility

Climate Change and Insurgency-Induced Migration and Its Implication

For sustainable Development: Case of Lagos Megacity, Nigeria

OYEKAN, T.K

NATIONAL POPULATION COMMISSION, LAGOS, NIGERIA, taioyekan@gmail.com

Abstract

The causes and effects of recent migration to Lagos megacity and its implication for sustainable development are the objects of this research. The country is diverse geographically, culturally and ethnically with her North-Eastern Region being ravaged since last 7 years by a group called "Boko Haram" demanding full implementation of Sharia Law in a secular nation, bounded at that part by Cameroon, Niger and Chad. The negative impact of climate change already being felt in the region as exemplified by the shrinking Lake Chad; coupled with the insurgency of Boko Haram generated IDPs and precipitated rural-urban migration especially towards the socio-economically more developed southern regions, notably Lagos megacity as destination. It confirms the Push and Pull theory of migration and also the division of its factors in Lee's laws. The major challenge of this study is unavailability of relevant secondary data. Within the context of the concept of origin and destination, the analysis of primary data derived from randomly selected respondents shows that the 'refugee migrants' were both internal and international migrants from the affected neighbouring countries; a newly emerging pattern of migration. Lagos is naturally an attractive destination for these refugee migrants despite the long distance – the pull factor. The implication of this is the increased pressure on the resources of the receiving city.

Effects of urban impervious surfaces on land surface temperatures: Spatial scale dependence, temporal variations, and bioclimatic modulation

Ma, Q, Wu, J, He, C

Center for Human-Environment System Sustainability (CHESS), State Key Laboratory of Earth Surface Processes and Resource Ecology (ESPRE), Beijing Normal University, Beijing, 100875, P. R. China, hcy@bnu.edu.cn

Abstract

Quantifying the relationship between urban impervious surfaces (UIS) and land surface temperatures (LST) is important for understanding and mitigating the environmental impacts of urban heat islands in human-dominated landscapes. Our main goal was to examine how the UIS-LST relationship changes with spatial scales, seasonal and diurnal variations, and bioclimatic context in mainland China. We took a hierarchical approach that explicitly considered three spatial scales: the ecoregion, urban cluster, and urban core. In general, UIS and LST were positively correlated in summer daytime/nighttime and winter nighttime, but negatively in winter daytime. The strength of correlation increased from broad to fine scales. For example, the mean R^2 for winter nights was 3 times higher at the urban core scale than at the ecoregion scale. The relationship showed large seasonal and diurnal variations: generally stronger in summer than in winter and stronger in nighttime than in daytime. At the urban core scale, for instance, the mean R^2 was 2.2 times higher in summer daytime than in winter daytime, and 3.1 times higher in winter nighttime than in winter daytime. Vegetation and climate modified the relationship during summer daytime on the ecoregion scale. Our study reveals several trends on the scale multiplicity, temporal variations, and context dependence of the UIS-LST relationship, which deserve further confirmation. Importantly, high mean R^2 values with large variations on the local urban scale suggest that a great potential exists for mitigating urban heat island effects via urban landscape planning.

Key words:

Urban impervious surfaces; Land surface temperatures; Urban heat islands; Urban landscape sustainability; China

Examining Urban Tree Health using High Resolution Worldview-2 Satellite Image in Hong Kong

Li, Q.S., Wong, F.K.K., Fung, T.

Department of Geography and Resource Management, Faculty of Social Science, The Chinese University of Hong Kong, Hong Kong, leeqiaosi@link.cuhk.edu.hk

Abstract

Increasing cases of diseased tree fall in urban area causes serious casualties in Hong Kong. There are more than a hundred diseased trees which are listed under the category of old and valuable tree in Hong Kong. On one hand, they are old trees with historical and cultural value; however, on the other hand, they threaten public safety at all time. High spatial resolution satellite image can identify individual tree crowns and allows examination of tree health in dense urban area. This study utilized 8-band WorldView-2 image acquired in 2012 and 2014. Innovative vegetation indices (VI) were derived from the spectral data, which provides information about vegetation vigor of a common urban tree species, *Ficus microcarpa*. With reference to the government database, more than 20 crown samples were collected for both healthy and diseased trees. The diseased group was further divided according to density and the types of disease they suffered from including Brown Root Rot Infection (BRR), Dead branches, Bodies, Obvious wound, Dieback twigs, Cavity, Decay. Four VIs emphasising different aspects of vegetation characteristics and minimizing the external effects were computed. The vegetation spectra and 24 VIs were analysed for the diseased and healthy groups statistically. The result showed that canopy water content index yielded significant difference between dense and sparse diseased group. Broadband greenness index such as Enhanced vegetation index (EVI); narrowband greenness index involving pigment content and red edge slope index were able to distinguish the types of disease especially for BRR and when the trees suffered from serious cavity. Results from two years' image showed similar trend. It is suggested that satellite images with higher spatial resolution and with red-edge band have potential in examining individual tree health condition.

Key Words:

WorldView-2; Spectrum Analysis; Vegetation Index; Individual Tree; Tree Health Examination

Growth of Industries and its future with reference to Land Acquisition in Peripheries of Large Metropolitan Cities of India

GUHA. Pallabi and GOMES. Veronica

Centre for the Study of Regional Development, School of Social Sciences, Jawaharlal Nehru University, New Delhi 110067, pallabig10@gmail.com, veronica200790@yahoo.com

Abstract

The process of urbanisation and urban expansion in India has been alacritous. Large cities are growing at a much faster rate in comparison to small towns although core areas have declined. They have developed large peripheries to sustain itself. These peripheries are dynamic in nature and hold a promising future for development. Government policies have played a big role in creation uneven distribution and creating further degeneration and overcrowding of the peripheries.

Policies in particular related to industries have caused their relocation from the city cores to the peripheries. Shifting of the industries in the peripheries has resulted in congestion, land degradation and increase in pollution. The resource mostly affected by such industrial expansion is land. Land around the Metropolitan cities is a scarce resource. Especially in an agriculture dominant country such as India, it is closely tied to livelihood and sentimental values. Policies to accommodate the industries have resulted in land acquisition from the farmers in peripheries. Land acquisition has resulted in destitution of farmers and prosperity for industries.

This paper would attempt to study the growth of industries, its nature of growth, with particular reference to the growth of informal sector over decades. With aid of statistics and mapping an effort would be made to assess the situation. Special emphasis would be on government policies and procedures for land acquisition. The impact of land acquisition in all the six major metropolitan cities for industrial purpose would be studied in order to aid in designing future policies.

Key words:

Peri urbanisation; industrial growth; Land acquisition; livelihood

Research on the Development of New-type Urbanization in Chongqing from the Four-dimensional Perspective of PILE

ZHANG Lin

School of Geography and Planning, Sun Yat-sen University, Guangzhou 510275, China, linzhang930301@163.com

Abstract

New-type urbanization is an individual-oriented process, which intensifies to complete the transformation from “rural” to “urban” on the basis of various aspects such as industrial upgrading, changing land use patterns, and construction of residential environment, and eventually accomplish the aim of coordinative development and integration of urban-rural area, city-industry integration, saving and intensive using, ecological and livable residence and harmonic development. Chongqing is in a critical period of extensive development of new-type urbanization. Studying the development of new-type urbanization from a scientific point of view could promote the process and lay a good foundation for building a well-off society. Therefore, this paper analyzed the background condition of natural resources and the social-economic development strategy of Chongqing and then discussed the development of the new-type urbanization by applying the four-dimensional framework of PILE (Population, Industry development, Land use and Environment) and related econometric model. The results showed as follows:(1) During the period of 2011 to 2013, the composite scores of new-type urbanization developing level raised from 11.7719 to 97.1804 and developmental level experienced three stages: lower level-intermediate level-good level. (2)In the future, the coordination degree of the four elements: population, industry development, land use and environment, will experience a rising trend and gradually achieve the balanced sustainable development, in addition, the five functional areas will present a good trend of growth both in characteristic and differential development.(3)Starting from the actual situation of the five functional areas and combining the need of regional development, to build a different developmental mode of New-type urbanization that reflects the regional characteristics.

Keywords:

new-type urbanization; four-dimensional framework of PILE; five functional areas; Chongqing

The influence of population agglomeration on urban air pollutants' concentration:

Based on 159 prefecture-level cities in China

Xue Yang

Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing, 100101, P. R. China, yangxue_r@126.com

Abstract

Based on 159 cities in China, this paper studied the influence of population agglomeration on concentration of $PM_{2.5}$, PM_{10} and NO_2 . Specifically, population and population density were used to represent population agglomeration, and quadrant diagram method was used to show the relationship between air pollutants' concentration and population agglomeration. The results show that: (1) Only three cities are megacities, that is Beijing, Shanghai and Chongqing. On the other hand, mega-density cities are just four which are Zhengzhou, Shijiazhuang, Baoding, and Handan. It is noted that big population does not represent big population density, and there is no direct causal relationship between them. (2) Xingtai, Baoding and Shijiazhuang have the highest $PM_{2.5}$ concentrations and these places also have the highest PM_{10} concentration. By contrast, the highest NO_2 concentration is mainly distributed in Hebei, Shandong, Henan, the Yangtze River Delta and part of Pearl River Delta cities. (3) $PM_{2.5}$ and PM_{10} concentration are higher in most high population density cities, while these figures are lower in most low population density cities, which demonstrates that $PM_{2.5}$ and PM_{10} concentration are more effected by population density, and the greater the population density is, the greater the concentrations are, and vice versa. (4) NO_2 concentration is higher in cities with high population and high population density, yet this figure is lower in cities with low population and low population density, which illustrates that NO_2 concentration is affected by population and population density at similar extent.

Key words:

population agglomeration; air pollutants' concentration; population density; urban municipal districts

Urban Heritage Conservation and sustainable development: A Geographical Analysis of Udaipur City of Rajasthan, INDIA

Vyas P. R., Paliwal V.S,

Mohanlal Sukhadia University, Udaipur, Rajasthan, India 313001, prvyasgeog@gmail.com

Abstract

“Urban heritage one area that always considered as humane, socio- cultural and economic asset observed by various historic layering of values that have been produced by successive and existing cultures and an accumulation of traditions and experiences, recognized as such in their diversity. Paper focuses on basic policies, issues and challenges toward conservation of urban heritage in historic city Udaipur City of Rajasthan state of India. It is generally supposed that such historic urban centres are most abundant and diverse manifestations of our common cultural heritage, shaped by generations and constituting a key testimony to humankind’s endeavours and aspirations through time and space. Paper discusses the present status of urban heritage and projecting the future position. Further major components urban heritage studied and classified under two major categories, viz., tangible heritage which includes traditional buildings with architectural and historical significance and intangible heritage, comprising socio- cultural traditions. It is considered that emphasis needs to be put on the integration of heritage conservation, management and planning strategies into local development. For this purpose, field study conducted to understand the impact of urban developmental activities on heritage due to urban expansion. Paper also analysed interrelationships between dependant variable like heritage conservation and independent variables like urban growth, tourism development, socio-economic and cultural background of the society. Finally, landscape approach is suggested for heritage conservation towards urban sustainability.

Key words:

World Resource Geography: The Present Status, Deficiency and Opportunity of China's Resource Geography

Qinli Lu, Xianjin Huang

School of Geographic and Oceanographic Sciences, Nanjing University, 163 Xianlin Street, Jiangsu Province 210023,
Chinapassionbyqin@163.com

Abstract

The globalization of resources is highly related to that of economy, while the rapid development of China has benefited a lot from the globalization in recent decades. China is urgent to get the supply of world resources, but the researches in this field are considerably weak. More efforts should be focus on geography of global resources and these measurements play an important role in sustainable development as well as the implementation of strategies. Currently, the researches about world resources cannot keep pace with the demand of them, as the main researches still focus on the analysis of the domestic fields. As for China's closed trading partners, the Eurasian continent and the areas of extending to Africa, it still lacks of specific systematic, target-oriented, in-depth studies, which are behind the pace of development of China's globalization and strategic needs; the similar situation exists in some important countries with global investment strategy. Considering the initiative of One Belt and One Road, it is critical for China to call for international cooperation and forming an international research team for global resources, as well as strengthening top-level strategic direction. Ongoing training for institutional and educational talents is one of the key factors to keep a competitive research team. It is also helpful to enhance the utilization and research of global resources for the further development by establishing a set of complete database for the whole world's resources gradually.

World resource geography; globalization; space; order dislocation

A Comparative Study on the New Urbanization in the Eastern Coastal Provinces of China

Sun Xiaoyue, Ren Jianlan

Abstract

With the continuous improvement of the level of industrialization, urbanization process significantly accelerated in China and process includes the tortuous development, the rapid development and the scientific development. But the traditional model of urbanization is mainly reflected the rapid growth of the urban population, disorderly expansion of urban space, consume a lot of resources and a significant deterioration of the urban environment, the dilated expand hindered the process of the urbanization development seriously in turn. Therefore, the “Eighteen Meeting” clearly stated that China would implement “New urbanization” in the future. The area where new urbanization process developed faster most concentrated in the eastern coastal areas in China, research in eastern coastal provinces and cities in the development of new urbanization process has great meaning to promote the new urbanization of other part in China. The according to previous research, in fully understand on the basis of new urbanization connotation, establish the new urbanization comprehensive evaluation index system with the “urbanization of the population, the level of economic and social life and environmental protection,” using the entropy method to determine the index weight, calculation of eastern coastal provinces new urbanization comprehensive score, the provinces of new towns of differences in degree of development. The results showed that influence factors and their effect are different, the comprehensive development process is also quite different provinces should take different measures according to their own conditions and level of development are the further development of its own new urbanization.

The analysis on industrial water-saving effect of jining city based on the structure and the efficiency factor

Jinna, Qiufangdao

Jiangsu normal university, China, Xuzhou, 221000, 792473914@qq.com

Abstract

Adopting the Laspeyres analysis method, the influence of structure and efficiency factors on industry water-saving are deeply analyzed in Jining from 2005 to 2013. The result indicates that structure and efficiency factors both played a positive role in industry water-saving of Jining from 2005 to 2008, at the same time, the contribution of efficiency factors is superior to structure factors in industry water-saving. From 2008 to 2011, the efficiency factors play a positive role for water-saving in industry, but the structure factors on the water-saving in industry present an inhibitory effect; The structure factors play a positive role for water-saving in industry from 2011 to 2013, which is superior to efficiency factors.

Key words:

water-saving in industry; efficiency factors; structure factors; method of Laspeyres; Jining

Coupling relationship between urbanization efficiency and economic development level in the northern slope of Tianshan Mountains

Zhang Tingting^{1,2}, Cao Yuee^{1,2}

¹College of resources and Environmental Science of Xinjiang university, Urumqi, 830046, P. R. China, 497653407@qq.com

²Key Laboratory of Oasis Ecology, Urumqi, 830046, P. R. China

Abstract

The paper used the DEA model, analytic hierarchy process and a model for coupling degree to analyze urbanization efficiency, economic development level, and the coupling relationship between the two for the 12 cities on the northern slope of Tianshan Mountains from 2005 to 2014. As a result, theoretical exploration was conducted and a conceptual model was proposed. The results showed that: During the 10 years of evolution, the economic development level in the northern slope of the Tianshan Mountains has been in an upward trend; regional development reached a balanced stage, and the coupling relationship between urbanization efficiency and economic development level exhibited slow rise-sharp, the regional gap is large and persistent. Four cities are in better coordinated development, including Karamay, Shihezi, Urumqi and Kuytun. There is a dynamic coupling relationship between urbanization efficiency and economic development level. The main types of coupling relationship in the cities are low coupling type, medium level coupling type, the highest coupling type, which are concentrated in spatial pattern and show stability in distribution of the annual variation, higher coupling type closes to the highest coupling type. Those cities with higher economic development level are the first to be independent of the effect of urbanization efficiency. The root cause is the congenital endowment and coordination development imbalance situation of cities in urban agglomeration.

Keywords:

urbanization efficiency; input and output; economic development level; coupling relationship; the northern slope of the Tianshan Mountains

Density, Distance, Division: Analyzing Industrial Pollution Emissions of Yangtze River Delta from the 3D Framework

Chen xiaofei¹, Liu guilin², Zhang luocheng¹

¹Nanjing Institute of Geography and Limnology, Chinese Academy of Sciences

²Department of Environmental Remote Sensing and Geoinformatics, University of Trier

Abstract

The relationship between economic development and environmental pollution has been widely studied in the context of the EKC (Environmental Kuznets Curve). However, this study employs a 3D (Density, Distance, Division) analysis framework proposed by the World Bank to analyze the relationship between density, distance, division and industrial pollution emission. Economic density has a significant impact on the industrial pollution emission, the regression coefficients of 0.617, 1.880 and 1.402 for SO₂, wastewater, and soot emission, respectively. Integrated transport distance plays a negative role to wastewater (−1.331) and soot emission (−0.511), but is not significantly correlated with SO₂ emission. No obvious relationship is reported between division and industrial pollution emission. Foreign direct investment (FDI) has a positive influence on industrial pollution emission. However, the manufacturing specialization indexes (MSI) has a negative effect on SO₂ and soot emission. FTV also has a negative effect on wastewater and soot emission.

Key words:

industrial pollution emission; 3D framework; Yangtze River Delta

Evaluation on Spatio-temporal Development and Coupling Relationship between ecological civilization construction and urbanization in China

Bi GH, Yang QY

School of Geographical Sciences, Southwest University, Chongqing, 400715, P. R. China, 895559691@qq.com

Abstract

Assessment on spatio-temporal development and coupling relationship of ecological civilization construction and urbanization is helpful for China to promote the sustainable development of socio-economy. This paper, focusing on the coupling relationship between ecological civilization and urbanization, evaluated the spatio-temporal development and coupling relationship between ecological civilization construction and urbanization in China during 2008~2014, using the model of coupled coordination degree which based on the index system of ecological civilization construction and urbanization. The results show that: (1) From the data of coupling coordination degree we calculated, in provincial level administrative level, on the whole, 85.48 percent regions were in the running-in stage (the stage means the coupling coordinated development stage between ecological civilization construction and urbanization), 6.15 percent regions were in the antagonistic stage and the rest of 8.07 percent regions were in the coordination stage. (2) During 2008~2014, the coupling coordination development between ecological civilization construction and urbanization in China was in the running-in stage generally, and the level of ecological civilization construction still lag behind urbanization development. (3) The couple coordinated development process of ecological civilization construction and urbanization have existed volatility. To promote the coupling development between ecological civilization construction and urbanization, China should pay attention to improve the quality of ecological civilization construction.

Examining the Long-Term Bidirectional Relationship Between Urbanisation and Energy Consumption, and CO₂ Emissions in China

Kunlun Chen^{1,2}

¹Faculty of Resources and Environmental Science, Hubei University, Wuhan 430062, China

²Regional Development and Environmental Response Key Laboratory of Hubei Province, Wuhan 430062, China,
ckl_2001@163.com

Abstract

Currently, Chinese new-type urbanisation is an important engine for steady, economic transformation and its development. Meanwhile, the key to Chinese new-type urbanisation is the transformation and development from the urbanisation of land to the urbanisation of people. Faced with this trend, governors of cities at different levels, who make policies regarding the sustainable development of towns, can be supplied with scientific, empirical analysis to fully understand the influence of the urbanisation of the population on changes in energy consumption and carbon dioxide (CO₂) emissions. This paper studies the long-term relationship between the urban population, energy consumption and CO₂ emissions in China's provincial capital cities. We use the fully modified ordinary least squares (FMOLS) model to analyse samples of the time series of urban residents' primary energy consumption and the total amount of CO₂ of all Chinese provinces and municipalities directly under the central government from 1980 to 2011. The results show that, there is a long-term, positive, bidirectional relationship between the population urbanisation, energy consumption and CO₂ emissions in all provinces of China except Yunnan and Shanxi provinces. Based on this conclusion, this paper suggests that governors of cities at different levels should not only attach greater importance to the optimisation and upgrading of urban industrial structures, energy conservation and CO₂ emission reduction, but should also place more importance on the social aspects of a low-carbon lifestyle and focus on constructing a low-carbon urban life.

Keywords:

population urbanisation; energy consumption; carbon emissions; FMOLS

Hotspots and knowledge base of sustainability science research: based on data of sustainability science

SU Fei*, YING Rongrong

School of Tourism and City Administration, Zhejiang Gongshang University, Hangzhou 310018, China

Abstract

Sustainability is the theme of our time and also the grandest challenge to humanity. As a science that provides the theoretical foundation and practical guidance for sustainable development, sustainability science began to emerge in the beginning of the 21st century and became a hotspot research in global environment change research. Firstly, according to the web of science database from 2006 to 2015 which included the literatures of sustainability science, the paper analyzed the sustainability science's distribution status, in terms of subject, author, organization etc, by using statistics and visualization. The results show that the quality and influence of the sustainability science research is on a rising trend, mostly specializing in the subject of geography, ecology, environment, or other related topics. Five countries (i.e. Japan, United States, Germany, Australia, and Canada) and research institutions of Tokyo University, United Nations University, Arizona State University, Ibaraki University, Kyoto University, Osaka University, and Chinese Academy of Sciences show great research strengths of sustainability science. Secondly, applying the information visualization software CiteSpace, this paper drew the document co-citation network of sustainability science, and discussed the knowledge base and core authors. Scholars like Komiyama H, Lang D J, Miller T R, Talwar S, Clark W S, etc. and their representative works laid a solid foundation in the establishment of the theoretical elementary knowledge and other related researches. Finally, based on the keywords and burst phrases analysis of co-word and word frequency, this paper drew the evolution network of sustainability science research hotspots, and explored the frontier proposition research of climate change, management, sustainability, framework, adaptation, vulnerability, resilience and so on. Knowledge base of sustainability science research mainly includes the "discipline development", "interdisciplinary research", "planning mechanism", "disaster management", "information management", "island environment", "coastal vulnerability assessment", "land use", and "landscape".

sustainability science; research hotspot; knowledge base; visualization analysis

Land reform of the Dongguan village-based development: Impact analysis and implications

Jin Haoran, Liu Shenghe

Institute of Geographic Sciences and Natural Resources, 100101, P. R. China, 7787167@qq.com

Abstract

Expropriation of collectively owned farmland has long been blamed for depriving farmers of their rights and equitable sharing of potential benefits from subsequent profit-led developments. Expropriation has also led to serious social problems such as the “Three-No Farmers” (no land, no job and no social security). During the Third Session of the 18th Central Committee of the Communist Party of China held in November 2013, a deepened reform was undertaken to allow rural land to enter directly the land market under certain conditions. This paper explores the feasibility in implementing this new approach and examines its positive and negative impacts based on the Dongguan Model in Guangdong province. The paper has three main sections. Section 2 introduced the background of Chinese land policy system and related studies. Section 3 overviewed the Dongguan land development model, including its creation, characteristics and operating mechanism, and then examined the changes brought about by the new model including land use, income, population mobility and attitudes of the local population towards urbanization and newcomers. Section 4 summarized the potential economic, social and environmental impacts through impact analysis on the Dongguan model, and gave some discussions and policy implications. This paper supports the new model that collectively owned construction land should be allowed to enter market-based operations in conformity with land use planning and use control measures.

land reform; Dongguan model; village-based development; impact analysis; implications

On the new driving mechanism of urbanization process: a case study of Wuhan City

yanping wen

china university of geosciences

Abstract

With the economic development of transportation and communication technology, industrial agglomeration in the city caused by the original polarization effect has not become only direction, the agglomeration and diffusion of the two direction are prevailing. The thesis discusses the reasons of the new trend, including the traffic jam and the rapid development of metro and express way, the rapid development of electronic commerce, and changes in consumption patterns and ect. The thesis will discuss the process of the urbanization, the reasons and spatial evolution, takes Wuhan city as an example.

Key words:

driving mechanism; urbanization

Potential exposure of vulnerable groups to air pollution in major Spanish cities: a GIS-based method for assessing environmental justice

Moreno-Jiménez A

Department of Geography, Universidad Autónoma de Madrid, 28049 Madrid, Spain, antonio.moreno@uam.es

Abstract

The concept of environmental justice (EJ) has recently gained currency, both as a factor for and a goal of city sustainability. Its measurement in practice implies focusing on a kind of man-environment interaction causing unequal burden distribution among sociodemographic groups, and setting a standard procedure to elucidate the amount of unfairness.

To measure inequalities more objectively and consistently it is proposed a method based on two complementary techniques: the goodness-of-fit type one-sample χ^2 test and the environmental justice balance or scale diagram, to test the null hypothesis (H_0) that the proportional exposure of a given population group to unacceptable levels of atmospheric pollution (as stated by international regulations) is identical to that of the resident population as a whole (taken as baseline criterion). Some Spanish largest cities have been chosen as case-studies. Firstly, the spatial pattern of an air pollutant has been modelled, and secondly it has been related to the geographic distribution of some vulnerable population groups (children, elderly people and international immigrants) in the year 2010. This GIS-based methodology has provided insightful results uncovering which groups, and how much, suffer potential exposure to air pollution exceeding the maximum permitted levels disproportionately, which would imply a case of environmental injustice.

Key words:

environmental justice; urban pollution; vulnerable groups; spatial interpolation; Spanish cities

Research and Assessment of City Competitive in Wanjiang Urban Belt Based on Principal Component Analysis

Fengyun Mu, Shuaiqi Li

Chongqing Jiaotong University, Chongqing, 400074, P. R. China, 76237408@qq.com

Abstract

With the rapid development of economic globalization and the rise of Multi-national Corporation, the role of city in the national and regional economy has become increasingly prominent. As the first industrial transfer demonstration zone, Wanjiang urban belt is playing a decisive role in connecting economy and trade of east and west China, also in realizing the rise of central China and the Pan Yangtze River Delta. The comprehensive competitiveness evaluation index system is constructed in this paper. Economic, science and technology, infrastructure, government efficiency, opening-up policy are selected as indexes to evaluate a city's competitiveness. Statistical data related to the research is collected for quantitative evaluation of competitiveness on the basis of principal component analysis. He-fei, Wuhu, Ma'anshan, Tongling, Anqing, Chuzhou, Xuancheng, Chizhou, Lu'an is the ranking result of wanjiang urban belt. Competitiveness of each index is also analyzed in order to evaluate the competitiveness of each city accurately. Finally, proposal to enhance the comprehensive competitiveness of Wanjiang urban belt city is put forward.

Research on Spatial and Temporal Pattern of Healthy Urbanization Based on Status-Driving analyzing frame in Henan Province

LIU Jingyu, SONG Qiong, XIE Zhixiang, DING Fangfang, DING Zhiwei

Research center of Region Development and Planning/College of Environment and Planning, Henan University, Kaifeng, 475004, P. R. China, jingyuli2003@126.com

Abstract

On the base of understanding to healthy urbanization, the Evaluation index system of healthy urbanization was established which included status index system and driving index system. Entropy weighted grey correlation model, Theil indexes and Coupling harmonious degree model were used to analyze the spatial and temporal pattern of Healthy Urbanization in Henan province. Results were shown as follow. From the perspective of time, at the angle of status side the level of healthy urbanization in Henan province from 2002 to 2014 was increasing continuously; the obvious influencing factor of healthy urbanization to sustain side became social development, economic development, and optimizing of resource and environment, et.al, but former factor was only social development. And at the angle of driving side, the supporting capacity of pulling and pushing was weak; and pushing sustain system side arrived at the stage of reluctant coordination in 2011, however pulling sustain system side steadily arrived at the stage of reluctant coordination in 2011, pushing sustain system side and pulling sustain system side all arrived at the stage of primary coordination in 2014. From the perspective of space, at the angle of status side the level of healthy urbanization for every city in Henan Province from 2002 to 2014, kept increasing and the regional difference among 18 provincially-administered cities became small. And at the angle of driving side the contribute from pulling sustain system to healthy urbanization was increasing contentiously and its regional difference became small; and the change of Comprehensive coordination index and Coupling coefficient which explaining the coupling coordination degree was contrary. And the contribute from pushing sustain system to healthy urbanization was increasing and its regional difference became small; and two index, Comprehensive coordination index and Coupling coefficient, to explaining the coupling coordination degree became small respectively. At 2002 and 2014, the important factors to affect healthy urbanization from driving angle side was different.

Rethinking of China's Population Urbanization and Land Urbanization Allometric Growth Based on the Structure

Wang Botao, Wang Chengxin, Wang Xiangyu

College of Geography and Environment, Shandong Normal University, Ji'nan, 250014, Shandong, 404122665@qq.com

Abstract

Recalling the 20 years of China's rapid urbanization process, the contradiction between the shortage of land resources and the sharp increase in the demand for urbanization has been sharp. It has become the consensus of government and experts that the speed of land urbanization is faster than the population urbanization. But from the perspective of urban systems, it is only a surface phenomenon. From the perspective of regional structure, construction land and urban scale structure, and adopting the allometric growth model, this paper analyzes the internal relations between land urbanization and population urbanization allometric growth from 2001 to 2014. The results showed that land urbanization in the eastern and central regions of China is always faster than the population urbanization while the western region does not exist the problem from the perspective of regional structure; From the perspective of the construction land structure, administration and public services land, logistics and warehouse land, residential land do not exist the phenomenon. Although industrial land, green space and road and transportation land expand faster than urban population growth, it reflects the optimization and upgrading of urban functions; From the perspective of the urban scale structure, below 0.2 million, more than 5 million urban land intensive utilization level is higher; 0.2-0.5 million and 0.5-1 million urban land urbanization is faster than population urbanization phenomenon obviously. There are significant regional and structural differences between Chinese population urbanization and land urbanization, and the new urbanization policies should adjust the measures to local conditions in the future.

Key words:

Population Urbanization; Land Urbanization; Allometric Growth; Structure; China

Spatio-temporal Differences and Optimization Simulation of Safety Warning on Carbon Emissions in China

RONG Pei-jun^{1,2}, YANG Qun-tao¹, QIN Yao-chen^{*1}

¹College of Environment and Planning/Collaborative Innovation Center for Coordinating Industrialization, Urbanization and Agriculture Modernization in Central Economic Zone, Henan University, Kaifeng 475004, Henan, China

²Yellow River Conservancy Technical Institute, Kaifeng 475004, Henan, China

Abstract

Carbon emissions secure is an important part of ecological security. This paper used statistics which is from 1996 to 2012, took 30 provinces(except Tibet) of Chinese mainland for study units, analyzed energy consumption carbon emissions secure spatial and temporal differences, which can provide some guidance on the regional carbon emissions reduction strategy and sustainable development. The early warning indicator system of energy consumption carbon emissions was built based on the pressure-response model, three levels: economic, social and environmental. The results showed that: from 1996 to 2012, energy consumption carbon emissions security alarm degree of the whole China had been worse and there was some spatial agglomeration phenomenon; most provinces faced more and more pressure while paid more and more attention to the responding measures; the sensitive indexes of Pressure system focused on the energy structure, industrial structure, economic development pressure and social development; sensitive indexes of response system focused on economic investment, technical improvement and increasing carbon sink; from the point of the simulation results, except the provinces of Zhejiang and Guizhou, the contribution of pressure system in other provinces to carbon emissions safety state change was bigger; each province should adjust measures to local conditions to cope with carbon security early warning.

energy-related consumption carbon emissions; security warning; space-time differences; China

Temporal and spatial variation of the precipitation in Huang-Huai-Hai plain from 1963 to 2012

LI Yanan

College of Environment and Planning, Henan University, Kaifeng 475004

Abstract

based on daily precipitation data for 85 national meteorological stations in the Huang-Huai-Hai plain during the period 1963-2012, this paper analyzed the variation of precipitation days and intensity, trends, periodicity and abrupt change. The results indicated that: (1) In recent 50 years, both the average rainfall days and intensity gradually decreased from southeast to northwest. The distribution characteristics of extreme rainfall index similar to annual precipitation index; (2) The annual variation trends of the average rainfall days showed an obvious decrease in contrast to the trend of precipitation intensity, that of the extreme rainfall index of the same level are consistent. The spatial of annual variation trends are quite different. The trend of the average rainfall days and intensity are consistent with the overall trend. The extreme rainfall index variation trend of some regions are in contrast to that of the overall trend; (3) Indicated from the precipitation periodicity, precipitation index showed obvious different periodic oscillation during the period, the number and strength of the precipitation index are different between different time scales, all the precipitation index had a same oscillation of 28a. (4) Indicated from the precipitation abrupt change, Precipitation index are all abrupt changed under the 0.05 significance level. The abrupt change of annual precipitation days and precipitation intensity are significantly decreased, while that of the extreme rainfall index are non-significant.

Key words:

Temporal and spatial variation; Huang-Huai-Hai plain; Rainy days; Precipitation intensity

The pattern and trend of China's urbanization on two sides of Hu Huanyong population line

Mingxing Chen, Yinghua Gong

Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing, P. R. China, chenmx@igsnr.ac.cn, mengmengff@hotmail.com

Abstract:

In November, 2014, Chinese Premier Li Keqiang raised a problem about Hu Huanyong population line (hereinafter referred to as "Hu line"), when visiting the exhibition of sciences of human settlements in National Museum of China, which was called "Premier's Question" by the press. Hence, Hu line has become a highlight currently, and aroused great controversy and different views. Aiming at such dilemma of cognition, this paper gives a general review of the origins of Hu line, which was put forward by the famous population geographer Hu Huanyong in 1935, under the background of a debate on the surplus of domestic population. Based on population census data and GIS platform, the paper analyzes the change of population scale, proportion and density in both southeast and northwest sides of Hu line. The results indicate that the population urbanization and migration do not change the pattern of population distribution determined by Hu line. On such basis, the pattern that the population density of southeast part is large, while that of northwest part is relatively small will not radically change over a longer period, and the pattern that urban agglomeration is mainly located in southeast part as well. The long-term existence of Hu line depends on integrated physical geographical conditions, like climate. At the meantime, this paper argues that the core issue of the Premier's concern is solvable, by positive policy guidance and reasonable spatial organization. It is definitely promising for western China to realize a higher level of modernization and a better quality of urbanization, and central region as well.

Hu Huanyong population line; The Premier's doubt; urbanization; pattern; trend

The Resource Environmental Capacity Evaluation Of The Pearl Island

jieyi lu

School of Geographic Science

Abstract

With the accelerating of China's urbanization process, the urban agglomeration has become the most vitality and potential core-area among the pattern of China's economic development. It dominates the lifeblood of our country's economic development. At the same time, the regional urban agglomeration is an area where series of problems of resources and environment happened. As for this situation, the concept of "capacity of the resource environmental" is presented on the capacity of the resource and the capacity of the environment. It refers to the capacity that the environment can support the total population and the corresponding social economic among the area of different scale in a certain period of time. We applies the principal component analysis to evaluate the capacity of the resource environmental and the difference of nine cities in the pearl island. We selected eleven variables to be as the analysis indicators of the resource environment capacity, including population density, GDP, Unit GDP year-on-year and so on. We construct an evaluating index system and a principal component of integrated model. And the results of our study show that the internal resource environment capacity between nine cities in the pearl island is significantly different. The bigger of the city it is, the better resource environment capacity it has. Geographically, the cities which have the better resource environment capacity are located in the coastal areas. By contrast, the cities which have lower resource environment capacity are located in the inland area.

resources and environment; capacity; the pearl island

The Spatial and Temporal Variation of Haze and Its Relativity in the Beijing-Tianjin-Hebei Region

Zhao XuYang, MA XiaoQian, LIU Zheng

The Geographical Society of China, Shijiazhuang, 050035, P. R. China, log2008@163.com

Abstract

Beijing-Tianjin-Hebei Region is typical haze-prone area, haze temporal distribution of research in this area and its distributing characteristics are good for the prevention of significant haze. Research in November 2014. During this period the article this area in December 2013 showed that: ① Beijing, Tianjin and north-south distribution of haze during this period varies greatly, late fall to early winter $PM_{2.5}$ concentration suddenly increased, the spatial extent of constantly expanding from southeast to northwest. Late winter to early spring $PM_{2.5}$ concentration decreased rapidly shrinking space range from northwest to northeast. ② When the weather is cold high pressure control, no wind or the wind is relatively small, the most vulnerable to the formation of fog haze; ③ The second industrial energy consumption and $PM_{2.5}$ concentrations closer relationship, especially industrial energy consumption. ④ Meteorological elements are gathering haze, transfer and diffusion of important influencing factors, and socio-economic factors that affect the fundamental reason for Beijing, Tianjin and haze-prone. Therefore, prevention of haze, should be based on weather conditions in different time periods, and to take appropriate preventive measures. The socio-economic factors as the fundamental starting point, the search for effective measures to control the haze.

The sustainability and conflicts of urban development (on example of Kyiv and some cities of Ukraine)

Rudenko L., Lisovskyi S., Maruniak Eu., Mozgovyi A.

Institute of Geography of Ukraine NAS, Kyiv, 01030, Ukraine, cerebralis@gmail.com

Abstract

Transition to sustainable (balanced) development was announced as the main task for humanity on the XXI century. Today more than half of world population lives in cities. So, sustainable development of cities is a key element for provision of global society's progress. However today, cities, with an impressive concentration of population and production within a small area, show incredible intensity in social and natural systems as well as significant number of development conflicts. Therefore, modern urban concepts are based on a search of acceptable balance of economic, social and environmental parameters for prospective urban development. The most developed countries have achieved visible success in straightening of the urban development sustainability indicators by improvement of planning system, utilization of new technologies, and infrastructural investment.

Unfortunately, Kyiv and other Ukrainian cities have performed badly in sustainability rankings. Authors investigated causes which contribute to the current low level of Kyiv and other major cities sustainability. The conflicts of urban environment in these cities were also analyzed. As a result recommendations to ensure sustainability and reduce conflicts in Ukrainian cities to lower level were developed.

Key words:

sustainable (balanced) development; sustainability; urban conflicts; environment; Kyiv; Ukraine

Urban green space as an urban heat island mitigation: case study of Shenzhen, China

LEUNG KW, QIAN J, PENG SH, SUN B

Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, 1068 Xueyuan Avenue, Shenzhen University Town, Shenzhen, 518055, P. R. China, jw.liang@siat.ac.cn

Abstract

Urban heat island (UHI) is not uncommon to find in the highly urbanized area. There are many impact brought by the UHI to the cities, such as altering local micro climate, changing the urban habitat, affecting the energy consumption, causing negative impact of human health and etc. Urbanization is one of the vital factors in causing UHI. Since the 'Open Door Policy' of China in late 1980s. Shenzhen is the city have been experiencing a very fast urbanization rate. Therefore this study would use Shenzhen as a case study to investigate the UHI. The remotely sensed data from LandSat is adopted to analysis the UHI-prone area and the urban green spaces distribution. On the other hand, urban green space are located in the city to understand how it helps in mitigate the UHI in the study area. The ultimate aim of this study is to suggest the effective urban green space distribution in order to ease the effects of UHI for the study area. It is hoping that the experience can be share with other cities share similar situation.

Urban Heat Island; UHI; urban green space; Shenzhen

Vegetation Cover Dynamics Associated with Rapid Urbanization in Metropolitan Areas of East China (1998-2010)

Weifeng Li¹, Jiansheng Wu², Qian Lin²

¹Department of Urban Planning and Design, University of Hong Kong, Hong Kong SAR, China, wfli@hku.hk

²School of Urban Planning and Design, Peking University Shenzhen Graduate School, Shenzhen, 518055, China

Abstract

It has recently gained increasing attention to promote sustainable urbanization in China due to the environmental consequences associated with the rapid urbanization in the past two decades. How vegetation cover, as an important indicator for environmental sustainability, was affected by different urbanization trajectories in China's major metropolitan areas is of great interest but rarely studied. In this paper, we used DMSP/OLS nighttime light time series images and SPOT-VGT satellite-derived Normalized Difference Vegetation Index (NDVI) to evaluate effects of urbanization on vegetation cover in the six major metropolitan areas (urban agglomerations) of East China over the last decade. We mapped urbanization dynamics at regional scales with nighttime light data and identified different urbanization trajectories based on the temporal signatures. The NDVI was then added to study the characteristics and change of vegetation cover in the areas with different urbanization trajectories. The study revealed that in general the vegetation cover decreased with an increase in level of urbanization. When compared to the average change rate of NDVI in the non-urban areas (which in fact showed an improvement trend in all six regions), the result indicated a negative average change in vegetation cover in all of the selected metropolitan areas. However, we should be aware that the trend was not merely a downward trend but was a U-shaped curve. In other words, the decrease rate accelerated at the early stage of urbanization and recovered in the later stage of urbanization, and the peak value appeared in different stages across different regions. We believe different patterns of NDVI changes were closely linked with these regions' policy-oriented differences in urbanization dynamics, which also highlighted the importance of implementing a sustainable regional growth policy.

An Analysis of Urban Residential Densification and Urban Expansion of the city: The Case of Shenyang, China

Jiang D, McWilliams C, Morgan J

Institute for Social Policy, Housing, Environment and Real Estate (I-SPHERE)

School of Energy, Geoscience, Infrastructure and Society

Herriot-Watt University, Edinburgh, EH14 4AS, United Kingdom, dj62@hw.ac.uk

Abstract

Residential development in urban areas is a complicated process, and it has two main characteristics: substantial spatial; and temporal variation. Essentially, urban residential development has two main features: new housing construction within existing urban areas; and new housing construction on new residential land. The former one is defined as residential densification, and the latter one is defined as urban residential expansion. For over three decades now, China has experienced urbanization at a rapid speed due to large scale rural-to-urban migration of millions of people. Most Chinese cities are currently experiencing both residential densification and urban expansion simultaneously. Urban residential densities can explain and demonstrate the recent urban residential development, and changes of urban residential densities depend on several factors, such as the urban planning system, urban land supply and land acquisition, residential mobility, and government intervention. This study will focus on the urban residential development processes in the city of Shenyang, including an analysis of the key features and the processes which have influenced contemporary residential densities using GIS data and statistical method, plus semi-structured interviews for residential policy implementation.

Key words:

Residential densification; urban expansion; residential density; GIS mapping

Distinguishing the 'Geographical City' from the 'Administrative City': A Field Based Study of Bhubaneswar, Eastern India

Pradhan Gourabamaya

Centre for the Study of Regional Development, School of Social Sciences, Jawaharlal Nehru University, New Delhi, 110067, INDIA, gourabamaya.jnu@gmail.com

Abstract

The increasing pace of urbanisation is resulting in rapid changes manifested through demographic, social and economic connotations not only within cities but also in their surrounding region. Together, the city and the dependent settlements surrounding it constitute a functional region. Past approaches to urbanisation and development studies focusing on urban and rural areas separately have failed to provide a clear understanding of a region. Therefore, in recent years, there has been increasing scholarly interest on the theme of rural urban interaction. The fact that people's activities in peri-urban areas are very much assimilated into the urban processes and vice-versa triggers the necessity of urban and regional planners to understand more clearly about the geographical city which extends much beyond the administrative city in a multidirectional manner. The tremendous increase both in terms of population and area has led to the more than doubling of the area earmarked to be developed by Bhubaneswar Development Authority (BDA) in 2011. In that backdrop, it is here attempted to distinguish the geographical city of Bhubaneswar by identifying the broader framework of rural – urban interaction in Bhubaneswar Development Plan Area (BDPA) as one functional region. Following a multi stage stratified random sampling technique, 473 households in selected 26 villages, were surveyed to gather data on transport connectivity, accessibility, commuting pattern, frequency and purpose of visits of rural inhabitants to the four urban centres in the study area. The interaction pattern varies considerably across three distance zones-inner, middle and outer.

Key Words:

Rural urban interaction; geographical city; urban and regional planning

Geographical basis of improvement of the population settlement system of Kazakhstan

Akiyanova F., Yegemberdiyeva K., Temirbayeva R., Lyy Yu., Zinabdin N., Bekkuliyeveva A., Valeyev A., Kitapbayev A.

Kazakhstan National Geographic Society, Astana, 010000, Republic of Kazakhstan, akiyanovaf@mail.ru

Abstract

Development of population settlement systems is characterized by irregularity and depends on several factors: geopolitical, socio-economic, demographic and environmental. The current population settlement system of Kazakhstan generally was formed as a result of a long evolution. By the early twentieth century, Kazakhstan was still a country with a rural settlement. In Soviet times, there was the formation of the settlement system that met the requirements of the Union State. Given the gap between social and economic links due to the collapse of the USSR, also the problems of settlement aggravated, which had to be solved by Kazakhstan in the period of independent development. At that, in the system of settlement, the necessity of solving a number of problems, the main of which include reducing number and unsettling of rural settlements, has ripened. Problematic issues include the condition of many single-industry towns and small cities of Kazakhstan, problems of overpopulation of large cities and their suburban areas had also appeared, the population in them is not provided with places of work. Solution of this problem can be based on an integrated approach based on a "green economy", the regulation of settlement systems of architectural and planning tools, as well as implementation of the principle of unity of natural and natural-cultural landscape with technological system of cities by creating a natural and ecological framework. To develop geographical bases of formation population settlement system based on the principles of environmental comfort and safety of life of the population.

Key words:

population settlement system of Kazakhstan; problems of settlement; geographical bases; green economy; the principles of environmental comfort

India's Residential Rental Housing

Arjun Kumar

Jawaharlal Nehru University, New Delhi, India, arjunsingh5184@gmail.com

Abstract

In 2011, more than one-tenth of the households in India lived in rented houses (27.4 million), of which almost four-fifth were in urban sector. Practically, renting a house may form a pragmatic and a deliberate choice to some households. The guiding reasons may range from choices of migration, mobility, and flexibility in managing household finances. It has the potential to improve productivity and promote entrepreneurship. Despite holding such value and developmental potential, rental housing market has been broadly neglected. In India, landlords have assumed an upper hand, and they exploit the poor and vulnerable tenants, especially poor migrants for whom rental housing offers an important option particularly in informal settlements, through exorbitantly high rents for crowded and sub-standard housing. It is unfortunate that governments, over the years, have done little to support the improvement of the existing rental markets or the expansion of the supply of rental houses, and neither have there been any development of loan programmes to encourage it. Indiscreet, successive rent control acts, which were primarily intended to protect tenants from eviction and unfair increases in market rent, have only ended up shrinking all future investment in rental housing and, in many cases, led to housing stock being withdrawn from the rental market, leading to the rise in Vacant houses in the market and hence aggravating the rental housing supply shortage. Ignoring rental housing in policy has simply deepened the inadequate quality of housing and basic services for urban poor tenants, making them more vulnerable. This paper analyses the situation of rental housing in India. Various facets like the existing market mechanisms, legislations, policies and emerging issues relating to it are discussed, apart from the analysis of the empirical evidences on - residential rental housing's magnitude, trends, nature and characteristics in aggregation, across consumption expenditure classes, and across states and size classes of towns/cities, besides trends in rent price and vacant houses – using data from the Census of India (houselisting and housing data) and National Sample Surveys (housing condition rounds). Empirical findings suggest that the share of the households living in rented houses out of the total number of households in India was substantially more in Union Territories (UTs), in developed and urbanized states, and also in larger towns/cities. Across economic categories, the share of households living in rented houses was found to be higher towards the top MPCE quintiles, especially in the urban sector. The government, through Pradhan

Mantri Awas Yojana, Atal Mission for Rejuvenation and Urban Transformation (AMRUT), and (upcoming) The Model Tenancy Act, 2015, must work to ensure that there is sufficient rental and housing stock so as to meet the diverse needs of all the families in the country. Developing sustainable social rental housing is possibly the most effective and efficient way towards the formulation of a more inclusive and balanced housing policy.

Property Development and Capital Circulation in a Resource Boomtown, with Reference to Ordos City, China

SuX, Qian Z

School of Planning, University of Waterloo, Waterloo, ON, N2L 3G1, Canada, x34su@uwaterloo.ca

Abstract

Ordos is a natural resource-abundant frontier city located in China's Inner Mongolia Autonomous Region, where its property market has experienced dramatic rise and fall during the past 15 years. Few existing studies have examined the flow of capital regarding the property development during a housing boom and bust cycle in a mid-sized Chinese city. Under the theoretical discourse of circuits-of-capital argument with regard to commodity production and built environment introduced by David Harvey, this study investigates the flows of capital among various agents with different interests and characteristics. Our findings suggest that, firstly, capital movement regarding property development is not solely conditioned by the relative profitability of the production sector, but rather significantly affected by the local government. Secondly, In Ordos City, the profitability of production sphere and the investment into built environment witnessed similar trajectories, rather than the contrary trends as Harvey's argument suggest in an advanced market economy. Thirdly, this study discovers that self-gathered funding raised by the general public in Ordos City plays a dominant role in fueling local property development, which brings new insights for the theoretical discourses of capital switching. Last but not least, this research reveals the existing policy deficiencies in the realm of urban investment and property development in Ordos City and makes policy implications.

Key words:

capital circulation; property development; self-gathered funding; Ordos City

Relationship between Spatial Renovation and Collective Memory of Inhabitants in Historical Districts: Situationists' Mapping of Da Shi-Lar

ZHAO YIZHOU, HUANG HUAQING

School of Architecture, Tsinghua University, Beijing, 100084, P. R. China, yizhou_zhao@163.com

Abstract

With rapid urbanization, spatial planning and renewal in historical districts at its core has been an essential issue and research frontier. With new perspective and new method, this paper use situationists' mapping to analysis the relationship between contemporary spatial renovation and collective memory of inhabitants, which involves two aspects, the influence of spatial renovation on inhabitants' collective memory inheritance, and the inspiration from inhabitants' collective memory to spatial renovation strategies as well.

Precisely, based on collective memory theory and its objective elements, this paper illustrate the concordances and discrepancies between collective memory of inhabitants and objective elements of spatial renovation, by means of investigating, situationists' mapping and layer drawing on typical spaces. The results shows that situationists' mapping could lead a better understanding of the inter-relationship between different specific renewal spaces with collective memory, and same typical renovation space with collective memory of different inhabitants. Based on the results, reasonable thinking and strategies were put forwards, which would have significant and creative implications both for research and practice.

Key words:

West Da shi-lar district; situationists' mapping; spatial renovation; collective memory

Third kind of settlement an approach to livable and sustainable communities

Mahmoud jomehpour

social, urban and Regional planning, Allameh Tabataba'i University, Tehran, Iran, jomehpoor@atu.ac.ir

Abstract

The main idea of this paper is that the present rural and urban settlements could not provide of good life and wellbeing for citizenships. It is necessary to seek for a new pattern of settlement that to behaving compatible with the needs and demands of modern society and also provide sustainable development term and reduce the imbalance in the current rural and urban settlement.

This article is based on the method of conceptual analysis of the theoretical and experimental with use from theoretical and statistical evidence and qualitative analysis of the current situation and idealistic realist favorable settlement of the situation in Iran. The theoretical basis in this research is empirical studies by researcher and 20 years experience in field of towns and villages. However, the social and ecological views have formed to the idea and sustainable development approach have effective role in idea construction. The rural and urban settlements issue analysis shows that transition from traditional to modern society led to that settlement patterns could not adapted it new live patterns and social and economical needs of peoples. The sequence of this trends have been rapid rural- urban migration and to appear of urban problems. The main finding of this study is to solve the rural and urban problems with alternative solutions. The alternative solution is third kind of settlement that named Rostak in here.

Urban and regional development policies and the Greater Mekong Sub-region in continental Southeast Asia

Ikuta, M

Ritsumeikan University, Kyoto, 603-8577, Japan, mit05356@lt.ritsumei.ac.jp

Abstract

The regional economies in some nations are changing rapidly and complicatedly, with both industrialization and urbanization in continental Southeast Asia. The development projects of the Greater Mekong Sub-region (GMS) have been realized insofar as the country has believed that improvements in infrastructure, roads, power stations, and in other areas can effectively contribute to economic growth. China, a member country, has been contributing especially in the northern GMS. A number of foreign companies have invested directly in the regions, and some border areas are growing promptly due to the difference in labor and land cost. These nations, until today, could not firmly establish their own regional policies to reduce regional disparities that can be clearly distinguished from industrial policy. A socio-political stage is still ahead to realize regional policy due to the transition from a socialist to a capitalist system, achieving national unity, and creating new economic and industrial policies. Myanmar's new capital, Naypyidawz characterized by national unity and security, among other attributes. Suggestive regional policy, instead of the above-mentioned specific regional policies, is reflected in this move of locating a new capital. On the other hand, Thailand represents a complicated situation wherein the economic rivalry between the capital and the other local regions is deeply connected to the national political opposition. It is not an easy task that the central government can firmly establish coordinated and comprehensive regional policies including industrialization and job creation in the cities.

Key words:

Greater Mekong Sub-region; border area; suggestive regional policy; specific regional policy; relational economic geography

Urban Growth and Its Spatial Manifestation: An Implication of E-Means of Communication and Transport Network in Indian Metropolitan Cities

GOMES. Veronica and GUHA. Pallabi Research Scholars

Centre for the Study of Regional Development, School of Social Sciences, Jawaharlal Nehru University, New Delhi

110067, pallabig10@gmail.com, veronica200790@yahoo.com

Abstract

Urbanisation in India has been very rapid, even extending beyond the municipal boundaries. India's definition of Urban has not been updated since 1951. Therefore it has become moribund as only 30% is urbanised while according to international measure it was estimated to be 52% urbanised. It gives an inaccurate picture of urban scenario, as it difficult to assess the process, trend and extent of urbanisation.

Mumbai, Delhi, Kolkata, Bangalore, Hyderabad and Chennai are the leading metropolitan cities which exhibit regional primacy. Globalisation, new international division of labour, and policies has changed the nature and structure of the urban agglomerations. Cities are now shrinking, while expansion is taking place along the fringes. New satellite towns have come up in *Peri Urban* areas as a result of the urban sprawl, to accommodate the migrants. Also the rampant usage of electronic communication has stoked the expansion of the urban units. With the nascency of the 'Information Revolution' the utilization of electronic means of communication is often recognized as one of the most important indicators of development of any society and country.

The paper firstly, attempts to measure the level of urbanisation among the six cities in a new light of globally comparable measure of Urban Agglomeration Index (population density, size and commuting distance) and compare them with the present census definition in order to identify the downward bias in urban statistics over two decades. Secondly, an assessment of spatial connectivity between the core cities and their hinterland in terms of transport network and electronic means of communication would be made, with particularly reference to Information Technology such as Internet etc. Therefore, building of networks which bridges the gap between core and peripheral areas of the agglomeration are to be analysed over a time period along with the analysis of the change in urban space.

Key words:

Urban Agglomeration Index; E-Communication; Globalisation; Urban Fringes; Communication network

Zoning planning based on spatiotemporal analysis

Tsogtdulam Munaa, Bolorchuluun Chogsom

Department of Geography, National University of Mongolia, tsogtdulam@num.edu.mn

Abstract

Land use zoning is a regulation system of classifying land to control the development and use allowed in an area. Zoning regulates the types of activities that can be accommodated on a given piece of land, as well as the amount of space devoted to those activities, and the ways that buildings may be situated and shaped. Zoning describes the control by authority of the use of land, and of the buildings thereon.

The urban development sector in Mongolia has been greatly influenced by the rapid rate of urbanization in the country over the past 20 years.

During the former Soviet Union, Mongolia's economy and urban services were centrally planned and managed. By the early 2000s, Mongolia had established proper legal and institutional frameworks for the urban sector. At the time urban land described into 6 zones by Purevtseren's land use classification. In 2014 the new city land use zoning system introduced in Ulaanbaatar that includes 7 zones. But that cannot be directly copied this zoning category due to the socio-economic characteristics in the towns and small villages of countryside.

This research introducing new and more comprehensive functional zoning system based on spatio-temporal analysis in Zuunmod city. The zoning system will cover all land around Zuunmod city and includes 19 sub and 9 main zones: residential, commercial, industrial, open space, mixed use, engineering infrastructure, green zones, water body zone and special reservation use zone.

Key words:

Urban planning; Functional zoning

A New Concept Model of Reginal System Under the View of Chinese Traditional Philosophy

Wang, PZ, Xu JG

School of architecture and urban planning, Nanjing University, Nanjing, 210093, P. R. China, wangzhen_1018@126.com

Abstract

Since 1978, China's urban and rural landscape has been changed a lot by urbanization. But for rapid development and urban-rural dual structure, the gap and social justice issues between urban and rural are getting worse, and the characteristic of complexity and uncertain is presented in regional system, all of which become serious problems to the national economic development and social stability. The limitation of western traditional research method with reductionism is serious in solving China's urban development issues. A new view, which is consistent with system science, is supplied by Chinese traditional philosophy to learn the world not using western philosophy. For a reason that many conclusions of complexity research return to eastern thought and some ancient proposition of Chinese traditional philosophy, a new idea is proposed to recognition urban-rural relationship and regional system. Firstly, based on the Taoism, the five elements theory of negative and positive, the traditional recognition of urban-rural system, regional system is divided into natural environment system and artificial ecological system including ten subsystems, such as atmosphere, water, land, biology, mineral, society, economy, urban-rural, transportation, government and so on. Secondly, each subsystem's connotations, interrelation and evolution mechanism are explained with the concept of sustainable development and urban-rural integration. Lastly, theoretical foundation of regional system is summarized through the view of urban-rural planning and social governance

Keywords:

Taoism; The Five Elements Theory of Negative and Positive; Regional System; Urban-rural Integration; Sustainable Development

Analysis of the commercial agglomeration and economic effects in small scale: a case study of Nanluoguxiang Commercial Street

Qi Han, Can Yue, Yi Zhang

Beijing Normal University, Beijing, 100875, P. R. China, 2063976711@qq.com

Abstract

In recent years, the development of business agglomeration in wide range tends to be obvious and accelerated. Likewise, there is a similar phenomenon of agglomeration in small Commercial Street. Will the effect of agglomeration be consistent with business agglomeration in wide range when we scale down to the shops as unit? In this paper, scale is narrowed to shop as unit when Nanluoguxiang Commercial Street is taken as an example. We draw a map that shows the distribution of shop type in Nanluoguxiang based on the field measurement data using ArcGIS software. And the shops' upgrading in Nanluoguxiang was investigated. As our survey shows, Nanluoguxiang Commercial Street is mainly dealing in the catering industry, clothing accessories and handicrafts at this stage, most of which are small shops. And the update speed is fast whereas the change of the shop's type is not significant. Preliminary questionnaire analysis shows that consumers have more demand for snacks. But as we see, the food retailers are too concentrated in Nanluoguxiang Commercial Street, which has exceeded consumers' demand. Accessories and crafts shops are more dispersed. It is difficult to reflect the cultural characteristics. As the comprehensive analysis indicated, the food retailers will be suited to be scattered, and commercial agglomeration is an ideal layout to clothing accessories and crafts shops.

Key words:

Commercial agglomeration; Commercial Street; Nanluoguxiang; small scale

Based on the new urbanization studies of urbanization under the background of zhongyuan urban agglomeration

Shuwei Yang

Abstract

Level of urbanization is the measure of a country, region or even a city clusters of industrialization and modernization level of important symbol, also is the main trend of the development of social economy. Urban agglomeration will play an important role in economic and social development in our country, the central plains urban agglomeration as the important urban agglomeration in central China will become the main pulling plate of regional economic development strategy. Based on this, this article takes the new town into the background, and deeply discusses the present situation of zhongyuan urban agglomeration and urbanization and facing the contradictions and problems put forward the corresponding countermeasures, so as to offer reference to successfully implement the strategy of zhongyuan urban agglomeration in the urbanization.

Keywords:

The new urbanization; urbanization; zhongyuan urban agglomeration

Establishing the Rural settlement Unit for Improving Spatial Development Dynamic in Poor Mountainous Area: A case study in ChangyangTujia Autonomous County, China

QIAO Jie , HONG Liangping

Huazhong University of Science & Technology (HUST), Wuhan, 430074, P. R. China, qiaojie2016@yahoo.com

Abstract

The organization of rural settlement space in China has been enduring long restriction from natural geography, grass-roots administration, cultural and social concept. The traditional organization model of rural settlement can't adapt to present aspirations for spatial development well when facing the continuous vitality release in rural China. The Aim of establishing rural settlement unit is to realize the symbiosis of 'Land-Human-Scene' in rural space according to local decision of settlement spatial structure. It will promote the rural spatial productivity sustainably in mountainous area based on constantly adapting to the characteristics of the rural social and economic development level, improving efficiency of public service facilities and lowering cost of grassroots social governance, strengthening the rural community consciousness of "rights+responsibility". This paper response to national policy "taking targeted measures in poverty alleviation" in China. It has three aims. The first is to propose the small watershed as basic unit of the organization framework of rural settlement by recognising Changyang Tujia Autonomous County rural settlement space. The second is to build evaluation index system and spatial gravity model for development of settlement space considering cultural tourism resources integration, ecological agriculture layout, infrastructure construction, public service facilities supporting as forces. The third is to establish settlement spatial system for promoting comprehensive space dynamic and realizing the bundling of rural settlement development and poverty eradication in Yantou stream watershed according to the theory and analysis results above.

Key words:

mountainous rural areas; rural settlement space; spatial unit; poverty alleviation; Changyang Tujia Autonomous County; China

Space characteristics and mechanism of Yangtze River delta urban agglomeration economy network structure under high-speed rail

WANG Zhao, YANG Shan*

School of Geography Science, Nanjing Normal University, Nanjing 210023, Jiangsu, China

Abstract

Based on location quotient index and gravity model, we build the economic network of Yangtze River delta urban agglomeration under different traffic conditions, then try to use the GIS technology and network analysis model to measure and compare the spatial pattern and variation characteristics of these networks. The aim is to explore how the high-speed rail influent the urban agglomeration economy network in regard to network connectivity ability, center node characteristics and core - edge structure, etc. The conclusions can be drawn as follows: (1) Urban agglomeration economic ties are joint efforts of inflow and outflow degree and distance between cities, high-speed rail network promote the connecting ability of economy network, shortening the average distance between nodes, but less effect on network density; The network centrality is decreasing, and it shows a multicenter trend. (2) High-speed rail polarize economic contact of city nodes with high foreign-service value. At the same time, weakens the intermediary role of 70% of the total number of cities in urban agglomeration economic network. Besides, connectivity differences between nodes have been expanded, and the network power of center cities have been reinforced; (3) According to cohesive subgroups analysis, high-speed rail strengthened the radiation ability of secondary core node, and make each subgroups getting closer. Development axis of "Nanjing - Hangzhou" and "X" -like network structure of whole economic network are more perfected, multiple hub-and-spoke nested economic network are forming. (4) "time- space compression" shows an imbalanced influence to cities with different service ability and location, we should improve the level of foreign economic service of those who get more inflow degree, strengthen the combination of high-speed network and the high-speed rail network of those cities who changed less in inflows and outflows degree.

Key words:

high-speed rail; Foreign-service economy; Economic network; Yangtze River delta urban agglomeration

Spatial planning issues of intensive gravity and influence zone of the capital

Ulaanbaatar city

Bazarkhand Ts, Chinbat B, Myagmartseren P, Munkhnaran S, Zaya Ch, Enkhtuya N

Department of Geography, School of Arts and Sciences, National University of Mongolia, bazarhand_0319@yahoo.com, chin_bat2002@yahoo.com, land_management@num.edu.mn, mnkhnrn@yahoo.com, zaya_ch2006@yahoo.com, enkhtuya0130@gmail.com

Abstract

The capital city Ulaanbaatar, main place of over centralization, has been losing its definite spatial structure and organization and facing many problems such as ecological, social, economic, and transportation condition. Urban spatial structure, transportation networks are being improved and urban development process is taking places as for decision of above mentioned problems. So developments of satellite cities are suggested for urban decentralization policy. Many regional issues including expansion of urban intensive gravity and influence area, heightened role of urban regions and change in functions of towns within urban intensive gravity and influence zone are needed to be considered and reviewed as development plans for satellite cities, suburbs and edge cities are started to be implemented. Some solutions for development of Tuv region coherently with Ulaanbaatar city and other settlements nearby Ulaanbaatar city are considered in current Mongolian Regional Development Program and Development Programs of Tuv Region and Ulaanbaatar Region, however these are cannot being the basis for urban and land use planning as well as for rational spatial organization. Therefore, it is necessary to develop city-regional policy and planning which are based on development trend to develop the capital city as a region, considered functions of group settlement in urban intensive gravity and influence zone and estimated demands of central city substantively.

Key words:

urban intensive gravity and influence area; satellite cities; central city; urban region

Spatiotemporal Changes Analysis of Economic Relation Among Cities of Jiangxi Province

LUO Jin, ZHANG Caixia, ZU Xiaofang

¹School of Geography and Environment, Jiangxi Normal University, Nanchang, China, 330022, gislj@126.com, 1449882252@qq.com

²Key Laboratory of Poyang Lake Wetland and Watershed (JXNU), Ministry of Education, 330022

³Key Laboratory of Watershed Ecology and Geographical Environment Monitoring, National Administration of Surveying, Mapping and Geoinformation, Nanchang, 330209

Abstract

Taking Jiangxi Province as the study area, with applying the model of urban flow intensity and the method of GIS spatial analysis, this paper carries out the calculation on the urban external function capacity, urban flow intensity, urban flow tendency and some other indicators during 2003-2012 of 11 prefecture cities of Jiangxi Province, and also conducts comparison and analysis on the values in time and space. The results show that the external function capacity, urban flow intensity and urban flow tendency of the 11 prefecture cities are on the rise, but the growth rate varies. Nanchang plays a central role in the economic relation throughout the areas, with a strong concentration and radiation effect. The cities' overall economic strength and comprehensive service capability are inconsistent, and the overall economic strength of the other cities except Nanchang is all lower than the comprehensive service capability.

Key words:

intensity of urban flow; spatiotemporal dynamic analysis

Study on cities' differential development countermeasures based on the functional structure analysis: A case study of ShanDong Province

MIAO Yi , WANG ChengXin, WANG Gefang

Shandong Normal University

Abstract

China is in the period of new urbanization construction and urban functional structure is constantly changing. Taking Shandong Province as a typical region, the urban functions were calculated by Scale-Location Quotient method, and the functional structure difference of every two cities was analyzed by the difference degree of functional structure. Analysis shows that the urban functional structure and some urban functions have clearly characteristics of spatial differentiation ; Eastern coastal cities show highly urban functional structure similarity while Jinan Metropolitan cities not. Based which put forward the optimization idea:deepening traffic and industrial development to promote regional development; the eastern coastal cities should work together to build a modern industrial system, focus on collaborative tourism and foreign trade functions; the metropolitan area of Ji'nan cities should strengthen the regional center city,Ji'nan, adjustment and optimization the regional functional structure complementary advantages is the main goal; the south Shandong cities should pay attention to grasp the opportunity, accord to new development ideas to make up the weakness of economic development.

Key words:

functional structure; Spatial difference; countermeasures; ShanDong province

Temporal and spatial evolution characteristics Study of Urban and Rural Harmonious Development with ESDA-GISFramework in the Qinling-Daba Mountains

PENG CUI, XIN WU

College of Urban and Environmental Sciences, Northwest university

Abstract

This paper uses the multi index comprehensive evaluation method to measure the level of urban and rural harmonious development in the Qinling-Daba Mountains, constructs evaluation index system of urban and rural harmonious development by the 18 basic indicators composed of five sub-systems. Using linear weighted sum methods integrates indicators, Using the network analysis method to determine the weight of each index, In order to get in the Qinling-Daba Mountains' counties of urban and rural harmonious development coordination index, and through exploratory spatial data analysis and GIS technology researches temporal and spatial evolution characteristics of urban and rural harmonious development in recent 10 years. The results show: urban and rural harmonious development in the Qinling-Daba Mountains levels in the space at the stage of the unbalanced development, presents the case to the ends of gathering, the high level counties with high levels of aggregation, the law from west to east in the space accumulation is low and land conditions of urban and rural development, industrial base , external transport have a high space coupling.

Abstract

The rural area is the important carrier of ecological civilization construction in China.Dealing with the harmonious relationship between ecologyandhuman in the rural living environment construction is the inherent requirements of rural planning and also essential aims of ecological civilization construction.This paperfirstly propose that rural planning should contain three important aspectsin the context of ecology concept and humanistic thoughts,they are the livelihood planning of the villagers, rural settlement planning and rural community development planning, and secondly build the working humanistic logic of rural planning: base on"census of geography andhuman living";build triplecollaboration platform in"county-town-village" for rural plnning; make sure that adapting to grassroots development demands and respecting the local villagers requirement is the core values; follow squire and technical guidance;abidethe planning strategy of "low technology + highparticipation + raisewisdom from all relative.It aims to promote the comprehensive system efficiency of human settlement environment construction.

The Perspective of Urban Block System Reformation in China

Wang Chengxin¹, WangBotao¹, WangGefang²

¹College of Geography and Environment, Shandong Normal University, Ji'nan, Shandong 250014

²Marx Institute, Party School of the Shandong Provincial Committee, Ji'nan, Shandong 250103, 404122665@qq.com

Abstract

Recently, *The CPC Central Committee and State Council on further strengthening the management of urban planning and construction several opinions* was promulgated. It pointed that "new residential neighborhoods should popularize the block system, and in principle, it doesn't allow to build closed residential community", "the residential quarters and units should open gradually", which caused the whole society discuss widely. This paper expounds the realistic significance of the urban block system reform, such as ease urban traffic congestion, intensive use of urban land, building a harmonious society and proposes the difficulties such as the conflicts between new policy and the real right law, the incongruity between the policy-making and public opinions, the asynchronism between policy and compensation expense. It seriously affects the block system implementation. To this end, this paper puts forward the paths to promote the urban block system reform implementation successfully, for example, initiative propaganda, setting an example by the government, the planned scientific advance, the sufficient compensation, the implementation of adjust measures to local conditions and to reform step by step.

Abstract

Based on the first Census of National Geographical Condition, an indicator system, in constitution of Centrality, Traffic Accessibility and Spatial Connecting, was built to probe the urbanization pattern in Hubei Province in the prospect of prefecture level and county level by using Analytic Hierarchy Process method, Cost Matrix and Gravity Model on the platform of ArcGIS and YAAHP.

The results shows that there exists an obvious urbanization pattern of “One Main Two Vice” in Hubei. To be specific, Wuhan, joined with Ezhou, taking the central place of all the cities in the province while Xiangyang, together with Yichang, occupied the two sub-centers. Meanwhile, the centralities of the 103 counties in Hubei present high in east and low in west.

In terms of traffic, Wuhan, Xiaogan, Xiangyang and Yichang, as the node cites, score highly on Traffic Accessibility and locate in the half hour traffic circle of the central cities. 29% of the counties can arrive the central cities in 1 hour.

It also shows that Certain concentric circles has formed in Wuhan metropolitan area, with Wuhan as the centroid, Xiaogan, Ezhou, Huangshi, Xiantao as the core circle, Huanggang, Tianmen, Qianjiang and Xianning as the close circle, Suizhou as the radiation circle. Xiangyang has a prominent connection with Shiyan while Yichang shows a close but not prominent connection with Jingmen and Jingzhou. Both Enshi and Shennongjia shows a weak connection with Wuhan, Xiangyang and Yichang.

Urbanization, Spatial Spillover Effects and Regional Differences of Urban-rural Income Gap in China: Based on Provincial Spatial Panel Data

ZHANG Yingjie , ZHANG Juntao

Linyi University, Linyi, 276005, P. R. China, zhangyingjie2001@126.com;

Dongbei University of Finance and Economics, Dalian, 116025, P. R. China, jtzhang001@163.com

Abstract

The backwardness of urbanization and expansion of urban-rural income gap are two major challenges for China at present. The Third Plenary Session of the CPC's Eighteenth Central Committee adopted a major strategic decision to take the road of new urbanization which is aimed at balancing urban and rural development, narrowing the gap of urban-rural areas and promoting social harmony and stability. Previous theoretical and empirical studies show that the impact of urbanization on urban-rural income gap has two sides: narrowing or widening urban-rural income gap. Based on provincial spatial balanced panel data of China from 2001 to 2013, using exploratory spatial data analysis (ESDA) and spatial panel data model, the paper empirically studies the effect of urbanization on urban-rural income gap in four economic region of China(the eastern, midland, western and northeast) by controlling some key factors of affecting urban-rural income gap. Thereby, this paper puts forward to some suggestions aiming at narrowing the urban-rural gap between four economic regions of China and promoting the coordinated development of regional economy.

Key words:

urbanization; urban-rural income gap; spatial spillover effect; regional difference

Applying WUDAPT to Local Climate Zone classification in Urban Heat Island study: a case of Beijing

Zhang MD, Zhang ZX, Wen QK, Li N

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing 100101, China,

zhangmd@radi.ac.cn

Abstract

Traditional urban heat island (UHI) analysis based on land use and land cover types and simplistic separate urban and rural climate field site. Local Climate Zone (LCZ) system comprehensively classifies natural and city landscapes into 17 categories for UHI study. This article followed the workflow provided by World Urban Database and Access Portal Tools (WUDAPT) to identify LCZs in Beijing. For thermal differentiation analysis of LCZs, the previous studies obtained temperature data from fixed stations and automobile traverses. This research use land surface temperature retrieval from ETM+ data for UHI analysis, in order to experiment its effectiveness in LCZ study. The result demonstrates that 1) LCZ system can perform purposeful in UHI analysis by recognizing landscapes accurately and enhance the importance of 3D data. 2) Numerous spatial analyses can be done based on LCZ method as it analysis land surface temperature in several homogeneous zones rather than pixels. 3) To some extent, temperature retrieval from remote sensing data can replace those from automobile traverses in LCZ research.

Local Climate Zone; land cover; urban climate; WUDAPT; surface temperature retrieval

Climate Migration and Built Environment: An Urban Resettlement Perspective

Muhammad AbdurRahaman

Climate Change Impact & Response Professional, ADAMS, Khulna, Bangladesh, rana@b-yes.org

Abstract

This study examines the complexity of climate displacement, rural-urban migration and built social and physical environmental domains in informal settlements at urban areas of Bangladesh with particular attention to internally displaced people by climatic impacts. Being the most vulnerable country, urban areas of Bangladesh have already been experiencing increasing climate induced problems like drainage congestion, water logging, property damage, fresh water unavailability, groundwater depletion and tidal inundation (coastal urban areas). The study was conducted in three major cities (Dhaka, Chittagong, and Khulna) and three district towns (Cox's bazar, Noakhali, Satkhira). Over 80% of the climate-displaced people are living in the congested informal settlements in urban who are pushed by climate-induced extremities like sea level rise, tidal surge, salinity intrusion, cyclone, water logging in coastal belt; flood, river erosion, water logging in floodplains and drought, agricultural drought in northwest Bangladesh which make them climate refugees, extreme poor and hunger. They have limited access to technical and social services, alternative livelihoods and entail various socio-physical environmental dimensions. Current study investigates how climate-migrants occupied urban informal settlements affect the built environmental systems and their adaption strategies to urban built environment at individual household levels. Adopting an exploratory case study and focus group discussion approach, the study reveals that in informal settlement areas, urban built environmental systems are disrupted in multidimensional ways and lack of understanding on adaptive capacity, climate migrants are living in the more vulnerable environment than origin. To overcome this worsening situation, climate resilient urban policy response and optimized adaptive capacity of cities must be recognized for climate-displaced people at household and community level adaptive practices.

Does Urban Greenery Reduce the Cost of Cooling Homes?

Borthakur Monjit

OKD Institute of Social Change and Development, Guwahati- 781036, India, monjit01@gmail.com

Abstract

The study investigates the effect of urban land use change to land surface temperature and how urban greenery have moderating impact in reducing the cost of cooling in residential units of Guwahati Metropolitan Area. During the last decade, Guwahati has undergone phenomenal urban change with high population growth and major changes to land cover. The complex urban fabric with high rise multistoried, roads and pavements increase the urban surface temperature due to their high heat storage capacity. The complex urban fabric also reduces the horizontal air flow in residential buildings. The study reveals that the city has a prominent urban heat island effect. The result of the panel data model shows that the densely populated urban areas with less than 10% greenery are on an average 1°C warmer than the areas with 50% greenery. Due to this additional heat, the daily increase in electricity demand for the city is estimated as 5.4 Mw with 1°C increase in surface temperature. Considering one unit cost of electricity, the study estimates that the urbanites residing in the downtown areas of the city are paying an additional amount of Rs. 846,000 per month to cool their residential units. The study offers conclusive evidence of the significant economic gains deducible from urban greenery. The results clearly show that the annual welfare gain to the city from urban greenery is significant in terms of reduced electricity consumption.

Key words:

Urban Heat Island; electricity; greenery

Environmental Effects of Land Use Change in Rapid Urbanization: The Case of Hangzhou, China

Zhonghua Huang

Zhejiang University of Technology, hzhzjut@163.com

Abstract

Land use changes sharply in rapid urbanization, yet its environmental effects are often ignored in land use decision and policy making. Using the case of Hangzhou, China, We analyze the environmental effects of land use changes including ecosystem service value, carbon emission and landscape pattern, based on the Landsat TM images from 1995, 2000, 2005, 2010 and 2014. We found significant environmental effects of land use changes in rapid urbanization. The ecosystem service value in Hangzhou decreased from 3.24 billion Yuan in 1995 to 2.40 billion Yuan in 2014, and the ratio of ecosystem service value to GDP reduce from 5.86% to 0.56%. The net carbon emissions increased from 4.26 million tons in 1995 to 15.10 million tons in 2014, mainly due to a huge increase of built-up land carbon emissions and a decrease of forest land carbon sink. The ecosystem service value was unevenly distributed spatially and low ecosystem service value spread from the central to the peripheral area. The pattern of land use changes showed decreased fragmentation, increased connectivity and decreased diversification. We use scenario analysis to show that economic growth and environmental protection could be coordinated by bringing environmental effects into land use decisions.

Key words:

land use change; environmental effect; ecosystem service value; carbon emissions; Hangzhou

Estimated reduction of resident exposure to respirable particulate matter and health risk in Beijing if source control measures during the “2015 military parade” were sustained

Abstract

Metropolitans in developing countries are experiencing over-urbanization and industrialization which leads to severe air-pollution issues. There are lot studies about PM_{2.5} in Beijing, but the limitations are that these studies did not present the picture of PM_{2.5} distribution and chemical composition meanwhile; the difference between indoor air and ambient air are usually ignored. Most people spend more than 80% of their time indoors, considering indoor particle pollution and chemical composition exposure is important for understanding the impact of particle pollution on human health. Therefore, this article presents the simulated concentration of PM_{2.5} distribution based on Land-Use Regression model with recent data from 35 monitoring stations in Beijing... With the chemical analysis of the samplers during the “2015 military parade” the chemical compositions distribution can be also simulated. Furthermore, we employ the Monte Carlo method to modify the difference between indoor and outdoor environment. Finally, we explore human exposure and assess potential health effects in the situation that source control measures during the “2015 military parade” were sustained. Results illustrates that traffic and plant contribute the most of PM_{2.5} articles. Add also, certain source control measures reduce the exposure in a considerable quantity.

Abstract

The uncontrolled spread of the built up environment into the surrounding rural and natural land, and the consequent increasing urbanites' demand for natural resources are among the most important causes of the dramatic consequences of global environmental change in many parts of the world. This study investigates soil consumption due to urbanization in the last decades in Italy, which has undergone relevant urban expansion, although not coupled by a comparable population growth, thus suggesting that such degree of urban expansion may be unjustified. Besides it aims also at presenting different forecasts for soil consumption, loss of agricultural potential, and increase in energy demand for the coming future. The methodological framework features past trend data analysis coupled with modelled projections; the data used is a fusion of archived thematic maps, classified satellite imagery, census data, and forecast data from cellular automata model (SLEUTH). The authors analysed urban and population growth through the evolution of spatial explicit data over time according to 3 scenarios: business as usual, "booming expansion", "fostering conservation". The results of this study provide realistic figures of future land cover change in Italy, estimates which regions are likely more prone to urbanization and where urban growth will likely feature a sprawled pattern. Furthermore, it discusses what are the potential risks related to the projected soil and energy demand and how these may be avoided. In conclusion, it aims at providing policy makers with useful tool and information to support and favour resilient and sustainable development.

Key words:

Land-use change; urbanization; Italy; land-use change modelling

Green space and urban form: a historico-geographical approach

Yiting Zhang

School of Geography, Earth and Environmental Sciences, University of Birmingham, Birmingham B15 2TT, United Kingdom, xiwenyutian@hotmail.com

Abstract

There is a significant gap, in respect of both research and practice, between urban morphology and urban ecology. Studies of urban ecology have hitherto been largely ahistorical and almost entirely acultural. In contrast, key concerns of urban morphologists have been how urban physical expressions of culture have changed over time. This is notably the case with research that has adopted a Conzenian or Muratorian approach. Such approaches have stimulated research on the characteristics and planning of the form of cities that has been largely divorced from concerns about ecosystem services. Employing a case study in Birmingham, UK, this paper examines the connection between urban morphological research on the fringe-belt concept, as developed by M. R. G. Conzen and others, and the character and distribution within cities of major areas of green space. The principal focus is on how green spaces within those fringe belts that are embedded within cities (for example, parks, recreation grounds, allotment gardens, golf courses, and land attached to educational and medical institutions) have changed over time, especially during the past 100 years. The contribution to both understanding the historico-geographical and sustainable development of urban form and in linking urban morphology and ecosystem services is emphasized.

Key words:

fringe belt; urban morphology; historical geography; sustainable development and planning; spatial analysis and mapping

Spatial Distribution of Supermarkets in Kano Metropolis, Nigeria

Dambazau, A.M., Suwaiba M.A, Bichi, A.M.

Department of Geography, Kano University of Science and Technology, Wudil, Nigeria

abalhafasah@yahoo.com

Abstract

The study focused on the spatial distribution of supermarkets and factors influencing their utilization in metropolitan Kano, North Western Nigeria. Primary data was obtained from field observation and Questionnaire survey. The field exercise involved the collection of coordinates of all modern supermarkets in the study area using a hand held Garmin GPS 76 Model. Also a total of 252 instruments were distributed to the users of the various supermarkets using a systematic sampling technique. The coordinates of the supermarkets collected were analysed by digitizing the map of the study area using the ILWIS software. Multiple regression analysis was used to determine respondents who to patronize the supermarkets in instead of the traditional markets. Result of the analysis shows an uneven distribution of supermarkets in the metropolis while the multiple regression analysis results reveal an R-square value of 0.83% (F. Sig = 0.006 P <1%) which was significant at 1% confidence level. The study recommends the location of more supermarkets in other areas poorly served to reduce the problem of access faced by users.

Key words:

Supermarkets; distributions; spatial; Kano metropolis; patronage

Toward green use of industrial land in China: a non-radial Malmquist index approach

Xie Hualin

Co-innovation center for institutional construction for Jiangxi eco-civilization, Jiangxi University of Finance and Economics

Abstract

Industrial production activities are the main contributors to the environmental pollution in China. Industrial land is not only an important input to industrial production, but bears most industrial pollutants. Therefore, a detailed analysis of industrial land use incorporating bad output caused by industrial production is necessary to make reasonable policies aiming at promoting sustainable use of industrial land. This paper aims at analyzing the status of total-factor green use efficiency of industrial land (TGUEIL) by employing a non-radial global directional distance function (NGDDF). We propose a non-radial Malmquist industrial land performance index (NMILPI) to measure the dynamic changes of the TGUEIL, and then try to find the main source of the growth of TGUEIL by decomposing the NMILPI into an efficiency change (EC) index, and a technological change (TC) index. The empirical results show that the TGUEIL in China enjoys rising trend during 2003–2012. The eastern region performs much better than the central and western regions, and the regional gaps of TGUEIL are narrowing. The growth of TGUEIL is mainly driven by technological progress, and provinces in the eastern region perform better than those in the central and western regions in the innovation of environmental friendly industrial production technology. The results of influencing factors analysis show that introducing more environmental protection policies, expanding the scale of industrial economy, increasing industrial R&D investment, decreasing the energy intensity and reducing the use of coal in the process of industrial production, and properly solving the problem of labor surplus in the industrial sectors would be helpful to improve the TGUEIL.

green use; industrial land; Malmquist productivity index; China

Urban Expansion and Its Impact on Agricultural Land: A Case Study of Rajpura Tehsil, Patiala, Punjab, India

Kaur, Preetinder

Department of Geography, Panjab University Chandigarh 160014, preetinder.randhawa@gmail.com

Abstract

Urban expansion takes into account two processes, internal reorganization and outward expansion of urban areas. This expansion appears to exert direct impact on agricultural land around the urban areas leading to the shrinkage of agricultural land. Through this paper the attempt has been made to evaluate the extent, composition of urban expansion and its influence on agricultural land using unpublished revenue records data from 2001 to 2011 in Rajpura Tehsil district Patiala(Punjab). Three urban areas namely Rajpura (Municipal Council), Ghanaur (Nagar Panchyat) and Nilpur (Census town) have been selected to carry out the research at micro level. Analysis suggests that area under non-agricultural uses has expanded from 11.2 percent (2001) to 13.5 percent (2011) in the tehsil. The loss of agricultural land has taken place basically under commercial uses (31.5 percent) along the National Highway in the tehsil. It followed by Industrial uses (31.1 percent) in north-western part and residential uses (25.4 percent) in central part of tehsil. At the town level built up land has constantly increased in all the three towns respectively by 1 percent in Rajpura, 3 percent in Ghanaur and 15 percent in Nilpur during 2001-2011. The latter has experienced highest urban expansion and consequent loss of agricultural land as it got transformed into a Census town (2011), due to doubling of its population. This change from agricultural to non-agricultural uses clearly point towards need of making policies for saving good agricultural land and for increasing agricultural production by using state of art technology in agriculture.

Key words:

Urban Expansion; Agricultural Land; Non- agricultural Uses; Punjab

Use of an inside buffer method to extract the extent of urban areas from DMSP/OLS night-time light data in North China

Minghong Tan

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, People's Republic of China, tanmh@igsnrr.ac.cn

Abstract

Defense Meteorological Satellite Program (DMSP)/Operational Linescan System (OLS) night-time imagery provides a valuable data source for mapping urban areas. However, the spatial extents of large cities are often over-estimated because of the effect of over-glow from night-time light if a fixed thresholding technique is used. In the work reported here, an inside buffer method was developed to solve this issue. The method is based on the fact that the area over-estimated is proportional to the extent of the lit area if a fixed threshold is used to extract urban areas in a region/county. Using this method, the extents of urban areas in North China were extracted and validated by interpretations from Landsat Thematic Mapper images. The results showed that the lit areas had a significant linear relationship with the urban areas for 120 representative cities in North China in 2000, with an R^2 value of over 0.95. This demonstrates that the inside buffer method can be used to extract urban areas accurately. The validation results showed that the inside buffer model developed in 2000 can also be directly used to extract the extent of urban areas using more recent night-time light imagery. This is of great value for the timely updating of urban area databases in large regions or countries.

DMSP/OLS data; inside buffer model; northern China; over-glow effects; urban areas

Using CLUE-S model to determine Urban Growth Boundary in Shenyang, China

Huang Daquan, Huang Jing, Zhao Xingshuo

Beijing Normal University, School of Geography, 19 XinJieKouWai Str, Beijing 100875, P. R. China,
yakamozper@163.com

Abstract

In the past several years, China has experienced the urbanization process that offered unprecedented challenges to cultivated land protection as well as urban and rural coordinative development. As an important policy to guide urban development, Urban Growth boundary(UGB) has been implemented in many countries. However, In China, current research on scientific UGB determine method has still been in the exploration. In this passage we have designed an UGB model applied to Shenyang, one of the highest urbanization city in northwest China. Here we show that coupling a Markov chain on CLUE-S model simulate the urban growth process well. We use stepwise logistic regression analysis to find the main factors of influencing urban growth. We find that access to road, population and policy influence city development significantly. Furthermore, we design three types of UGB based on different development concept. Our results demonstrate how Shenyang are likely to be in 2020, offering a rational planning for future development. We anticipate our research to be a referential UGB model applied in China and offer proposal for the growth of Shenyang.

Evaluation of urban land intensive use with emerging fine-scale data: a case study of Jiangsu Province

Wenxin Wang, Xiaobin Jin^{1,3}, Xuhong Yang¹, Ying Long^{2,3}, Yinkang Zhou^{1,3}

¹ School of Geographic and Oceanographic Sciences, Nanjing University, China

² School of Architecture, Tsinghua University, China

³ Natural Resources Research Centre of Nanjing University, Nanjing University, China

Abstract

Facing the large amount of population, limited farmland resources and the rapid development of urbanization, China must take effective measures to strength the intensive use of land resources. Currently, urban land intensive use has been one of the hot topics of study on LUCC in urban areas, and a few studies have been conducted from different aspects and different spatial scales. Based on the traditional evaluation method i.e., focusing on social and economic development and confining in an administrative boundary, characteristics of the urban infrastructure, urban population concentration, urban functions vitality were explored by emerging fine-scale data including urban transport networks, Points of Interest (POIs) in urban areas, cellular signaling data, Weibo data and other Location-based services (LBS) data to establish a technical framework for urban intensive land use evaluation. Jiangsu Province in China was taken as a case study and a result at a resolution of 1km*1km was achieved. It indicated: (1) the integrated urban vitality evaluation broadensthe connotation of the intensive in urban land use. Emerging fine-scale data provide effective support for conducting urban land intensive use evaluation; (2) there are significant differences among major cities (city groups) on urban land intensive use. The utilization level, the economic development level and city size are positively correlated; (3) there are also some obvious differences within a city area especially in urban functions and vitality between the new developed city area and the old town.

land intensive use; urban area; fine-scale data; Jiangsu

Identifying conservation priorities in a rapidly urbanizing landscape: a habitat network perspective

Bin Xun

College of Urban and Environmental Sciences, Northwest University

Abstract

Biodiversity conservation is challenging in urbanizing landscapes where there is recurring habitat degradation and limited space for subsequent restoration. Conservation efforts based on natural reserves can not necessarily maintain certain ecological processes that take place across whole habitat network. There is a need to conserve or restore critical habitats outside protected areas for maintaining the functional connectivity of networks. In this study, we developed a connectivity modelling approach associated with varying conservation scenarios to identifying habitat conservation priorities in a rapidly urbanizing area of Shenzhen, China. We incorporated unprotected habitat patches into the reserve network via four scenarios and prioritized the contributions of those patches to the overall network connectivity. We also investigated the responses of species with different dispersal abilities to habitat changes under each conservation scenario, respectively. The results showed that habitat patches around protected areas could create large connectivity gains and should be prioritized for conservation. Connectivity benefits from different scenarios were closely linked with species' dispersal abilities. Key patches that could enhance connectivity substantially were also identified as conservation priorities. The species-specific and site-specific conservation schemes we provided are useful to making informed decisions in urban planning and management.

Abstract

Intensive utilization of land is an important means of maximum benefits and allocation of land resource. It is a great significance for building the resource-conserving and environment-friendly society. During the process of construction and development of rural construction land in, lacking of system planning, low utilization of land, imbalance in the structure of land, and hollowing out, caused great waste of rural land.

According to the connotation of intensive utilization of land, widely absorbing the domestic and foreign research results, this paper based on the land compensation law theory, the land scarcity theory and the land location theory, used quantitative and qualitative analysis, combining the theoretical research and empirical research method, studied 13 villages of rural construction land in the coordination degree of population and construction land in Zuofang County in Jinxi and 7 typical villages of intensive utilization from macroscopic and microscopic scales. By measuring the theoretical capacity and practical capacity of the 7 typical villages, it can help us explore the stock capacity of rural construction land and the ways of mining.

In the macro scale, it mainly aimed at the fitting degree of the rate of resident population changing and rural construction land changing, and then, separating the 13 villages into different types.

In the micro scale, it mainly aimed at the intensive utilization evaluation analysis of the 7 typical villages which is choose from different types of the 13 villages. First, divide the rural construction land into different land types. And then, evaluate them by a set of index system which is a composition of land using structure, land using intensity and the social economic benefits.

The land potential capacity is divided into two aspects. One is theoretical potential capacity which is calculated by the area of construction land per people. Another is practical potential capacity which is calculated by totaling up the leisure land and the idle houses.

According to the result, the 13 villages is low coordination degree in population and construction land. And the land intensive level of the 7 typical villages is extensive. Since the structure of construction land is single and the land using is extensive, it existed a large amount of potential capacity. In order to form an intensive style of land use, we need to change traditional development conception, design scientific program, speed up

the transformation and upgrading of rural to urban, tear down the idle houses, expanse the public infrastructure, optimizing the land layout, provide a more convenient and comfortable living environment for famers.

Risk assessment of land use competition in the fringe of the valley city: A case study of Lanzhou

Yongnan Wang, Peiji Shi, Chunfang LiU, Wenxia Zhou, Xuebin Zhang, Jing Kang

College of Geography and Environment Science of Northwest Normal University, Lanzhou 730070, Gansu, China, wyn1699@163.com

Abstract

Due to the limitation of terrain, the construction land is scarce in the valley city. The relationship between stakeholders is particularly complex in the urban fringe. The contradiction of land use competition is prominent. This paper chooses Lanzhou - a typical Valley City, as the research area. Based on GIS multi-criteria analysis (GIS-MCDA), Questionnaire Survey and Interview, Delphi method, combined with the city development, ecological protection and stakeholders will, the risk evaluation index system of land use competition was established and the land use competition risk was evaluated in urban fringe of Lanzhou City. The results show that: there is a small area of high risk land use competition in Lanzhou, which was mainly distributed in the valley basin inside of the undeveloped areas in the city edge. The relatively high risk areas are widely distributed, which was mainly distributed in the central city east, west and the north low-slope hilly land region. The centre city eastern land use competition was in the highest risk, which is inconsistent with the strategy of development the Heping-Dingyuan group as the eastern city of Lanzhou.

Key words:

land use competition risk; GIS-based multi-criteria analysis; urban fringe; Lanzhou

Study on Spatial-temporal Change of Water environment in Suzhou and its

Relationship with Land Use

YANG J, XU YP, YANG L, XIANG J, XU Y

School of Geographic and Oceanographic Sciences, Nanjing University, Nanjing 210023, yueyingliuyun@126.com

Abstract

Taking Suzhou with the rapidest economical development for example, using entropy model, selecting 5 indexes including dissolved oxygen (DO), ammonia nitrogen ($\text{NH}_3\text{-N}$), permanganate index (COD_{Mn}), total phosphorus (TP), total nitrogen (TN), the temporal and spatial variation of the water quality in research area from 2002 to 2014 were analyzed, and the relationship between water quality indexes and social-economical indexes and land use type in 2002 and 2014 was discussed and analyzed separately. The results showed that: (1) The water quality in Suzhou was general bad but become slightly better in recent years. (2) From the perspective of spatial variation, water quality of central urbanization area which was influenced by intense human activity was poorer, and that in surrounding areas was relatively good. (3) The results of related analysis showed that the influence of different economic social indexes and land use type to water quality indexes was not identical. For $\text{NH}_3\text{-N}$, TN, TP and COD_{Mn} , the positive influence of industry and agriculture pollution was larger. For the impact of land use type on water quality indicators, there was a strong correlation between the proportion of urban land along riparian and those indicators. But the influence decreased from 2002-2014. Meanwhile, the affect of riparian land use on river water quality was larger in wet season compared to dry season.

Water Environment Change; Entropy assessment; Urbanization; Suzhou

The Effect of Green Open Space on Sense of Belonging

Zhu Yuemei, Zhu Qing, JiXuze, Ding Junxiang, Kong Cuicui

School of Geography, Beijing Normal University, Beijing, 100101, P. R. China, igc2016@igsnnr.ac.cn

Abstract

Previous studies have overwhelmingly focused on the effects of residents' individual condition, dwelling time and social relations on sense of belonging. Little attention has been paid to the relationship between green open space and sense of belonging. Using the 2014 data of three communities from Beijing, this study pioneers the application of SEM to examine green open space correlates of sense of belonging. Results from structural equation modeling and path analysis suggest that the green open space have 16% of interpretive force to sense of belonging, and the residential satisfaction of green open space would positively affect sense of belonging. The sense of belonging would indirect impacted by convenience, importance and quantity of green open space.

Key words:

greenopen space; sense of belonging; structural equation model; hierarchical regression; shape index

The Relationship Research of Spatial and Seasonal Distribution of Atmospheric Particulates and Urban Heat Island (UHI) Intensity with Landsat Images in Xi'an, China

Xinming Zhu, Dajiang Yan, Wenting Mao, Xuhong Wang

Northwest University, Xi'an, 710000, P.R. China, zhu03fu30@163.com

Abstract

In the movement of speedy urbanization, the problem of atmospheric particulates pollution has drawn great attention in some large cities. In the past five years, some studies have demonstrated Difference Vegetation Index (DVI), NDVI, MNDWI have impacts on the concentration distribution of atmospheric particulates and Urban Heat Island (UHI). However, the relationship between distribution of atmospheric particulates and UHI intensity has not been clearly explained in basin topography region. Therefore, this paper combines the methods of thermal infrared images retrieval and mathematical statistics, with four different seasons Landsat images for Xi'an, China in 2013 and 2014, using multiple index data including UHI intensity index, DVI, NDVI and MNDWI to quantitatively study the relationship between spatial-temporal distribution of atmospheric particulates and UHI intensity. By regression analysis, in the study area, the results demonstrate that DVI has a strong correlation on UHI intensity for two images in summer half year, and the correlation coefficient is all greater than 0.7. When UHI intensity is less than -0.1, DVI has a positive effect on UHI intensity. But, when UHI intensity is above -0.1, DVI tends to be exponentially negative correlated with UHI intensity. In addition, in the four Xi'an images, due to the influence of vegetation and water, the spatial distribution of the smaller DVI values and the larger UHI intensity values is located in fallow land and urban district usually, which conforms to the natural law.

Key words:

atmospheric particulates; UHI intensity; DVI; NDVI; MNDWI; Xi'an

Employment-oriented Urban-ward Migration and Migrants in Urban Labour Market in Post-reform India

Guin, D

Centre for the Study of Regional Development, Jawaharlal Nehru University, New Delhi, India,

debarshi.guin.1988@gmail.com

Abstract

Since the liberalization of Indian economy in 1991, a lot of changes have occurred in both urban and rural labour markets which have some direct influence on the employment related urban-ward migration, its composition and labour market outcomes of the urban migrants which the current study aims to explore.

The study is based on 49th, 55th and 64th round National Sample Survey data on migration. Stepwise regression, multinomial logistic regression and Herfindahl's index of concentration have been employed to analyze the data.

Findings show that, push factors are more powerful than the pull factors to control the growth of employment related urban-ward migration. Among the employment-oriented migrants, majority have migrated 'in search of employment' and 'in search of better employment'.

Labour market outcomes of the urban migrants before and after migration reveal marked decline in the rate of unemployment and significant improvement in work participation rate and the nature of employment. However, it is also found that chances of being employed is much higher among the illiterate and less educated migrants as compared to highly educated migrants. But they are more likely to be employed as casual labourers while better employment (regular salaried workers) is more or less exclusive to the better educated urban migrants only. Thus, it is clear that liberalization led new-economy does not bring any hope to the millions of less educated urban migrants and they are continued to be absorbed in informal sectors (or as casual workers in formal sectors).

Key words:

employment-oriented migration; urban labour market; urban migrants; employment, liberalization

Floating characteristics and formation mechanism of rural-urban migrants in China based on the urban house purchasing

Wenheng Wu, Jingsa Zhang, Kaiying Xu, Yinghao Qu, Hongying Zhu

College of Urban and Environmental Science, Northwest University, Xi'an 710127, China

Abstract

At present, more and more rural-urban migrants purchase urban housing in China, and the National New-type Urbanization Plan released by the central government also encourage rural-urban migrants to gradually become the permanent residents by possessing urban housing. To study on the floating characteristics of purchasing urban housing for a permanent home and to deeply understand the direction and difference of rural-urban migrants might help to know about public migration intention from the demand side. Further, relevant policies of urbanization and citizenation can be better formulated from the supply side and the effective supply may be implemented. In this study, 1327 valid information from China's 24 provinces and autonomous regions such as Jiangsu, Henan, Shaanxi and so on was collected through random questionnaire survey of farmers, migrant workers, undergraduate students, graduate students and their family members. Basic situation of rural-urban migrants and their family members of purchasing urban housing were filled out by participants' memories or telephone inquiries according to the questionnaire. Floating characteristics of rural-urban migrants for purchasing urban housing was summarized by data analysis. Furthermore, causes and formation mechanism of differences between floating directions were probed into from the perspective of individual or the family by Spearman bivariate correlation analysis and multiple classification Logistic regression analysis methods. The results show that firstly, few rural-urban migrants purchase urban housing in China during the 1980s~1990s, whereas migrants of purchasing urban housing are gradually growing and tend to be younger since 2000. What's more, migrants of higher education level purchase housing in the cities of larger scale or higher grade in general. Secondly, cities within the province or autonomous region, especially, county-level cities are the main destination of rural-urban migrants purchasing urban housing, and the attraction of town is weak as a whole, so it is particularly important for promoting the new-type urbanization and citizenization process to strengthen the construction of county-level cities. It can be seen from the data that the original location of migrants affects the floating orientation of purchasing urban housing, namely, rural households of ordinary township move to the county-level cities and towns nearby, but the households near

big cities specially provincial cities prefer to purchase their housing in those higher-level cities. Thirdly, cities and towns of different levels in the eastern provinces of China have relatively high proportion of purchasing housing, and towns have the highest percentage of rural-urban migrants for purchasing urban housing among the eastern, central and western regions. Those indicate there the relatively developed regional economy and the urbanization pattern of coordinated development between large, medium and small cities and small towns; Rural-urban migrants dispersedly purchase their housing in cities at or above the county level in the central provinces, where the county-level cities and cities of other provinces at prefecture level and above have the largest proportion of purchasing housing among the three regions. There the rural-urban migrants is decentralized; In the western provinces, migrants who purchase their urban housing in the cities of prefecture level and above account for more than half, and the proportion of migrants flowing to towns by purchasing housing is the lowest among the three regions. Those reflect that there it still is underdeveloped and unbalanced inside. Finally, it should say that the interaction between the urban and rural demand, the interference of other cities and the distance from the city influence spatial distribution of migrants with purchasing urban housing. Moreover, the desired economic income and the attraction of the city should be the underlying causes that migrants purchase the urban housing where they work. People prefer to choose the housing in the county-level cities and towns of their hometown or the higher levels of cities nearby if they do not have the stable work in the cities. We also found through the quantitative analysis that the floating differentiation between migrants for purchasing urban housing is significantly correlated with the personal or family factors such as education degree, fixed a job or not, whether work in the city of purchasing the housing, work time in the current city, the age of buyers, and so on. In a word, the macro-level social environment and policy implications, the middle level all media in the urban and rural system, and the micro-level subjective behavior of individual or family members comprehensively drive the spatial differentiation of rural-urban migrants.

Return Migration, Non-agricultural Employment and Urbanization Plan: An Empirical Study Based on Chinese General Social Survey 2010

Jiangbin YIN

Shaanxi Normal University, Xi'an, 710079, P. R. China, yinjb@snnu.edu.cn

Abstract

Return migration has becoming a significant phenomenon of migration process, and will influence the prospective of economic development and urbanization in emigrating regions profoundly. Because of the particularities of the experience in employment and residence, return migrants have been proposed more likely to employ non-farm work and settle in cities. Based on nationally-representative data from the Chinese General Social Survey (CGSS) carried out in 2010, we build one single-indicator path analysis model with Mplus 7.0 software to examine the mechanism between return migration, non-agricultural occupation and urbanization plan. Our purpose is to find whether migration experiences influence the urbanization behavior of return migrants, and to explore the inner mechanism of return migration influencing urbanization plan, especially for the impacts of employment choice. Empirical result indicates that migration experience has a significant positive impact on aspiration of settling towns, and the direct impact shows bigger than indirect impact by non-farm employment. The age at return, years of migration, and workplace during migration have significant influences on urbanization behavior of return migrant. Finally, we provide some related policy suggestions to local governments.

The Gond Tribe in Transition- Negotiating Boundaries and the Politics of Intrusion in India

Saha, Shreya

Jawaharlal Nehru University, New Delhi, 110067, India, sahashreya129@gmail.com

Abstract

An unusual demographic change has been noticed in the pattern of distribution of Gond tribes in India post Independence. It has been found that the Gond tribes had a compact core in 1961 while in 1981 the core is seen to be fragmented. However, by 2001 the Gonds have tended to cluster more closely and project a compact core and compact periphery once again and are widespread across more districts. This kind of reshuffling of the Gond population could be primarily attributed to their very location itself in the mineral rich Central Indian plateau that attracts the exploitative character of powerful authority be it State or global capital. The State in its attempt to promote 'national development' has almost turned a blind eye to the socio-cultural dismantling of tribal societies that the policies are bringing about. At a micro level, it is found that Bastar, the largest Gond inhabited district is also experiencing a change in its demographic profile with large scale intrusion of non tribal population owing to the resource worth of the region and this change is accompanied by a gradual transition in the work activities of the home population. Thus, the present paper intends to bring to light the territorial reconfiguration of the Gonds using the core- periphery model and for micro level changes simple population growth rate and occupational shift proves the reality.

Abstract

Migration has become one of central concerns in China, which influences climatic changes, ecological construction, water and land resources use, and economic development. The data of population investigation and census are provided at the form of points, while spatial distribution of population is important and necessary for various scientific research. This study simulated population densities of China with a resolution of 1 km×1 km in 2000 and 2010, using the population data from the fifth and the sixth censuses in China and night-time light imagery provided by The Defense Meteorological Satellite Program (DMSP) and Operational Linescan System (OLS). The results showed that there were some significant features in spatial distribution of population in the 2010s. First, the regions with a population density between 500 and 1500 persons/km² were “disappearing”, which were located in main grain productive areas in China. Second, the regions with a high population density increased significantly. For instance, the regions with a population density over 1500 persons/km² increase by 76% in the 2010s. Third, the regions with a low population density also increased quickly. These features exert great impacts on land use, ecological construction.

Disparities of Urbanization in Maharashtra State of India

Parag A. Khadke, Pramod B. Waghmare.

School of Earth Sciences, Swami Ramanand Teerth Marathwada University, Nanded, Maharashtra, 431606, pakhadke@gmail.com

Abstract

Towns and cities have taken shape as centre of administrative and cultural significance through the centuries. As we can observe that the population in urban area is increasing too rapidly. Mostly people are moving to urban from rural area to have a more comfortable life, higher salary and better educational environment. At the moment, India is among the countries of low level of urbanization. Number of population residing in urban areas has increased from 2.58 crores in 1901 to 37.71 crores in 2011. India is the most populous countries in the world. Our country covers only 2.4 per cent of the land area of the world, whereas it is the home of more than 16.87 per cent of the world's population. Since the new economic policies were adopted in the country, Maharashtra has seen fast urban growth. Maharashtra has the highest level of urbanization in India at 45.23 per cent compared to 29.5 per cent as the all India average. Census data were used to study the nature and pattern of urbanization in India with special reference to the state of Maharashtra. Urbanization depends on the socio-economic system of the society and the rate of its development. Maharashtra state urban population growth is considered for the period 1901 to 2011. It has increased from 3217202 persons in 1901 to 50818259 persons in 2011. The highest urban population growth in the all census was 1961 i. e. 62.42 per cent, and Lowest urban population growth in the census 1911 i.e. 0.99 per cent.

Immigration and Its impact on Demographic Scenario and Socioeconomic Condition among Tribal in Tripura

DebbarmaSolomon

International Institute for Population Sciences (IIPS), Mumbai, India-40088, Email-sollu37@gmail.com.

Abstract

Tripura was a glorious princely state ruled by 184 kings before it merged with Indian union on 15th October 1949, after which there was a serious social, political and demographic ramification with the great influx of Bangladeshi immigrant from 1947 to 1971. Attempt will be made to study the consequences of this event. The Present study will analyse the changes in the demographic and socio-economic scenario of the tribal and non-tribal population from Census of India 1941-2001 and National Sample Survey (NSSO) 52nd, 64th and 71st round using univariate and bivariate analysis.

The result shows that the tribal who are once majority are now sharing only 31% of the total population, further the language composition shows that only 26% speaks tribal dialect while about 67% speaks Bengali and 7% other (Census 2001). The wealth quintile from NSSO data shows that non-tribal are better than tribal people; as the majority of the tribal people are still poor or middle category. Tripura has been ruled by the ruling party "Communist party of India" since 1993. On the other hand In-spite of being a tribal state; there was only one chief minister from these tribes so far.

As a result of these change, there happen to be many communal clashes and emergence of insurgency group, which disturb the communal harmony of the state. So there is a need to explore the status of this tribe, in order to through light to the policy maker for implementing the better policy for this tribes.

Spatial distribution of migrants returning from metropolis based on the fluid dynamics theory: taking Guangzhou as an example

Yueyue Zhang

Guangdong Key Laboratory for Urbanization and Geo-simulation

Abstract

With more and more migrants returning from metropolis, the urbanization in future will more likely take place in medium cities, small cities and towns. Moreover, urban planning in those areas will be different from it in metropolis, and will be influenced remarkably by the scale and the direction of the migrants flow. Thus, the spatial distribution of migrants returning from metropolis should be paid more attention. This paper takes Guangzhou as an example. Based on the fluid dynamics theory, a model will firstly be constructed to analyze the spatial movement of migrants. Secondly, the spatial distribution of returning migrants will be concluded by inputting influence factors of migration obtained through questionnaires and data from National Health and Family Planning Commission of the People's Republic of China into the model. Finally, the result of it will be mapped by GIS accurately and vividly, and corresponding advice could be suggested to the planning in these areas, such as the layout of the infrastructure and the way of improving attraction of satellite towns.

spatial distribution; migrants returning from metropolis; fluid dynamics theory

Study on Residential Segregation of Migrants and The Influencing Factors in Period of Transition: A Case Study on Wuxi

Chen J, Liu FB

Nanjing University, Nanjing, 210000, P. R. China, 517839443@qq.com

Abstract

Since reform and opening-up, the migrants who come to city from countryside usually concentrate in certain areas in city, forming a special agglomeration space, which produces impacts to the general urban space of the city. With the concentration of migrants, the problems of the social spatial fragmentation, the privatization of public space and social tagging of community residents become more conspicuous. The social space heterogeneity is unceasing deepening. Meanwhile, the social relations and order of the community have been severely disturbed and destroyed. Taking Wuxi city as an example, this paper analyzes the concentration characteristics of the living space of migrants, and the differentiation features of the urban residential space of the city by referring to related study methodologies in China and abroad. Moreover, the paper also explores the inference of the social space elements via methodologies of fitting and comparison, with the aim to explore the pattern, extent as well as mechanism of migrant residential segregation in transitional China.

Demography of Disasters – The Role of Demography in Planning for and Mitigating Impacts from Disasters in Developed Nations

Karacsonyi D.¹, Taylor, A.²

¹Geographical Institute, Hungarian Academy of Sciences, Hungary, karacsonyidavid@gmail.com

²The Northern Institute, Charles Darwin University, Australia

Abstract

Both slow onset disasters (like the loss of polar ice from climate change) and rapid onset disasters (such as cyclones and man-made or industrial disasters) have the capacity to fundamentally change the profile of populations at local and regional levels. Impacts vary according to the type, rapidity and magnitude of the disaster, but also according to the pre-existing population profile and its relationships to the economy. It is well known that sub-sections of populations, like elderly, homeless and Indigenous populations, may be more vulnerable than others to the effects of disasters.

Demographic impacts from disasters might range from a magnification of demographic trends observed in the past to a complete bifurcation in the form of de-population or a collapse in the viability or sustainability of communities. In all cases, the key to understand impacts is to have research based knowledge about the number and compositions of those who might be or who are immediately affected. Tools and techniques for assessing population impacts are a first step for responding to immediate needs and for understanding longer term impacts and appropriate responses. Policy responses should be informed by knowledge of pre-existing demographic conditions and how different populations react under situations of disaster onset.

In the on-going book-project entitled “The Demography of Disasters” we compile case studies which provide cross-national cases of population responses to disasters in order to provide practical and theoretical insights for understanding the role of demography in planning for and mitigating impacts from disasters in developed nations.

Key words:

demography; disasters; resettlement; vulnerability

Disaster Management in Future Indian Smart Cities: Issues and Challenges

Dr. Janki Jiwan

Assistant Professor, Shaheed Bhagat Singh College, University of Delhi, jjjwan@gmail.com

Abstract

In India, proposed smart cities are vulnerable to variety of natural hazards (floods, hurricanes, earthquakes and volcano eruptions) and man-induced emergencies (technological or industrial accidents, usually involving the production, use or transportation of hazardous material, and occur where these materials are produced, used or transported). These recurrent disasters have potential to disrupt components of smart cities viz., Smart Health, Smart IT & Communications, Smart Transportation, Smart Environment, Smart Energy, Smart Governance, Smart Environment and Smart Buildings. This paper looks into the vulnerability of these components to mainly two disasters namely earthquake and flood with focus on two proposed smart cities viz., New Delhi and Chennai (Earthquake vulnerability in New Delhi and Flood Vulnerability in Chennai). This paper also studies various models, issues and challenges for making disaster resilient components of smart cities so as to enable decent living for their residents, a clean and sustainable environment and adopt smart solutions to meet their ends.

Smart City; Disaster Management; ICT; Issues and Challenges

Ecological Risk Assessment of Landslide Disasters in Southwest Mountainous Area: A Case Study in Dali Bai Autonomous Prefecture

Yueyue Du, Jian Peng, Shiquan Zhao, Zhichao Hu, Yanglin Wang

Peking University, China, duyueyue91@pku.edu.cn

Abstract

Facing the background of land creation project strategy, huge development potential for gentle hillside, high frequency of geological disasters and fragile ecological environment in southwest of China, the ecological risk assessment on geological disasters is particularly important to the sustainable development of regional social economy and ecological environment. The existing assessments working on geological disasters are likely to focus on the risk of economic loss instead of the risk of regional ecosystems. Besides, the process of how risk receptor exposure and then response to the stressors has been paid less attention. Choosing Dali Bai Autonomous Prefecture as an example, the study assesses ecological risk of landslide geological disasters considering risk stressors, risk receptors, exposure and response process, and ecological end points. To be specific, this research firstly uses the information method to evaluate the hazard of landslide disasters. Secondly, ecological vulnerability is evaluated based on landscape pattern metrics. Thirdly, the potential ecological damage of the study area is obtained according to ecosystem service assessment. Finally, this paper comprehensively evaluates the ecological risk of landslide geographical disasters, and distinguishes the partitions of risk precaution and governance. The results showed that, (1) 10 aspects including geography, geology and human activity factors such as elevation less than 1800 m, slope within 15-25 °, NDVI less than 0.31 are the best information combination for inducing landslide geographical disasters in Dali Prefecture. As to the hazard of landslide geological disasters, the whole Dali prefecture is generally in middle and high risk level of landslide and debris flow disasters. And the risk of northwest is lower than that of southeast; (2) the areas with high ecological vulnerability mainly concentrated in the south of Hong River watershed, southeast of Jinsha River watershed and the central of Lancang River watershed. Watersheds with low ecological damage occupy relatively poor water conservation service and food supply service. Watersheds with middle ecological damage have obvious advantage in providing net primary production and soil conservation service. Watersheds with high ecological damage would have relatively strong food supply and water conservation service. (3) the ecological risk of landslide geographical disasters shows a circling structure in which the lower risk level is distributed on the periphery, and the higher risk always occurs in the middle of the study area. What more, the area and number of watersheds in different risk level decreases gradually. 367 small watersheds contain 8 kinds of structures of ecological risk and 4 partitions of risk prevention and governance strategies. The results will do great help to the decision making of ecological risk prevention and macro ecological management in Dali Prefecture on the background of gentle hillside construction.

Key words:

Ecological risk of landslide disasters; Geological hazard; Ecological vulnerability; Ecological potential damage; Risk prevention and governance; Dali Bai Autonomous Prefecture

Livelihood and Vulnerability in the Peri-Urban Interface. A Case from Developing India.

Nasrin Banu

Department of Geography, Aligarh Muslim University, Uttar Pradesh-202002, India, nasringeo@gmail.com

Abstract

The present study is an attempt to depict the picture of livelihoods and its vulnerability in the transforming Peri-Urban Interface of Aligarh city which is located in the shadow of the national capital, Delhi. The study assumes that process of peri-urbanization adds complexity to household livelihood security. To measure this stress, the study adopts the Sustainable Livelihood Approach of DFID. It also evaluates the coping strategies adopted by the households to cope with urban stress.

The study is based on both primary and secondary sources of data. The primary data was collected through stratified sampling where on the basis of distance the PUI has been divided into three zones. From the city boundary up to 5 km is termed as immediate PUI, 5-10 km is intermediate and 10 -15 km is distant PUI. After the zonation, 44 villages were sampled and 757 households were surveyed.

Indices of Asset, Exposure and Sensitivity have been made for preparing Livelihood Vulnerability Index. On the basis of LVI's score the PUvillages have been categorized into three stages which include accumulating, adapting and surviving stage. Better status is in accumulating stage which has the ability of absorbing urban stress. But interestingly none of the immediate PUI is found in this stage. The second stage of livelihood ladder is adapting stage in which livelihood situation is improving. The third stage of livelihood ladder is surviving stage in which life is a constant battle and higher number of the villages in immediate PUI falls under this stage.

Key words:

sustainable livelihood; peri-urban interface; coping strategy; exposure; asset; sensitivity and livelihood ladder

Probabilistic Risk Analysis Application on Evaluating Ocean Surge Related Disasters' Impacts: A Case Study at Hainan Island China

Peihong Jia¹², Miao Wang³, Shu Gao¹², Yong Yin¹², Ling Li¹², Zhi Gu¹²

³Department of Civil, Environ & Geomatic Eng, University College London, London

Abstract

Ocean storm surge is a serious marine disaster occurred with rapid and strong destructive force to cause many disasters that seriously threaten coastal area and cause huge property and life losses. Hainan Island is being developed to be International Tourism Island and the research area is admitted to be a pilot zone by China National and Hainan Provincial Government, meanwhile, it is one of the provinces affected by tropical cyclones in a higher frequency and causes serious damage to the environment, people's life and economic properties. Nanjing University has finished some research works and collected abundant surveying and research data in Hainan Island. Ocean storm surges in history, Geo-Ocean, social and economic etc. data, combined DEM data, remote sensing data, other social and economic data are overlaid in ARCGIS10.1, plus QASER model to integrated analyse with 2D/3D styles to assess multi-risk of storm surge disasters. More sustainable and resilient urban planning to all disasters is emphasised to require urban planner to have a thorough understanding on the potential impact of natural disasters and then make a resilient urban planning to resist multi-risk assessments in this area as prediction to direct the infrastructure construction rationally by science data and policy, to provide an important theoretical basis for risk zoning and assessment of disaster losses, and to support scientific decision-making for the preparation of evacuation routes, the design of disaster prevention project, and the guidance of the coastal economic layout taken into account in long-term urban/land use planning.

Key words:

Ocean storm surge disaster; Multi-risk assessment; integrated analysis; city resilience; QASER model

Spatial Analysis of the Relationship between Urban Development and Tsunami

Disaster Risk in Cold and Heavy Snow Area

-A Case of Tomakomai City, Japan-

Takeshi KAWAMURA, Yuichi HASHIMOTO

Graduate Student of Hokkaido University, Sapporo, Japan :t_kawamura@eis.hokudai.ac.jp

Abstract

This study aimed to clarify the tsunami disaster risk of port city in cold and heavy snow area. The study area is Tomakomai City in northern part of Japan. Tomakomai City is a coastal port city. The port of Tomakomai is a particular international hub port. For the purpose of this study, we analyzed the change in building location and population in the evacuation difficult zones using a geographical information system(GIS). We used the city planning basic survey data and the tsunami simulation data in this analyzed. As a result, manufacturing facilities and the daytime population increased around the port. On the other hand, in the western part of the city, houses increased in the 1990s. The result of this analysis showed that the location of manufacturing facilities around the port and suburbanization of houses increased tsunami disaster risks. In the evacuation difficult zones, setting of evacuation facilities reduces tsunami disaster risks. However, because of the drop of the walking speed by the snow, the people who cannot arrive at the evacuation facilities increase. This study showed that factors of the increase of tsunami disaster risks differ from region to region, and the risk changes by a season. Thus, it is important that development of the disaster prevention plan depending on locality and seasonality.

Key words:

geographical information system(GIS); city planning basic survey data; simulation data of tsunami disaster; spatial analysis of building location; coastal port city; evacuation facilities; evacuation behavior

A Visualized Simulation Study on the Rainstorm Water Logging Risks in Nanguan District of Changchun from Multi-Scenarios Perspective

Chen P¹, Zhang JQ², Sun YY¹, Liu XJ¹

¹Travel and Geographical Sciences, Jilin Normal University, Siping 136000, P. R. China, pp11290@163.com

Abstract

Frequent urban rainstorm water logging is severely threatening the lives of urban residents and safety of property. The simulation of urban rainstorm water logging risks will provide evidences for the forecast and early warning of the disaster. In this paper, Nanguan District of Changchun was selected as study area for urban rainstorm water logging. From the multi-scenarios perspective, this paper proposed a multi-scenarios simulation framework of urban rainstorm water logging risks. For this purpose, it synthetically built a numerical model of urban rainstorm water logging risks taking one-dimensional and two-dimensional unsteady flow as the governing equation and irregular grids as the frame. The results are as followings: ① the study area has 12 water logging points with the maximum accumulated water depth of 0.69m, after a 30-year rainstorm in intensity of 60mm/h; ② 15 water logging points with the maximum accumulated water depth of 1.035m after a 50-year rainstorm in intensity of 89.5mm/h; and ③ 22 water logging points with the maximum accumulated water depth is 1.58m, after a hundred-year rainstorm in intensity of 103.2 mm/h. These results can be referenced by urban water logging emergency management authorities for the forecast and early warning of disaster.

Abstract

Extreme heat events will become more intense, more frequent, and longer durative with a continuous climate change in the foreseeable future, leading to an increased human health risk of diseases and excess deaths. (Extreme climate events are expected to further intensify in the near future, last longer and occur more frequently in particularly coast regions such as the Monsoon Asia, having significant implications to human health.) In hazard risk assessments, there is always a spatio-temporal mismatch between hazard data and exposure data, due to the fact that demographic data is generally updated every couple years and not available at sub-census unit level, which hinders the ability to diagnose human risks. In this study, an exposure model based on multi-sensor remote sensing data was applied in population distribution estimation on a per-pixel basis. Urban heat island effect was taken into account in hazard (heat stress) measurement. The heat health risk was spatially explicit assessed and mapped at a 250m×250m grid across Zhejiang Province, China. The assessed risk and the heat-related deaths during the same period have a good spatial correlation at county level ($R^2=0.66$). The analysis of heat-related deaths indicated higher deaths, a higher spatial death density, but a lower mortality in urban areas compared with non-urban areas.

extreme heat; human health

Assessment of Vulnerability to HIV/AIDS in Mizoram, India: A Study of Groups-at-Risk

Nayak Debendra Kumar, Zou Khupmuanlal

Department of Geography, North Eastern Hill University, Shillong-793022, India. dknak@rediffmail.com

Abstract

Based on interviews conducted among four high risk groups in Mizoram- a state in India perceived to be highly vulnerable to HIV/AIDS owing largely to its location and space relation with countries and states already experiencing a spurt in HIV positive cases., vulnerability to HIV/AIDs has been probed in this paper including a sample of those who have already contracted the disease. The latter includes a sample of those who are HIV Positive and the former consists of the commercial sex workers (CSW), the intravenous drug users (IDUs) and the truck drivers. The reason for including HIV positive group in the study was felt necessary as it provides a direction to HIV/AIDS vulnerability among the groups at risk. Information extracted from them helped build an understanding of the extent of vulnerability to HIV/AIDS. It is important to see as to how they got infected and the conditions that made them contract the virus. A schedule was designed for thirty respondents (HIV positive persons) with their prior consent and with the help of concerned NGOs. Besides the HIV Positive, the study includes a sample of the commercial sex workers, intravenous drug users and the truck drivers- the three most important groups who, by the very nature of their profession can easily be considered as highly at risk. As many as 30 respondents from each of these groups were interviewed on several facets of their personal and professional works in order to assess the extent of their vulnerability to the dreaded disease.

Study of Urban Vulnerability Evaluation in Northwest China Based on TOPSIS Model

LI Hai-ling, MA Bei-bei, JIANG Jun

College of Tourism Environmental Sciences, Shaanxi Normal University, Xi'an 710062, Shaanxi, China,
710391063@qq.com

Abstract

As the underdeveloped area in China, Northwest region's development in eco-environment and society and economy are crucial for China. However, both the basic infrastructure and sustainable development of this territory are flawed. Making a research on the urban vulnerability and its dynamic evolution are of great significance to promote the territory sustainable development. This paper aims to evaluate the urban vulnerability and its change trend in capacity Northwest (Xi'an, Lanzhou, Xining, Yinchuan, Urumqi) from 2000 to 2014 by using the TOPSIS method. The assessment can be divided into four parts, they are resources, eco-environmental systems, economics, and social development. Results show that the urban vulnerability in five cities is relatively high vulnerability, and high vulnerability. The overall urban vulnerability change high vulnerability to relatively high vulnerability from 2000 to 2014, but resource vulnerability is abnormal, which can be indicated by the moderate vulnerability change into the relatively high vulnerability. Resources and eco-environment can be the factors affecting the changes.

Key words:

the urban vulnerability; capacity northwest; TOPSIS method; change trend

Enhancing Passenger Safety and Security in Ghana: Appraising Public Transport Operators' Recent Interventions

¹Sam, E.F. and ²Abane, A. M.

¹Dept. of Geography Education, University of Education, Winneba, Winneba, Ghana, efsam@uew.edu.gh

²Dept. of Geography and Regional Planning, University of Cape Coast, Cape Coast, Ghana

Abstract

Descriptive cross sectional study in nature, the paper examined passenger safety and security interventions of public transport (PT) operators in Ghana. Data were drawn from in-depth interviews with six (6) major inter-urban PT operators as well as questionnaires administered to 273 inter-urban PT passengers. Field data were presented and analysed using both narratives and descriptive statistics.

A number of recent safety and security interventions adopted by the surveyed operators were appraised. For the operators, these have resulted in reduction in road accidents and highway robbery attacks involving their buses and invariably their passengers. On the part of passengers, interventions geared towards addressing reckless driving and police escort on buses were commendable.

The study emphasised the need for periodic review of the regulatory framework establishing public transport undertaking by the Metropolitan, Municipal and District Assemblies (MMDAs) to reflect changing safety and security circumstances.

Key words:

Spatial Imprint of Road Transport and Its Impact on Spatial and Sustainable Urban Form: A Study of Lucknow Metropolis, U.P., Lucknow, India

kashif imdad

PPN PG College, CSJM University, Kanpur, India, kashifimdad@gmail.com

Abstract

Urban form refers to the spatial imprint of an urban transport system as well as the adjacent physical infrastructures. The evolution of road transportation has influences and determined the direction of change in urban form and spatial arrangement of the cities. The most important change in the urban form is the evolution of new cluster because of a change in urban activity and its mobility from old cluster. With continue transformation of cities and change in urban activity a complex urban structure continues to develop. Because each city has its own unique form of geography, transportation, history, social and economic characteristics, it develops a unique set of urban form and spatial structure. Present study intends to study spatial imprint of road transport and its impact on spatial and sustainable urban form. For this purpose road traffic data has been collected along all major highways and crossings. Various other associated parameters of road traffic have also been collected to determine different parameters of selected segments of roads and nodes. The result indicates positive relation between of road transport imprints on spatial and sustainable urban form of Lucknow metropolis.

The Influence of Household Structure on the Travel Behavior of Young Couples in China

Z. Wang, Sylvia Y. He

Department of Geography and Resource Management, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong, P. R. China, zhenzhen_jane@link.cuhk.edu.hk

Abstract

Existing studies have documented that individual's travel behaviour is affected by intra-household interactions about the allocation of household tasks and out-of-home activities among family members. China's unique household structure, extended household with co-residence of senior parents, is supposed to significantly affect intra-household interactions and therefore influence individual's travel behaviour. Based on the data of 2013 Huzhou Residents Travel Survey, this study will attempt to explore how China's unique household structure affects young couples' travel behaviour, including travel frequency and duration for various purposes. Descriptive analysis method will be adopted at first to compare the difference in travel behaviour of young parents with different household structures, and then multivariate regression models will be established to further investigate how travel behaviour of young parents is affected by household structure. The finding of this study may have potential implications for urban transportation policy in China.

Key words:

household structure; travel behaviour; young couples; China

Understanding the Relationship between the Development Degree of Public Transport and Economic Development of Cities in China

Fengjun Jin, Jingjuan Jiao

Key Laboratory of Regional Sustainable Development Modeling, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, China, jinfj@igsnrr.ac.cn

Abstract

Influenced by the rapid development of economy, the levels of mobility have increased substantially in China, which leads to many traffic (congestions), environmental and other problems in some megacities and very large cities (e.g. Beijing and Shanghai). To solve these problems, the strategy of developing public transport is proposed by many governments. However, the studies about the development degree of public transport and its relation with economic development in China are rare. Therefore, this paper will firstly analyze the evolution of public transport (including subway, light rail and bus) in China. Secondly, this paper will use the factor analysis to evaluate the development degree of public transport and economic development in the city level and explore their spatial patterns. Thirdly, this paper will explore the relation between the development degree of public transport and economic development in China and classify the study objects into several categories. Lastly, this paper will try to give some suggestions to the development of public transport in China.

Key words:

public transport; development degree; economic development; China

Spatial Dependency of Bus-line Distribution Based on Bipartite Network: A Case Study of Beijing City

DUAN Dezhong, LIU Chengliang, GUI Qinchang

Institute for Innovation and Strategic Studies, East China Normal University, Shanghai, 200062, P. R. China,

dezhong_tuan@163.com

Abstract

Based on the idea of binary network, this paper discussed the local and global spatial dependency of Beijing bus-line distribution by the space correlation matrix construction of bus-line and city road, and the introduction of dependency measures from 1-mode network. We found that in terms of local dependence, the layout of bus-line is highly dependent on a few city trunk roads and express roads from downtown to suburb, so its spatial dependence pattern forms a corridor diffusion pattern of core-periphery which takes the downtown of Beijing as the core, and takes the suburban rapid corridors for the channel. In terms of global dependence, the distribution structure of bus-line was imbalance, which seemed more fragile and greatly influenced by the city road traffic conditions. The downtown area taking the Forth Ring as the boundary was the core space of bus-line dependence. In terms of space division, the layout of Beijing bus-line presented good correspondence to the city districts, Chaoyang District, Haidian District and Within Third Ring Area were the three most density area of bus-line distribution.

Key words:

bus-line; city road; spatial dependency; bipartite network; Beijing City

Spatiotemporal Evolution of Land Subsidence around Subway, Determined by Time-Series Insar and the Entropy Method

Chen WF, Chen BB, Gong HL

Base of the State Key Laboratory of Urban Environmental Process and Digital Modeling, Capital Normal University, Beijing, China, cnugis@cnu.edu.cn

Abstract

Land subsidence caused by over-mined groundwater and engineering construction has become a serious problem in urban Beijing, China. As the main urban infrastructure, the underground railway network has burgeoned with the expansion of Beijing City. However, the influence of subway construction and operation on regional subsidence has received minimal attention. In this study, the land subsidence information around Beijing Subway Line 6 was determined by the PSI (Permanent Scatters Interferometry) method. Synthetic Aperture Radar data we used were the Radarsat-2 satellite with a resolution of 25 meters. Based on the land subsidence information, we generated 39 ring buffers between Huangqu and Changying Station. The expectation (Ex) and entropy (En) of the deformation rate in each buffer were then calculated. In land subsidence, the Ex and En respectively reflect the overall level of regional land subsidence and the temporal degrees of non-uniformity of the regional land subsidence. in time and space. By comparing the changes of Ex and En, we estimated the spatial influence range of the subway on land subsidence. The influenced area mainly lied in the area between 60 m and 80 m from the subway line in the north and south, respectively. After calculating the time series Ex and En of deformation rate of PS (Permanent Scatter) points in the affected area again, we revealed the the evolution of land settlement before and after the subway operation. The land subsidence was most altered during the subway construction stage. During operation, the deformation rates along the subway slightly increased in the first two years, then tended to stabilize.

Assessment of Sustainable Development Level on China National Sustainable Communities—A Case Study of Rizhao City

Min Liu

Capital Normal University, China, 990855838@qq.com

Abstract

Under the direction of sustainable development theory, China National Sustainable Communities (CNSCs) is an important experimental and demonstrations base to explore the coordinating development mode of economic, social, resource and environment. Taking Rizhao for example, considering the characteristic of CNSCs, from four aspects of economic, social, resource and environment, and choosing the assessment index system, adopting Principal Component Analysis method, this paper analyses by synthesis the sustainable development level. The results show that the sustainable development level of Rizhao improves significantly in recent years, but the difference is very prominence contrasting with the same prefecture-level cities. In the end, this paper puts forward some countermeasure promoting sustainable development of CNSCs about Rizhao, which will contribute to the sustainable development of CNSCs about Rizhao and other same type cities.

China National Sustainable Communities; sustainable development level; Principal Component Analysis; Rizhao

Change in Ecosystem Service Values and Related Factors in Zhoushan Island

Cao W, Li R

School of Earth Sciences, Zhejiang University, Hangzhou, 310000, P. R. China, zhedalirui@zju.edu.cn

Abstract

Many islands in developing countries are undergoing intensive development. Ecosystem service values (ESVs) there may change considerably. The ESV changes in Zhoushan Island during 1995-2011 were quantified by land use proxy based approach. Furthermore, a geographically weighted regression (GWR) model is used to explore the relationships between changes in ESV and related influential factors. We employed the Defense Meteorological Satellite Program/Operational Linescan System (DMSP/OLS) nighttime lights and topography as two influential factors.

The results showed that with the booming island development, the land use in Zhoushan Island changed dramatically in the past decades, 37% tidal flat and 12% farmland were transformed into construction land. As a result, its total ESV decreased from 811.6 RMB Yuan/yr in 1995 to 759.8 million RMB Yuan/yr in 2011, reducing annually at a rate of -0.4%. The ESV changes exhibited significant positive autocorrelation, changing greatly along the coast, but less in the central mountains. Furthermore, the decline of ESVs occurred mostly in the south-facing blocks along the coast. The topography played a considerably crucial role in the location and degree of EVS changes. The Changes in DMSP/OLS nighttime lights were spatially negative correlated with ESV Changes. This is conducive to quickly identify and map the spatial heterogeneity of ESV Changes. It is urgent to formulate an environmental function zoning of the island, to protect a certain land sections with higher ecosystem value coefficient from construction, to draw a red line for the protection of tidal flat and farmland.

Ecosystem service; DMSP/OLS nighttime lights; GWR; Zhoushan Island; Topography; Sustainability

Framing Global Cropland Dynamics during 2000-2010

Wenbin Wu, Qiong Hu, Miao Lu, Di Chen

Institute of Agricultural Resources and Regional Planning, Chinese Academy of Agricultural Sciences, Beijing 100081, China, wuwenbin@caas.cn

Abstract

Croplands cover 1.53 billion hectares (about 12% of Earth's terrestrial surface), with great implications for global food production, food security and the environment. There has been much research to investigate the spatio-temporal changes of croplands at local scale or in specific small regions, few study was performed at the global level. This presentation aims to introduce the latest research on detecting and monitoring the dynamics of global croplands during 2000-2010. The China's 30 meter resolution land cover dataset (GlobeLand30) was used and multiple indicators including total areas of change, conversion-in/out areas, cultivation index, multiple cropping index and other landscape index at different levels were calculated to depict the quantitative and spatial characteristics of changes in global cropland over the past decade. The preliminary results show that global cropland increases by 7.83 million mu during 2000-2010, which is mainly due to the reclamation of grassland and deforestation. South America and Africa have the largest changing rate in terms of cropland area. Those countries such as India, Argentina, Eastern European, USA and Northern China have relatively high cultivation index, which are the important regions for producing global grains. Moreover, countries near the equator (e.g., Philippines and Nigeria) or surrounded by ocean (e.g., Malaysia and Bahamas) are found to have high multiple cropping index largely due to the abundant heat and water resources. The regions with high cultivation index but low multiple cropping index may have some potential to increase global food production by increasing the cropping intensity. These results may provide some helpful information to better understand the agriculture development and the multi-dimensional interactions of the coupled human and natural systems.

Key words:

Globeland30; global cropland; dynamics; cropping intensity

HANPP Dynamics Due to Land Use Change in China

Jian Peng, Tian Zhang, Yanxu Liu, Yanglin Wang

College of Urban and Environmental Sciences, Peking University, Beijing 100871, China, jianpeng@urban.pku.edu.cn

Abstract

Increasing human activities will enlarge human demanding for biophysical resources, including land use and biomass, which also influence the biological productivity of land, altering material and energy flows in the biosphere. In recent years, with the sharpening contradiction between human activities and ecological system, it becomes a common challenge to quantify the intensity of human-induced changes on ecological system. The human appropriation of net primary production (HANPP) is an integrated socio-ecological indicator quantifying the human domination of the productivity and harvest in biosphere, indicating regional ecological sustainability.

Meanwhile, land use and land cover change (LUCC) is one of the most important factors in global environmental change, as an key issue in geography. From the perspective of human activities, LUCC is the most typical way of terrestrial ecosystem transformation. Quite amount of biophysical resources was dominated during the human transformation, which is a key composition of the HANPP and is defined as the biomass losses caused by the LUCC ($\Delta\text{NPPlucc}$). The other part of the HANPP is the harvest of biomass (NPP_h), which combined as the grain harvest from cultivated land, the wood harvest and the animal products. It is obvious that LUCC could directly influence the $\Delta\text{NPPlucc}$ and thereby alter HANPP, and the intensity of cultivated land development also has a direct relationship with the grain harvest. Therefore, the regional HANPP would dynamically alter due to the land use change.

As a hotspot in the domains of human-induced environmental change, research on HANPP has received much attentions in recent years. However, most of the studies focus on the concrete accounting of the HANPP at the global scale, the research at China is quite rare especially lack of the one focus on provincial scale. More attentions should be especially paid on the relationship between HANPP and the regional land use/cover change. In this study, we quantified the HANPP in China's 31 provinces during 1982 to 2010 based on remote sensing data, meteorological data as well as China Statistical Yearbook in forestry and animal husbandry. We mainly analyzed the spatial and temporal distribution pattern of HANPP as well as discussed how the HANPP alters along with the long term land use change among different provinces.

Key words:

HANPP; Land use change; Spatial-temporal dynamics; China

Level of Food Security in the Districts of Kerala and Bihar: A Comparative Analysis

SHUCHI, Baraik VIJAY KUMAR, Nathawat MAHENDRA SINGH

Discipline of Geography, School of Sciences (SOS), Indira Gandhi National Open University (IGNOU), New Delhi-110068, India, me_shuchi17@rediffmail.com

Abstract

Zero hunger is one of the 17 Sustainable Development Goals adopted by the United Nations in September 2015, which aims to end hunger, achieve food security and improved nutrition and promote sustainable agriculture by 2030. The issue of the level of food security and its assessment has become increasingly important for the framing of hunger reduction strategies. The concept of food security encompasses the three components- availability of food, accessibility of food and absorption of food. It is the combination of the varying levels of these components, which results in varying levels of food security in different regions. Two States of India-Kerala and Bihar rank highest and lowest respectively in terms of accessibility of food based on certain indicators, which determine the economic and physical accessibility of food.

In this study, a detailed district level comparative analysis of the level of food security in the two States is done for the reference year 2011 to explore the inter-district patterns and characteristics within the States of highest and lowest levels of accessibility of food. It identifies the gap areas in the fulfillment of the nutritional needs of the population. Composite Indices are calculated using selected indicators, which represent the three pillars/components of food security- Availability, Accessibility and Absorption. The study is based on secondary data using simple statistical techniques.

Key words:

⁴Key Laboratory of Regional Geography, Beijing Normal University, Beijing 100875, China

Abstract

Substantially reduce the mortality and affected people due to natural hazards by 2030 are two of the most important targets of supporting the assessment of global progress in achieving the outcome and goal of *Sendai Framework for Disaster Risk Reduction 2015-2030*. This paper firstly systematically reviewed the methods and indicators to assess the impacts on human society by multiple natural hazards. Then based on the assessment result of expected annual multi-hazard intensity (Mh) at grid unit ($0.5^\circ \times 0.5^\circ$) of eleven hazards in the *World Atlas of Natural Disaster Risk*, including earthquake, volcano, landside, flood, storm surge, tropical cyclone, sand-dust storm, drought, heat wave, cold wave and wildfire, a vulnerability model among Mh , the coping capacity indicator (GDP Per Capital) with mortality rate or affected population rate is developed to estimate the mortality and affected population per 100,000 during 2005-2015 and 2020-2030. Finally, the global mortality risk and affected population risk are mapped at grid unit and ranked at national unit. The result shows that: countries and regions with high multi-hazard intensity have significantly high mortality risk and affected population risk if the development of coping capacity cannot match the growth of population, such as India, Bangladesh, Philippines and Pakistan; countries and regions with high multi-hazard intensity and high growth rate of population but with low socioeconomic status, also have high mortality risk and affected population risk, such as Bangladesh, Philippines and Vietnam. Hence, to achieve the target in *Sendai Framework*, it is necessary to enhance the disaster coping capacity, especially for the developing countries with high multi-hazard intensity, large population and less developed economic. The proposed method to quantitatively calculate the mortality and affected population in this paper can provide scientific and technical support of the assessment of global and national/regional progress in achieving the outcome and goal of the *Sendai Framework*.

Multi-hazard, Mortality risk, Affected population risk, Global scale, Sendai Framework for Disaster Risk Reduction 2015-2030

Quantifying Spatiotemporal Dynamics of Ecosystem Services across Landscapes: Four Mega-Sandy Lands, China

ZHAO, Y.

School of Soil and Water Conservation, Beijing Forestry University, Beijing, 100083, P. R. China,

yuanyuan0402@126.com

Abstract

The four mega-sandy lands (Hulunbeir, Horqin, Otindag, and Mu Us) are reported to be the most seriously desertified regions in China. Ecosystem services in these regions are of great value for improving human well-being. The main objectives of this study were to quantify the spatiotemporal dynamics of ecosystem services across the sandy landscapes and explore the possible driving forces during 2000-2014. We estimated multiple ecosystem services including food and meat production, soil conservation, and carbon sequestration, using model simulation and statistical methods. Then the relationships between ecosystem services and possible driving factors were investigated. We found that ecosystem services generally showed a significant increasing trend in all sandy lands during the past 15 years. Changes in all ecosystem services were positively correlated with those in vegetation cover. Wind speed was significantly correlated with the soil conserved from wind erosion. However, the correlation strength varied among the four sandy lands, and ecosystem services and their dynamics exhibited large spatial heterogeneity across the study region. Vegetation cover and wind speed interactively determine ecosystem functions and thus ecosystem services in these drylands. Vegetation coverage was a major determinant for the variations and spatial patterns of provisioning services. Both vegetation and wind speed played important roles in regulating soil erosion. To improve ecosystem services in drylands such as sandy lands, we need to adopt measures focusing on the major drivers and landscape heterogeneity.

Key words:

Ecosystem services; Sandy land; Vegetation change; Soil conservation; Carbon sequestration; Food and meat production

Simulating Land System Dynamics at Local Scale with the CLUMondo Model: A Case Study in Hohhot in Inner Mongolia, China

Liu, Z.

Center for Human-Environment System Sustainability (CHESS), State Key Laboratory of Earth Surface Processes and Resource Ecology (ESPRE), Beijing Normal University, Beijing, 100875, P. R. China, Zhifeng.Liu@bnu.edu.cn

Abstract

Understanding land system dynamics is essential for assessing their effects on environments and improving regional sustainability. Recently, the CLUMondo model, which can simulate changes in both land cover type and land use intensity, provides an innovative approach for understanding land system dynamics. However, the CLUMondo model has not been applied at local scale. The objective of this study was to simulate land system dynamics in Hohhot, the capital of Inner Mongolia in China, from 2013 to 2030 based on the CLUMondo model. The land system maps in 2000 and 2013 were respectively used to calibrate and validate the model, and three scenarios for land system change from 2013 to 2030 were developed based on the trend of historical land system change, the regional planning, and the biodiversity conservation target. We found that the land system in 2013 was well captured by the CLUMondo model with an overall accuracy of 76.96% and a quantity disagreement of 1.62%. From 2013 to 2030, the intensity of cropland was projected to increase in Hohhot under all the three scenarios. Additionally, the forest was projected to increase to a large extent under the scenario of planning, whereas the natural grassland was projected to increase obviously under the scenario of biodiversity conservation. Our results evidenced that the CLUMondo model is an effective land system model at the local scale. In addition, we suggested that the increases of natural grassland, forest, and intensity of cropland are needed to achieve socioeconomic development and environmental conservation in Hohhot simultaneously.

Change in Socio-economic Behavior in Urban Rural Interface Area in North India: A Geographical Analysis

Khan Nizamuddin

Department of Geography, A.M.U. Aligarh, India, nizamuddin_khan@rediffmail.com

Abstract

The urban rural interface area is dynamic in nature, moving in response to horizontal expansion or urban sprawl. It is passing through transitional stage of modification slowly under mutual exchange of socio economic interaction. Rurality of area is threatened and urban influence is imposed and consequently remarkable transformation is observed. The study is based on primary and secondary sources of data. Dynamics of urban rural interface region is also identified by GIS and remote sensing technique. Four villages were selected for detailed survey in the interface area of Aligarh city. Study revealed that the interface area witnessed change in house type, food habits, and means of livelihoods as well as socio cultural transformation to a considerable level. Environmental challenges are also emerging on account of socio-economic transformation in the study area.

Spatiotemporal Pattern of Urban Land Use and Contributions on Regulating Urban Climate

Wenhui Kuang

Key Laboratory of Land Surface Pattern and Simulation, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China; kuangwh@igsnrr.ac.cn

Abstract

The relationship between urban land components and thermal characteristic has been studied for long years including examining the impact of urbanization on urban thermal environment. Previous studies pointed out that impervious surface have positive effects on urban heat island while water and vegetation have negative effects. This paper took Beijing as a case study to illustrate urban land component change and its impacts on land surface temperature. The Landsat TM from 1984 to 2014 in autumn were downloaded through the USGS online portal and consistently calibrated to surface reflectance and brightness temperature (BT). The land surface temperature was derived using the single channel algorithm because it required only the parameters of water vapor and land surface emissivity and had a reported error close to 1 K. The urban components were extracted through the unmixing technology and multi-index. A comparison of different components in urban areas showed different patterns of urban components have different impacts on thermal environment. Next, temporal thermal signatures were created to characterize and quantify the impact of urban component changes. Decomposition analysis showed that the conversion of urban components' pattern and areas generated the largest difference in LST and the largest trend difference.

spatiotemporal pattern; regular thermal environment; urban components

Spatio-Temporal Variations of Ecological Conditions and Its Relationship with Urbanization Efficiency in the Yangtze River Delta, China

Min Liu^{*}, Fang Yang, Qiannan She, Xia Peng, Ning Wei, Weining Xiang

Shanghai Key Lab for Urban Ecological Processes and Eco-restoration, School of Ecological and Environmental Sciences, East China Normal University, Shanghai, 200241, P. R. China, mliu@re.ecnu.edu.cn

Abstract

The Yangtze River Delta (YRD), including Shanghai City, Jiangsu and Zhejiang Provinces, is the largest metropolitan region in China and the sixth largest in the world. In the past three decades, the region has experienced an unprecedented process of rapid and massive urbanization which dramatically altered the landscape and detrimentally affected the ecological environments in the region. In this paper, we analyzed the spatio-temporal variations of ecological conditions (EcoC) and the urbanization efficiency (UrbE) in the Yangtze River Delta during 1990-2010, the fastest-ever period of urbanization development. Moreover, with the 25 cities in YRD as the basic elements, a coupling analysis was also illustrated to examine the relationship between EcoC and UrbE. The result showed that: (1) The averaged classification of EcoC in the YRD was “moderately high”, which exhibited slow upward trend during the study period. (2) The EcoC in SHYRDUA demonstrated obvious spatial variations between south and north, with Shanghai--Suzhou-Wuxi-Changzhou-Nanjing as a demarcation belt. The EcoC of the south area in Zhangjiang province were generally better than that of the north of Jiangsu province. (3) There were negative correlations between ecological conditions and urbanization level in 25 cities of SHYRDUA. The coupling degree between EcoC and UrbE was relatively high and showed an inverted U-shape curve, with the coordinated degree increasing first, reaching the peak and then decreasing. It is hoped that the information provided in our study could serve the purposes of raising public awareness, informing urban and regional sustainability planning across different levels, and facilitating governmental decision-making.

The Impacts of Land Use Change on Flood Peak Discharge in Urban Areas: A Spatial View Point

Du, Shiqiang¹, Shi, Peijun², Van Rompaey, Anton³, Wen, Jiahong¹

¹Shanghai Normal University, Shanghai, 200234, P. R. China, shiqiangdu@shnu.edu.cn

²Beijing Normal University, Beijing, 100875, P. R. China

³Katholieke Universiteit Leuven, Heverlee, 3001, Belgium

Abstract

To date, limited attention has been paid to the role of impervious surface (IS) location in influencing flood processes. However, this topic is of tremendous significance for developing guidelines for urban planning and flood management. This study uses the Hydrologic Engineering Center's Hydrologic Modeling System (HEC-HMS) to investigate the impact of land-use change on flood processes, and proposes a new index to quantify the impact of IS location on basin peak discharge. The results indicate that rapid urban expansion in the Longhua Basin, China, has increased peak discharge and flood volume by 140% and 162% over the past 30 years, respectively. The new index, named the Impervious Surface Impact Index (ISII), describes the spatially varying effects of IS increase in individual sub-basins on a basin's peak discharge. For the Longhua Basin, the index varies from 0.43 in downstream sub-basins to 5.91 in upstream sub-basins. An increase in upstream IS increases peak discharge nearly 14 times more than the same increase in downstream IS. Accordingly, the location of newly created IS can influence flood processes significantly. These findings can help to find suitable locations for urban development while mitigating the impact of land development on flood risks.

Key words:

Peak flow; flood risk; impervious surface; low impact development; flood mitigation

The Rapid Expansion of China's Industrial Land in the Rural Areas and the Environmental Costs

Chi Zhang, Wenhui Kuang, Ailin Liu

Xinjiang Institute of Ecology and Geography, Chinese Academy of Sciences

Abstract

China's industrial growth accompanied huge environmental costs. In response to the environmental awareness among city residents, the government relocated factories from urban areas to rural areas. Our study indicates that the area of rural industrial lands (RIL) was $30.0 \times 10^3 \text{ km}^2$ in 2010 in China. The expansion rate of RIL in the 2000s ($0.2 \times 10^3 \text{ km}^2/\text{yr}$) was about 7 times that in the 1990s ($1.6 \times 10^3 \text{ km}^2/\text{yr}$), about 70% of the expansion in the 2000s took place after 2005. The rural mining (RM) area has increased from $4.9 \times 10^3 \text{ km}^2$ in 2000 to $7.2 \times 10^3 \text{ km}^2$ in 2010. As the results, the RIL area under high risk of landslide has increased 172% from 1990 to 2010. About 80% of the increase took place after 2005. The RM area under high risk of landslide has increased 45% in the 2000s. The number of settlements within 1 km distance from the RIL and RM and the nature conservation areas within 4 km distance from the RIL and RM increased dramatically from 2000 to 2010. The crop production and the net primary productivity of the China's ecosystems lost due to the expansion of RIL and RM. We also found significant correlations between soil and water pollutions and the closeness from the RM in China.

China's industrialization; pollution; mining land; rural industrial land

The Study of Sustainable Urban Development: Case study of Yasouj, Iran

Momeni M,

Department of Geography & Urban Planning, Faculty of Humanities, Najafabad Branch, Islamic Azad University, Najafabad, Isfahan, Iran; momeni100@gmail.com

Abstract

The existence of inequalities and different dimensions of it significantly demonstrate underdevelopment; the distribution of development index in different levels should be revised in order to remove such deficiencies. In order to solve the problems which stem from regional imbalances, the first step is to study and classify the regions from the point of view their enjoyment in different fields. Based on this fact, some of the development indexes including therapeutic- hygienic indexes, cultural, economic, civil indexes in urban districts and infrastructure indexes in Yasouj were examined and studied. The methodology of the research is of analytic-descriptive one and the results of it can be applied in other studies. The required data have been collected using the statistic resources related to general census of population and housing, statistic calendar of Iran statistic center and other related organizations. The data collected are related to 2012. Data were analyzed using the interpretative approaches, fuzzy multi-indexes analysis, fuzzy hierarchical analysis and SWOT model. The findings of the research shows that according to the studies of selected indexes in the whole city, the development of Yasouj is not close to national indexes and there is a significant difference between these two, therefore the unsustainability of urban development is evident. Being far from the political, economic, social and other important centers of country and also being mountainous can be among the reasons of underdevelopment of the city which caused some of the social, economic and social indexes show unsustainability at the time of study.

Understanding Chinese Urban Expansion with Natural Cities

Long, Ying

School of Architecture, Tsinghua University, Beijing, 100084, P. R. China, ylong@tsinghua.edu.cn

Abstract

During the last several decades, China has experienced a rapid urban expansion, which has attracted extensive research from multiple dimensions. The existing studies rely heavily on official statistical data and remote sensing images which are labor-cost, time and finance consuming for a country as large as China. Moreover, their accuracy has been often criticized. Recent efforts made by fractal analyses provide possible alternatives to scrutinize the corresponding “natural urban area” to the change of urban context. To introduce a simplified method on detecting and evaluating the emergent urban expansion throughout China, we refer to Bin Jiang’s natural city (NC) methodology understanding China’s urban expansion in the light of open data based on the empirically observed heavy-tail distribution. We redefine cities with four types of open data and capture corresponding expansion on four dimensions. For evaluating the magnitude and pattern of urbanization and expansion, we also measure the urban size and relative maturity on the four dimensions. It turns out the urban expansion areas during 2009 and 2014 were associated with fast and extensive morphological development with expansion rate up to 70%; and the functional development (31.6%) fell behind. Considering the relative maturity which is the ratio of the density of expansion to the area in 2009, the proposed methods produce higher outputs (95.9% by road junctions and 91.8% by POIs) than the conventional methods (47.6% by road junctions and 28.6% by POIs). The bottom-up NC method contributes to our comprehensive understanding on China’s urban expansion.

urban expansion; road junction; points of interest (POIs); social network; China; natural city

Urban Expansion and Its Impact in China: A Perspective from Nighttime Light Data

He, Chunyang, Xu, Min, Liu, Zhifeng

Center for Human-Environment System Sustainability (CHESS), State Key Laboratory of Earth Surface Processes and Resource Ecology (ESPRE), Beijing Normal University, Beijing, 100875, P.R. China, hcy@bnu.edu.cn

Abstract

Effective and timely quantifying the spatiotemporal pattern of urban expansion and examining its impact is important for the sustainable development in China. However, the dynamics of the most recent urban expansions in China since 2012 have not yet been adequately explained due to a lack of current information. In this presentation, we want to quantify spatiotemporal patterns of urban expansion and assess its impact in China between 1992 and 2015 with the support of time-series nighttime light data. First, we extracted information on urban expansion in China between 1992 and 2015 by integrating nighttime light data, vegetation index data, and land surface temperature data. Then we analyzed the spatiotemporal patterns of urban expansion at the national and regional scales, as well as at that of urban agglomerations. Finally, we conducted the impacts of urban expansion on cropland. We found that China experienced a rapid and large-scale process of urban expansion between 1992 and 2015, with urban land increasing from $1.22 \times 10^4 \text{ km}^2$ to $7.29 \times 10^4 \text{ km}^2$, increasing in size nearly fivefold and with an average annual growth rate of 8.10%, almost 2.5 times as rapid as the global average. We also found that urban land in China expanded mainly by occupying $3.31 \times 10^4 \text{ km}^2$ of cropland, which comprised 54.67% of the total area of expanded urban land. We suggest that effective future management with respect to edge expansion of urban land is needed to protect cropland in China.

Urbanization and Its Implications in Building Energy Use

Zhou, Y

Dept. of Geological & Atmospheric Sciences, Iowa State University, Ames, IA, 50010, USA, yuyuzhou@iastate.edu

Abstract

Urbanization profoundly influences our physical and social world, for example, altering carbon cycling and climate. Understanding the consequences of urbanization for better scientific insights and effective decision-making unarguably requires accurate information on urban extent and its spatial distributions. We developed a novel method to map urban extents from the night-time lights remote sensing data and built a consistent 20-year global urban map series to evaluate the time-reactive nature of global urbanization. Supported by urban maps derived from nightlights remote sensing data and socio-economic drivers, we developed an integrated modeling framework to project future urban expansion by integrating a top-down macro-scale statistical model with a bottom-up urban growth model. With the models calibrated and validated using the historical data, we simulated urban growth at the grid level (1-km) over the next two decades under a number of socio-economic scenarios. Finally, we explored the implications of urbanization in building energy use in the context of climate change.

Dynamic Appraisal of Land Ecological Security for SiChuan Province Based on Matter-element Model

Huang Hai

Department of Geography, Chongqing Jiaotong University, Chongqing, 400074, P. R. China, lottery98@163.com

Abstract

Improper Land use has led to a series of ecological problems such as soil and water loss, land desertification and land pollution since the past century. Land ecological security has attracted much interest as a key factor for land sustainability issues. This research aims at how to establish the appraisal index and adopt scientific method for the objective appraisal of land ecological security, together with the countermeasures. Based on analysis of the land use and ecological environment situation of SiChuan Province, the paper adopted the conceptual model of “Driving forces–Pressure–State–Influence–Response” (DPSIR) to set up the land ecological appraisal index system. The matter-element model was put use to the appraisal of land ecological security of SiChuan Province. Research results showed the land ecological kept improving from 2006 to 2013. But it is not optimistic yet because it is still graded “Sensitive”. The countermeasures were given for maintaining land ecological security and land sustainability for SiChuan Province. The conclusion is drawn that DPSIR model and matter-element model are scientific and feasible for the appraisal of land ecological security.

Effects of Urban Expansion on Carbon Emission--A Case Study in Shizuishan, China

Lv Rongfang, Zhang Jianming

The College of Earth and Environmental Sciences, Lanzhou University, China, lvrf13@lzu.edu.cn

Abstract

Exploring the socioeconomic drivers of urban expansion and the effects of urban expansion on environment is vital for land use management. The unique features of the energy dependent city of Shizuishan make it a valuable case study to examine the effects of urban expansion on carbon emission at the city level. Using RS, GIS, spatial model and statistical model, we analyzed the dynamics of carbon emission by socio-economic activities and landscape change in the past 26 years and predicted carbon emission in the future 20 years. In the study, we used a new model by integrating Modified-SLEUTH model, InVEST model and regression model. First, we analyzed the socio-economic drivers of urban expansion. Then, we made a modification of SLEUTH model to make urban expansion adapting to different economic development by integrating the results of socio-economic drivers exploring. Next, we calculated carbon emission from 4 parts: industrial production, transportation, human respiration and temporary carbon storage change through InVEST model. The coupling model combines the advantages of these three models and can analysis the impacts of urban expansion on regional carbon emission in the past period and future period. In the urbanization process, carbon emission by socio-economic activities and landscape change would keep increasing, and in the energy dependent city carbon emission by fossil combustion occupy the absolutely dominate role in the whole carbon recycle. Therefore, we should improve utility efficiency of fossil and consider urban expansion speed seriously to realize the win-win of economic development and greenhouse effect mitigation.

Environmental Sustainability Assessment Based on DMSP/OLS Nighttime Light

Data: A Case Study of the Bohai Rim

Yang Y, Wang C

Department of Public Management, Ocean University of China, Qingdao, 266100, P. R. China, yang_ouc@163.com

Abstract

In recent years, the environmental sustainability assessment is becoming more and more important. The existing environmental sustainability indexes (ESI) are mainly created based on the statistical data. These studies are lack of enough spatial information and comparability. Therefore, a new environmental sustainability assessment method based on the nighttime light data and the ecosystem services value was proposed by using the remote sensing and GIS Technology. Then the method was applied in a representative study area, the Bohai Rim of China from 2000 to 2010. The results showed that the ESI of most regions was at low to medium level, and the most of the high level of ESI was concentrated in the northeast and northwest of the Bohai Rim. Furthermore, the ESI of 62.98% of the total area in the Bohai Rim was decreased from 2000 to 2010 and the coastal area experienced a significantly environmental degradation process. These findings could play an important role in regional environmental protection and optimization.

Key words:

Environmental sustainability; DMSP/OLS; ecosystem services; Bohai Rim

How Will Urban Expand in the Drylands in Northern China? Scenario Simulation Based on SLEUTH

Li, J

Center for Human-Environment System Sustainability (CHESS), State Key Laboratory of Earth Surface Processes and Resource Ecology (ESPRE), Beijing Normal University, Beijing, 100875, P. R. China, jingwei.li@mail.bnu.edu.cn

Abstract

Understanding the dynamics of urbanization in the drylands in northern China (DNC), where are characterized by water scarcity, infertile soil, and rapid population growth, is crucial for China's sustainable development. Urban expansion in the DNC has rapidly transformed the landscape in the past decades, resulting in a series of ecological and environmental problems. However, few studies have systematically simulated how the future urban would expand in the DNC under multiple economic and social scenarios. The goal of this study was to simulate the future urban expansion in the DNC for the next 30 years using SLEUTH model through setting socio-economic scenarios (SSP1, SSP2, SSP3, SSP4, SSP5) according to the Shared Socio-economic Pathways, based on the analysis of the historical urban dynamic in the DNC from 1992 to 2015 by the nighttime lights data. Our results showed that urban land increased from 4.10×10^3 km² in 1992 to 2.10×10^4 km² in 2015, with an average annual growth rate of 7.34%, which was 2.29 times as quick as the global average. During the next 30 years, urban land in the DNC will expand around metropolitan areas and the conflict between urban and cultivated land will become more severe. Understanding the historical urban dynamic and future expansion projection will enable decision makers to analyse and direct the future urbanization to realize sustainable development in the DNC. Effective policies should be implemented to achieve higher utilization efficiency of urban land with the optimization of urban growth modes and the mitigation of cropland loss.

Patterns and Processes of Dust Storms on the Mongolia Plateau in Recent 15 Years: A Multi-Scale Analysis

Huanbi Yue

Center for Human-Environment System Sustainability, State Key Laboratory of Earth Surface Processes and Resource Ecology, Beijing Normal University, Beijing 100875, P. R. China, yuehuanbi@mail.bnu.edu.cn

Abstract

The Mongolia Plateau is one of the major dust sources in Asia. Understanding the patterns and processes of dust storms on the Mongolia Plateau are important for desertification controlling. However, relevant research was still poorly in recent years because of difficulties in accurate monitoring of dust storms. Moderate Resolution Imaging Spectroradiometer (MODIS) data provide good alternatives for dust storm detection. The main objective of this study was to analysis the patterns and processes of dust storms over the Mongolia Plateau in recent 15 years using MODIS-based dust index. We firstly proposed an improved Brightness temperature Adjusted Dust Index (BADI) by integrating three MODIS thermal infrared bands of band20 (3.66-3.84 μm), band31 (10.78-11.28 μm) and band32 (11.77-12.27 μm). Then, BADI was applied to monitor dust storms over the Mongolia Plateau during 2000-2012. Our results showed that the annual mean dust density over the Mongolia Plateau is 20.32 ug/m^3 , and the annual dust density decreased with a rate of 0.30 ug/m^3 during 2000-2012. The annual mean dust density of Mongolia and Inner Mongolia are 14.69 and 25.43 ug/m^3 , respectively. The significant dust decrease area of the Mongolia Plateau was about 62523.8 km^2 , which is mainly located in Inner Mongolia. Meanwhile, the significant dust increase area was about 16365.9 km^2 , which was mainly located in the Mongolia. Dust density on the Mongolia Plateau showed a general decrease trend, and Inner Mongolia have a higher dust storms hazard than Mongolia. We need to pay more attention to high dust density region and dust density significant increasing region.

The Contribution of the “Technopoles” in Regional Sustainable Development: Moroccan Case.

EL HADAD. I,

University Of Hassan II, Casablanca, Morocco, e.imad@live.fr

Abstract

In response to the centrifugal process of remodelling that operates the globalization of economies in everyday life, a sort of territorial anchoring is felt in terms of discovery, revenge or simply rediscovered near concepts, participatory management, local development initiatives, SPL, clusters, territorial competitiveness, territorial marketing ... This renewed interest underlies two major restructuring seating both on innovation and intelligence: the first is that large companies are not the only guide to the act produce and innovate. Globalization requires a degree of flexibility which SMEs can respond better than large firms (flexibility synonymous with globalization). Hence the need to strengthen the presence of SMEs / SMIs internationally as a guarantee of competitiveness, innovation and flexibility-Flexicurity. As a requirement for Morocco especially since its productive fabric is 93% of SMEs / SMIs. The second, in perfect symbiosis with the first based on the networking of intelligent territories (J. Bouinot-2003). This process creates interconnectivity between SPL and clusters harbouring clusters of flexible entities pooling the risks and costs of strategic operations. As illustration recall here the statement of Ch. Laplaud¹ saying which opened the Moroccan and Brazilian markets his group is export based on innovation and knowledge sharing. He argues that the creation of trust between SME networks open to business and market is a prerequisite for the knowledge economy.

The Influence Analysis and Radiation Effect Research of the Center City in Hainan Province

Yan Li

Hainan Normal University, China, 763343120@qq.com

Abstract

This paper is mainly based on the background of the construction of new of urbanization, through the application of gravity model and the breaking point formula, pay more attention to the influence and the radiation of the four center city in Hainan province. The results of the study show that, the influence and radiation of Haikou largely influences the northern area , and the influence and radiation of Sanya in the south of Hainan is larger, Dan Zhou plays an larger important role in the neighboring cities in the south of Hainan. Qionghai have a big influence and radiation on the neighboring cities in the east of Hainan. The influence and radiation of center city is mainly contributed to the level of economic development, geographical location, topography, traffic and cultural diversity.

Abstract

Understanding the socio-biophysical drivers of urban landscape changes is critical to land use decision-making for sustainable environmental management. This study presents a scale-dependent analysis of the underlying socio-biophysical drivers of urban landscape dynamics in two large American metropolises: Atlanta, Georgia and Chicago, Illinois. The two metropolises contrast each other not only in their geographic locations but also in the underlying urban development processes. In this paper, we firstly identify a set of major driving factors of urban land change in each metropolis. Specific focuses will be given to the factors at three dimensions: socio-economic, biophysical, and proximate causes of urban landscape changes. Then, we derive the proxy variables for the various drivers using GIS and spatial analysis. The spatial data integration techniques used in this process will be discussed. Lastly, statistical analysis is performed to evaluate the various driving factors of urban landscape changes across different spatial scales. A comparison study highlights both the common processes and unique dynamics underlying urban landscape changes in the two American metropolises.

Changing Social Values of Ecosystem Services during Urbanization: The Case of Changyang Township, Beijing

Zhifang Wang, Yujing Ma, Ankang Cao

College of Architecture and Landscape Architecture, Peking University, Beijing, 100871, P. R. China,

zhifangw@pku.edu.cn

Abstract

Despite of the fact that ecosystems are capable to provide multifaceted values for human well-being, social values in general is often underscored in research paradigm. The evolutionary mechanism of ecosystem social services during urbanization and its roles in decision-making is not clear. This research selects Changyang township, Fangshan district, Beijing as the study area. Based on the related definition and classification of social values of ecosystem services, through field survey and remote sensing image to obtain research data, this study explores spatial distribution and dynamic change of ecosystem social services and social - ecological hotspots in the process of Changyang town urbanization from the aspects of time and space. Local perception with spatial mapping is incorporated into the research as a supplement of expert knowledge to strengthen planning decision-making. The findings demonstrate that there are clear spatial differences in the distribution of ecosystem social values. And social values of Changyang town in general have experienced decreasing and then increasing trend in the process urbanization. Areas with low urbanization rates (rural villages) have more concentrated but less influential ecosystem social values. When demolition for urbanization starts, local ecosystem social services begin to decrease and be more dispersed. Following further urbanization with new buildings and parks, ecosystem social services in urbanized areas tend to be more concentrated with larger service areas. Many factors contribute to the differences spatially and timely. Based on the analysis, urban management strategies are then proposed accordingly.

Social value of ecosystem services; Urbanization; Cognitive mapping; Social - ecological system

Economic Landscape Large Planted Area in Menglian County Study on Change of Ecosystem Service Value

GU Zexian, ZHAO Xiaoqing*, Tang Wei

College of Resource Environment and Earth Science, Yunnan University, Kunming, 650091, P. R. China,

guzexian@sohu.com

Abstract

From the point of spatio-temporal changes of ecological system type, function and value, in Menglian County, land using/cover data was based on three Landsat images which were interpreted as basic information sources by using RS and GIS technology and then revising ecosystem service value per unit area in Menglian County. This paper has researched on the changes of ecosystem service value of economic garden for large area planting as well as evaluated ecosystem service value scientifically in Menglian County combined with the sensitivity analysis. The Results showed that: (1) In Menglian County, from 2000 to 2015, land use pattern manifested as the transformation from large areas of dry land, forest land and shrub to the economic landscape, the economic landscape is increased by 24478.96hm^2 ; (2) Changes of ecosystem service value is closely related to economic landscape development in Menglian County. The situation of ecosystem service value shows the changing trend from improvement to severity in 2000-2015. ESV is increased by 96.39×10^6 Yuan from 2000 to 2005, But in the year of 2005 to 2015, ESV is reduced by 120.24×10^6 Yuan; (3) From the aspect of space distribution, ecosystem service value in Menglian County is relatively high in central area and relatively not high in western and eastern area. The temporal and spatial variation of ecosystem service value in Menglian County is affected by natural and human factors. The key to the development of economic landscape is rational land use according to the practical situation, which can create economic value and also keep its ecological value.

Key words:

Large area of artificial landscape introduction; Ecosystem service value; Temporal and spatial variation

Effects of Urbanization on Ecosystem Service Values in an Oasis City - A Case Study in Zhangye City, China

Huali TONG, Peiji SHI, Jiafang LI, Guofeng ZHU, Xuebin ZHANG, Yongnan WANG, Yuanfeng LIU

College of Geography and Environmental Science, Northwest Normal University, Lanzhou 730070, China,

tonghl_mail@sina.com

Abstract

Arid areas accounted for about 30% of the global land. Oasis city is a major city mode in this area. A dramatic urbanization process might severely impact the ecosystem service functions in an oasis city, affecting the quality of life for the residents. Taking Zhangye, an oasis city in China as a case study, this paper evaluates its urbanization level and analyzes the relationship between the level of urbanization and ecosystem service values during the period of 1995-2013, using Xie's ecosystem unit service value table. The results show that Zhangye's level of urbanization has progressed gradually during the study period while ecosystem service values increased. Moreover, the relationship between the level of urbanization and ecosystem service values over time exhibits an irregular "U" shape. From 1995 to 1998, Zhangye's ecosystem service value slowly rose with the growing urbanization level, while it kept no change from 1998 to 2006 and during 2006-2013 there was a remarkable rose.

Identification of Urban Expansion Pattern in Bangkok Metropolitan Region through the Time Series of Remote Sensing Data

Losiri, Chudech, Nagai, Masahiko

Ph.D. Student, Remote Sensing and Geographic Information Systems FoS, School of Engineering and Technology, Asian Institute of Technology, Pathumthani, 12120, Thailand, chudechlosiri@gmail.com

Abstract

Urban expansion has different patterns which affect to a land development and police planning. Increasing in the number of population puts the force to expand the built-up areas in the Bangkok Metropolitan Region (BMR) predominantly in vicinity of Bangkok, which causes several problems in terms of physical and social aspects. Therefore, understanding the pattern of the urban expansion is a key challenge to allocate enough infrastructures and respond the land demand for inhabited people in this area. The classification of the pattern of urban expansion analyzed from Landsat5-TM images in 1988, 1993, 1998, 2003, 2008, 2011, and 2014 respectively. The urban area, built-up construction, was mainly extracted by supervised classification. The result could be found that the origin on the urban area of the BMR was established in the eastern of the Chao Phaya River with a clustered or radial settlement. Each province of the BMR extended the urban area itself from the center of the city and also connected together via the main roads as a linear settlement. Finally, a dispersed settlement could be discovered in the areas which are far away from the road network like an urban sprawl.

Land Use and Water Quality at the Margin of the Metropolitan Region of Porto

Alegre, RS-Brazil: the Case Study for the Barragem Mãe d'Água

MOURA, Nina Simone Vilaverde, BASSO, Luis Alberto

Department of Geography of the Federal University of the Rio Grande do Sul, Porto Alegre, Brazil,

nina.moura@ufrgs.br; lbasso@terra.com.br

Abstract

This study comprises an analysis of the process involving the development of the vegetation cover and land use, as well as the consequences on the quality of surface water within the catchment of the dam system Barragem Mãe d'Água. This system belongs to the larger Arroio Dilúvio watershed, set within the Metropolitan Region of Porto Alegre, Rio Grande do Sul, Brazil. To this objective it was necessary: to characterize the physical elements and its anthropic related change; to analyze the urbanization impacts on the quality of the surface water; to characterize the environment conditions during the occupation process and field survey to check information and to collect water samples. It was determined that the basic land forms of this area are made up of hills, slopes and plains, and that the urban occupation, began on the slopes and, more recently, related to significant modifications to the original morphology, was extended to the plains and steeper sides of the hills, resulting in the intensification of the erosive and depositional processes. The quality of surface water is considered low for most uses based of the Brazilian environmental laws, due the discharge of non-treated water to the inflowing streams of the catchment. Such processes, involving the development of vegetation cover and land use, express the socioeconomic relations of the territory, revealing of the appropriate of nature by society, significantly altering the environmental quality of the area especially of the water resources.

Key words:

land use evolution; quality water; urban geomorphology

Mapping and Interpreting Vegetation Patterns in Urban Areas: Research Status and Challenges

Yang X¹, Shi D¹, and Liu T²

¹Department of Geography, Florida State University, Tallahassee, FL 32306, USA, xyang@fsu.edu

²Department of Geography and Environmental Studies, Northeastern Illinois University, Chicago, IL 60625, USA

Abstract

Vegetation is an essential component in urban ecosystems because it not only can affect environmental conditions and energy fluxes but also provides humans and other life with all kinds of ecological services. Mapping the spatial distribution of vegetation types and understanding the socio-ecological processes determining the observed patterns are critical for urban planning and resources management. The purpose of this paper is to review the research status and challenges in the areas of mapping and interpreting vegetation patterns in the urban environment. First, we will review the status of urban vegetation inventorying with focus on various remote sensing methods for large-scale mapping applications. Some strategies that can be used to deal with the spatial and spectral heterogeneity in urban areas will be discussed. Then, we will review several conceptual frameworks that can be used to understand the observed vegetation patterns in urban areas, which are drawn from such disciplines as geography, ecology, and sociology. Third, we will present a case study for mapping and interpreting vegetation patterns in a large metropolitan area in North America through the combined use of remote sensing, GIS, and spatial statistical analysis. Lastly, we will identify several areas that need further work concerning theories, methods, and technologies in urban ecological research.

Plant Species Composition and Bioculture of Greenspace in Urban Campus and

Parks of Kunming City, Southwestern China

Wu Liangzao, Shi Huiling, Wu Zhaolu*, Lei Yuan

Institute of Ecology and Geobotany, Yunnan University, Kunming 650500, China

*Corresponding email: zlwu@ynu.edu.cn

Abstract

Plant species composition in urban greenspace reflects the natural environment, human management and cultural connotation of the city. But many studies do not discuss the cultural connotation of urban plants. The plant species composition and bioculture were studied based on the field data.

A total of 143 families, 448 genera and 716 species of vascular plants was recorded, of which, 649 species were in the campus and 374 species in the parks, indicating the higher species diversity in the campus. In terms of growth form, the herbs, trees, shrubs and vines respectively accorded for 46.51%, 27.79%, 22.49% and 3.21%. The proportion of trees in the parks (33.69%) was higher than that in the campus (28.35%). In terms of species origin, the proportion of alien plants in the total species, campus species and park species were 39.25%, 38.52% and 41.44% respectively. More tropical plants introduced caused annually a large number of plant frost damage and management input.

The plant composition in the urban greenspace embedded the distinct traditional morality and real aesthetic. Most plants played the roles of afforestation and beautification, reflecting the season changes of colorful flowers and leaves. More local bioculture was showed in the aged greenspaces, compared the dull afforestation and visual sense in the new ones. The key taxa of plant system evolution, state or local protection plants and local endemic species were highlighted in the plant configuration of campus green, promoting the culture service functions for teaching and scientific research.

urban greenspace; plant composition; cultural service functions; bioculture; campus and park

The Effects of Green Landscape on Urban Thermo-Environment: A Case Study in

Beijing

Chen LD¹, WU ZF

¹State Key Laboratory of Urban and Regional Ecology, Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences, Beijing 100085, liding@rcees.ac.cn

²University of Chinese Academy of Sciences, Beijing 100049

Abstract

With the rise of global human population moving to the urban areas, the demand of improving human living environment is becoming increased. Rapid urban expansion may lead to extensive replacement of natural surfaces by artificial alternatives and massive anthropogenic heat emission that may result in urban heat island and thermal environmental deterioration. Increasing more green landscape seems to be a vital and useful measure in ameliorating urban thermal environment and meeting human needs on ecosystem services. However, how is the effect of green landscape on urban macroclimate and thermo-environment is still in dispute. In this study, a residential quarter with high-rise building in Beijing was chosen to study the effects of green landscape and their configuration on thermo-environment. Land surface temperature of each landscape type was compared based on on-site measurement and air temperature above each landscape type was compared by using ENVI-met model. Green landscape may contribute much to lower LST of itself other than surrounding areas, and the air temperature under the tree or shade is much lower than it at open space. This means that green landscape may affect air temperature and microclimate in situ and little contribution to thermal environmental amelioration in surrounding areas.

Key words:

Urban heat island; green landscape; land surface temperature (LST); air temperature; microclimate; ENVI-met model; thermo-environment

The Flowering Phenological Response of Early Spring Herb to the Urbanization

Process in Beijing

Chang Qing, Liu Xiao, Wang Jing

Department of Ornamental Horticulture and Landscape Architecture, China Agricultural University,
Beijing, 1001093, P. R. China, changqing@cau.edu.cn

Abstract

The response of vegetation phenology to the urbanization is a hotspot in the research field of global changes and urban ecological effects. Through observing the flowering times of 7 kinds of early spring herbs and temperature changes from May to June in 2012-2013 in the northwest urbanization gradient in Beijing, this paper founded that the closer to the urban center, the higher of temperature and the earlier of vegetation phenology of early spring herb, while the average flowering duration and speed did not change with the urbanization gradient distinctly. Additionally, the average flowering time change of 7 kinds of early spring herbs was most sensitive to the accumulated temperature change of 5°C. The perennial early spring herb was more sensitive to the urbanization gradient than the annual early spring herb. It is suggested that the cumulative effects of land use/cover changes and urban heat island in the urbanization process on the physiology and phenology of vegetation deserve more attention and thus to reveal the response of plant phenology to the urbanization and climate changes.

Key words:

Urbanization gradient process; Early spring herb; Flowering phenology; Response; Urban heat island

The Major Issues for Management of Urban Green Spaces in Nepal

(Case Study of Pokhara City, Nepal)

Bhandari Jyoti^{1,2}, G.C Dhruba Bijaya^{1,2}

¹Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China

²University of Chinese Academy of Sciences, Beijing 100049, China

Corresponding author: gc10dhruba@yahoo.com

Abstract

This study aimed to identify the major issues for management of urban green spaces in Nepal. It also assessed the level of awareness and perception of people towards urban forestry. Direct observation Semi- structured interview and open discussion with key-informants and secondary data through literature review were used to assess urban tree activities. The obtained data were analyzed both quantitatively and qualitatively using SPSS and Microsoft Excel. There are number of NGO and INGO institutions working in the field of urban forestry. These institutions are not fully devoted towards urban forestry but only contributing part for it. The major urban tree species are Schima-Castanopsis, Pinus, Alnus, Nigalo and Bamboo The study also showed that the major obstacles in the development urban green spaces are there due to less participation of local people in urban forestry management since all the people were not known about the importance and benefits of urban forestry. There are not adequate action and activities such as Park development; roadside plantations tree hazard prevention, nursery establishment, city beautification and raising awareness to the local people from government and other institution. As result of unplanned urbanization, green spaces are shrinking and pollution issues are rising in the cities of Nepal. Municipal authorities should realize that a sustainable management of urban forestry without the participation of local beneficiaries is not viable and that this should be encouraged at all stages of activity starting with planning, implementation and management to care and maintenance.

Understanding the Spatial Configuration of Trees on Urban Heat Mitigation: A Comparative Study

WeiQi Zhou, Jia Wang

Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences

18 Shuangqing Road, Haidian District, Beijing, China 100085, Email: wzhou@rcees.ac.cn

Abstract

Urban greenspace has significant cooling effects on urban heat mitigation. It is widely recognized that increasing percent coverage of greenspace can greatly reduce temperatures in urban environments. However, recent studies investigating the effects of spatial configuration of greenspace show significant, but inconsistent results. To investigate the causes of this inconsistency, we conducted a comparison study at Baltimore, MD and Sacramento, CA, USA, two cities with very different climatic conditions, using different statistical approaches and analytical units with varied sizes. Trees were mapped from 1m spatial resolution imagery, and land surface temperatures(LST) were estimated based on TM thermal band. We found: (1) The effects of spatial configuration of trees on LST varied greatly in terms of magnitude, significance, and even sign, between the two cities. (2) When using different statistical approaches, the relationships between LST and configuration metrics could dramatically change. Our results underscored the necessity of controlling the effects of percent cover of trees, when quantifying the effects of spatial configuration of trees on LST. (3) Spatial autocorrelation could influence the relationships between landscape metrics and LST, particularly when the unit of analysis is relatively small. (4) With the increase of the size of analytical unit, the relationships between spatial pattern metrics and LST became stronger. This study can enhance our understanding on the effects of spatial configuration of greenspace on UHI. It also provides important insights on how to mitigate the impact of urbanization on UHI through urban design and vegetation management.

Urban forest; Spatial configuration; Urban heat mitigation; Urban Ecology

Urban Growth, Landscape Changes, and Coastal Vulnerability in Southwest Florida

Fang Zhang, Xiaojun Yang

Florida State University, Tallahassee, 32304, United States, fz13@my.fsu.edu

Abstract

Anthropogenic impact on the environment has become much stronger than ever before due to the rapid growth of world population over the past several decades. Urban growth associated with the quick concentration of population has become a key driver of environmental changes worldwide. Such phenomena causes more concerns in coastal areas where humans have settled for a very long period of time because of the high biodiversity and accessibility. How to sustain a coastal city has become an urgent topic. This study aims to develop a geospatial approach to explore the relationship between urban growth and coastal vulnerability in Southwest Florida. Urban ecology together with remote sensing and GIS advances the methodological approach for landscape transition studies through analyzing the spatial patterns and temporal sequencing. In this study, the land cover change will be analyzed through a time series of Landsat images. Landscape fragmentation will be examined because of its implication in biodiversity degradation. Last, the coastal vulnerability resulted from the landscape change will be discussed. This study will lead to a better understanding of urbanization's impacts on the coastal environment, and the projected vulnerability will be highly relevant to sustainable coastal planning and management.

Key words:

Coastal vulnerability; landscape change; urban growth; spatial and temporal analysis

Urbanization Spatial Process and Its Environmental-Ecological Effects in the Pearl River Delta, China: Perspective from Remote Sensing

Zhifeng Wu, Guanghua Guo, Yingbiao Chen, Jianzhou Gong

School of Geographical Sciences, Guangzhou University, Guangzhou, 510006, P. R. China, gzuwzf@163.com

Abstract

The Pearl River Delta area have experienced rapid economic growth and urbanization over the past three decades, accompanied with the accelerated built-up land expansion. At different scales (e.g. Pearl River Delta, Coastal Area of the Pearl River Estuary, Guangzhou-Foshan metropolitan area, the urban fringe, and villages in city, etc.), the environment-ecological effects brought by rapid urbanization are explored through analyzing the urban spatial information and its evolution. Remote sensing, combined with geographical analysis and integrated earth observation techniques are adopted in this research. The results show that the urban space in the Pearl River Delta has undergone a rapid expansion in the recent 30 years. Specifically, nearly 65 % of agricultural land in the Bay Area of the Pearl River Estuary have been converted to built-up land. The ecosystem service of the Pearl River Delta has received heavy threat from a urban sprawl. The strengthening urban heat island(UHI) , impervious surfaces growth, disappearance of surface waterbody and soil sealing are the main performances of ecological stress on human settlements during the dramatic urbanization process.

Abstract

Urban landscapes are geospatial elements, characterized by extreme deviations from the natural structure of the respective geosystem. Thereby, their ecological processes possess distinctive functions and dynamics. The main factor which determines their development is the higher concentration of population and its derivative balance of socio-economic assets and liabilities, under conditions of ever increasing demands for a more favorable living environment. This fact is a serious challenges in territorial planning and geospatial management: to improve the wellbeing of the population, the characteristics of urban landscapes should allow extraction of maximum benefits from the in-situ ecosystem services.

The study aims at creating an ecosystem based geo-information system about the state and the ecosystem services provided by the urban ecosystems in Bulgaria situated outside the NATURA 2000 zones. It includes development and implementation of a system of indicators for assessment and mapping of urban ecosystems. Emphasis is given to the evaluation of the heterogeneity of urban landscapes (soil sealing, urban development structure, local climate, etc.), which determines the state of green infrastructure and the overall potential of urban systems to produce ecosystem services. The assessment tool includes the following stages: typologization of urban ecosystems derived from the MAES (2013), assessment and mapping of the ecosystems state (using 10 mandatory and 27 recommended indicators), and assessment and mapping of 18 groups of ecosystem services.

The results are oriented towards a better understanding of the ecosystem services’ concept and its implementation in sectoral policies and territorial development.

Assessment of Ecosystem Service Importance in Yan-Long-Tu Region

GONG Xue, Zhao Xiaona, Tian Fenghao, LI Mingyu

The Department of Geography, Yanbian University, Yanji Jilin, 133002, P. R.China, 18844736158@163.com

Abstract

This paper used analytic hierarchy process and comprehensive index method to evaluate the regional ecosystem service function of Yan-Long-Tu region. It was Analysis of the importance of water resources conservation, carbon fixation and oxygen release, biodiversity protection, regulating micro-climate, agricultural products supply and landscape visual retention of Yan-Long-Tu region and showed its spatial distribution. It was analysis the comprehensive evaluation of regional ecosystem services. The results showed that the most important areas of ecosystem service were 72.03% of the total area of Yan-Long-Tu region. More important areas and important areas were 13.57%, 10.69% of the total area, respectively. Generally important areas were only 3.21%. It provided scientific basis for the scientific management of regional ecosystem and ecological function zoning. And it played an important role in the maintenance of regional ecological security of Yan-Long-Tu region.

Ecosystem Services Assessment in the Rapidly Urbanizing Zhangye Oasis, Northwest China

Youjia Liang^{1,*}, Lijun Liu²

¹School of Resources and Environmental Engineering, Wuhan University of Technology, Wuhan 430070, China, yjliang@whut.edu.cn

²Gansu Meteorological Bureau, Lanzhou 730000, China

Abstract

Although advances in conceptual frameworks and different decision making tools, the integrated assessment of ecosystem services in data scarce oases remains limited. In this study, we presents a methodology for quantifying spatio-temporal change in multiple ecosystems services and biodiversity as an impact of land use change mainly using the InVEST model. The integrated modelling methodology was used to simulate carbon storage and sequestration, sediment retention, water yield and biodiversity for the rapidly urbanizing Zhangye oasis of northwest China based on land use of 2000, 2009, land management scenarios of moderate protection (S1) and strict protection (S2). Specifically, the ecosystem services indicators and biodiversity based on the oasis condition were used to analyze land use change impacts on the spatio-temporal change of ecosystem services at the pixel and oasis scale. The limitations and uncertainties of the study in the oasis were also discussed. The integrated modelling of ecosystem services illustrates a methodology that can be employed by local land managers in exploring multiple land management scenarios and their implications for multiple ecosystem services and biodiversity change. The application of ecosystem services assessment in this study showed it could support decision making and ecological conservation in other similar regions of northwest China.

Impact of Rapid Urbanization on Water Resources in The Context of Climate Change Using Remote Sensing and Gis: A Policy Perspectiv

Prof. Kamal, Narain Joshi

Senior Fellow (ICSSR, New Delhi), Institute of Development Studies, Jaipur-302 004 (India), joshi.knjoshi@gmail.com

Abstract

Increasing pressure of population and industrialization has threatened the quality and quantity of water resources in and around urban areas. Protecting surface water resources like lakes, rivers, streams, and ponds etc in the vicinity of urban area has become a very difficult task for urban planner and administrators. The haphazard growth of colonies, slum squatters and unplanned land use has not only broken down the natural flow of hydrological net work but also deteriorate the quality of water that directly affects health of people. The present paper investigates that how the urbanization and industrialization has changed urban land use of Jaipur urban Agglomerate which ultimately affected the surface water bodies and reduced the recharge area of ground water. The changing rainfall pattern due to possible climate change has exaggerated the situation. The study has been carried out with the help of Indian remote sensing satellite data and GIS techniques.

It was found that increasing pressure of population and un-systematic anthropogenic activities have made negative impact on water resources. Recharge of ground water has stopped due to increased pavement area for urban development like infrastructure development, industrial development and other urban development activities. On the other hand Average annual number of rainy days has been reduced from 35 to 28 days in last 34 years. *17 years out of 34 years (1985 - 2014) have received less than average (650 mm) rainfall. Average number of days having High temperature has increased.

Urbanization; Water Resource; Climate Change; Remote Sensing; GIS

Impact of the Spatial Pattern of Regional Urbanization on Landscape Pattern and Ecosystem Services: A Case Study of Xi'an Metropolitan

Zhongxue Zhou

College of Tourism and Environment, Shaanxi Normal University, Xi'an, 710119, P. R. China, zhouzhx@snnu.edu.cn

Abstract

The impact on landscape pattern and ecosystem services is strongly varying with transformation of the spatial pattern of regional urbanization from single central-city to multiple central-cities. These are rarely researched. In paper the spatial patterns of regional urbanization and its characteristics were analyzed by employing the degree of centralization and Moran's I in Xi'an metropolitan. Also the influence and mechanism of regional urbanization on landscape pattern and ecosystem services were explored under the spatial patterns of single central-city and multiple central-cities. These conclusions were reached: (1) the level of comprehensive urbanization in Xi'an metropolitan is increased by 40%, and the spatial pattern of regional urbanization are transforming from a single central-city stage to multiple central-cities stage from 1988 to 2013. (2) Regional urbanization has resulted in fragmentation of landscape and decreasing of ecosystem services. The expansion of urbanized area, the stretch and networking of transportation infrastructures and the transformation from traditional agriculture to modern urban agriculture are observably driving the fragmentation of landscape and the decreasing of ecosystem services in multiple central-cities stage, in which these influences are stronger than in single central-city stage. (3) Under regional urbanization pattern of multiple central-cities the stronger negative influences were occurred in the region of urban-rural transition zone and near transportation infrastructures. The results indicate that the fragmentation of natural or semi-natural landscape and the decrease of ecosystem services will be alleviated by maintaining or replanting enough large area of forest, grassland or orchard, by developing fruit sector and horticultural crops and by constructing ecological corridors near roadside and riverside.

Key words:

Regional urbanization; spatial pattern; landscape; ecosystem services; Xi'an metropolitan

Spatiotemporal Variation of Urban Vegetation and Its Response to Rapid**Urbanization in Shenzhen City**

WANG Zhi, WANG Yanglin, XIE Miaomiao, CHANG Hsiaohei, SONG Zhiqing, LIU Yanxu

China University of Geosciences, Beijing, 100083, P. R. China, wangzhi@cugb.edu.cn

Abstract

The characteristics of urban vegetation, such as vegetation type, area, coverage, and spatial pattern, can reflect regional climate conditions, soil and water resources, human activities, and so on. Urban vegetation provides ecological service functions such as microclimate regulation, environmental purification, provision of leisure and recreational spaces, and other functions. We selected Shenzhen City, a typical rapidly urbanizing city in China, as our study area. Analyses of variation tendency, and spatial evolution, and response to urbanization of urban vegetation were based on remote-sensing images collected between 1980 and 2014, which were subjected to a linear regression model. Urbanization was found to have a significant effect on vegetation in Shenzhen City. Vegetation cover first decreased and then increased during rapid urbanization; the effects of urbanization on vegetation were negative at first, but become positive as urban development progressed. The spatial distribution of vegetation was principally dominated by vegetation coverage, which was largely distributed in higher-altitude areas. Over the course of urbanization in the last 35 years, the area under natural vegetation has decreased significantly; the area under woodland has decreased and was largely restricted to mountainous areas; cultivated land first increased and then decreased; and landscape fragmentation increased with urbanization. The ecosystem services of urban centre are mainly provided by urban parks and other artificial green spaces.

Key words:

vegetation characteristics; urban; urbanization; Shenzhen City

Status of Urban Slums Dwellers in Varanasi City: An Analysis

Sinha, Braj Raj Kumar¹, Singh, Brijendra Nath²

¹Professor of Geography, Department of Geography, Institute of Science, Banaras Hindu University, Varanasi, 221005, U.P. India, sinha_brk@yahoo.co.in

Abstract

Slums are the part of urban environment and they are identified by the presence of features of living conditions that are undesirable like overcrowding, lack of sanitation and hygiene, inadequacy of drinking water and poor construction etc. The objective of this study is to represents the socio-economic status of slums dwellers in five slum locations of Varanasi city. This paper also investigates the problems of slum dwellers in the study area. The analysis and interpretation of this paper is based on the primary data sources collected from personal field survey. Different statistical and cartographic techniques are used to represents the actual status of urban slum dwellers. Living standard and environmental conditions of the slums areas is very bad. There is need to develop good social amenities facility in this slum areas. The result of this study represents the social and economic conditions of the slum dwellers are very poor. They are facing various types of problems. Finally this paper produces the appropriate suggestion for reducing the problems related to slums dwellers in Varanasi city.

The Urban Land Ecological Suitability Evaluation of Yan-Long-Tu Region

ZHAO Xiaona, GONG Xue, TIAN Fenghao, LI Mingyu

The Department of Geography, Yanbian University, Yanji, 133002, China, 18844736102@163.com

Abstract

The resistance evaluation system of this paper included 12 factors which were from the natural geography, social economy and ecological limit three aspects. This urban land ecological suitability evaluation of Yan-Long-Tu region primarily used GIS spatial analysis method which was based on the resistance model and minimum cumulative resistance model. The results showed that: the urban land ecological suitability of Yan-Long-Tu region can be divided into the key construction area (538.55km²), the optimized construction area (743.53km²), the restricted construction area (1887.46km²) and the forbidden zone (1919.16km²). This paper made the space distribution of all different levels clear and put forward some suggestions correspondingly in order to provide the theory, technology, decision-making and other support for the urban land ecological planning and management of Yan-Long-Tu region.

Key words:

land ; ecological suitability; minimum cumulative resistance model; Yan-Long-Tu region

Analyze on Spatiotemporal Evolution Characteristics of Resources-environment-economy Efficiency in Urban Agglomeration in China Based on Mixed Direction Distance Function

Lin Xueqin, Wang Yu

College of Resources Environment and Tourism, Capital Normal University, Beijing, 100048,

P. R. China, lin-xueqin@139.com

Abstract

With the continuous improvement of the market mechanism in China, regional market is gradually formed, and the social and economic relations between cities have become more and more closely. Urban agglomeration has become an important regional spatial organization form to promote the development of economy and urbanization in China, and also is the most significant and frequent area of human and land interaction. Based on hybrid directional distance function, this paper estimates resources-environment-economy efficiency of 20 urban agglomerations in China from 2005 to 2013, analyzes their spatiotemporal evolution characteristics, and finally explores the relationship between them. The main conclusions are as follows: (1) the resources, environment and economy efficiency of urban agglomeration in China are generally low, the growth of economy efficiency is the fastest, the second is environment efficiency, and finally the resource efficiency; (2) the resources-environment-economy efficiency gradually reduce from the east coast to the western interior. Within the urban agglomeration, the distribution of the efficiency is dominated by low values; (3) three efficiencies has the long-term coordinated development relationship. With the improvement of economic efficiency, resource efficiency increase synchronously, while environmental efficiency increase little.

Convergence of Carbon Dioxide Emissions in the Yangtze River Delta, China

Jianbao Li, Xianjin Huang

School of Geography and Oceanography Sciences, Nanjing University, Nanjing, 210023, P. R. China, lijianbao888@126.com

Abstract

As China's industrialization and urbanization have grown rapidly in recent years, China has become the world's largest CO₂ emitter in 2006. The Chinese government has attached great importance to the issue of carbon emission and set the target of decreasing carbon intensity to 60-65% of 2005 levels by 2030. The investigation of convergence for carbon intensity is contributed to decomposition of the target for decreasing carbon intensity. Yangtze River Delta Region is one of the key regions of carbon emissions in China, with the higher urbanization level and larger carbon emissions, thus we employed prefecture-level panel data between 2000 and 2010 to investigate whether the σ -convergence, stochastic convergence and β -convergence exist in the carbon intensity across prefecture-level cities in the Yangtze River Delta Region. Spatial econometric models were utilized to investigate β -convergence of carbon intensity. The results indicate that carbon intensity shows divergence during the period 2002-2004 and σ -convergence over other periods. Carbon intensity exhibits stochastic convergence, indicating that the shocks to carbon intensity of every prefecture-level city to the average level are only transitory. Carbon intensity exists spatial spillover effect and β -convergence, which means that the prefecture-level cities with higher carbon intensity tend to reduce rapidly in carbon intensity, when other conditions keep unchanged, we should consider the present situation of carbon intensity, spatial factors, social and economic factors, such as per capita gross domestic product, population density and industrial structure, when we conduct the allocation plan for carbon intensity reduction.

Key words:

convergence; carbon intensity; spatial econometric models; Yangtze River Delta

Decarbonizing China's Cities Urban Agglomerations

Shaojian Wang¹, Chuanglin Fang²

¹Sun Yat-sen University, China, 1987wangshaojian@163.com

²Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, China

Abstract

China's urban agglomerations contribute 64.0% to China's greenhouse gas emissions and thus play a vital role in determining the future of climate change. There is little information available about city-level energy consumption and carbon emissions, thus we employ spatiotemporal modeling using DMSP/OLS nighttime light imagery. Our findings show that such agglomerations have in fact experienced a remarkable decline in CO₂ emission intensity—from 0.62t/thousand Yuan to 0.26t/thousand Yuan between 1995 and 2010, which constitutes an average annual decline of 5.6%. Despite still very high CO₂ intensities in western China, a convergence of CO₂ intensities across the country has occurred over the last few decades. Using panel regression modeling we show the main driving forces behind this decline in CO₂ emission intensities—specifically economic growth and associated technical change, population density, and foreign direct investment. Factors that have been hampering an even further decline where the ongoing industrialization of China's economy and increasing investment in infrastructure and the housing stock.

Key words:

Delineate and Extend China's Functional Urban Areas with Geographical Open DataKang Wu^{1, 2}, Ying Long³, Xin Zheng⁴, Hongmou Zhang⁴, Merrick Lex Berman²¹Capital University of Economics and Business, Beijing, 100070, P. R. China, wukang@cueb.edu.cn²Harvard University, Cambridge, 02138, MA, U.S.A³Tsinghua University, Beijing, 100084, P. R. China⁴Massachusetts Institute of Technology, Cambridge, MA, 02142, U.S.A**Abstract**

Functional Urban Area (FUAs) refers to the functional economic units, consisting of highly densely populated municipalities (urban cores) as well as any adjacent municipalities with high degree of economic integration with the urban cores, measured by social economic activity flows. In China for a long period of time, there is a gap between the urban administrative region and urban functional region, which caused a number of confusions in terms of the “cities” and “city-regions”. Due to the inconsistency of different urban statistics ranges, researchers often feel uncertainty about how to define an accurate city boundary and how to collect a data for urban studies. This paper aimed to introduce how to delineate a functional urban areas (FUAs) in a Chinese context by using available geographical open data. Three different scale FUAs: Metropolitan Areas(MAs), Metropolitan Coordinating Region (MCRs) and Megalopolis were delimited and extended at the township level for the first time. The results show China has been initially shaping 151 different size MAs which cover a total population of more than 376 million, 27 MCRs and 5 Megalopolis.

Functional urban area; metropolitan area; megalopolis; spatial structure

Dynamic Econometric Analysis of the Relationship between Urbanization and Desertification Reversal Trend: A Case of Yanchi County in Ningxia

WANG Ya, ZHOU Lihua

Cold and Arid Regions Environmental and Engineering Research Institute, Chinese Academy of Sciences, Lanzhou, 730000, P. R. China, wy_2005@yeah.net

Abstract

Urbanization subsystem and ecological subsystem is a pair of function formula that mutually mapping at the stage and regional scale. There were complex relationship between them in different regions and different phases. This paper explores the interactive process and quantitative mechanism of urbanization to desertification reversal trend during 2003-2013 in Yanchi, a typical area of desertification reversed, Ningxia, China. The paper measures the comprehensive level and its dimension of urbanization and desertification reversal with entropy method, examines causal relationships between sub-indexes with ADF stationary test and Granger causality test, analyzes the dynamic process during 2003-2013 with impulse response and variance decomposition of VAR model. Results showed that: (1) Yanchi County's urbanization level had been gradually increasing since 2003, meanwhile the desertification reversal trend remained at more 0.3 level. (2) The comprehensive index of Urbanization did not directly effect the desertification reversal trend, but its component indicators impacted desertification reversal trend, pressure, status and response. (3) The explanatory power of urbanization to desertification reversal was gradually improving. Population migration, economic growth, social progress and urbanization development impacted on desertification reversal trend-pressure-state-response were maintained at the level of 78%, 58%, 13% and 9%. As an effective way to improve the ecological environment of inland arid area, Yanchi County should regard the population urbanization and society urbanization as the key breakthrough to enhance the urbanization's positive effect to ecological environment.

Key words:

Urbanization; Desertification reversal trend; Granger causality test; VAR model; Yanchi County

Ecological and Landscape Dimension of the Suburbanization of the Warsaw Urban-Rural Region

Bozena Degorska

Institute of Geography and Spatial Organization, Polish Academy of Sciences, bodego@twarda.pan.pl

Abstract

Studies of the spatial suburbanization process in terms of ecological and landscape aspects require a broader reference to the geographical space and particularly to the environment. They introduce new research subject fields combining geography, natural science, urban planning and socio-economic science. Extension of the substantial scope of studies of the ecological and landscape aspects in terms of systemic and functional approach, is one of the most value added from discipline development point of view, that is, the geography in the context of spatial analysis. Study involved Warsaw urban-rural region in central Poland, due to the very intense process of urban sprawl and its consequences for the environment and spatial planning. It was indicated, that there are some problem areas in terms of spatial processes, that decrease the ecological and landscape value. Moreover, the stability and the spatial cohesion of the natural system were assessed from the functional and landscape point of view. Recognition of the spontaneous urbanization process and its consequences to the environment and the landscape enabled the identification of preventive measures against the negative outcome of the suburbanization, and setting of the directions and forecasts for the functioning and stability of the ecological and landscape structures, with special stress put on the ecological corridors and green belts which on the one hand relate to the Warsaw Metropolitan Area, but on the other, have also universal character, referring to the best practices of spatial planning in selected European countries.

Key words:

suburbanization; urban-rural region; environment; spatial planning

Ecological and Livable Agglomeration

Xiaofeng DONG¹, Yanyan LI¹, XingGuang Liu²

¹Beijing Jiaotong University, China, xfdong@bjtu.edu.cn

²Lanzhou University, China

Abstract

As the main approach of urbanisation on urban densely populated areas, sustainable development on urban agglomeration is significant. The key point of approach is to take the path of ecological and liveable development, which sets the habitable environment and economic prosperity as a goal, and follows the principle of ecological urban and rural planning, construction and management. Firstly, we have analysed the domestic and international research-practice progress of the livable and ecological urban agglomerations, and chose both international and domestic best practices, for example the Great London and Randstad urban agglomeration as international cases and Pearl river delta urban agglomeration, Changsha-Zhuzhou-Xiangtan urban agglomeration and Lanzhou-XiNing urban agglomeration etc. as domestic cases. Then, we have analysed the advanced experiences on the liveable and ecological development of London urban agglomeration and Lanzhou-Xining urban agglomeration. The overall characteristics are summarised as follows: to respect the demand of ecological environment, make a rational distribution of urban system structure, develop diversified green economy (including tourism) based multi-centre urban function system, connect cities via expressway and rail transit, and pay attention to the natural landscape pattern and ecological environment protection. Finally, we have discussed the ecological development approach of BeiJing-TianJin-HeBei urban agglomeration, that is, constructing functional system and spatial distribution of world city on the economic and social function, taking the knowledge industry and high-end business information service based ecology economy approach, building ecological protection system on the basis of ecological function zoning, developing ecological infrastructure such as low-carbon transport, sponge city, green energy, balancing development of basic education, health care, housing and social security system between urban and rural areas. Ecological and liveable urban agglomeration mode is the inevitable way of transition and new development on Chinese urban densely populated areas.

Ecological; livable; Agglomeration

Ecological Vulnerability Recognition and Sustainable Development Strategy of Mainland China's 'Economic Polarized Areas'

Xuejun DUAN, Lei YE, Lei WANG, Hui Zou

Key Laboratory of Watershed Geographic Sciences, Nanjing Institute of Geography & Limnology,

The Chinese Academy of Sciences, Nanjing China, xjduan@niglas.ac.cn

Abstract

This paper explores an empirical analysis of ecological vulnerability and sustainability in the development of Mainland China's space-economy by operationalizing the concept of 'economic polarized areas (EPAs)'. The concept of 'economic polarized area' presents an effective tool to study the spatial agglomeration of the key components of Mainland China's regional development under the conditions of economic globalization, and to recognize spatial pattern of Mainland China's ecology and sustainability, and relationships between development and ecology. The paper focus on reorganization of ecological vulnerability in 16 EPAs by analysis of soil erosion, desertification, rocky desertification, ecosystem types, key ecological function areas, water resources and land resources. The results show that (1)most EPAs locate in less vulnerable areas which are relatively suitable for reasonable economic development and polarization, (2)ecological vulnerability of Chengdu-Chongqing, Beijing-Tianjin-Hebei Metropolitan Area, Guanzhong Tianshui Economic Zone, Central Plains Area, Wuhan City Circle and Guangxi Beibu Gulf Economic Zone is severe relatively, and (3)the more severe ecological vulnerability of EPA situates, the lower development level EPA reveals. Subsequently the paper puts forward several sustainable development suggestions for Mainland China's EPAs.

Key words:

economic polarized areas; mega-regions; ecological vulnerability; sustainable development; China

Environmental Monitoring and of Soil Heavy Metals Pollution in Ulaanbaatar Area

Tugjamba.N, Erdenetsogt.O

University of the Humanities, Ulaanbaatar, Mongolia, tnavch@humanities.mn

Abstract

Last two decades, urban extension and population growth has been increased dramatically in Ulaanbaatar, the capital city of Ulaanbaatar. Due to uncontrolled and poor managed urban planning, environmental issues has been arising seriously in the city. A total of 22 soil samples from 6 locations were collected from Ulaanbaatar city, in 2012-2015 period.

The purpose of this survey is to investigate the current status of soil morphology and heavy metals (Cu, Fe, Pb, and Mo), in Ulaanbaatar. Soil samples were collected from different parts of the city and measurements made in the laboratory of the University of the Humanities. Laboratory results were analyzed by statistical methods. However, metal pollution was not a serious problem in the city and there was no significant evidence of infiltration of metal solutions into subsoil (at a depth of 30 cm) in the past, some exceeding of heavy metals at the alert level were identified in the sensitive and residential areas. Pb, Mo, Fe Cu contents in most samples were higher than normal. Correlation of different elements in soil samples were calculated by the non-parametric Spearman rank method.

Estimating the Impact of Urbanization on Air Quality in China Using Spatial

Regression Models

Chuanglin Fang, Haimeng Liu, Guangdong Li, Dongqi Sun

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing, 100101, P. R. China, haimengliu@163.com

Abstract

Urban air pollution is one of the most visible environmental problems to have accompanied China's rapid urbanization. Based on emission inventory data from 2014, gathered from 289 cities, we use Global and Local Moran's I to measure the spatial autocorrelation of Air Quality Index (AQI) values at the city level, and employed Ordinary Least Squares (OLS), Spatial Lag Model (SAR), and Geographically Weighted Regression (GWR) to quantitatively estimate the comprehensive impact and spatial variations of China's urbanization process on air quality. The results show that a significant spatial dependence and heterogeneity existed in AQI values. Regression models revealed urbanization has played an important negative role in determining air quality in Chinese cities. The population, urbanization rate, automobile density, and the proportion of secondary industry were all found to have had a significant influence over air quality. Per capita Gross Domestic Product (GDP) and the scale of urban land use, however, failed the significance test at 10% level. The GWR model performed better than global models and the results of GWR modeling show that the relationship between urbanization and air quality was not constant in space. Further, the local parameter estimates suggest significant spatial variation in the impacts of various urbanization factors on air quality.

Air Quality Index; air pollution; PM_{2.5}; urbanization; spatial regression models

Evaluation of Resource-Environmental Carrying Capacity and Sustainable Development Strategy of the Yangtze River Economic Belt, China

Zou H, Duan X J

Nanjing Institute of Geography and Limnology, Chinese Academy of Sciences, Nanjing, 210008, P. R. China,
zoucas@163.com

Abstract

The Yangtze River Economic Belt (YREB) has been undertook multiple missions of urbanization, economic drive and environmental protection when it became national stagey in 2014. Based on the Pressure-State-Response (PSR) model, build resource-environmental carrying capacity (RECC) evaluation method and indicator system. Results show that: (1)cities in the middle and lower reaches of the Yangtze River reveal better in pressure system and response system, however cities upstream show better in state system. Urban agglomeration in the middle reach of Yangtze River and Chengdu-Chongqing urban agglomeration are more coordinated in pressure, state and response systems. (2)Regions with better RECC distribute in the Yangtze River Delta, the Wuhan Metropolitan Area, south-eastern Jiangxi Province, north-western Hubei Province, western Sichuan Province, etc. Cities downstream the Yangtze River reveal better than upstream and cities northern the Yangtze River show better than southern.(3)High pressure of resource consumption and environmental pollution and inadequate human feedback response are major constraints of cities with poor RECC, which can be attributed largely to technology and management constraints. Shortage of water resources per capita and pollution load are main constraints of cities with better RECC. Finally, from aspects of urbanization and economic activities layout guidance, resources utilization improvement, pollution defence and regional competition and basin management, puts forward sustainable development strategies for the YREB.

Key words:

resource-environment carrying capacity; sustainable development; PSR model; the Yangtze River Economic Belt

Fulvic Acid Mediates Chromium (Cr) Tolerance in Wheat (*Triticum aestivum* L.) Through Lowering of Cr Uptake and Improved Antioxidant Defense System

Farid M, Ali S, Rizwan M. Ahmad R,

Department of Environmental Sciences and Engineering, Government College University Faisalabad, Pakistan,

mujahid726@yahoo.com

Abstract

Proliferation of population triggers the scarcity of food worldwide. The intensive agricultural practices reduced the fertility of soil and introduced a number of organic and inorganic pollutants in soil and water biota. Among different inorganic pollutants chromium (Cr) stress is one of the most adverse environmental factors that affect plant growth and cause food chain contamination. Fulvic acid (FA) is known to enhance the growth and production of crops, but the studies are scarce regarding the application of FA on metal tolerance in plants. The effects of FA application on alleviating Cr phytotoxicity in wheat plants were investigated in a pot experiment conducted in sand- and soil-grown plants. Three Cr (0, 0.25, and 0.50 mM) treatments in the form of $K_2Cr_2O_7$ were applied in both soils with or without foliar application of 1.5 mg L^{-1} FA. Plants were harvested after 4 months of treatments, and data regarding growth characteristics, biomass, photosynthetic pigments, and antioxidant enzymes were recorded. FA application increased plant biomass, photosynthetic pigments, and antioxidant enzymes while it decreased Cr uptake and accumulation in plants as compared with Cr treatments alone. We conclude that FA application contributes to decreased Cr concentrations in wheat grains and could be used as an amendment when aiming for decreased metal concentration in plants.

Hotspots of Relationships between Urbanization and Eco-Environment in Different Spatial Scales

Haitao Ma, Chuanglin Fang, Haimeng Liu, Kui Luo

Institute of Geographical Sciences and Natural Resources Research, CAS, Beijing, 100101, P. R. China, maht@igsnrr.ac.cn

Abstract

Urbanization and eco-environment are two major topics existing in human society currently. The relationship between Urbanization and eco-environment has been widely considered. However, existing studies rarely noticed differences in different spatial scales, ignoring comparison and discussion about the characteristics of this relationships in different spatial scales. Based on a review of a large number related research, this paper proposes the geographical features, political background, research focus, problems and the future direction of interest of different spatial scales on the relationship. Human development should be considered in global scale, and considering how the improvement of urbanization affect the change of eco-environment. When talking about the relationship in a country, the socio-economic development phase should be considered. How administrative division affect the relationship is worth study, because inter-provincial regions have no regulatory agencies. Each province has a different natural basis, so relationship research should be based on their characteristics. The interaction with the surrounding area should fully take into account in prefecture-level city. Research on urbanization and eco-environment in different spatial scales can't be confused. We need to design targeted research framework and issues, so as to effectively serve human development of various regions.

Urbanization and Eco-Environment; spatial scales; hotspots; differences

Huai Hai City Ecological Civilization Degree Evaluation and Spatial Analysis

Yang Chen

Jiangsu Normal University, China, 1842015457@qq.com

Abstract

Ecological civilization is the human social development after the primitive civilization, agricultural civilization and industrial civilization of a new type of social civilization. Ecological civilization refers to the human in the process of the development and utilization of natural, from safeguarding the interests of the whole society, economy and natural environment, the respect nature, protect nature, committed to the modernization of ecological environment construction, improve the quality of ecological environment, make the modern economic and social development based on the ecological system of virtuous cycle, in order to effectively solve the demand of the human activities and natural ecological environment system, the contradiction between supply and realize the common development of man and nature. The first of the 17th national congress of the "construction of ecological civilization" into political report, and the construction of ecological civilization as one of the new requirements to achieve the comprehensive construction well-off society goal. Party's description in the eighteenth big and well-off society goal, will be promoted to the ecological civilization construction and economic construction, social construction, cultural construction, political construction of parallel strategic height. And the evaluation of ecological civilization is the premise and basis for the construction of ecological civilization, based on constructing evaluation index system of city ecological civilization, on the basis of using the factor analysis method, ecological civilization degree is evaluated on the huaihai urban agglomeration and spatial analysis.

Impact of Floating Population Spatial Distribution on Polycentric Spatial Structure in Guangzhou-Foshan Metropolitan Area, 2000-2010

Xinjian Li, Miaoqi Zhao, Liming Tang

South China University of Technology, Guangzhou, 510641, P. R. China, arLiXinjian@mail.scut.edu.cn

Abstract

Migration plays an important part in the sustainable development of urban agglomerations. However, there are few studies about the relationship between floating population and polycentric spatial structure from the perspective of metropolitan area. In this paper, we use one case study, Guangzhou-Foshan Metropolitan Area, to explore the floating population spatial distribution and polycentric spatial structure with an aim to understand their relationship and its influence mechanism. With the census and enterprise data from 2000 to 2010 for Guangzhou and Foshan, we investigate the spatial distribution of floating population by spatial analysis, Moran I and location quotient, meanwhile measuring polycentric spatial structure of population and employment by polycentric population density models and rank-size distribution models. According to the basis above, we use descriptive statistical to preliminarily analyse the impact of floating population spatial distribution on polycentric spatial structure. To further explain the influence mechanism of floating population spatial distribution to polycentric spatial structure, we create a regression equation, carry out a residual analysis and describe the migration flows in figure. The results illustrate that: 1) the floating population from inner cycle has been growing and spilling over, concentrated sub-centres in peripheral areas. 2) the floating population is the main reason of sub-centres formation and its redistribution has a greater impact on the evolution of the sub-centres. 3) origin constitution of floating population has been more widely, which strengthened the polycentric spatial structure. We believe the research will have implications for population management and urban agglomerations plan.

Key words:

India and ASEAN Trade Relations: A Spatiotemporal Analysis

Dr. Purva Yadav

Assistant Professor, Centre for the Study of Regional Development (CSRD), Jawaharlal Nehru University, New Delhi-110067, India, purvayadav@hotmail.com, purvayadav@mail.jnu.ac.in

Abstract

Asia's aim of single market would depend on the existence of a flexible and efficient logistics and transportation system. At present the market is fragmented and is often a hindrance to free flow of goods and services, and technical barriers in the market lead to expensive mobility within Asia. To create an efficient single market in Asia, it is necessary to overcome infrastructure gaps. Undoubtedly, distance is a key determinant of a region's trade prospects and in the absence of an adequate connectivity, vast opportunities created by the dynamic growth poles of Asia may diminish at their international borders. Connectivity is important as it encourages trade, and brings regions closer and integrates economy with the world. In India, Delhi-Mumbai Industrial corridor (DMIC) is conceived to develop as the global manufacturing and trading hub supported by world class infrastructure and enabling policy. Developing the Chennai-Bangalore-Mumbai Industrial Corridor and integrating it with DMIC, would provide significant boost to the industrial and economic growth not only for these regions but also for the country. Efficient connectivity between manufacturing cores along the Chennai-Bangalore-Mumbai region, on the one side, and the East Asian countries, on the other, would give considerable boost to the trade potential between India and ASEAN. In the recent years, ASEAN has become one of India's largest trading partners. Hence, an attempt is made through this paper to compare volume of trade and commodity composition (in particular manufacturing goods) of export and import between India and ASEAN countries from 1990s onwards.

Scientific Selection and Grading Cultivation of China's Urban Agglomeration to Adapt to New Normal in China

Chuanglin Fang, Siao Sun

Institute of geography and resources, Chinese academy of sciences, Beijing, 100101, P. R. China, fangcl@igsnr.ac.cn

Abstract

The urban agglomeration is a city group that highly integrated and regional Co-coordinating, which has experienced with four extension process from the city—metropolitan area—metropolitan circle—urban agglomeration—the metropolis. Urban agglomeration is the main land of One Belt And One Road(OBAOR) and where the world economy focus will transfer to, the main part of the new urbanization, and the core areas that the most dynamic and with the highest potential in the economic development pattern today and the future. But a series of "city disease" should be solved, such as "arbitrary range, strive for grandiose projects, spoil things by excessive enthusiasm, out of thin air, and knock together" et al. These problems embodied in: the strategic position of urban agglomeration has been exaggerated overvalued, appeared "only group theory" in the new urbanization; spatial scopes of urban agglomeration expand excessively, and violate the basic purpose of urban agglomerations for state construction; Urban agglomeration scopes depend too much on subjective will, and break away from the basic stand of urban agglomerations; the choice of cultivation of urban agglomeration make endless concessions to local interests and affects the nation's overall strategic security structure; urban agglomerations become sensitive area and the "problem" area that ecological environment problems centralized in, such as fog and haze. To solve these problems, we suggested that selecting urban agglomeration should be in accordance with the scientific standard and objective law and cultivating urban agglomeration step by step, and the understanding urban agglomeration development objective standards and laws of nature; distinguish the essential difference between urban agglomeration and city cluster, avoiding confused them in government documents and academic research; cultivate and construct China's urban agglomeration in large, medium and small gradient scientifically, and construct five big national-Level urban agglomeration, nine medium Regional-Level urban agglomeration and six small Local-Level urban agglomeration; make urban agglomeration planning adapt to the resource environmental bearing capacity; innovate public finance system and public fiscal reserves mechanism of urban agglomeration; play the main role of market mechanism in urban agglomeration development to construct market-leading urban agglomerations, and guide urban agglomeration comply with the new normal of economic development to realize healthy and stable development.

Spatial and Temporal Span of Multi-scale——The Comparison of Spatial Evolution Simulation Based on Urban Agglomeration and Single City

HUANG Jinchuan, LIN Haoxi

Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing, 100101, P. R. China, huangjc@igsnr.ac.cn

Abstract

Under the background of rapid urbanization around the world and worsening conditions of over population, resource scarcity and environmental degradation, cities, as well as urban agglomeration, experience the growing contradiction between human and land being the main carrier of urbanization. Changzhou and Beijing-Tianjin-Hebei Urban Agglomeration, respectively as the typical city in the Yangtze River Delta and one of the three most important urban agglomerations in China, they both profoundly embody the characteristics of urbanization process in China. Moreover, with the continuous strengthening of policies like collaborative development, the spatial evolution of Changzhou and Beijing-Tianjin-Hebei Urban Agglomeration will continue and further present new features. It's of great importance to dive deep into the micro mechanism of urbanization and spatial dynamic. Meanwhile, conducting spatial evolution simulation according to multiple scenarios has very strong realistic guiding significance, which places more emphasis on answering "What if" rather than pursuing the so-called precision prediction. As the basic methodology, city model regards city as a plane and focus more on the internal change within the city while the regional model emphasizes the interaction between cities and regard cities as points. Therefore, after introducing the simulation theory and method with spatial-temporal dynamic characteristics, we establish spatial evolution simulation of multiple scenarios model for Beijing-Tianjin-Hebei Urban Agglomeration and Changzhou, aiming at exploring the similarities and uniqueness of urban model and regional model. To be more specific, on the basis of Cellular Automata (CA), we integrate the neighborhood concept of CA with multiple restrictive factors such as traffic routes, socio-economic indexes and ecological patterns on the basis of clustering analysis of geographical space partition and iterative algorithm, which jointly builds up the synthesized algorithm for spatial evolution simulation model. Then, we apply the model to simulate the expansion of urban built-up area of multiple scenarios for Beijing-Tianjin-Hebei Urban Agglomeration and Changzhou, attempting to provide decision-making support for the adjustment of the current urban development direction and for the next round of town planning. Finally, we discuss the spatial and temporal span of multi-scale.

Beijing-Tianjin-Hebei Urban Agglomeration; Changzhou; Spatial Evolution Simulation; Scenario Analysis

Spatial-Temporal Characteristics and Determinants of PM_{2.5} In China: A City-Level Perspective Analysis

Fang Chuanglin, Wang Zhenbo*, Xu Guang

Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China,
Key Laboratory of Regional Sustainable Development Modeling, Chinese Academy of Sciences, Beijing 100101, China,
wangzb@igsnrr.ac.cn

Abstract

Haze pollution has become a severe environmental problem in the daily lives of people in China. PM_{2.5} makes a significant contribution to poor air quality. This paper, based on observed data from 945 newly located monitoring sites in 2014 and industrial working population data obtained from International Standard Industrial Classification (ISIC), reveals the spatio-temporal variations of PM_{2.5} concentrations in China and the correlations among different industries. We tested the spatial autocorrelation of PM_{2.5} concentrations in the cities of China with the spatial autocorrelation model. A correlation coefficient to examine the correlativity of PM_{2.5} concentrations and 23 characteristic variables for 190 cities in China in 2014, from which the most important ones were chosen, and then a regression model was built to further reveal the social and economic factors affecting PM_{2.5} concentrations. Results: (1) Hu Line and Yangtze River were the divide between high and low values of China; (2) The pm_{2.5} concentrations shows great seasonal variation; (3) PM_{2.5} concentrations had a distinct characteristic of spatial agglomeration; (4) PM_{2.5} concentrations have a close relationship with Urban population size, per capita GDP, urbanization rate, building industry, health and social security, social welfare industry, and public management and social organization industry in China.

Spatial-temporal Characteristics of Eco-efficiency of the Pearl River Delta Urban Agglomeration

Shi C Y, Zhou C S

School of Geography and Planning, Sun Yat-sen University, Guangzhou, 510275, P. R. China, chenyiemily@hotmail.com

Abstract

Eco-efficiency indicates the development level of circular economy. Based on super-efficiency DEA model, this paper measured the eco-efficiency of the Pearl River Delta Urban Agglomeration from 2005 to 2014. With malmquist index and ESDA, it analysed the spatial-temporal characteristics of eco-efficiency. The results show that: in terms of temporal changes, the eco-efficiency of the Pearl River Delta Urban Agglomeration has taken a fluctuating increase, rising by 7.3%. Shenzhen's eco-efficiency is especially high, which locates at the production frontier together with Foshan, Guangzhou and Zhongshan. In terms of spatial changes, there are clear regional differences, with the East Coast as a whole being more than the West, but having more serious polarization. Also the spatial distribution of eco-efficiency demonstrates a trend of focusing on the regional center. The traditional extensive economic growth mode restricts the improvement of regional eco-efficiency. To realize sustainable development, the transformation of economic growth mode and technological promotion are needed.

Pearl River Delta; Urban Agglomeration; Eco-efficiency; Spatial-temporal Characteristics

Summary of the Correlation Study of Urbanization and Ecological Environment

XIAO HUA YU

Key Laboratory of Regional Sustainable Development Modeling, Beijing 100101, China, University of Chinese Academy of Sciences, Beijing 1000493, China, Institute of Geographic Sciences & Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China, yuxh.14s@igsnr.ac.cn

Abstract

Urbanization is not only the inevitable trend of economic and social development, but also is the impetus to promote the further development of economy and society. But such rapid extensive mode of urbanization has caused tremendous pressure to the urban eco-environment, which has become a stress factor in our society and urban development. During the rapid urbanization, the correlation of urbanization and eco-environment is paid attention from urban geography. This article summarized the study on the correlation of urbanization and urban eco-environment conducted by researchers at home and abroad and put forward the views from four aspects.

Urbanization; Ecological Environment; Summary

The Airport Economy Development of ZAEZ's Innovation on the Regional Development Pattern

Zhang Zhancang, Chen Ping, Peng Junjie

The Henan Academy of Social Sciences, Zhengzhou, 450002, P. R. China, zzcang09@126.com

Abstract

As the growth pole of regional economic development, the pathway that airport economy leads the development of regional economy includes: changing the regional elements endowment in the micro scale, coupling with the regional industries in the medium scale, accelerating the tax revenue increase and employment growth in the macro scale. As a representative of Chinese airport economy, Zhengzhou Airport Economic Zone (short for ZAEZ) has played a significant leading and demonstrating role in the following fields: deepening the system reforms in an all-round way, promoting the "synchronization of five modernizations", building "one carrier and four systems", constructing "Four Henan", advancing the structural reform of supply-side and integrating the resources of Henan airport. The article concludes: the structural reform of supply-side needs to be accelerated to integrate into the international frontiers of airport economy. Airport economy is promising under the "One Belt, One Road" initiative. The ZAEA development has promoted the innovation of regional development pattern and showed the tendency of new "four modernizations" of the future regional development. The airport economy has developed rapidly based on the international aviation transportation system, which may change the traditional development pattern that the regional development center located in the coastal areas usually since the Industrial Revolution, and open up a new era that the regional development center will return to the inland regions.

The Correlation and Dual Structure of City Tourism Resources, Tourists, Star Hotels and Revenues in Guangxi

Lu Yi-ling, Sun Gen-nian

Shaanxi Normal University, Xi'an, 710062, China, yilingdlc@163.com, gnsun@snnu.edu.cn

Abstract

The correlation between resources attraction, tourists visiting, star hotels reception and tourism revenues is the basic characteristic of the coupling relationship in tourism system elements. This paper taking Guangxi Zhuang Autonomous Region as the example, discuss the correlation between four elements on the basis of total scale classification. It is found that resources attraction and the reception of tourists show a clear dual structure. Inbound tourists mainly concentrated in Guilin, which has three 5A scenic spots; while domestic tourists are attracted by all kinds of scenic spot. In addition, there is a significant difference in the scale of tourists. Star hotels mainly receive domestic tourists in the era of mass tourism. There is a linear relationship between star hotels and domestic tourists, while inbound tourists and star hotels form three groups. Tourists and tourism revenues are positively correlated, in which domestic tourism is still expanding in linear. The dual structure of tourism industry in Guangxi leads to the inbound and domestic tourism orientation obviously among cities.

resources attraction; tourists; star hotels; tourism revenues; correlation

The Evaluation of Territorial Utilization Quality in China: From the Aspect of Production-Living-Ecological Space

LI Qiu-Ying

Shandong Academy of Social Sciences, Jinan 250002, China skyliqiuying@163.com

Abstract

At present, with the rapid development of the urbanization process in China, some conflicts such as the larger gap between urban and rural area, the imbalance development in different regions, the wasting resources and damaging environment severely and other problems are accompanied. From the concept of production-living-ecological function, this paper has built the production territorial utilization quality index (*PTQI*), living territorial utilization quality index (*LTQI*), ecological territorial utilization quality index (*ETQI*) with a total of 12 subtype indices and several elements of the comprehensive quality of territorial utilization (*TQI*). On the basis of the data in 2012 in provincial unit, comprehensive evaluation method is used to calculate China's territorial utilization quality and type characteristics. The results has showed that the *TQI* is relatively low and it has showed differentiated in spacial distribution. *PTQI* and *LTQI* in the east are higher than that in the middle, and that in the middle are higher than that in the west. *ETQI* is higher in in the northeast areas and the southeast coastal areas. This paper can give suggestion to the development of production space with intensive and efficient use, the living space with livable and the ecological space with green mountains and clear water.

Key words:

territorial utilization quality; production-living-ecological space; evaluation

The Identification and Development Pattern of Urban Agglomeration in China

Weiping Zeng, Peijuan Zhu

Hunan Normal University, China, 1663468484@qq.com

Abstract

Accurate identification of urban agglomeration is the premise and foundation for the effective development of urban agglomeration planning, the full release of urban agglomeration to lead the potential of economic and social development in the region. At present, regardless of the levels of government and academia, temporarily have not yet formed a unified urban agglomeration identification standard, resulting in the understanding of China's urban population and development degree of divergent. In view of the previous research methods have different degrees of limitations. In this paper, the macro partition method recognition of urban agglomeration, and combined with the index method for the identification of urban agglomeration development pattern analysis, to urban agglomeration identification method and theory research to provide some reference for accurate planning of urban agglomeration development to provide valuable reference. Research shows that: Currently, China have 18 urban agglomeration, including five national urban agglomeration, six regional level of the urban agglomeration and seven regional level urban agglomeration, their developmental pattern showing a degree of development level, regional differentiation and along the main traffic economic axial belt distribution characteristics. The result of this research method has strong objectivity and high accuracy, which is consistent with the mainstream of the country. It has a certain value of popularization and use for reference.

The Level of Employment Security and Its Spatial Pattern in China's Urbanization

Process

FANG Chuanglin¹, LUO Kui^{1,2}

¹Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing 100101, China

²University of Chinese Academy of Sciences, Beijing 100049, China, luok.15b@igsnrr.ac.cn

Abstract

In order to promote a new-type urbanization of people oriented, the level of employment security and its spatial pattern should be carefully studied in China's urbanization process. Based on the interaction mechanism between industrialization and urbanization, this paper analyzed the relationship between urbanization and the level of employment security, and the level of employment security and its spatial pattern of provincial and prefecture level has been discussed based on two types of evaluation index system of the level of employment security, respectively. The main conclusions are as follows. (1) It's found that an obvious U shape curve relationship is existed between the urbanization process and the level of employment security, and the inflection point of the curve roughly appeared in the early stages of rapid urbanization. (2) The overall level of employment security is relatively low in provincial level, Beijing has the best performance, while Guizhou is the worst. From the spatial distribution, the coastal and border provinces show a better level of employment security than other provinces, while the southwestern provinces have the worst performance. (3) The overall level of employment security is also relatively low in prefecture level, Xiamen has the best performance, while Shuangyashan is the worst. From the spatial distribution, eastern coastal areas and some western region with lower level of urbanization have the best level of employment security, while the central and northeastern regions are the worst. Thus, A variety of measures need to be applied to enhance the level of employment security in order to promote the sustained and healthy development of new urbanization in the future.

Key words:

urbanization; employment; security level; spatial pattern; U-shaped curve

The Relationship between Water Use and Urbanization

Siao SUN, Chuanglin FANG

Institute of Geographic Sciences and Natural Resources, Chinese Academy of Sciences, Beijing, 100101, P. R. China,
suns@igsnrr.ac.cn

Abstract

Predictions of national water use is important for water management and planning as well as for making national water resources related development strategies. A few literature studies have addressed water use as a function of economic factors (e.g., GDP). Results were inconsistent, depending on used data and methodology. This study examines the relationship between national water use and urbanization levels. Annual water use data from FAO (<http://www.fao.org/>) and urbanization level data (urban population percentage) from the World Bank (<http://data.worldbank.org/>) are used. Data from 31 countries with over 5 data points (two neighbouring data points are usually with a temporal gap of 5 years) are available. The linear and quadratic regression relations are applied to cross-sectional data and panel data of water uses and urbanization levels. The relationships are not significant so that it is difficult to draw any conclusion from cross sectional and panel data analysis using the regression method. The Mann-Kendall trend analysis method is applied to data series of each country to study the evolution pattern. Data series of one country may present increasing, decreasing or first increasing then decreasing trend, probably representing one part of the Environmental Kuznets curve, i.e., an inverted U curve. But the water use of some countries presents randomness. Different water use curves are characterized for different countries due to different water resources endowments and varied urban and technique development stages. This also explains why regression analysis has difficulty to provide valuable information in water use when pooling data of all countries together.

Key words:

Water use; urbanization; regression; Mann-Kendall trend analysis; cross-sectional data; panel data;
Environmental Kuznets curve

Understanding the Dynamics of Shanghai's Urban Public Safety

Danlin Yu, Ph.D.¹, Chuanglin Fang, Ph.D.²

¹Earth and Environmental Studies, Montclair State University, Montclair, NJ, 07043, yud@mail.montclair.edu

²Department of Urban Development, Institute of Geographical Science and Natural Resources Research, Chinese Academy of Sciences, Beijing, China

Abstract

Due to rapid urbanization during the past decades in China, cities in China are facing increasing challenges from a variety of aspects. Among them, urban public safety concerns including urban crime, urban livability and urban disasters that would potentially impact upon urban development and prosperity start to attract governmental, academic as well as public attention. Applying a system dynamics modeling scheme, this research investigates and attempts to predict the urban public safety dynamics of Shanghai, the largest and most developed city in China, with a set of collected indicators that describes aspects of Shanghai's infrastructure and development, population, crime, livability and disaster during the past decade (2001 – 2009). The feedback loops are constructed based on intensive, exploratory data mining through regular statistical analyses and grey system modeling techniques. The analytical results suggest Shanghai's public safety is increasing during the past decade due to high level of urban socioeconomic development, which provides a foundation (or asset and investment) for urban public safety. In the meantime, factors that 'expend' such asset and investment (crimes and relevant events and disasters) increased at a relatively lower level. Dynamic prediction on Shanghai's public safety, however, indicates that the city could still enjoy its continuous improvement of public safety providing the city continues to develop like in the past decade, which might not be the case in the long run. A few scenarios are presented by altering a few critical variables to demonstrate potential public safety dynamics of Shanghai in the next 15 years.

Key words:

Urban public safety; System dynamics; Grey system simulation; Prediction; Shanghai

Urbanization and Eco-Environment in Yangtze River Delta: Improved EKC and Coupling Analysis

Yabo Zhao¹, Shaojian Wang²

¹Beijing Normal University, China, zhaoyabo3@163.com

²Sun Yat-sen University, China

Abstract

The Yangtze River Delta (YRD), one of China's most urbanized areas, plays a significant role in China's economic development. However, its rapid urbanization has resulted in many eco-environment issues. Thus, a better understanding of the relationship between urbanization and eco-environment (U&E) would contribute to the coordinate development between them. This study established a comprehensive index system of U&E and further empirically investigates the relationship between U&E in YRD. The improved environmental Kuznets curve (EKC) model and dynamic coordination coupling degree (CCD) model were used in this study and the period 1980-2013 was considered. The main conclusions were as follows: (1) Economic urbanization and eco-environment endowment accounted for the highest weight of urbanization system and eco-environmental system respectively, thus being the key factors for U&E system. (2) Further analysis found the existence of differentiated inverted-U curves between U&E across cities, thus the improved EKC hypothesis is confirmed. From the viewpoint of the empirical curves, we found that when the inflection point appears, economically developed area has a higher urbanization level while less developed area has a higher eco-environment pressure. Before the inflection point, a striking positive correlation was observed between the eco-environment pressure and urbanization level, while a negative correlation after the inflection point. (3) There was a dynamic coordination coupling relationship between U&E, which conforms to the "S" curve. The coordination coupling process has stepped into the break-in development stage from low-grade symbiosis stage gradually, but the pattern of coordination always belonging to eco-environment lagged. What's more, the dynamic CCD showed a difference in spatial distribution, and presented the pattern of "higher in the around, lower in middle" during the study period. The improved EKC and coupling analysis may help Chinese decision makers to formulate sustainable measures to balance urbanization development and eco-environment protection.

Urbanization; Eco-environment

Xinjiang Urban System Level and Development Countermeasures

Zibibula-simayi, Feng gang, Zhao xuepeng, Lu youbin

Xinjiang University, Urumqi, Xinjiang, 830046, zibibulla3283@sina.cn

Abstract

In this paper, using the theory of "city center", combined with the actual situation of Xinjiang, screening of 14 indicators, rule of these indicators can be divided into four layers: the city size, urban economy, urban quality of life and urban ecological environment, using the index analysis of the size of the cities contribute value to other cities in Xinjiang, through the city center of theoretical calculation, the results show that: only in Urumqi, Xinjiang Uygur autonomous region in the central city's first regional central city of Karamay and Korla, and regional secondary center cities and regional central cities, the more the view from the space distribution, regional central cities around Urumqi urban agglomeration, and regional secondary center cities and regional central cities are mostly around the edge of Xinjiang; Then it is pointed out that urban system development in Xinjiang and accordingly puts forward the future for a period of time the mode of city development in Xinjiang.

Changing and Differentiated Urban Landscape in China: Spatio-Temporal Patterns and Driving Forces

Li G, Fang C, Wang S

Key Laboratory of Regional Sustainable Development Modeling, Institute of Geographic Sciences and Natural Resources Research (IGSNRR), Chinese Academy of Sciences (CAS), 11A Datun Road, Chaoyang District, Beijing 100101, China
ligd@igsnr.ac.cn

Abstract

Urban landscape spatio-temporal change patterns and their driving mechanisms in China are poorly understood at the national level. Here we used remote sensing data, landscape metrics and a spatial econometric model to characterize the spatiotemporal patterns of urban landscape change and investigate its driving forces in China between 1990 and 2005. The results showed that the urban landscape pattern has experienced drastic changes over the past fifteen years. Total urban area has expanded approximately 1.61 times, with a 2.98% annual urban-growth rate. Compared to previous single-city studies, although urban areas are expanding rapidly, the overall fragmentation of the urban landscape is decreasing and is more irregular and complex at the national level. We also found a stair-stepping, urban-landscape changing pattern among eastern, central and western counties. In addition, administrative level, urban size and hierarchy have effects on the urban landscape pattern. We also found that a combination of landscape metrics can be used to supplement our understanding of the pattern of urbanization. The changes in these metrics are correlated with geographical indicators, socioeconomic factors, infrastructure variable, administrative level factor, policy factor and historical factor. Our results indicate that the top priority should be strengthening the management of urban planning. A compact and congregate urban landscape may be a good choice of pattern for urban development in China.

Urban Landscape; self-organization map; Spatio-Temporal Patterns; Driving Forces

Coupling Relationships and Constraining Effects between Urban Agglomeration Development Quality and Water Resources Utilization

BAO Chao, CHEN Xiaojie

Key Laboratory of Regional Sustainable Development Modeling, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China, baoc@igsnrr.ac.cn

Abstract

During China's rapid urbanization, traditional urbanization development pattern with high resources consumption, high pollution emissions and low economic efficiency has been greatly criticized. China's urbanization has been turning to new-type urbanization which focuses on urbanization development quality. Urban agglomeration is an important organization form of urbanization. It is also the main spatial pattern for China to promote new-type urbanization. On the other hand, as an important kind of natural resources and one of the key eco-environmental elements, water plays an important role on the sustainable development of China's urbanization, particularly for urban agglomerations in arid area of Northwest China. The imbalance between water supply and demand has greatly constrained the promotion of urban agglomeration development quality. Therefore, Lanzhou-Xining Urban Agglomeration was taken as a case, and the following issues were discussed: (1) a comprehensive evaluation index system was constructed for the economic development quality, social development quality, resources and environment development quality, and then the development quality of Lanzhou-Xining Urban Agglomeration was evaluated. Its evolution law was analyzed. (2) Based on a coupling and coordinating degree model and a grey correlation degree model, key elements of the development quality of Lanzhou-Xining Urban Agglomeration were identified. (3) Based on a cubic function model and the Granger Causality Test, the coupling relationship between the development quality and water resources utilization of Lanzhou-Xining Urban Agglomeration was analyzed. (4) Water resources constraint intensity on the development quality of Lanzhou-Xining Urban Agglomeration was measured. (5) The modes and countermeasures were put forward to improve the development quality of Lanzhou-Xining Urban Agglomeration under the restriction of water resources.

Key words:

urbanization development quality; water resources constraint; evaluation index system; Granger Causality Test; Lanzhou-Xining Urban Agglomeration

Decoupling Analysis between Population Growth and Constructed Land Expansion in Fast-emerging City

Hongmei Zhang, Yanqing Liang

Hebei Normal University

Abstract

Understanding and grasping the population growth and coordination of the construction land expansion and regional differences is of great significance to making overall district development and accomplishing fast and efficient urban development. Take Shijiazhuang as example, it was analyzed based on the characteristics of population growth and the construction land expansion from 2003 to 2011 by the decoupling theory. The results indicated that: ① the relationship of population and construction land in Shijiazhuang reflects the phenomenon of expanded junction, land use types tends to be extensive trend; ② the relationship of population and construction land in Shijiazhuang and in Luancheng reflect the phenomenon of expansion negative decoupling, population growth and the construction land expansion are more reasonable; most of the counties and cities are not unreasonable. The quantitative research of population growth and the construction land expansion are of great significance to improving the efficiency of construction land and controlling the total construction land, have certain theoretical and practical significance for sustainable development and strategy formulation.

Key words:

Fast-emerging City; population growth; the construction land expansion; decoupling state; Shijiazhuang

Evolution Characteristics and Driving Factors of Urban functional land in Zhangye City

Feng LIANG, Qianguo LI, Peiji SHI

College of Geography and Environment Science, Northwest Normal University, Lanzhou, Gansu, 730070,

liangfeng_nwnu@126.com

Abstract

The transition of urban functional land is the spatial reflection of urban functional agglomeration and diffusion, which can profoundly reveals the internal characteristics of horizontal expansion of urban space. This paper takes Zhangye City's planning scope as a study case and based on remote sensing image and social and economic data. The GIS's spatial analysis methods is adapted to analysis spatial evolution characteristics and driving forces of three functional land: residential land, industrial and storage land and public facilities land in Zhangye City since 1981, and aiming at providing guidance for reasonable division of urban internal function space. The study shows that: (1) the urban residential land and public facilities land have been gradually increasing, have been farming a trend which spreads from cohesion to scattered outside. They spread around the old city. But industry and storage land has been increased first and decreased after, forming a mixed to concentrative trend. On the whole, it concentrated in northeastern industrial park. (2)Zhangye City's urban functions evolution is the result under the direct force of population and economic growth, traction of the traffic organization, together with guidance of policy and planning. (3) In order to meet the supply-side structural reformation in city space development under the new normal background, Zhangye City needs to form a spatial structure type: one cores with four zones to enhance the comprehensive function of urban system.

Feature Identification of Wuhan Urban Agglomeration Spatial Pattern Evolution and Construction of Optimization Model

Mengjie Zhang, Chong Peng

Architecture and Urban Planning Department, Huazhong University of Science and Technology, China, dreamthought0530@163.com

Abstract

Based on the night light data, urban area, population scale and GDP of Wuhan urban agglomeration from 2009 to 2013, use city order - scale law, spatial self-correlation analysis and weighted standard deviation ellipse to conduct systematic analysis on the evolutionary features and development features of spatial pattern, form pattern and organization pattern in Wuhan urban agglomeration. The research results prove that: The system level of Wuhan urban agglomeration is obvious, forming the pattern of "agglomerating in one center and competitive balance in multiple points" and presenting the development tendency of "stronger in the west and weaker in the east". Ezhou, Huangshi and Wuhan gradually aggregate to urban core group. At the same time, the contract between the low-level cities and urbans is gradually strengthened, forming several secondary regional space, while the agglomeration tendency is not obvious enough. Between 2009 and 2013, Wuhan urban agglomeration expanded gradually from northwest to southeast and presented the dynamic evolution features of "along the river, the road and the side". In the future, the spatial development center of Wuhan urban agglomeration will become the main urban area of Wuhan and the spreading circle expansion will be kept within layering period. According to the recognition of spatial pattern features, problems and tendency in Wuhan urban agglomeration and based on central geological theory and multi-center network theory, construct a "network and circle" spatial pattern optimization model, present "network + circle" model system (including the interaction mechanism of spatial elements and each element) and present the evolutionary organization model according to the different development stages of urban agglomeration.

Research on County Development Potential in the Jing-Jin-Ji Region Based on Modified Potential Model

ZHAO J L, SONG J P, ZHANG X B

School of Geography, Beijing Normal University, Beijing, 100875, P. R. China, 964634068@qq.com

Abstract

The evaluation of regional development potential can play an important role in understanding future regional development patterns and promoting coordinated development, but accepted evaluation methods have both advantages and constraints. In this paper, we explore the evolution of spatio-temporal patterns of county regional development potential and analyze the restricting factors by combining a proposed potential model with a synthetic quantified assessment method to address some shortcomings in existing methods. The Jing-Jin-Ji region, which is representative of unbalanced regional development in China, is the selected study area. Key findings include: 1) the modified proposed potential model is more effective at measuring regional development potential than previous methods; 2) a growing Matthew effect in county development in the Jing-Jin-Ji region is indicated by a steady increase in global Moran's I and in the variation coefficient during the period from 2000 to 2013; 3) features of the local spatial agglomeration of most counties remain relatively stable and display some clear rules, that is, most of the counties with higher potential are concentrated in the Jing-Jin-Tang region and tend to extend to eastern neighbouring areas, while counties with lower potential are widespread in Hebei Province; 4) three types of restraint are present in areas that are mainly concentrated where there is low potential, and there is significant overlap between them. Finally, suggestions for exploiting and promoting the development potential of low potential areas are proposed on the basis of the results.

Abstract

This paper establishes the conceptual framework and calculation method for the quantity and rate of land urbanization process. The study evaluates the spatial differentiation pattern of absolute and relative process of land urbanization in 658 cities in China from 2000 to 2010. The spatial distribution of cities with rapid land urbanization process is discussed and the contribution rate and its spatial heterogeneity of major land use types are explored through application of GIS. Based on this, the major drivers and their variation among cities of different sizes have been analyzed. The main conclusions are as follows: (1) Land urbanization in China shows a clear spatial difference. The greater the city scale, the faster its land urbanization; (2) Over the last 10 years, the average quantity of land urbanization in the 656 cities was 3.82 km², the quantity of land urbanization is differentiated by administrative grade. The rate of land urbanization reveals a pattern of differentiation between coastal and other cities; (3) In the past 10 years, the two primary land use types associated with land urbanization in China are residential and industrial, with a combined contribution rate of 52.49%. The greater the scale of the city, the more significant the driving effect of industrial land. (4) Overall, urban population agglomeration, industrial growth and investment are the three drivers of land urbanization in China, but different scales cities have the different drivers.

Strategies for Coordinated Development of Jingjinji Region Based on Limited Water Resources —A Case Study of Baiyangdian Area

XiYu Liu, Sijia Cheng, Sitong Huang, Han Zhoua

Tsinghua University, China, 1261027209@qq.com

Abstract

With urbanization in Beijing, Tianjin and Hebei region, water scarcity has been one of the main factors restraining the development. Building green, livable and civilized capital ecological space increasingly becomes an important goal to achieve. This article analyzes current situation of water resource together with its relationship with urban construction, and then sums up the patterns and the main problems. What's more, taking Baiyangdian area for an example, we make advices as well as verification by GIS simulation and also spatial strategic planning under the concept of the harmony between ecology and regional development. We learn from and expand the concept of "Yuan" culture in ancient China, making Baiyangdian area a national livable place.

System Simulation of the Rational Scale of Jing-Jin-Ji Urban Agglomeration Constrained by Water Resources

BAO Chao, HE Dongmei

Key Laboratory of Regional Sustainable Development Modeling, Institute of Geographic Sciences and Natural Resources Research,
Chinese Academy of Sciences, Beijing 100101, China

Abstract

Urban agglomeration is an important spatial organization form of socio-economic development in China. It is also the major form of China's new-type urbanization. As one of the world-class urban agglomerations in China, Jing-Jin-Ji Urban Agglomeration is an important spatial carrier of the coordinated development strategy among Beijing, Tianjin and Hebei Region. Along with the promotion of its national and international strategic position, the urban scale (i.e. population, gross domestic product and constructive land) is becoming larger and larger. However, Jing-Jin-Ji Urban Agglomeration is located in North China, where water resources are greatly scarce. Water resources have become the key stress to the development of Jing-Jin-Ji Urban Agglomeration. Therefore, we carried out the following research: (1) we analyzed the coupling relationship among water resources utilization, population growth, socio-economic development and eco- environmental evolution in Jing-Jin-Ji Urban Agglomeration, and revealed the interaction mechanism between socio-economic system and water resources system; (2) Taking system dynamics model as the main model, and water resources supply threshold model, population growth threshold model, economic development threshold model, urban land expansion threshold model as the auxiliary models, we constructed a system simulation model on the rational scale of Jing-Jin-Ji Urban Agglomeration constrained by water resources; (3) Based on multiple scenario setting and key variables controlling, we simulated the rational population scale, economic scale, constructive land scale and urbanization level which are compatible with the water resources carrying capacity in Jing-Jin-Ji Urban Agglomeration in 2016-2030; (4) we finally put forward the coordinated development mode of Jing-Jin-Ji Urban Agglomeration constrained by water resources, aiming to provide a scientific policy-making foundation for the sustainable development of Jing-Jin-Ji Urban Agglomeration.

The Analysis of Spatial Distribution of PM_{2.5} in Pearl River Delta Urban

Agglomeration

Jie Liu, Jingchuan Huang

Institute of Geographic Science and Natural Resources Research, UCAS, Beijing, liujie815@mailsucas.ac.cn

Abstract

In recent years, severe weather headed by the haze swept China, which attaches great importance to bring pollution under control and protect the environment. As the main contents of the haze, the research of the characteristics and spatial distribution of PM_{2.5} has important significance to the management of the haze. This paper use ArcGIS, study the spatial distribution of the annual mean and the four quarter of PM_{2.5} in the Pearl River Delta Urban Agglomeration in 2014, calculate the contribution degree of four pollutant source and the purification capacity of PM_{2.5} in different city, and analysis the cause of the spatial distribution of PM_{2.5} in the Pearl River Delta Urban Agglomeration. The results show that the spatial distribution of PM_{2.5} in the Pearl River Delta Urban Agglomeration shows obvious ladder distribution pattern of high in the northwest and low in southeast, the industrial structure is the biggest factors affecting the city's total PM_{2.5} emissions. Affected by the wind and other natural conditions, high concentration centers of the spatial distribution moved from Zhaoqing to Guangzhou, then to the Jiangmen. Shenzhen has the strongest purification capacity of PM_{2.5}, and the purification ability of PM_{2.5} in Zhaoqing city is seriously insufficient. Therefore, in addition to strengthen the purification capacity of PM_{2.5} by taking reasonable measures, it's very helpful to strengthen the whole Pearl River Delta region PM_{2.5} emission control.

The Changing Landscape and Characterization of Air Pollution Index in Urban Areas of the Yangtze River Delta

Tan Chen, Qiu hao Huang, Manchun Li

Jiangsu Provincial Key Laboratory of Geographic Information Science and Technology, Nanjing University, Nanjing 210023, China

Department of Geographic Information Science, Nanjing University, Nanjing 210093, China

Tan Chen (Corresponding author), E-mail: tanchen_gis@126.com

Abstract

The hallmark of development in the Yangtze River Delta has been sprawling urbanization. However, air pollution is a significant problem in these urban areas. In this paper, we investigated the urban spatial structure and analyzed the air pollution index (API) in four cities (Shanghai, Nanjing, Hangzhou, and Ningbo) in East China at latest ten years. We try to empirically examine the relationship between sprawling urban patterns and air quality in urban areas of the Yangtze River Delta. According to the monitoring data, the API in the four cities was down slightly. Clear interannual, seasonal, and monthly variations of API were analyzed, which indicated air quality was poorest in winter but improved in summer and air quality level varied in different weather conditions. Quantitative correlation analysis showed that there is a high coefficient among the largest green vegetation landscape patch area index, green patch of vegetation landscape fragmentation, urban landscape patch fragmentation and API. Some other indexes like landscape diversity, fractal dimension and fragmentation index have a weak correlation with API. The study also showed that landscape diversity is sensitive to the change of pollution concentration when the concentration of pollutants in the air reaches a certain value.

The Differentiation of Agglomeration Degree and Pattern of Spatial Polarization in the Ha-da Giant Urban Belt

Tian Junfeng, Liu Yanjun, Fu Zhanhui, Wang Binyan

School of geographical Sciences, Northeast Normal University, Changchun, 130024, P. R. China, tianjf135@nenu.edu.cn

Abstract

On the basis of defining the concept of the space polarization, apply the evenness index, the Gini coefficient, Cui Wang index to analysis the urban agglomeration degree of differentiation characteristics and spatial pattern of polarization, the conclusions are as follows: (1) From 1990 to 2012, time and space differentiation of the element agglomeration degree in the big giant urban belt is obvious, and the "Core - periphery" structure lead by the central city is gradually appearing, At the same time, its internal can be divided into two secondary area based on element agglomeration degree differences: Ha-Chang area and the central and southern of Liaoning area ;(2) There are significant spatial polarization for element agglomeration in the giant urban belt. The "four cities" dominated the space polarization of the city belt, and the degree of space polarization in the central and southern of Liaoning area is stronger than the Ha-Chang area;(3) The internal force is the main factor for the space polarization of the city belt, while urban development investment intensity, the inner attractive of the city and the level of economic development also have significant influence on the urban space polarization. Besides, the influence factors of the two sub-regions are different: The influence factors of Ha-Chang area is the urban investment intensity and the level of economic development. While the endogenous force is the main factor that influence the space polarization of the central and southern of Liaoning area. Beside, the location conditions also have obvious influence on the urban internal spatial polarization differentiation.

The Driving Effect Decomposition and Space-Time Difference of Carbon Emissions in Xuzhou Metropolitan Area

Yuanhe, Qiufangdao

Jiangsu normal university, China, Xuzhou, 221000, 942358239@qq.com

Abstract

Adopting complete decomposition analysis method, taking the Xuzhou metropolitan area as the research unit, the spatial and temporal characteristics of carbon emissions and its driving effect are analyzed in growing metropolitan circle from 2000 to 2014. Based on the analysis, it can be found that it has positive correlation between carbon emissions and industrial growth, and industrial carbon intensity tends to decrease, presenting a cleft pattern that high in north-south and low in the middle; Resource and labor intensive industries are the highest industry in the carbon intensity, presenting a downward trend, but tech-intensive industry is the lowest industry in the carbon intensity; Scale effect for industrial carbon emissions showed the positive driving effect, but structure effect and technological effect for industrial carbon emissions presented an inhibitory effect; Scale effect presented a pattern from unidirectional incline with Jining as the core to middle high and east-west low. The spatial distribution of structure effect presented a pattern decreasing from south to north instead of declining from Xuzhou to peripheral in the past, at the same time, the effect of technology presented evolved from the pattern with middle high and low on both sides into high in east and low in west. Research suggests that cities should reduce carbon emissions by optimizing industry structure and improving energy utilization.

industrial carbon emissions; complete decomposition analysis method; the driving effect; space-time difference; Xuzhou metropolitan area

The Relationship between Water Use and Urbanization

Siao SUN, Chuanglin FANG

Institute of Geographic Sciences and Natural Resources, Chinese Academy of Sciences, Beijing, 100101, P. R. China,
suns@igsnrr.ac.cn

Abstract

Predictions of national water use is important for water management and planning as well as for making national water resources related development strategies. A few literature studies have addressed water use as a function of economic factors (e.g., GDP). Results were inconsistent, depending on used data and methodology. This study examines the relationship between national water use and urbanization levels. Annual water use data from FAO (<http://www.fao.org/>) and urbanization level data (urban population percentage) from the World Bank (<http://data.worldbank.org/>) are used. Data from 31 countries with over 5 data points (two neighbouring data points are usually with a temporal gap of 5 years) are available. The linear and quadratic regression relations are applied to cross-sectional data and panel data of water uses and urbanization levels. The relationships are not significant so that it is difficult to draw any conclusion from cross sectional and panel data analysis using the regression method. The Mann-Kendall trend analysis method is applied to data series of each country to study the evolution pattern. Data series of one country may present increasing, decreasing or first increasing then decreasing trend, probably representing one part of the Environmental Kuznets curve, i.e., an inverted U curve. But the water use of some countries presents randomness. Different water use curves are characterized for different countries due to different water resources endowments and varied urban and technique development stages. This also explains why regression analysis has difficulty to provide valuable information in water use when pooling data of all countries together.

Key words:

Water use; urbanization; regression; Mann-Kendall trend analysis; cross-sectional data; panel data; Environmental Kuznets curve

The Scope Definition and Prediction Research of Ha-chang Urban Agglomeration under the Revised of Daily-communication-area

Tian Junfeng, Wang Shijun , Wang Binyan

School of geographical Sciences, Northeast Normal University, Changchun, 130024, P. R. China, tianjf135@nenu.edu.cn

Abstract

To guide the construction of Ha-chang urban agglomeration, realize the reasonable and healthy development of urban agglomeration, based on the daily-communication-area, under the help of the GIS, considering the natural and ecological condition, national and regional development policy, the barrier of administrative boundaries in this region, defined the spatial scope of Ha-chang urban agglomeration with the combination of qualitative and quantitative methods. The study found that the spatial scope of Ha-chang urban agglomeration is dynamic. It will be changed by the change of modes of transportation and the optimization of transportation system. The current and recent range mainly include nine cities: Harbin, Daqing, Suihua, Changchun, Jilin, Songyuan, Siping, Liaoyuan....The forward range on the basis of existing would expand to east and west ,and it would include Mudanjiang, Yanbian Korean autonomous prefecture and so on ,summing to 13 cities (state). Finally it would form a wide-area urban agglomeration, which covers the north-central of the northeast region.

Key words:

daily-communication-area; transportation network; scope; Ha-chang urban agglomeration

Theoretical Analysis on Interactive Coupled Effects between Urbanization and Eco-Environment in Mega-Urban Agglomerations

Chuanglin Fang¹, Chenghu Zhou¹, Chaolin Gu², Liding Chen³, Shuangcheng Li⁴

¹Institute of geography and resources, Chinese academy of sciences, Beijing, 100101, P. R. China, fangcl@igsnrr.ac.cn;

⁴College of Urban and Environmental Sciences, Peking University, Beijing 100871, P. R. China

Abstract

Mega-urban agglomerations in China play a vital role in both national economic development strategies and national new-type urbanization, and undertake important historical responsibility with the world economic center transfer to China. However, they suffer a series of increasingly serious eco-environmental problems in the process of development. Thus, studies on the interactive coupled effects between urbanization and eco-environment in mega-urban agglomerations are the frontier areas and high priority tasks in the earth system science for the future ten years. This paper analyses the basic theory frame of the interactive coupled effects between urbanization and eco-environment in mega-urban agglomerations systematically. On theoretical aspect, based the nonlinear relationship and coupling characteristics of the natural and human elements in mega-urban agglomerations system, we could estimate the interactive coercing intensity, nearcoupling and telecoupling mechanism of the inside and outside mega-urban agglomerations system after scientific identifying the key elements, then form the basic interactive coupling theory. Moreover, we could build a spatiotemporal coupling dynamic model, which integrated with multi-elements, multi-scales, multi-scenarios, multi-modules and multi-agents. The model will be used to develop the intelligent decision support system for urban agglomeration sustainable development. On methodology aspect, the mega-urban agglomeration is regarded as an open complex giant system. We should establish the standardized shared database for exploring the interactive coupled effects between urbanization and eco-environment, then using new technology for analyzing big data and the integration methods incorporating of multi-elements, multi-scales, multi-targets, multi-agents, multi-scenarios and multi-modules, we can build a methodology framework to analyze the complex interaction coupling between urbanization and eco-environment. The technical route is that analyze spatiotemporal evolution characteristics, identify the key elements, interpret coupling relationship, reveal the mechanism of coercing effect, find the general rules, filtrate the control variables, solve the critical thresholds, conduct regulation experiments, simulate different scenarios, propose an optimized schemes, and achieve national goals. Further, we could put forward the overall optimization scheme. In general, this research could provide theoretical guidance and method support for the transformation and sustainable development in mega-urban agglomerations.

Professor Mark Stafford Smith is based in Canberra, Australia, and looks after coordinating Adaptation Research across CSIRO; he oversees a highly interdisciplinary program of research on many aspects of adapting to climate change, as well as regularly interacting with national and international policy issues. He has over 30 years experience in drylands systems ecology, management and policy, including senior roles such as CEO of the Desert Knowledge Cooperative Research Centre in Alice Springs. His significant international roles include being past vice-chair of the International Geosphere-Biosphere Programme's Scientific Committee. In 2012 he was co-chair of the Planet Under Pressure: New Knowledge Towards Solutions conference on global environmental change in the lead up to Rio+20. In 2013 he was appointed Chair of the inaugural Science Committee for Future Earth, which aims to help coordinate research towards global sustainability worldwide.

Professor Bojie Fu is a professor of physical geography and landscape ecology at the State key Lab. of Urban and Regional Ecology, Research Centre for Eco-Environmental Sciences, Chinese Academy of Sciences. He is President of the Geographical Society of China, Director-General of Department of Earth Sciences, National Natural Science Foundation of China. He is member of Chinese Academy of Sciences, Fellow of the Academy of Sciences for Developing World (TWAS) and Corresponding Fellow of the Royal Society Edinburgh UK. His research areas are land use and land cover change, landscape pattern and ecological processes, ecosystem services and management. He served as the Vice President of International Association for Ecology (INTECOL) and Vice Chairman of International Long-term Ecological Research Network (ILTER). He has published more than 400 scientific papers and 10 books, including *Science and Nature Geoscience*. His prizes include China National Natural Science Prize and Award of Distinguished Service from the International Association of Landscape Ecology.

Professor Woo-ik Yu was born in 1950 at Sangju, Korea. He studied geography at the SNU (Seoul National University) and got his B.A. and M.A. degree. After completing military service as an instructor at the Korea Military Academy, he then studied further geography, sociology, and history at the University of Kiel (Germany) and received his Ph.D. degree in philosophy (1980). Woo-ik Yu taught social geography and regional policy at the Seoul National University for 30 years (1980–2009). As dean of academic affairs, he led university reform to level up the SNU to a world class research university. He was also a visiting professor at Berkeley, Paris-Sorbonne and Nankai University. After organizing the 29th International Geographical Congress in 2000 Seoul, he was elected to the Vice President and Secretary General of the IGU (International Geographical Union), where he served for two terms (2004–2010).

During President Lee Myung-Bak's government (2008–2013), Woo-ik Yu left the SNU to serve as the first Chief of Staff to the President, Korean Ambassador to the People's Republic of China, and the Minister of Unification. While serving as Minister, he created the 'Unification Jar', a monetary campaign in preparation for the unification of Korea.

Now he has returned to Seoul National University as a Professor Emeritus and as a Distinguished Professor at the Korea Military Academy. He also serves as the chair of directors of 'The Initiative', a non-governmental organization for Korean initiative for unification, the Chairman for 'the President Lee Myung-Bak Foundation', and the economic advisor for Guizhou-sheng (China).

As an academic, Woo-ik Yu wrote many academic papers and books on geography and unification policies including "The Land Policy for the Unified Korea" and "Meaning of Places" (Vol. 1, 2).

Professor Denise Pumain trained in geography at Ecole Normale Supérieure, she was lecturer at University Paris I from 1970, researcher at the National Institute of Demography (1981–86), Professor at University Paris 13 (1986–89) then at University Paris I Pantheon–Sorbonne, member of the Institut Universitaire de France. Former Chair of the Commission on Urban Development and Urban Life of the IGU (1992–2000), founder of the research laboratory P.A.R.I.S. (1984), Director of the UMR Géographie–cités (CNRS 1992–2000), the European Research Group S4 (Spatial Simulation for Social Sciences, 2006–2013), Cybergeog, European Journal of Geography (founded 1996), Principal Investigator of the ERC advanced grant GeoDiverCity, <http://geodivercity.parisgeo.cnrs.fr/blog/> (2011–2016).

Her main scientific contribution is about building an evolutionary theory of urban systems and transferring concepts and models from self–organising complex systems towards social sciences. She was chief executive of education and research for the Académie de Grenoble (2000–2001) and first scientific coordinator for social sciences at the French Agency for research assessment (2007–2008). Doctor honoris causa at University of Lausanne and Liege, silver medal of the CNRS and Vautrin Lud International prize in Geography in 2010. Corresponding member of the Austrian Academy of Sciences since 2009 and corresponding fellow of the British Academy since 2012. Officer in French Order “Legion d’honneur” and “Ordre du mérite”.

Professor Mark W. Rosenberg is a Professor of Geography and cross–appointed as a Professor in the Department of Public Health Sciences at Queen’s University in Kingston, Ontario, Canada. He is also the Canada Research Chair in Development Studies. Professor Rosenberg received his undergraduate training at the University of Toronto and his graduate training at the London School of Economics and Political Science (LSE). Among the many honors, he has received, most recently, Professor Rosenberg received a Queen Elizabeth Diamond Jubilee Medal for his research on Canada’s aging population, contributions to gerontology and service to older Aboriginal and non–Aboriginal populations in 2012. He is an Honorary Professor in the Chinese Academy of Sciences – Institute of Geographic Sciences and Natural Resources Research. His research covers a wide range of

topics including health and the environment, access to health care and social services, and studies of vulnerable populations, especially older populations and Aboriginal Peoples. Publications from his research can be found in the leading journals of geography, gerontology, social science and medicine. Funding for his research mainly comes from the Canadian Institutes of Health Research and the Social Sciences and Humanities Research Council of Canada.

Professor Dahe Qin, a distinguished geographer, and an academicien of both the Chinese Academy of Sciences (CAS) and the Third World Academy of Sciences (TWAS). He also serves as a member of the Standing Committee of the CPPCC, Deputy Director of Population, Resources and Environment Committee of CPPCC, and vice chairman of China Association for Science and Technology. He served as Administrator of the China Meteorological Administration. Academician Qin was involved in the leadership of the preparation of the Third, Fourth and Fifth Assessment Reports of IPCC, and also the assessment of Chinese climate environment, making significant contributions to deepening the understanding of climate change science. He actively promotes the cryospheric science concept to build a theoretical framework of cryospheric science. He is the founder of the State Key Laboratory on Cryospheric Science. He led the preparation of the “Strategic Research on Development of Chinese meteorological Service”, a monumental

document that proposed a new concept of “public–, security–, and resources–oriented meteorology”, and took the lead in sharing scientific data. He has published more than 400 scientific papers/works. Among the numerous awards and accolades are the 2007 Nobel Peace Prize to recognize his involvement in the leadership of IPCC; the 53rd International Meteorological Organization Prize; the 2013 Volvo Environment Prize and the Second Prize of (China) National Natural Science Award.

Professor Mike Meadows was born in Liverpool, United Kingdom but has lived in South Africa for more than 30 years and has been Head of the Department of Environmental and Geographical Science at the University of Cape Town since 2001. He holds an undergraduate degree from the University of Sussex and a PhD from the University of Cambridge. Meadows has authored or co-authored more than 150 peer-reviewed research articles and edited several special editions of international journals. Major works include the recent co-edited *Southern African Geomorphology* (Sun, 2012) and *Geomorphology and Society* (Springer, 2016). His research interests are in the area of physical geography, more specifically concerning Quaternary environmental change and the geomorphological and biogeographical impacts of natural and human-induced climate change. In his reconstructions of past southern African environments, Meadows has engaged with a range of proxies, including pollen, diatoms, biomarkers, stable isotope geochemistry and sedimentology, using evidence from lakes, wetlands and, more unusually, accumulations of faecal and urine material deposited by *Hyrax capensis*, a small colonial mammal that lives in the arid mountains of southern Africa. This proxy in particular has facilitated the detailed reconstruction of late Quaternary environmental and climate change in localities about which very little was previously known. Professor Meadows has been Secretary-General and Treasurer of the International Geographical Union since 2010 and is a Fellow of the Royal Geographical Society, of the Royal Society of South Africa and of the Society of South African Geographers.

Professor Benno Werlen studied geography, sociology, cultural anthropology and economy at the Université de Fribourg (Switzerland). He holds a PhD of the Faculty of Philosophy (University of Fribourg) and a Habilitation of the Faculty of Natural Sciences (University of Zurich). He has held the Chair for Social Geography at the Friedrich-Schiller-University, Jena since 1997. He has taught at the universities of Fribourg, Kiel (Germany), Zurich, ETH Zurich, Cambridge (GB), Salzburg, Geneva and Nijmegen. Werlen is the Executive Director of the IGU-Initiative for an International Year on Global Understanding; Chair of the International Geographical Union (IGU)-Commission 'Cultural Approach in Geography'; a Panel Member of the 'European Research Council' (ERC/Brussels) for Society and Environment and 'Agence National de Recherche' (ANR/Paris) for the Social Sciences and the Humanities. Werlen is counted as one of the 'Key Thinkers of Space and Place' (Sage Publisher) and is one of the most cited social geographers. He has published 14 books and more than 200 papers in scientific journals and books, has given over 200 keynote presentations at universities across five continents in the fields of geography, sociology, economics, political sciences, philosophy, history, cultural anthropology, linguistics, and organized more than 50 scientific conferences and conferences sessions on all continents, except Oceania.

Professor Virginie Mamadouh is Associate Professor of Political and Cultural Geography at the department of Geography, Planning and International Development at the University of Amsterdam (UvA), The Netherlands. She has been the secretary of the Steering Committee of the IGU Commission on Political Geography since 2014 and the co-chair since 2014. She is one of the editors of the academic journal *Geopolitics* and *The Arab World Geographer*. Her research interests pertain to Political and cultural geography; Geopolitics and globalisation; Supranationalism and (multilevel) governance in the European Union; National political cultures; Geopolitics of multilingualism; multilingual cities; (Transnational) migration and territorial identities; Transnationalism and "new media"; Urban social movements and Electoral geography.

Professor Takashi Yamazaki is a professor of Geography at Osaka City University, Japan. He received his Ph.D in political geography from University of Colorado at Boulder in USA. His current research interest concerns the (de) militarization of Okinawa and critical geopolitics of Japanese foreign policy. He has been a Steering Committee member of the IGU Commission on Political Geography since 2004 and acted as a co-chair since 2014. He was also a co-chair of the Research Committee 15 on Political and Cultural Geography of the International Political Science Association from 2007 to 2012. Within Japan, he established and chaired the Political Geography Research Group of the Human Geographical Society of Japan from 2011 to 2015 and acted as a vice-chair of the Commission Committee for the IGU Kyoto Regional Conference in 2013. His publications include "Space,

Place, and Politics: Towards a Geography of Politics" (Nakanishiya, 2013 in Japanese), 'The US militarization of a 'host' civilian society: the case of post-war Okinawa, Japan' in S. Kirsch and C. Flint eds. "Reconstructing Conflict: Integrating War and Post-War Geographies" (Ashgate, 2011), and 'The re-institutionalization of island identities: the "textbook fight" in the Yaeyama Islands, Japan' in D. Kaplan and G. Herb eds. "Scaling Identities" (Rowman & Littlefield, forthcoming).

A 21st Century Agenda to Shape “Our Harmonious Worlds” through Research on the Geographies of Health and Care

Mark W. Rosenberg (Canada)

Abstract

“Shaping our harmonious worlds” is predicated on human and physical geographers working together alongside our colleagues in other parts of the humanities, and the social, natural and health sciences to improve health and care in a socially just way. To achieve the goal of improving health and care in a socially just way requires a 21st century research agenda for geographers that begins with how we understand social justice. We also need to understand demographic, environmental and urban change as processes that will frame health and care issues throughout the 21st century in very different ways than in the past. With particular attention to geographic scale, and out of our understanding of social justice, and demographic, environmental and urban change, some key health and care issues and challenges will be identified that might contribute to a 21st century agenda to shape our harmonious worlds through research on the geographies of health and care.

Back to the Future: Reasoning the Territorial Way of Life

Yu, Woo-ik (South Korea)

Seoul National University

Abstract

This is a story of a geographer about his life, thoughts, and work. In his plenary address, Yu Woo-ik will tell the participants about his unique experiences in and outsides of geography. The emphasis will be laid on the usefulness of geographical ways of thinking and its potential to contribute to solving actual problems and to formulating policies for the future.

Yu Woo-ik is a Korean geographer who belongs to the generation that was born and grew up during the time of war and poverty and then worked hard to make the 'miracle', the rapid industrialization and democratization of the country. Keeping in mind his family motto, '*study and requite the nation*' (學而報國), the geography student found the reason of his study in devoting to '*the unification*' of the country, and it became the theme of his life-long pursuits. Consequently, it was natural that his academic interest covered a wide area of geography and its adjoining disciplines including regional policy. After studying geography, history and sociology in 1970s' in Germany, another divided nation at that time, Dr. Yu went back to Korea and taught geography for 30 years at the SNU (Seoul National University).

Yu Woo-ik used to be the IGU Secretary General (2006-2010). He worked as a geography professor and Dean of Academic Affairs at the SNU until he was called to serve the Korean government. From 2008 to 2013 he worked as the Chief of Staff for the President, the Korean Ambassador to China, and lastly the Minister of Unification of Korea. Presently, he is back in academia as an honorary professor and is teaching geography and international relations at the SNU and the KMA (Korea Military Academy).

Though having served in these various positions, he remained a geographer in that he tried to think geographically, that is to say to think primarily about '*the life of the people*' with consideration of the relationships between: a) man and nature; b) time and space; c) matters, phenomena and places. He also tried to think d) holistically or convergent; and e) policy-oriented as well as practically.

In this context, he would like to remind his colleague geographers of the classical academic concept, '*reasoning the territorial way of life*' (地理).

At the dawn of the 21st century, Yu Woo-ik proposed a theme related to this task to the international geographical society, and consequently to the world. The theme he proposed was "*Living with Diversity*", a key concept for the way of life in the coming new era. It was the main theme of the 29th IGC in Seoul 2000 of

which he was the organizer. He emphasized three virtues of the concept: a) contributing to the stability; b) enhancing development potential; and c) expanding the capacity for creative activities.

Now 16 years later from then, he stands again on the platform of the IGC as a plenary speaker. He is pleased at the main theme of Beijing Congress "*Shaping Our Harmonious Worlds*", for he find the concept evolving continuously since Seoul 2000 via Glasgow, Tunis, Cologne and lastly to Beijing. In his neighborhood old Asian City, the speaker will go in depth about '*diversity in harmony*' in socio-cultural world just as it is in the biosphere.

Yu Woo-ik believes it is time for geographers with their geographical way of thinking to contribute positively to the creation of new civilization, and hopes especially the young geographers from various cultural realms to be encouraged.

Climate Change and Its Impact

Dahe QIN (China)

Abstract

Since October 2013, the Intergovernmental Panel on Climate Change (IPCC) had released the Fifth Assessment Report (AR5) including three Working Group Reports and Synthesis Report. New observations have further proved that the warming of the global climate system is unequivocal. Each of the last three successive decades before 2012 has been successively warmer at global mean surface temperature than any preceding decade since 1850. 1983-2012 was likely the warmest 30-year period of the last 1400 years. The ocean has warmed over the period of 1971 to 2010, the rate of global mean sea level rise has accelerated, anthropogenic global ocean carbon stocks were likely to have increased and caused acidification of the ocean surface water. Since 1971, the glaciers and the Greenland and Antarctic ice sheets have been losing mass, the extent of the Northern Hemisphere snow cover has decreased. Human influence has been detected in the warming of the atmosphere and the ocean, changes in the water cycle, reductions in snow and ice, global mean sea level rise, and changes in climate extremes.

The largest contribution to the increase in the anthropogenic radiative forcing was by the increase in the atmospheric concentration of CO₂ since 1750. It led to more than half of global warming since the 1950s (with 95% confidence). It is predicted that the global mean surface temperature will continue to rise for the end of this century, the frequency of extreme events such as heat waves and heavy precipitation will increase, sea level will continue to rise and cryosphere will continue to warm. If the increase in temperature is higher than 2°C than before industrialization, the mean annual economic losses worldwide will reach 0.2% to 2.0% of income, and cause large-scale irreversible effects, including death, disease, food insecurity, inland flooding and water logging, and rural drinking water and irrigation difficulties that affect human security. If taking prompt actions, however, it is still possible to limit the increase in temperature within 2°C. To curb the gradually out-of-control global warming and achieve the goal of sustainable development of the human society, global efforts to reduce emissions are needed.

From Inter-State to Multiscalar Political Geographies

Virginie Mamadouh (Netherlands) & Takashi Yamazaki (Japan)

Abstract

Since the early 1980s political geography has become one of the most prolific subdisciplines of human geography, but it is still largely dominated by geographers working in North America and Europe. The Commission on Political Geography of the IGU was established in 1984 as the study group on the World Political Map, this name was chosen then because the notion of political geography was contested in some parts of the world. Some of the issues addressed by political geographers remain sensitive in many countries and political regimes do not always allow much room for academics to do political geography. All the same, the wide range of issues pertaining to the geographies of power relations is highly relevant everywhere and often necessary for the study of other social phenomena, be it climate change or gender relations.

The lecture will present a broad review of the state of the art stressing how political geography evolved for the past thirty years from a state centric subdiscipline, focusing on state territory, borders and international relations, into a multifaceted field of multiscalar political processes, with examples from Europe and East Asia. In addition the lecture will stress the need to foster opportunities to engage in a dialogue between political geographers from different parts of the world and with other geographers, using as example the Joint meeting Earth, Society, Islands, and the Political in the Changing World (held in June 2016 in Taipei) and the International Conference on Geography of Peace (scheduled in April 2017 in La Paz).

Geographical sciences and Future Earth: Research for Solutions, From Local to Global Scales

Mark Stafford Smith (Australia)

Abstract

The world is facing a growing series of environmental challenges which are impacting human well-being at an accelerating rate. In the face of this, nations of the world last year signed off at least 3 major agreements that set sustainable development goals for the planet – I disaster management, climate change and the sustainable development goals; a major responsibility for research is now to deliver the understanding to enable these goals to be met, and to do so in ways that are more nimble in the face of the increasing rates of change.

Future Earth is a global platform for international research collaboration on global environmental change and sustainable development that aims to fulfil the commitment of the research community at Rio+20 to play its part in contributing to this more nimble global innovation system. It draws on the existing work of over 20 major global projects (<http://futureearth.org/projects>) which I will outline, and is now focused on eight major societal challenges (<http://futureearth.org/our-vision>), for which both fundamental and applied research across many disciplines is critical. The geographical sciences, with their overarching lens on spatial relationships and scale, have a major role to play in addressing these challenges.

Future Earth has a solutions orientation, emphasises principles of co-design, and is addressing the challenges of integrating across scales in ways that are particularly important in the Asian region, and again notably relevant to geographical agendas. The Future Earth platform has frankly taken a while to construct, but this presentation will outline how it is now active, and the ways in which the geographical research community can engage with it. The major vehicles for this engagement are our Open Network (<http://futureearth.org/future-earth-open-network>) and a growing suite of Knowledge-Action Networks (<http://futureearth.org/knowledge-action-networks>).

Geography and Future Earth: Perspectives from Africa

Michael E Meadows (South Africa)

Department of Environmental & Geographical Science, University of Cape Town, South Africa

Abstract

The environmental, cultural, social and economic diversity of the African continent is significantly underestimated and generalisations concerning these aspects are at best oversimplifications. Nevertheless, there are some prominent trends emerging in regard to its population and development, not least the fact that it is an increasingly urbanised continent. Across large parts of the continent, both rural and urban populations, however, face major physical environmental challenges including climate change and sea level rise that are exacerbated by issues around governance, civil strife and have contributed to, for example, land degradation, food insecurity and migration. Geography straddles the social and natural sciences and, as such occupies a virtually unique position as a discipline to explore (and help resolve) the set of 'wicked' problems that characterise the increasingly challenging relationship between people and their environments in Africa. Such challenges are, of course, recognised at the highest global level through the adoption of the United Nations Sustainable Development Goals. The International Council for Science (ICSU) and the International Social Sciences Council (ISSC) have jointly launched, along with several other key partners, the 'Future Earth' initiative, central to which is the concept of a dynamic but sustainable earth system that will enable future human development. In this paper, I reflect on the eight key Future Earth challenges confronting the planet and consider the role that Geographers can play in understanding the diverse interdisciplinary issues that these entail in the African context. A geographical perspective and the 'joined-up' thinking that it engenders, is perhaps one approach that can help develop a more robust understanding of the range of environment and development problems in Africa. While it is true that geographers cannot easily enforce wiser political decision-making, it is the case that a more nuanced and comprehensive understanding of how to address the complex array of challenges is at least a step in the right direction. Many of the International Geographical Union (IGU) Commissions conduct research that interfaces well with Future Earth and, coupled with activities associated with the IGU's International Year of Global Understanding (IYGU), offer excellent opportunities for engagement that has particular relevance to Africa.

Global Understanding for Global Sustainability

Benno Werlen (Germany)

Abstract

Global thinking and global action demand global understanding. The IGU Initiative for an International Year of Global Understanding (IYGU), proclaimed by the international councils for the Natural, Social and Human Sciences, aims to bridge the gap in awareness and knowledge between local acts and global effects through research, education, and information.

The IYGU recognizes that global social and climate changes require a global level of understanding. It provides information on culturally differentiated sustainable actions to reach global sustainability. And most of all: it develops a blueprint for a new geographical view of a radically changing world.

Every day we all experience how globalization has brought and is bringing far-flung places and people into ever-closer contact. New kinds of supra-national communities are emerging at an accelerating pace. At the same time, these trends do not efface the local. Globalization is also associated with a marked re-affirmation of cities and regions as distinctive forums of human action. All human actions remain in one way or the other regionally and locally contextualized.

The IYGU addresses the ways in which we inhabit an increasingly globalized world. Everyday geography-making is essential for the constitution of geographical realities. Our world faces social, cultural, and economic change, as well as a changing climate. Human actions play a key role in creating such worldwide challenges. However, human actions also provide solutions. If individuals know what their day-to-day routines mean for the planet, they can take appropriate action to help overcome global challenges.

The IYGU wants sustainable change that starts from the bottom and thus focuses on essential daily activities such as eating, drinking, housing, working, travelling, and communicating. Why do we make the choices that we do? Which societies make more globally sustainable choices? Natural and social scientists will jointly provide answers.

Ultimately, the IYGU encourages everyone to make daily decisions in the light of global challenges.

The presentations highlight the IYGU's action program and its network, the latest significant achievements, and how one can become an active part of the first international year initiated by the International Geographical Union and proclaimed by the international councils of the natural, social, and human sciences.

Understanding China's Geography: Linking Science and Society

Bojie Fu (China)

Geographical Society of China / Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences, China
bfu@rcees.ac.cn

Abstract

China has a long history of over 2000 years known geographical observations. After the founding of The People's Republic of China, geography in China has been significantly advancing. I will give an overview of China's geography from various respects including academic organization, education, research, and international cooperation with the geographical research in China as the core theme. Four sub-themes on this core will be briefly reviewed including the spatial differentiation and regionalizations of the China's geographical environment, infrastructure and data acquisition for China's geographical research, theoretical development and societal applications in China's geographical research, and new progress on regional integrative geographical research in China, with typical cases in point.

China is a large country with diverse environmental conditions and significant geographical differentiations both naturally and socioeconomically. Since the 1950s, modern geographical research in China started from Comprehensive Geographical environment and natural resources surveys and geographical regionalizations inspired by the urgent requirement from the socioeconomic development. After the 1990s, the regionalization research advanced towards more integrative with considerations of ecological and environmental issues and social and economic sustainable. Many of these researches have been feed into regional and national development and environment policy making processes.

As key infrastructure for advancing geography in China, ground based monitoring networks and earth observation networks have been established, which facilitated process based geographical research and pattern-process integrations across spatiotemporal scales. The contributions of Chinese geographers to advancing social relevant geographical science will be exemplified with key examples such as understanding the human-land relations, regional and global environmental change and urbanization and sustainable development. Indeed, China's geography has achieved great progress since the 1950s and also contributed much to the scientific understanding of the geographical environment and the development needs across scales. Much still to be done by Chinese geographers on new contributions to the science and societal needs of geography both in China and globally.

Urban Dynamics and Geo-Diversity: From Theory to Modeling

Denise PUMAIN (France)

University Paris 1 Panthéon-Sorbonne

Abstract

The evolution of cities is a major issue because it affects the majority of the world population. It is in cities that solutions must be invented to solve the problems of sustainable development in terms of quality of life, of resource management, of intelligent integration of technological and cultural innovation and of social cohesion, at the local and the global scales. The diversity of cities is such that it might seem difficult to develop a scientific knowledge about them for sustaining policies. However, cities have long been interdependent and organized into systems of cities, they co-evolve through the multiple relationships which connect them into networks for the exchange of materials, investments, people or information. These interdependencies drive and constrain the evolution of each city in the system, according to a complex set of dynamics which exhibit patterns regular enough to help understanding and even predicting certain trends.

For anticipating urban future, geographers have since long developed a theoretical framework relying on the observation, not only of the few megacities global stars but of thousands of cities and towns taken in a variety of world regions. These empirical observations were scrutinized through analytic methods inspired from the dynamics of complex systems and data and processes are now integrated into computer simulation models which are able to reconstruct the stylized facts and trends observed. The theory and the results of these modeling experiments emphasize the importance of interactions between the cities in the evolution of their size and the effects of the spatial diffusion of large innovations waves, which tend to reinforce the hierarchical unevenness and explain the reversal of trajectories in the specialized cities. The path-dependent role of the precocity and sustainability of settlement systems is confirmed as well as the bifurcations associated with colonization in having created at world scale a diversity of systems of cities which has been maintained for decades in terms of hierarchical inequality and the primacy of their metropolises. Adapted urban policies might partly counteract such self-organized trends. In any case, the urban geodiversity has to be taken into account in order to continue the major function of cities and towns which still are altogether remarkably efficient socio-spatial adaptors on the long run in the human history.
